Founder Chairman, MRGI
Hon'ble MP, Malkajgiri

MESSAGE

It gives me immense pleasure to pen a few words as prologue to our in-house magazine "Research Publications in MREC" with a collection of research papers contributed by the faculty members of our organization.

I believe this will flourish to become very useful source for the researchers, academicians and students who want to further improve their research profile and contribute to the arena of knowledge based wisdom. I hope this magazine will create interest and enhance inspiration of the readers to carry out new research ventures.

I extend my best wishes to bring more challenging research works which is useful to the society from the teaching fraternity with a sense of commitment in the future years to come.

C. H. Malla Reddy

Sri. Ch. Mahender Reddy
Secretary, MRGI

MESSAGE

I am pleased to know that MREC(A) is bringing out a magazine "Research Publications in MREC" which embrace the research contribution of faculty members of MREC. It is the outcome of our enthusiastic, dedicated and committed faculty members.

I take the pleasure to thank the Principal for providing continuous support and encouragement to the faculty members to publish their papers in Conferences and Journals.

I extend my heartfelt wishes for all to succeed in future endeavors.

Sri. Ch. Mahender Reddy

Maisammaguda, Dhulapally (Post Via Kompally), Secunderabad - 500 100.

Director

MESSAGE

Its my pleasure to know that our in-house magazine "Research Publications in MREC" is being brought out with a collection of research contributions by our faculty members. This collection will be an inspiration to upcoming researchers to set new aspirations in research. This edition is an evidence for comfortable environment provided by MREC(A) for teaching and research activities to the faculty members to improve their career.

I wish to express my heartfelt thanks to the Management for their support and encouragement. Also my sincere regards to the HOD's and faculty members for their continuous efforts and contribution in research fields.

I extend my heartfelt wishes for all to succeed in future endeavors.

DIRECTOR

Pounding Effects on Buildings under Seismic Loads

Binimol Babu[1], J. Rex[2]
[1, 2]*Department of Civil Engineering, Mallareddy Engineering College, Hyderabad.*

Abstract: Seismic pounding is a very prevalent phenomenon observed in metropolitan towns with densely packed structures without adequate gap in separation.
Pounding can cause severe structural harm and boost the risk level. Although there are structures that are resistant to earthquake, it is hard to regulate pounding impacts. The simplest way to decrease the impact of pounding is by maintaining an adequate separation gap between structures and this is not everywhere practical. There comes, shear walls and braces to enhance the stability of structures.
This project deals with the behaviour of adjacent buildings affected by seismic pounding. The assessment considers a comparative assessment of buildings, structures with and without shear walls and symmetric structures and asymmetric structures of equal and unequal height.
Building codes provides rules for structural engineering practice and play a significant role in transferring technology from studies and research to practice.
Keywords: pounding effect, shear walls, symmetric and asymmetric buildings, and base reactions.

I. INTRODUCTION

In metropolitan places, structures are very close to each other because of fast rise in urban development and the real-estate value. These buildings collide with each other when subjected to earthquake or any loads due to their closeness. The phenomenon pounding occurs when the adjacent buildings start vibrate out of phase during the earthquake which causes collision amongst the neighbouring buildings.
If the separation distance between adjacent buildings is not enough during seismic activities to compensate the relative motion, the pounding occurs.

A. What is Pounding Effect?

Pounding effect refers to collision between adjacent structures under seismic loads and it is occurred when structures with different dynamic properties, without proper separation gap between them.

B. Pounding can be Caused By

Seismic Pounding can be caused from the following:

1) Nearby buildings with the equal height and the equal floor level.
2) Nearby buildings of different height with the same floor level.
3) Nearby structures with different overall heights and with different floor levels.
4) Structures which are situated in a line or row.
5) Parts of the same buildings which are linked by one or more bridges or joints.
6) Pounding occurs along the unsupported components in building results in serious pounding damage.
7) The structures built according to the old codes that was vague on separation distance.
8) Buildings with uneven lateral load-resistance structures and torsional rotations, pounding can occur near the building premises around the nearby buildings.

C. Shear Walls.

Shear walls are structural elements of a reinforced concrete framed structure designed to withstand lateral forces including wind loads. They are used in tall buildings subject to lateral wind and seismic movements. This approach increases height of the storeys, hence increases the cost of buildings. . The best position for the shear walls is in the middle of every half of the tower, but this is never feasible, so they are usually at the ends.

II. OBJECTIVE OF THE STUDY

A. Seismic pounding is a serious phenomenon which involves local damage to structures during earthquakes.
B. The main objective of the project is to study pounding effect on different types of reinforced buildings.
C. Pounding effect is considered for symmetric (rectangular shape) adjacent buildings of different height and asymmetric (L-shape) adjacent buildings of same height.
D. A comparative study is done by analysing different parameters like storey response factors, deflections, and drift along with separation gaps with the help of E-TABS (2013).
E. Comparing analysis results of impacts of seismic and wind interactions in adjacent buildings with and without shear wall using E-TABS.

III. METHODOLOGY.

IV. STRUCTURAL MODELLING

The present study is by using ETABS 2013 technology to analyse the performance of symmetric and asymmetric adjacent framed structures with and without shear walls exposed to Zone V earthquake forces. Assumed separation distance is taken as 0.5m by trial and error method.

Four models are considered for the purpose of the study.

1) Six storey (G+6) and eight storey (G+8) adjacent buildings with shear walls.
2) Six storey (G+6) and eight storey (G+8) adjacent buildings without shear walls.
3) Two eight storey (G+8) adjacent buildings with shear walls.
4) Two eight storey (G+8) adjacent buildings without shear walls.

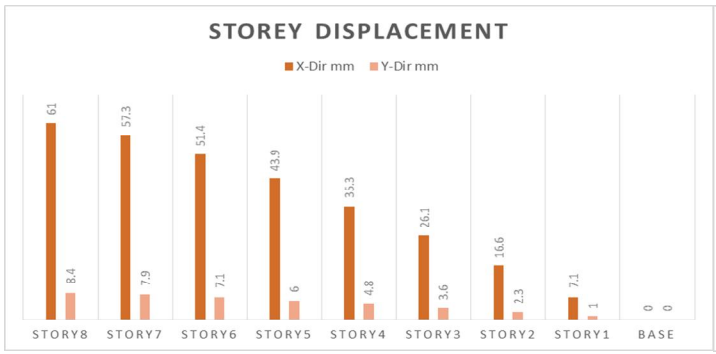
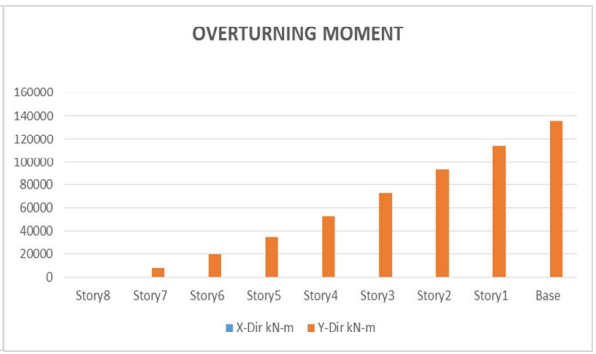
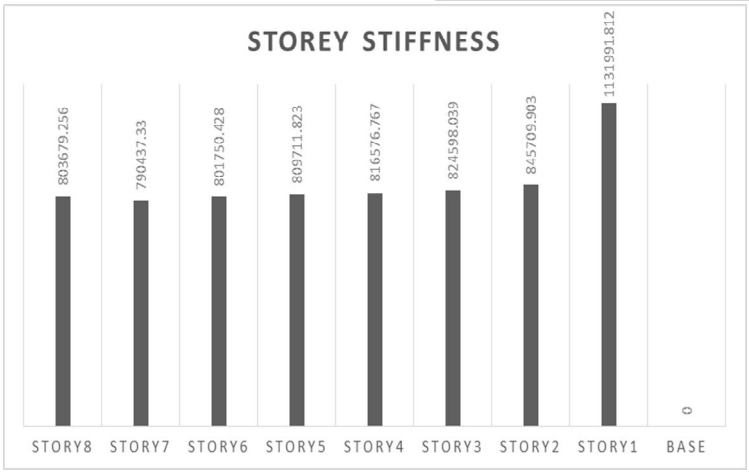
V. RESULTS AND DISCUSSIONS



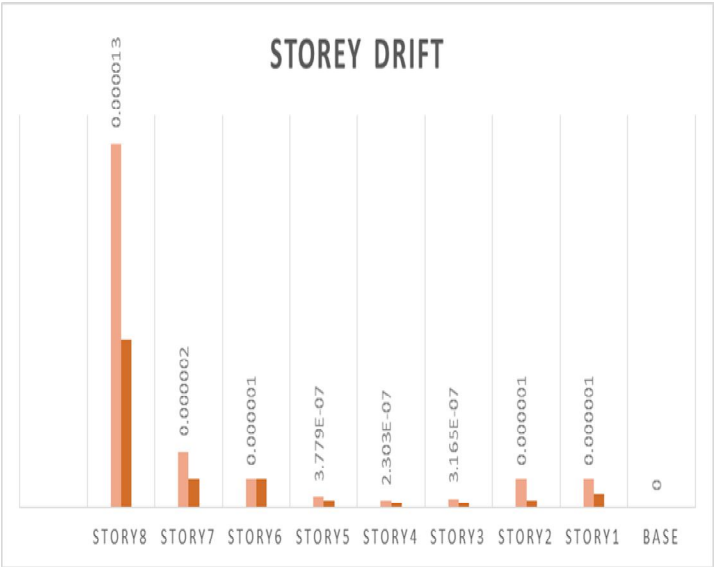
A. For Asymmetric L Buildings without Shear Wall

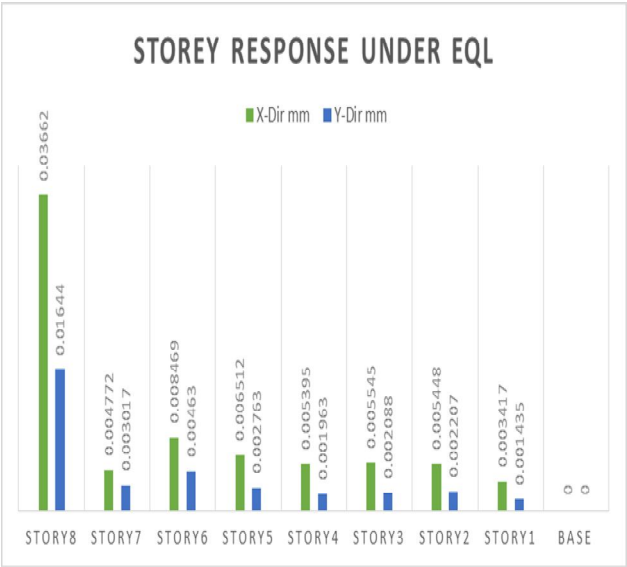


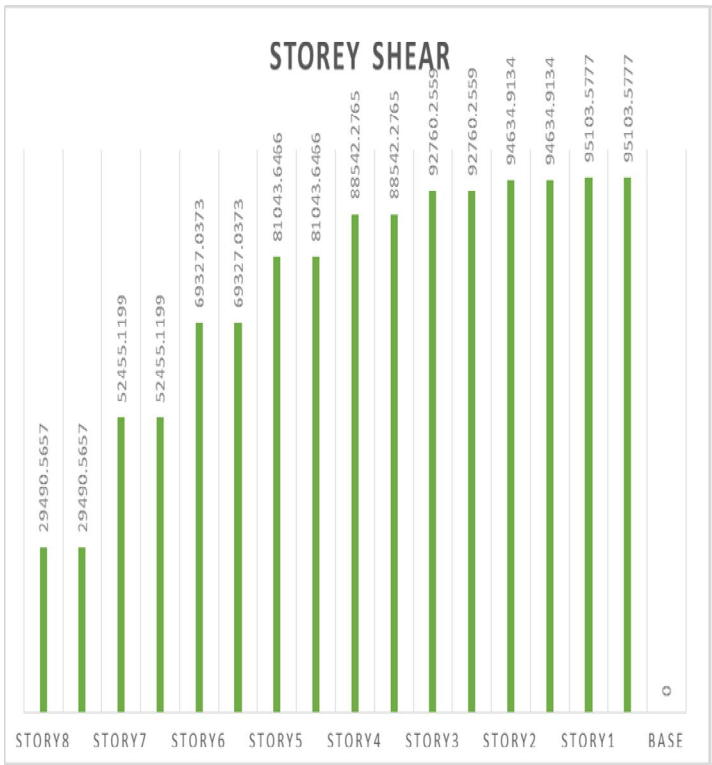
Storey drift is shift of one storey of building relative to the level below or above when earthquake occur. It is observed that at third storey level there is the maximum drift. Storey drifts are increased in first, second, third and fourth stories under earthquake loads and decreasing towards higher floor levels. The storey drift should not go beyond 0.004 or 0.005.Storey drift can be decreased by increasing the column and beam sizes.



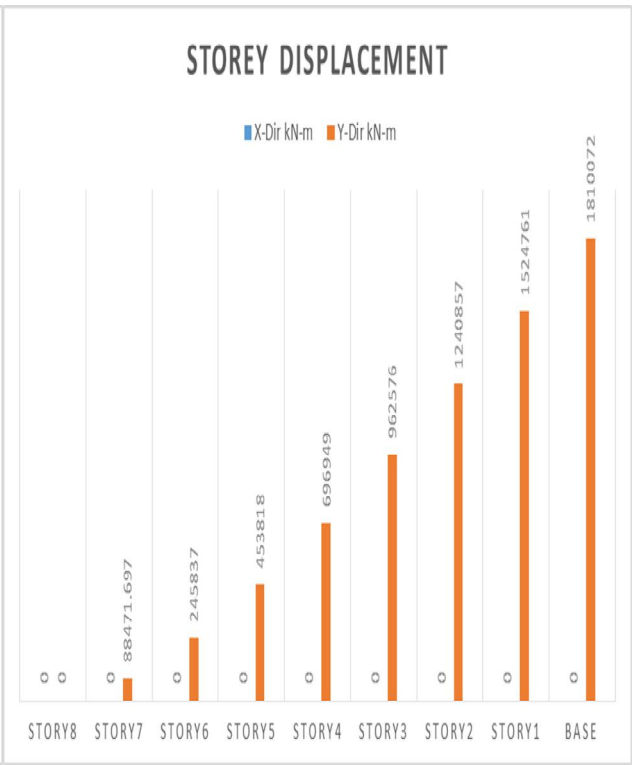
Storey shear is decreasing towards top floors and it is maximum in ground floor. Storey shear is caused by a portion of dead loads and live loads acting on each floors. It will be minimum at the topmost level of the building and maximum at the bottom of the structure. Overturning moment is maximum at base and minimum at the top. Storey displacement is displacement of stories with respect to the base of the building and it will be increasing towards top stories of the building. Storey stiffness is the ratio of storey shear to storey drift. In this graph we can observe it is maximum at the base and decreases gradually as we going up and maintaining a stable values throughout the height with slight variations.





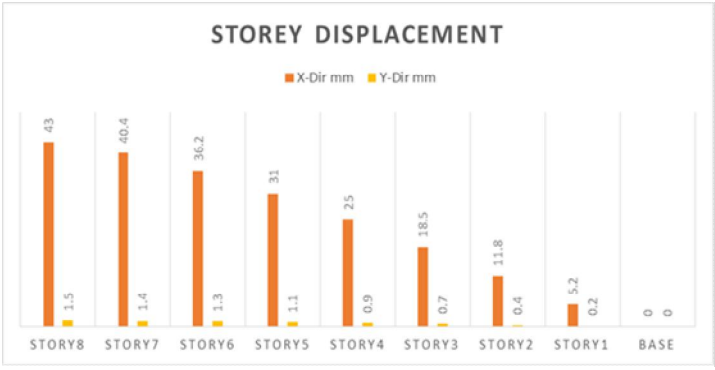


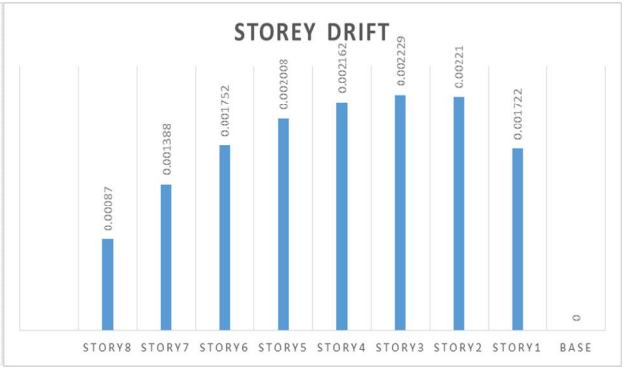
©IJRASET: All Rights are Reserved

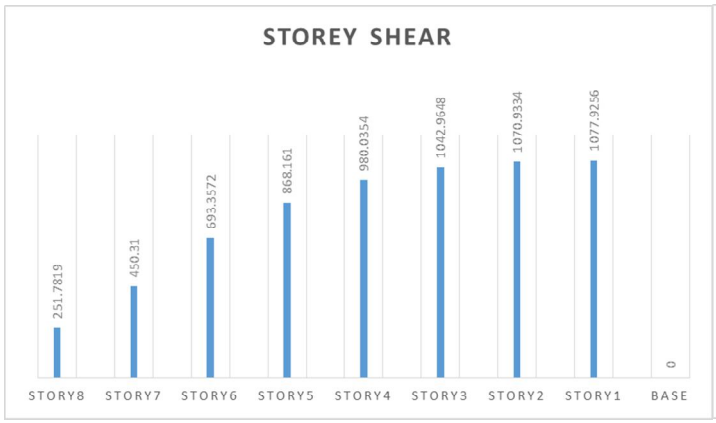


B. For Asymmetric L Buildings with Shear Wall

For structures with shear wall, storey drift is found to be very less and it is increasing towards the top of the building. Here it is observed that maximum variation occurs at the top storey and base is not affected. A gradual increase is seen up to storey 5 and at storey 6 there is a slight increment and later it decreases and steadily increased at the top storey. The storey shear is maximum at base and its gradually decreasing around the top. As we know dead load will be more in bottom floors than upper floors. As seismic forces are greater at base level, storey displacement will be higher in bottom storeys and it will be gradually decreasing towards top storeys.



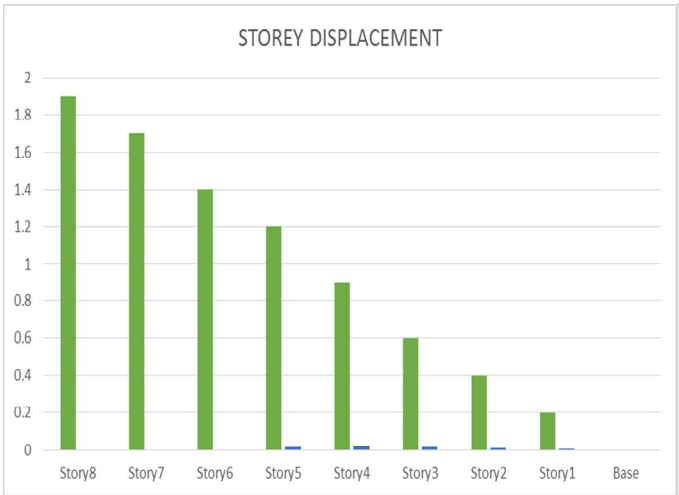


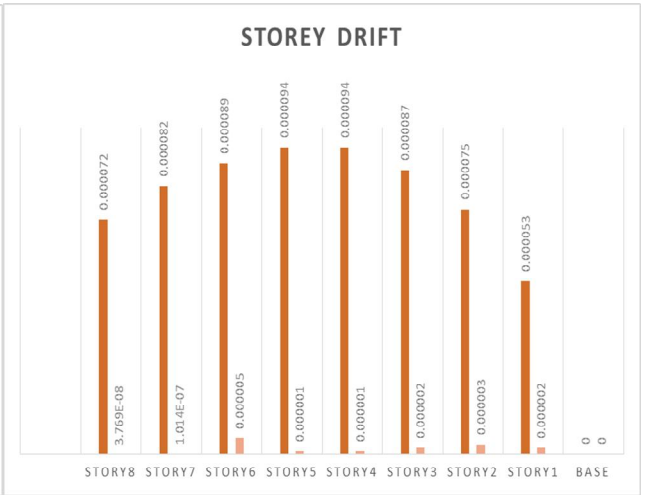


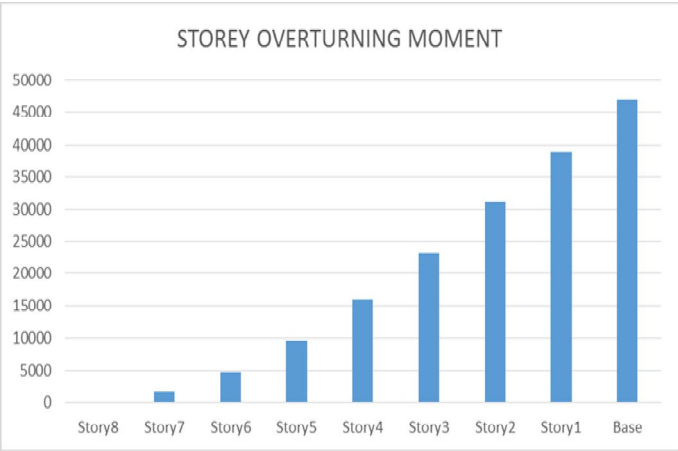
©IJRASET: All Rights are Reserved

C. For Symmetric Buildings without Shear Wall

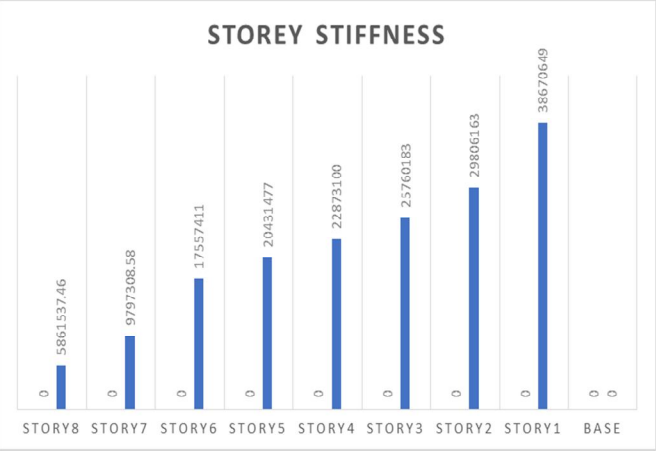
For symmetric buildings doesn't provided with shear wall, it is observed that the storey displacements are maximum at the top level storey and minimum at the base. As it is observed, all the values dint exceed the limit value of storey drift. It is visible that at storey 3 drift is maximum and at the top floor it is minimum. A slight decline in story shear can be observed from the first storey to the top storey. It is clear that at top levels stiffness is low and at the base level stiffness is more.







D. For Symmetric Buildings with Shear Wall



Top levels are more vulnerable for displacement and its increasing in a gradual rate difference of 0.2 from the base level of the structures. It is observed that at storey 5 and storey 4 storey drift is maximum. Overturning moment is maximum at base and minimum at the top. It is clear that at top levels stiffness is low and at the base level stiffness is more.

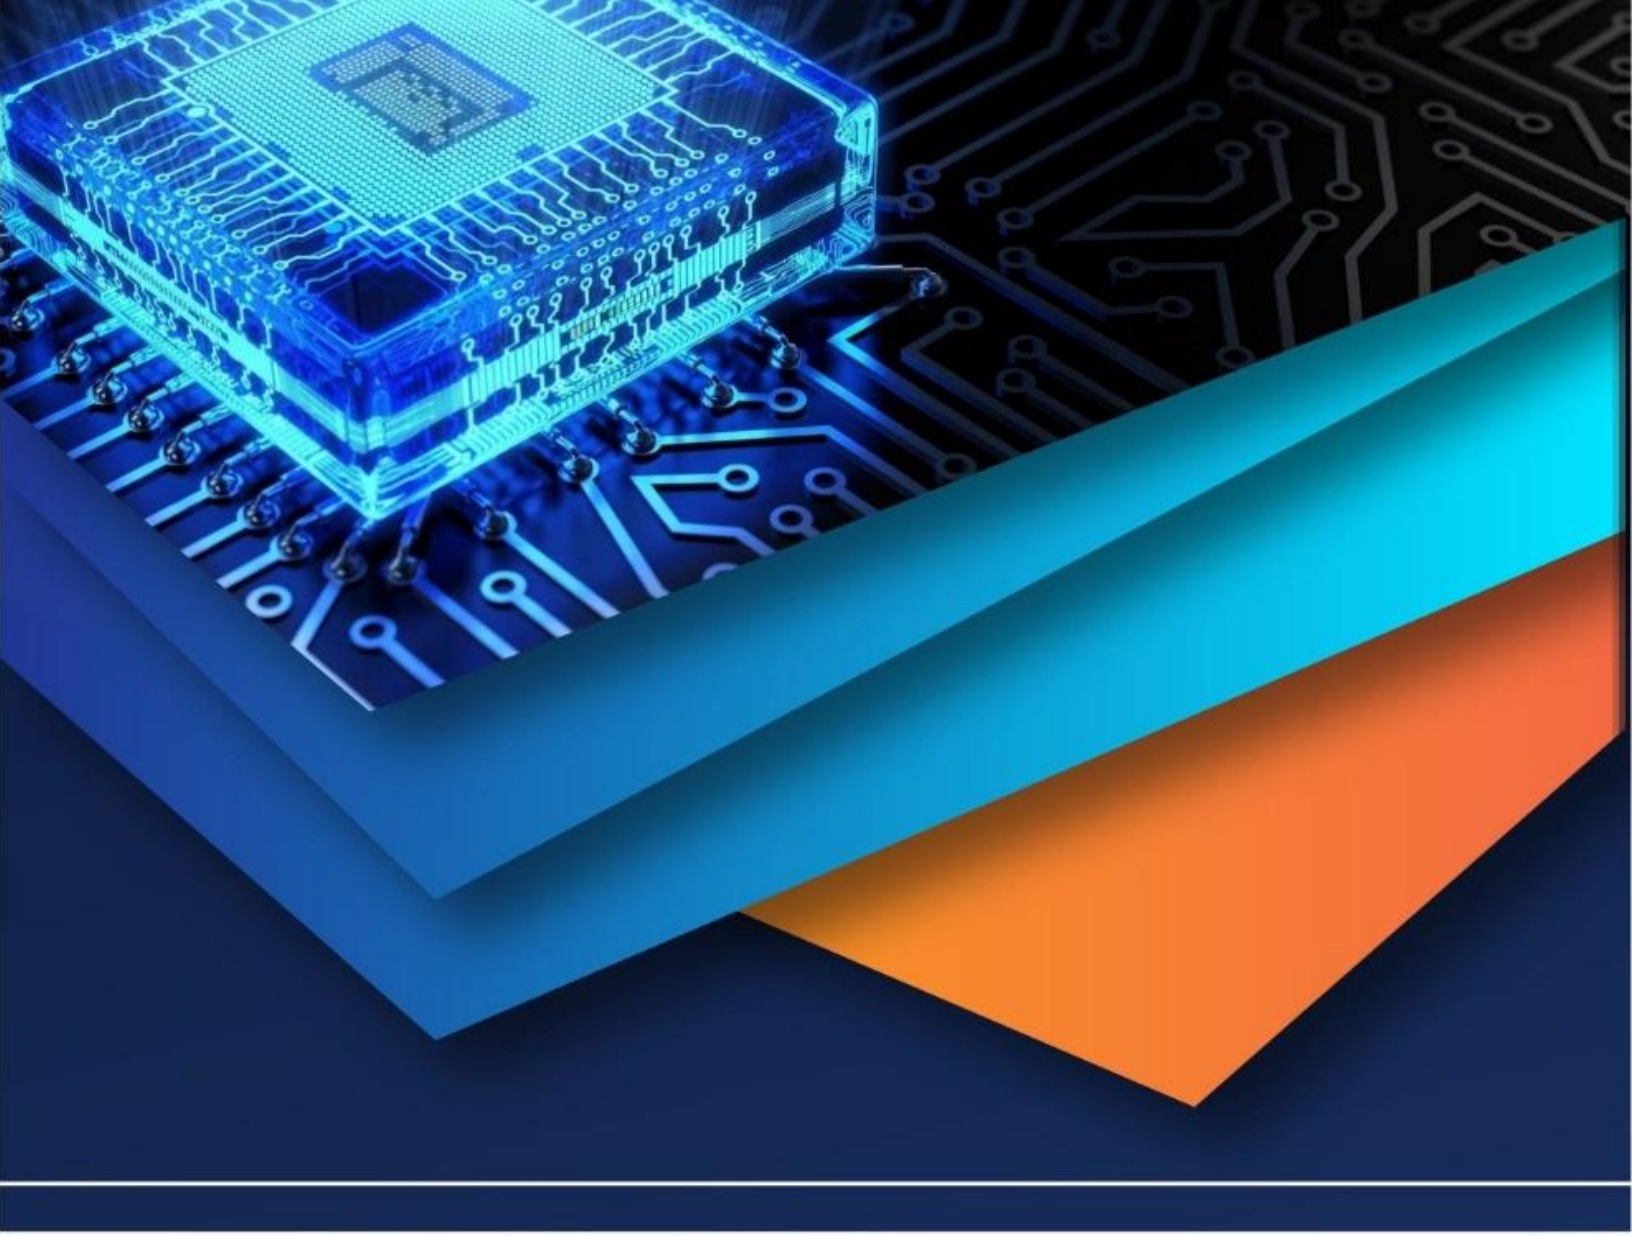
VI. CONCLUSIONS



Major earthquakes have significantly impacted large metropolitan areas in recent years, resulting in drastic pounding damage. In this study, it was established and analyzed the factors that influence seismic pounding of neighboring buildings. Pounding forces can be estimated using commercial software packages such as ETABS for measuring pounding forces using nonlinear gap elements between adjacent building levels. . A detailed study of the project pointed to the following conclusion:

A. It is concluded in this study that the installation of nearby buildings with similar floor levels and separation gaps significantly reduces the pounding effects.
B. Performance of Symmetrical buildings is better than Asymmetrical buildings.
C. For adjacent buildings the structural damage is more for unequal heights compared to equal heights, due to difference in their masses and periods.
D. It has been found that asymmetric neighbouring buildings with same heights are less affected to acceleration.

ABSTRACT:- *Podium surrounding tower walls are often widely preferred for multifaceted functionality of Tall buildings. Horizontal offset buildings constitute a class of structures that are particularly prone to in-plane floor deformation and torsion occurring simultaneously. It is found from previous studies that podium can impose significant differential restraint on coupled tower walls, these walls displaces under lateral loads contributing to the generation of in-plane strutting forces in podium floors leading to its un-conservative design. The in-plane rigid diaphragm assumption commonly adopted in practice can significantly suppress these strutting forces. Key parameters contributing to these in-plane strutting forces and drift at top of tower are analysed by way of parametric studies on representative models of the podium-tower assemblage by incorporating in-plane flexibility in modelling for different sizes of podium with beam-column frame and flat slabs structure, introducing extended blade walls and outriggers in podium to minimize the effect of strutting forces and study the contribution of podium in controlling tower displacement.*

Keywords: Podium-tower buildings, Backstay effect, In-plane Strutting forces, Floor diaphragms, Jump-formwork, Connectrix boxes.

1. INTRODUCTION

Modern architectural design of mixed use complex has introduced a building system which consists of multiple high-rise towers sitting on a common podium. Podiums are augmented floor area at the lower level of a high rise building surrounding it as shown in (Fig. 1.1). These are common in metropolitan areas in regions of low-to-moderate seismicity. A podium may be permitted in plot admeasuring 1000 sq.m or more. The podium provided with ramp may be permitted in one or more level, total height not exceeding 32 m above ground level [*DCR-2034*].

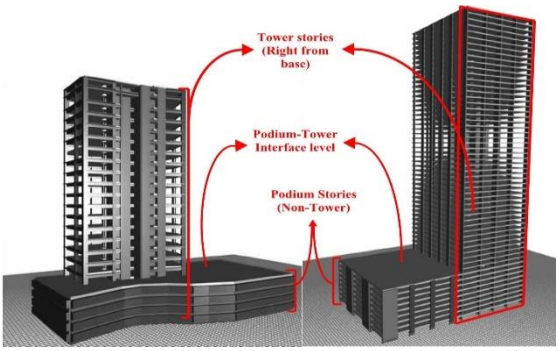

Figure 1.1

At the podium-tower interface, horizontal forces are transferred from the tower to the podium. Reactive forces are developed at the podium-tower interface to resist the overturning actions (Fig. 1.2). This reacting mechanism is similar to the backstay phenomena. It can induce high intensity shear force in the structural (tower) wall within the podium. The amplitude of the induced shear force is dependent on the in-plane flexibility of the floor structure connecting the pair of walls. This was recently studied by Mehair Yacobian et al.[1]. Avigdor Rutenberg [2] studied the prevalence of incompatibility (strutting) forces in slabs and beams connecting structural walls of different base dimensions. The Lateral load displaces tower walls and is responsible for generation of in-plane strutting forces in podium floors leading to its un-conservative design. But the in-plane rigid diaphragm assumption commonly adopted in practice can significantly suppress compatibility forces generated within the podium floor. Therefore, this strutting action can only be reported accurately if the horizontal in-plane deformation of the floor diaphragm has been incorporated into the modelling. This was stated by Gardiner et al. [3]. Therefore, podium slabs are defined as semi-rigid Shells in modelling and casted monolithic on site. [Refer Table 1]

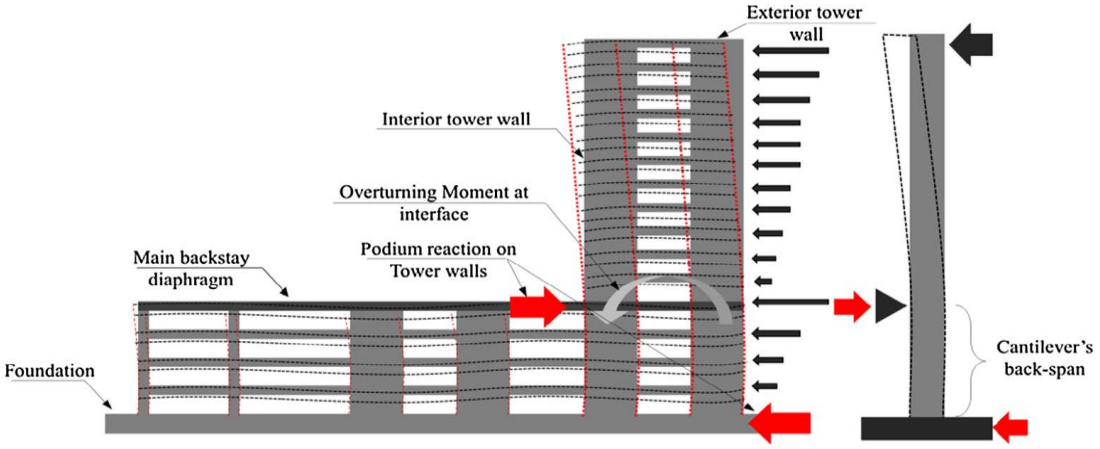

Figure 1.2

These reactive forces are *strutting forces* as shown in (Fig 1.3). One of the objectives of this study is to reduce strutting forces at podium-tower interface level.

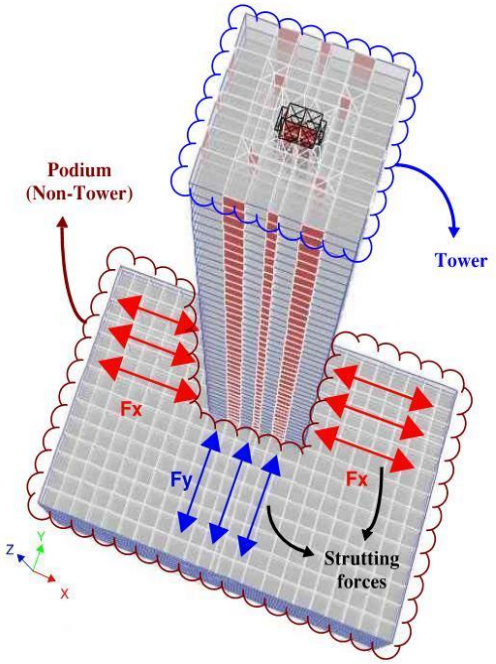

Figure 1.3

IS 16700-2017(Criteria for Structural Safety of Tall Concrete Buildings), clause 7.3.11 *"Stiffness of flat slab frames (that is, slab-column frames) shall be ignored in lateral load resistance, in all seismic regions".* Tall building code suggests that stiffness of slabs is ignored in all seismic zones, i.e., Slabs in tall buildings are infinitely stiff and lateral load is transferred 100% to vertical structural elements without any membrane deformation. Therefore, no in-plane stresses and no out of plane bending moments are reported in slabs of tower structure. To make this happen in software (ETABS) and practically on site, the slabs in tower are dealt as follows:

Software (ETABS): As discussed above, with reference of Table-1, we have to define modelling type of slab as 'membrane' (as it has no out of plane bending moments) and assign a 'rigid' diaphragm (as it has no in-plane stresses).

Practically on site: In order to satisfy the guidelines of code, stiffness of slab for lateral loads is ignored by implementing the latest construction practice of *"Jump formwork with* Connectrix *boxes"*

Table-1

Property of diaphragm/slab	In-plane stresses	Out of plane bending
Rigid	No	Yes
Semi-rigid	Yes	Yes
Membrane	Yes	No
Shell	Yes	Yes

Rigid diaphragms are infinitely stiff; therefore relative displacement between any two points/joints is zero. These diaphragms don't report shell stresses and in-plane forces, but reports out of plane bending, whereas Semi-rigid diaphragms report both in-plane stresses and out of plane bending. Membranes transfers load directly to supporting structural objects and do not take part in load bearing; load is transferred 100% to the vertical members (based upon their own stiffness). In shells, the stiffness of diaphragm and associated members contributes in load transfer; therefore resist a portion of the load through flexural deformation.

Jump formwork system (also referred as self-climbing or self-lifting) to construct the central core walls. The central core is typically constructed ahead of the residential wings by using a climbing formwork system as shown in Figure 1.4. The formwork supports itself on the

concrete cast earlier so does not rely on support or access from other parts of the building or permanent works.

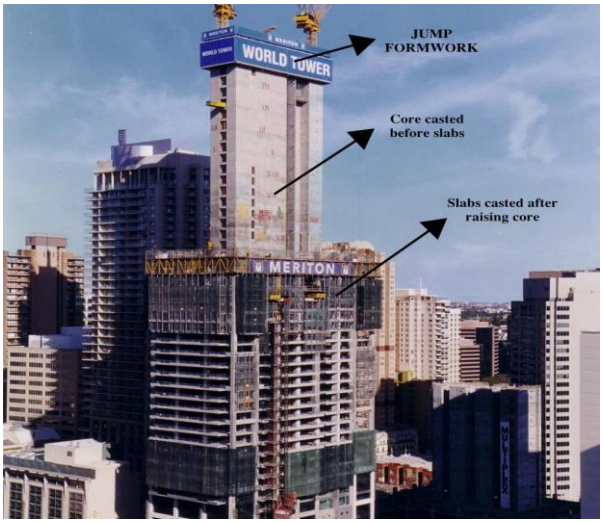

Figure 1.4

Connectrix connection box is used to eliminate/reduce the moment transfer from slab to vertical elements. Box installation is as shown in Figure 1.5 and is widely suitable for:

- Wall to Slab Connections
- Slab to Slab Connections
- Wall to Wall Connections
- Stair Landing Connections

Figure 1.5

2. NUMERICAL STUDY

The structural model adopted for the study is a tall building with 50 storeys, the plan area is 30 m x 30 m. The structural configuration is a 'tube in tube' lateral load resisting system. Later podium structure is attached to the existing tower and the studies are carried out on 18 models by changing the structural configuration of podium structure.

Case (I) : Independent tower model.

In order to understand the contribution of podium, we need to identify the analysis results of an individual tower model independent of podium.

Case (II) : Podium-tower with 10 m podium width.
Case (III): Podium-tower with 20 m podium width.
Case (IV): Podium-tower with 30 m podium width.
Case (V): Podium-tower with 40 m podium width.

From Case – II to Case – V, Podium (a non-tower structure) is attached to the tower on its three sides with 10 m, 20 m, 30 m and 40 m width. Tower is at one side of podium. The sensitivity study is done by varying structural configuration of podium as following options:

i. Slab with beams of 10 m span.
ii. Flat Plate with columns at 10 m distance.
iii. Flat Plate with columns at 5 m distance .
iv. Flat Plate with columns at varying distance.

Case (VI): Outrigger in podium.
Case (VII): Extended blade walls in podium.

2.1 Description of Building Model

The podium-tower assemblage adopted is as follows for loading in Table-2

- Number of floors = 3B+G+50 ***(153 m)***
- Number of podium floors = 3B+G+9 (***30m)***
- Storey height = 3 m *(3.5 m for basements)*
- Grade of concrete
  - Base to G+20 = M60
  - G+21 to G+40 = M55
  - G+41 to G+50 = M50
- Sectional properties changed for every 10 floors
- Cracking of elements (as per IS 16700-2017)
  - Beams = 0.7 (M.O.I about 2 and 3 axis)
  - Slabs = 0.35 (Bending M11 and M22)

Table-2

Type of load	Intensity
SDL(Finishes, ceiling and services)	1.5 (kN/m^2)
Live load	2.0 (kN/m^2)
Partition wall load	2.0 (kN/m^2)
Facade (Glass)	4.0 (kN/m)
Wind speed	44 m/sec (Hyderabad)
Terrain category -	2
Structure class -	C

Table-3: Sectional properties

Structural elements		Sectional Properties
Tower columns	G+41 – G+50	450 x 450
	G+31 – G+40	600 x 600
	G+21 – G+30	700 x 700
	G+11 – G+20	850 x 850
	B – G+10	1000 x 1000
Tower walls	G+41 – G+50	300
	G+31 – G+40	350
	G+21 – G+30	400
	G+11 – G+20	450
	B – G+10	500
Retaining wall		400
Depth of tower peripheral beams		750
Peripheral beams of tower in podium		400 x 1200

Peripheral beams in podium		300 x 800
Columns in podium		800 x 800
Tower slabs (rigid membrane)		250
Podium slabs (semi rigid shell)		270
Outriggers		7500 x 500
Blade walls		3500 x 600

2.2 Analytical Models

P-Delta effect is considered for analysis, which is a non-linear effect and studied for wind forces in X and Y directions to compare following results.

a) Displacement at the roof level.
b) Moment contributed by outer core, inner core and retaining wall at the base.
c) Moments in slab at podium-tower interface.
d) Stresses in slab at podium-tower interface.
e) Strutting forces in slab at podium-tower interface.

Case (I) : Independent tower model

An independent tower with plan and elevation views as shown in Figures 2.1 and 2.2. The tower has 3 basements and G+50 floors, total height of building above G.L is 150 m. Table-4 shows the results from analysis, it is observed that the tower displacement is exceeding the allowable limit.

Allowable displacement is **H/500**

=> (153000)/500 = **306 mm.**

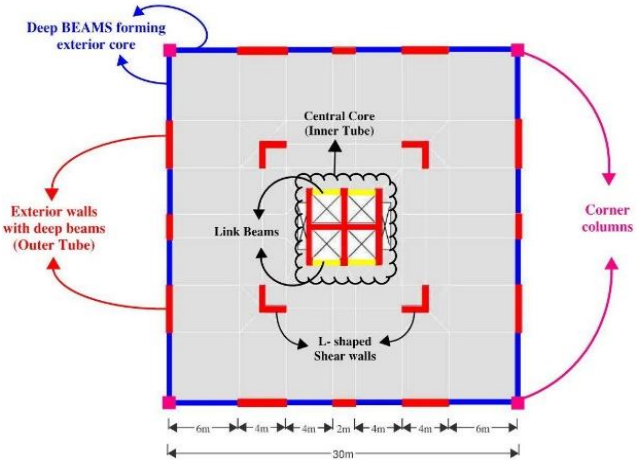

Figure 2.1

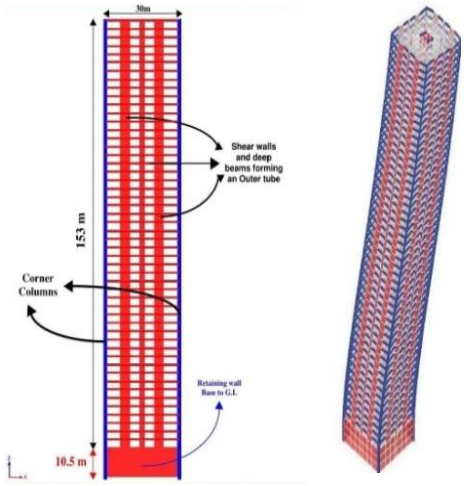

Figure 2.2

Table-4: CASE – I Independent Tower

Displacements (mm)	Wind X	488
	Wind Y	517
	Allowable (H/500)	306

	%	97.6
	Inner core (kN-m)	42543.24
	%	2.4
	Retaining wall (kN-m)	included with outer core
	%	-
Stresses/Moments/Axial forces	-	-

Case II - Podium-Tower with 10 m Podium Width

Option – (i) Slab with beams of 10 m span:

Podium (a non-tower structure) is attached to the tower on its three sides with 10 m width. Tower is at one side of podium as shown in Figure 2.3

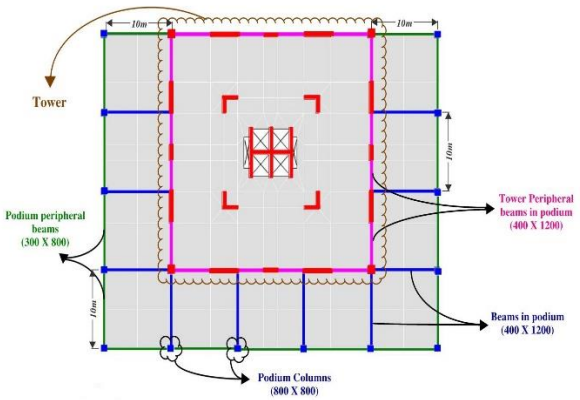

Figure 2.3

Table-5: Case II – (Option - i)

Displacements (mm)	Wind X	360
	Wind Y	384
	Allowable (H/500)	306
	% reduction for Wind X	-26.2
Total moment	My for Wx (kN-m)	1788293
	Mx for Wy (kN-m)	1814857
Moment contribution (Wind X)	Outer core (kN-m)	552582
	%	30.9
	Inner core (kN-m)	71531
	%	4.0
	Retaining wall (kN-m)	851227
	%	47.6
	Podium columns **(%)**	17.5
Moment contribution (Wind Y)	Outer core (kN-m)	662422
	%	36.5
	Inner core (kN-m)	29037
	%	1.6
	Retaining wall (kN-m)	878390
	%	48.4
	Podium columns **(%)**	13.5
Stresses in podium diap.	S11 for Wx (MPa)	2.2
	S22 for Wy (MPa)	2.1
Moments in podium diap.	M11 for Wx (kN-m)	29
	M22 for Wy (kN-m)	31
Axial forces in podium diap.	F11 for Wx (kN/m)	147
	F22 for Wy (kN/m)	133

From Table-5, the drift at top of tower is controlled by 26%, even though the allowable limit is not satisfied. On the other hand, depth of beams in podium is reducing the storey height. Simultaneously, axial forces are generated in beams and interface level slab of podium model, which makes the design complicated and requires more steel. Hence, there is a need to study with flat slabs instead of beam-slab.

Option – (ii) Flat slab with columns at 10 m distance:

The podium comprises of flat slabs with peripheral beams as shown in Figure 2.4. The interior beams in podium structure are eliminated because such deep beams are reducing the floor height.

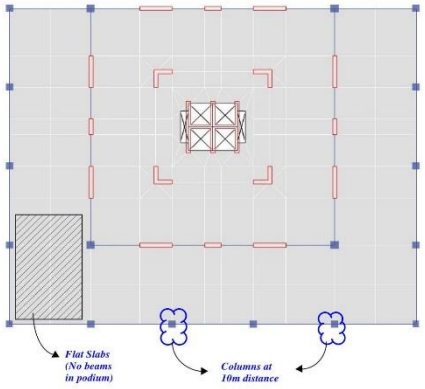

Figure 2.4

Table-6: Case II – (Option - ii)

Displacements (mm)	Wind X	385
	Wind Y	404
	Allowable (H/500)	306
	% reduction for Wind X	-21.1
Total moment	My for Wx (kN-m)	1788293
	Mx for Wy (kN-m)	1814857
Moment contribution (Wind X)	Outer core (kN-m)	763601
	%	42.70
	Inner core (kN-m)	80473
	%	4.5
	Retaining wall (kN-m)	661668
	%	37.0
	Podium columns **(%)**	15.8
Moment contribution (Wind Y)	Outer core (kN-m)	820315
	%	45.20
	Inner core (kN-m)	29037.712
	%	1.6
	Retaining wall (kN-m)	787647
	%	43.4
	Podium columns **(%)**	9.8
Stresses in podium diap.	S11 for Wx (MPa)	2
	S22 for Wy (MPa)	1.9
Moments in podium diap.	M11 for Wx (kN-m)	32
	M22 for Wy (kN-m)	37
Axial forces in podium diap.	F11 for Wx (kN/m)	136
	F22 for Wy (kN/m)	128

From Table-6 it is observed that around 21% drift is reduced, though axial forces at interface diaphragm are less but tower is not meeting the allowable drift. Therefore, the column spacing in podium is reduced from 10 m to 5 m and the effect of framing action on drift and diaphragm forces are noted.

Option – (iii) Flat Plate with Columns at 5 m design:

In this model column spacing in podium structure is 5 m as shown in Figure 2.5

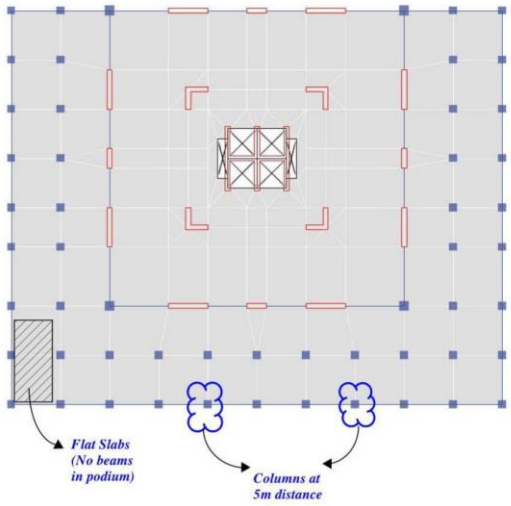

Figure 2.5

Table-7: Case II – (Option - iii)

Displacements (mm)	Wind X	362
	Wind Y	387
	Allowable (H/500)	306
	% reduction for Wind X	-25.8
Total moment	My for Wx (kN-m)	1788293
	Mx for Wy (kN-m)	1814857
Moment contribution (Wind X)	Outer core (kN-m)	581195
	%	32.50
	Inner core (kN-m)	69743
	%	3.9
	Retaining wall (kN-m)	706375
	%	39.5
	Podium columns (%)	24.1
Moment contribution (Wind Y)	Outer core (kN-m)	658793
	%	36.30
	Inner core (kN-m)	30852
	%	1.7
	Retaining wall (kN-m)	793092
	%	43.7
	Podium columns (%)	18.3
Stresses in podium diap.	S11 for Wx (MPa)	3.3
	S22 for Wy (MPa)	3.6
Moments in podium diap.	M11 for Wx (kN-m)	38
	M22 for Wy (kN-m)	41
Axial forces in podium diap.	F11 for Wx (kN/m)	256
	F22 for Wy (kN/m)	291

From Table-7 it is observed that with the increase of framing action in podium around 26% of displacement is reduced which is similar to that of Case – II (Option - i) i.e., beam-slab system. Simultaneously there is around 60% increase of strutting forces at interface diaphragm when compared to Case – II (Option – ii) model.

Case III - Podium-Tower with 20 m Podium Width

Option – (i) Slab with beams of 10 m span:

The assemblage is shown in Figure 2.6, Here width of podium is increased by10 m for previous case. Total width of podium from face of tower is 20 m.

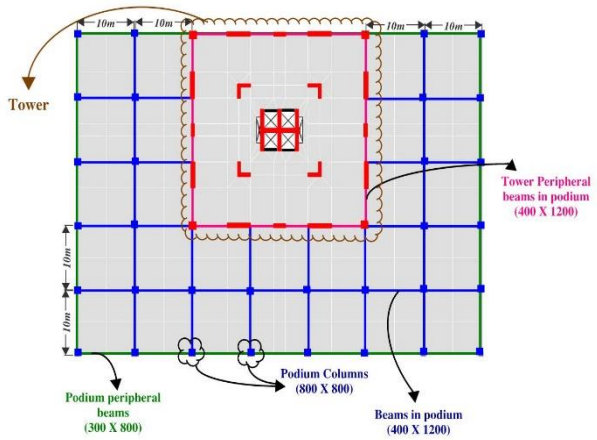

Figure 2.6

Table-8: Case III – (Option - i)

Displacements (mm)	Wind X	353
	Wind Y	377
	Allowable (H/500)	306
	% reduction for Wind X	-27.7
Total moment	My for Wx (kN-m)	1819357
	Mx for Wy (kN-m)	1872185
Moment contribution (Wind X)	Outer core (kN-m)	520336
	%	28.60
	Inner core (kN-m)	61858
	%	3.4
	Retaining wall (kN-m)	851459
	%	46.8
	Podium columns (%)	21.2
Moment contribution (Wind Y)	Outer core (kN-m)	634670
	%	33.90
	Inner core (kN-m)	35571
	%	1.9
	Retaining wall (kN-m)	962303
	%	51.4
	Podium columns (%)	12.8
Stresses in podium diap.	S11 for Wx (MPa)	2.85
	S22 for Wy (MPa)	3.25
Moments in podium diap.	M11 for Wx (kN-m)	21
	M22 for Wy (kN-m)	23
Axial forces in podium diap.	F11 for Wx (kN/m)	235
	F22 for Wy (kN/m)	267

Table-8 shows the lateral displacement of tower is reduced by around 28%, this is just 2% more than that of Case – II (Option – i) which was 26%. Though one more bay of 10 m width is added, there is not much change in tower drift. On the other hand, the axial forces are increased by around 45%. Retaining walls at the base are

sharing moments around 46% in X-direction and 51% in Y-direction.

Option – (ii) Flat slab with columns at 10 m distance:

This model has flat slabs in podium with 10 m column spacing as shown in Figure 2.7.

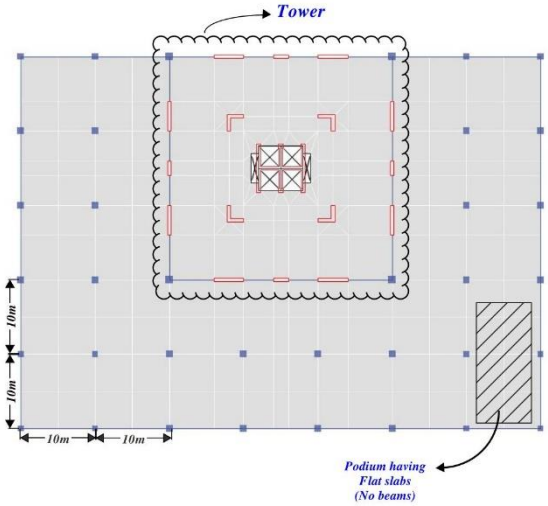

Figure 2.7

Table-9: Case III – (Option - ii)

Displacements (mm)	Wind X	382
	Wind Y	398
	Allowable (H/500)	306
	% reduction for Wind X	-21.7
Total moment	My for Wx (kN-m)	1819357
	Mx for Wy (kN-m)	1872185
Moment contribution (Wind X)	Outer core (kN-m)	764129.94
	%	42.00
	Inner core (kN-m)	78778.1581
	%	4.3
	Retaining wall (kN-m)	673162.09
	%	37.0
	Podium columns (%)	16.7
Moment contribution (Wind Y)	Outer core (kN-m)	748874
	%	40.00
	Inner core (kN-m)	33699.33
	%	1.8
	Retaining wall (kN-m)	926731.575
	%	49.5
	Podium columns (%)	8.7
Stresses in podium diap.	S11 for Wx (MPa)	2.2
	S22 for Wy (MPa)	2.3
Moments in podium diap.	M11 for Wx (kN-m)	30
	M22 for Wy (kN-m)	33
Axial forces in podium diap.	F11 for Wx (kN/m)	190
	F22 for Wy (kN/m)	163

From Table-9, analysis results show there is no change in contribution of podium in tower drift control when compared with Case - II (Option - ii). As there is no framing action in podium-tower, lateral drift is not reduced and less strutting forces are reported in diaphragm at interface level. This reveals that the podiums with flat slabs having columns at far distances has less framing action and no contribution in tower drift control beyond its first bay.

Option – (iii) Flat Plate with Columns at 5 m design:

As there was less framing action in previous model, we are trying to induce more framing action by maintain column distances at 5 m as shown in Figure 2.8

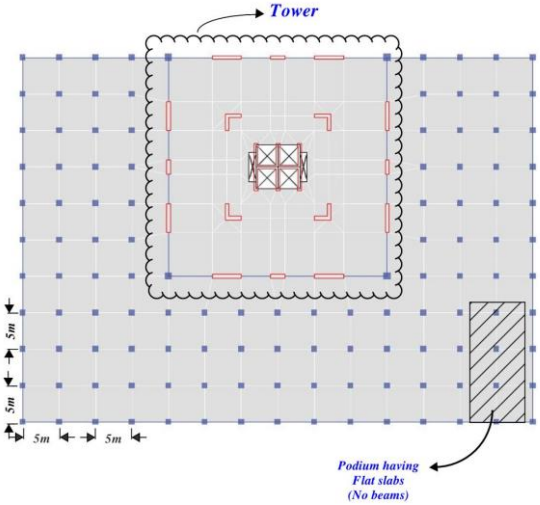

Figure 2.8

Table-10: Case III – (Option - iii)

Displacements (mm)	Wind X	354
	Wind Y	380
	Allowable (H/500)	306
	% reduction for Wind X	-27.5
Total moment	My for Wx (kN-m)	1819357
	Mx for Wy (kN-m)	1872185
Moment contribution (Wind X)	Outer core (kN-m)	564000.67
	%	31.00
	Inner core (kN-m)	65496.852
	%	3.6
	Retaining wall (kN-m)	764129.94
	%	42.0
	Podium columns (%)	23.4
Moment contribution (Wind Y)	Outer core (kN-m)	651520.38
	%	34.80
	Inner core (kN-m)	33699.33
	%	1.8
	Retaining wall (kN-m)	939836.87
	%	50.2
	Podium columns (%)	13.2
Stresses in podium diap.	S11 for Wx (MPa)	3.9
	S22 for Wy (MPa)	4.7
Moments in podium diap.	M11 for Wx (kN-m)	37
	M22 for Wy (kN-m)	47
Axial forces in podium diap.	F11 for Wx (kN/m)	354
	F22 for Wy (kN/m)	406

From Table-10, it is observed that podium is contributing around 27.5% in drift control, just 1.5% increase from that of Case – II (Option – iii).

Simultaneously there is around 30% increase in strutting forces at interface level diaphragm. Retaining walls at base has 50% of moment contribution. There is still a need for such configuration that reduces strutting forces.

Option – (iv) Flat Plate with Columns at varying Distance:

Podium columns are spaced by varying distances, first two bays are at 5 m and third one at 7.5 m making total width of podium as 17.5 m from face of tower as shown in Figure 2.9.

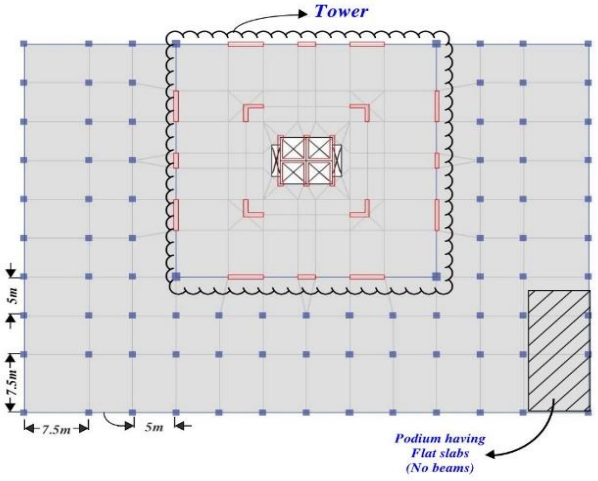

Figure 2.9

Table-11: Case III – (Option - iv)

Displacements (mm)	Wind X	358
	Wind Y	383
	Allowable (H/500)	306
	% reduction for Wind X	-26.6
Total moment	My for Wx (kN-m)	1812716
	Mx for Wy (kN-m)	1850703
Moment contribution (Wind X)	Outer core (kN-m)	543814.8
	%	30.00
	Inner core (kN-m)	67070.492
	%	3.7
	Retaining wall (kN-m)	696082.944
	%	38.4
	Podium columns (%)	27.9
Moment contribution (Wind Y)	Outer core (kN-m)	662551.674
	%	35.80
	Inner core (kN-m)	35163.357
	%	1.9
	Retaining wall (kN-m)	886486.737
	%	47.9
	Podium columns (%)	14.4
Stresses in podium diap.	S11 for Wx (MPa)	3.55
	S22 for Wy (MPa)	3.8
Moments in podium diap.	M11 for Wx (kN-m)	40
	M22 for Wy (kN-m)	47
Axial forces in podium diap.	F11 for Wx (kN/m)	326
	F22 for Wy (kN/m)	348

It is observed from Table-11, that there is decrease in contribution (tower drift control) by 0.9% and around 15% reduction in strutting forces when compared with previous Option – iii. This option with columns at varying distances is quiet productive in displacement and in-plane forces but the allowable displacement limit is still not achieved.

Case IV - Podium-Tower with 30 m Podium Width

Option – (i) Slab with beams of 10 m span:

Further proceeding the case study by adding more 10 m wide podium to the existing one. Total width of podium is 30 m with 3 bays of 10 m width as shown in Figure 2.10.

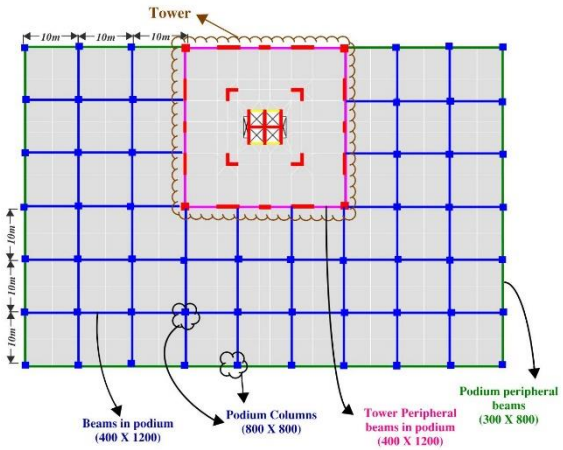

Figure 2.10

Table-12: Case IV – (Option - i)

Displacements (mm)	Wind X	345
	Wind Y	371
	Allowable (H/500)	306
	% reduction for Wind X	-29.3
Total moment	My for Wx (kN-m)	1846422
	Mx for Wy (kN-m)	1926114.0
Moment contribution (Wind X)	Outer core (kN-m)	553926.6
	%	30.00
	Inner core (kN-m)	51699.816
	%	2.8
	Retaining wall (kN-m)	899207.514
	%	48.7
	Podium columns (%)	18.5
Moment contribution (Wind Y)	Outer core (kN-m)	659694.045
	%	34.25
	Inner core (kN-m)	34670.052
	%	1.8
	Retaining wall (kN-m)	1088254.41
	%	56.5
	Podium columns (%)	7.5
Stresses in podium diap.	S11 for Wx (MPa)	3.38
	S22 for Wy (MPa)	3.88
Moments in podium diap.	M11 for Wx (kN-m)	21
	M22 for Wy (kN-m)	25
Axial forces in podium diap.	F11 for Wx (kN/m)	269
	F22 for Wy (kN/m)	337

From Table-12, it is observed that around 29% of tower displacement is reduced. Only 1.3% more than Case – III (Option – i), which was around 27.7%. Increase in size of podium has very nominal contribution in tower displacement; on the other hand, as framing action is increased around 21% strutting forces are increased.

Option – (ii) Flat slab with columns at 10 m distance:

Revising the previous model by eliminating beams in podium structure and making it as flat slab-column frame as shown in Figure 2.11

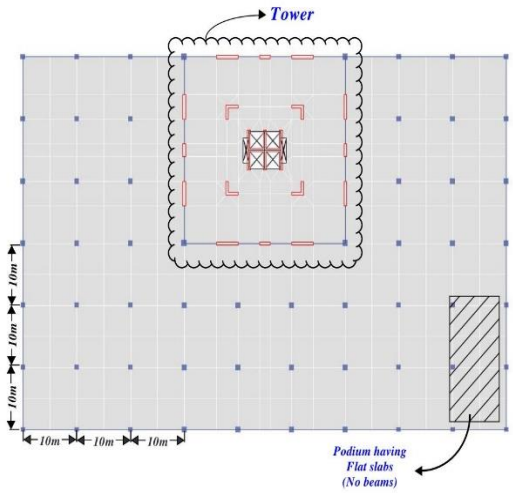

Figure 2.11

Table-13: Case IV – (Option - ii)

Displacements (mm)	Wind X	380
	Wind Y	396
	Allowable (H/500)	306
	% reduction for Wind X	-22.1
Total moment	My for Wx (kN-m)	1846422
	Mx for Wy (kN-m)	1926114.0
Moment contribution (Wind X)	Outer core (kN-m)	406212.84
	%	22.00
	Inner core (kN-m)	75703.302
	%	4.1
	Retaining wall (kN-m)	853046.964
	%	46.2
	Podium columns (%)	27.7
Moment contribution (Wind Y)	Outer core (kN-m)	494433.4638
	%	25.67
	Inner core (kN-m)	34670.052
	%	1.8
	Retaining wall (kN-m)	1016988.192
	%	52.8
	Podium columns (%)	19.7
Stresses in podium diap.	S11 for Wx (MPa)	2.89
	S22 for Wy (MPa)	2.7
Moments in podium diap.	M11 for Wx (kN-m)	35
	M22 for Wy (kN-m)	34
Axial forces in podium diap.	F11 for Wx (kN/m)	247
	F22 for Wy (kN/m)	217

From Table-13, it is observed that there is negligible contribution of podium on tower displacement when compared with Case – II (Option – ii), this is because flat slabs framing action depends upon spacing of columns, as columns are at far distance framing action is less and also strutting forces are reduced by around 36% when compared with previous Option - i.

Option – (iii) Flat Plate with Columns at 5 m design:

This model has column spacing of 5 m and remaining is same that of previous Option – ii model. Figure 2.12 shows the podium-tower assemblage.

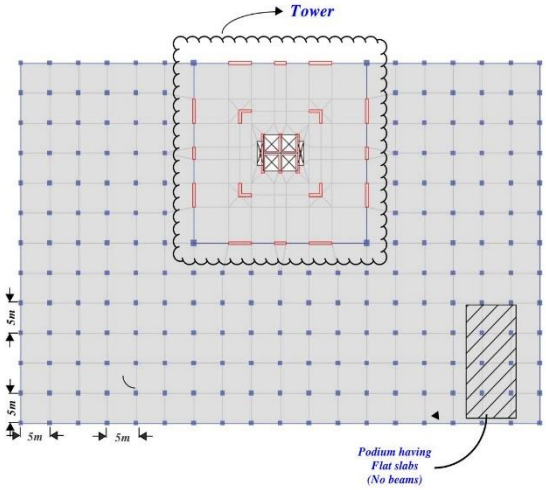

Figure 2.12

Table-14: Case IV – (Option - iii)

Displacements (mm)	Wind X	349
	Wind Y	374
	Allowable (H/500)	306
	% reduction for Wind X	-28.5
Total moment	My for Wx (kN-m)	1846422
	Mx for Wy (kN-m)	1926114.0
Moment contribution (Wind X)	Outer core (kN-m)	535462.38
	%	29.00
	Inner core (kN-m)	55392.66
	%	3.0
	Retaining wall (kN-m)	817964.946
	%	44.3
	Podium columns (%)	23.7
Moment contribution (Wind Y)	Outer core (kN-m)	609422.4696
	%	31.64
	Inner core (kN-m)	34670.052
	%	1.8
	Retaining wall (kN-m)	1020840.42
	%	53.0
	Podium columns (%)	13.6
Stresses in podium diap.	S11 for Wx (MPa)	4.96
	S22 for Wy (MPa)	5.51
Moments in podium diap.	M11 for Wx (kN-m)	41
	M22 for Wy (kN-m)	45
Axial forces in podium diap.	F11 for Wx (kN/m)	431
	F22 for Wy (kN/m)	486

The analysis results in Table-14. Shows that there is around 6% decrease in tower drift from Case – IV (Option – ii). Overall podium contribution in tower displacement is around 28.5% but need more to meet the allowable limit. Similarly, as we know the framing action is more than the previous model due to less column distance, there is huge increase in strutting forces by around 56%. Contribution of retaining wall in moments at base is 53%.

Option – (iv) Flat Plate with Columns at varying Distance:

As shown in the Figure 2.13, spacing of columns is varying. First two bays are of 5 m width; last two bays are of 7.5 m width.

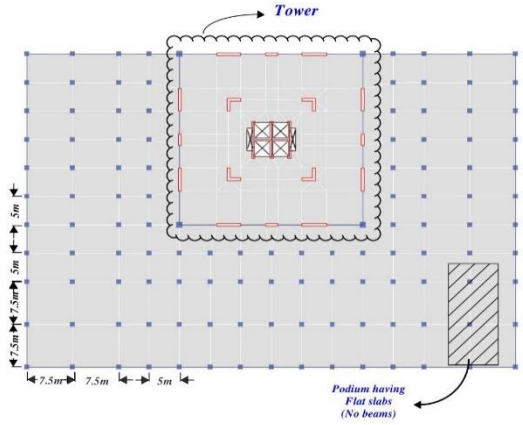

Figure 2.13

Table-15: Case IV – (Option - iv)

Displacements (mm)	Wind X	353
	Wind Y	378
	Allowable (H/500)	306
	% reduction for Wind X	-27.7
Total moment	My for Wx (kN-m)	1833139
	Mx for Wy (kN-m)	1895550.0
Moment contribution (Wind X)	Outer core (kN-m)	579271.924
	%	31.60
	Inner core (kN-m)	65993.004
	%	3.6
	Retaining wall (kN-m)	747920.712
	%	40.8
	Podium columns (%)	24.0
Moment contribution (Wind Y)	Outer core (kN-m)	664579.83
	%	35.06
	Inner core (kN-m)	36015.45
	%	1.9
	Retaining wall (kN-m)	1004641.5
	%	53.0
	Podium columns (%)	10.0
Stresses in podium diap.	S11 for Wx (MPa)	4.3
	S22 for Wy (MPa)	4.7
Moments in podium diap.	M11 for Wx (kN-m)	43
	M22 for Wy (kN-m)	48
Axial forces in podium diap.	F11 for Wx (kN/m)	363
	F22 for Wy (kN/m)	414

From analysis results as shown in Table-15, it is observed that around 15% of strutting forces are reduced by changing column positions at varying spans, but there is also decrease in tower displacement control by 2%.

Case V - Podium-Tower with 40 m Podium Width

Option – (i) Slab with beams of 10 m span:

In this case width of podium is further increased by 10 m, overall width of podium from face of tower is 40 m, column spacing is 10 m and slab is with beams as shown in Figure 2.14.

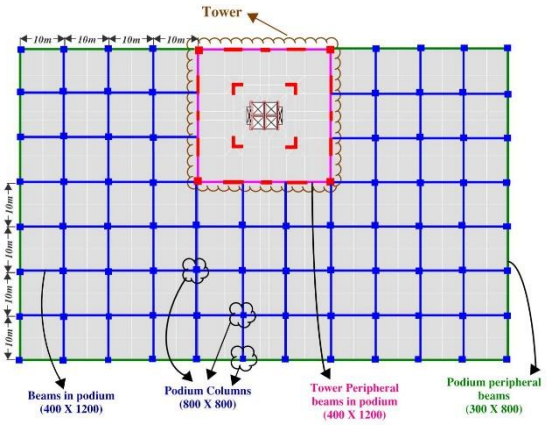

Figure 2.14

Table-16: Case V – (Option - i)

Displacements (mm)	Wind X	340
	Wind Y	365
	Allowable (H/500)	306
	% reduction for Wind X	-30.3
Total moment	My for Wx (kN-m)	1875986
	Mx for Wy (kN-m)	1962242
Moment contribution (Wind X)	Outer core (kN-m)	514020.164
	%	27.40
	Inner core (kN-m)	52527.608
	%	2.8
	Retaining wall (kN-m)	947372.93
	%	50.5
	Podium columns (%)	19.3
Moment contribution (Wind Y)	Outer core (kN-m)	588672.6
	%	30.00
	Inner core (kN-m)	35320.356
	%	1.8
	Retaining wall (kN-m)	1212665.556
	%	61.8
	Podium columns (%)	6.4
Stresses in podium diap.	S11 for Wx (MPa)	3.5
	S22 for Wy (MPa)	4.5
Moments in podium diap.	M11 for Wx (kN-m)	23
	M22 for Wy (kN-m)	26
Axial forces in podium diap.	F11 for Wx (kN/m)	309
	F22 for Wy (kN/m)	393

From analysis results as tabulated in Table-16, it is observed that podium is contributing by around 30% in tower displacement which is more than previous all cases, but this is an increase by just 1.7% from previous Case – IV (Option – i). Simultaneously the strutting forces are increased by 15%.

Option – (ii) Flat slab with columns at 10 m distance

Now in this model beams in podium are removed as shown in Figure 2.15

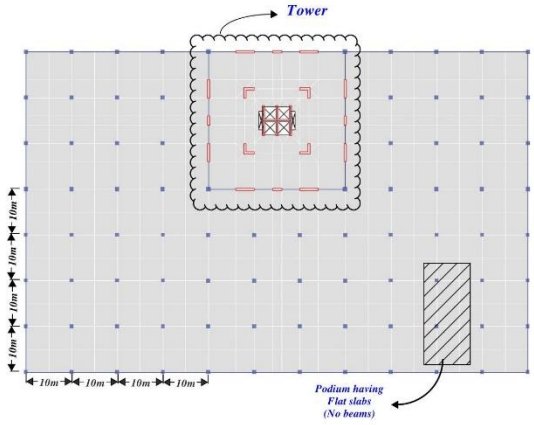

Figure 2.15

Table-16: Case V – (Option - ii)

Displacements (mm)	Wind X	378
	Wind Y	395
	Allowable (H/500)	306
	% reduction for Wind X	-22.5
Total moment	My for Wx (kN-m)	1875986
	Mx for Wy (kN-m)	1962242
Moment contribution (Wind X)	Outer core (kN-m)	761650.316
	%	40.60
	Inner core (kN-m)	71287.468
	%	3.8
	Retaining wall (kN-m)	769154.26
	%	41.0
	Podium columns (%)	14.6
Moment contribution (Wind Y)	Outer core (kN-m)	704444.878
	%	35.90
	Inner core (kN-m)	35320.356
	%	1.8
	Retaining wall (kN-m)	1110628.972
	%	56.6
	Podium columns (%)	5.7
Stresses in podium diap.	S11 for Wx (MPa)	3
	S22 for Wy (MPa)	3.1
Moments in podium diap.	M11 for Wx (kN-m)	33
	M22 for Wy (kN-m)	35
Axial forces in podium diap.	F11 for Wx (kN/m)	235
	F22 for Wy (kN/m)	260

It is observed from Table-16 that the tower drift is reduced by 22.5%, which is just 1% more than that of Case – II (Option – i). It is noted that increase in size of podium from 10 m width to 40 m width has effective contribution with its first bay only, further increase in number of bays with columns at 10 m distance has negligible contribution in tower displacement. Strutting forces are also reduced by 44% when compared with previous Option – i

Option – (iii) Flat Plate with Columns at 5 m design:

This model has columns at 5 m distance as shown in Figure 2.16, from this large sized podium model it is understood that in flat slabs framing action is more if columns are near.

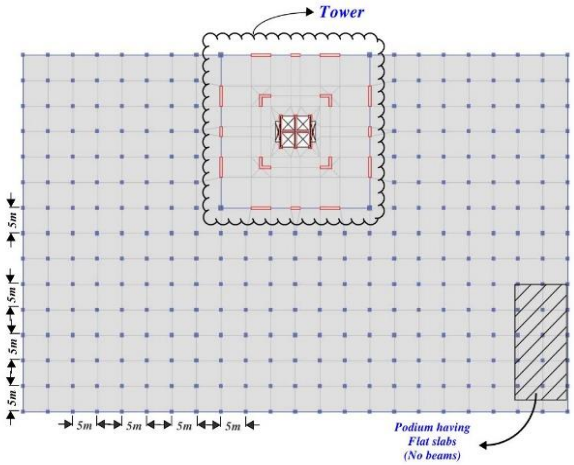

Figure 2.16

Table-17: Case V – (Option - iii)

Displacements (mm)	Wind X	343
	Wind Y	369
	Allowable (H/500)	306
	% reduction for Wind X	-29.7
Total moment	My for Wx (kN-m)	1875986
	Mx for Wy (kN-m)	1962242
Moment contribution (Wind X)	Outer core (kN-m)	510268.192
	%	27.20
	Inner core (kN-m)	50651.622
	%	2.7
	Retaining wall (kN-m)	874209.476
	%	46.6
	Podium columns (%)	23.5
Moment contribution (Wind Y)	Outer core (kN-m)	588672.6
	%	30.00
	Inner core (kN-m)	33358.114
	%	1.7
	Retaining wall (kN-m)	1008592.388
	%	51.4
	Podium columns (%)	16.9
Stresses in podium diap.	S11 for Wx (MPa)	4.49
	S22 for Wy (MPa)	6.5
Moments in podium diap.	M11 for Wx (kN-m)	37
	M22 for Wy (kN-m)	40
Axial forces in podium diap.	F11 for Wx (kN/m)	378
	F22 for Wy (kN/m)	546

From Table-17 it is observed that displacement is controlled by around 30%, which is just 1.2% more than the model in Case – IV (Option – iii). It shows that the contribution in displacement is increased by around 6% to 7% when compared with (Option – ii) of all cases. At the same time strutting forces are increased by around 55%. This is clearly because of more framing action.

Option – (iv) Flat Plate with Columns at varying Distance:

The assemblage of podium-tower is as shown in Figure 2.17. Columns in podium are at varying distances. First two bays are at 5 m distance, next two bays are at 7.5 m and last bay is at 10 m. Total width of podium is 35 m.

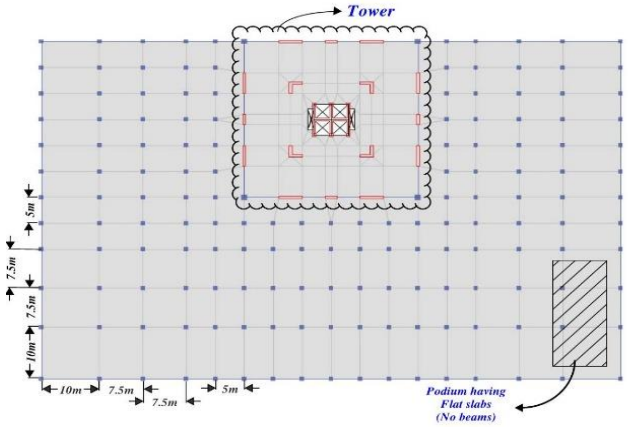

Figure 2.17

Table-18: Case V – (Option - iv)

Displacements (mm)	Wind X	347
	Wind Y	373
	Allowable (H/500)	306
	% reduction for Wind X	-28.9
Total moment	My for Wx (kN-m)	1862704
	Mx for Wy (kN-m)	1940678
Moment contribution (Wind X)	Outer core (kN-m)	541488.0528
	%	29.07
	Inner core (kN-m)	63331.936
	%	3.4
	Retaining wall (kN-m)	745081.6
	%	40.0
	Podium columns (%)	27.5
Moment contribution (Wind Y)	Outer core (kN-m)	641588.1468
	%	33.06
	Inner core (kN-m)	36872.882
	%	1.9
	Retaining wall (kN-m)	1036322.052
	%	53.4
	Podium columns (%)	11.6
Stresses in podium diap.	S11 for Wx (MPa)	4.6
	S22 for Wy (MPa)	4.9
Moments in podium diap.	M11 for Wx (kN-m)	39
	M22 for Wy (kN-m)	43
Axial forces in podium diap.	F11 for Wx (kN/m)	350
	F22 for Wy (kN/m)	418

From analysis results as shown in Table-18, it is observed that strutting forces are slightly reduced but there is also increase in tower displacement by 2%. This assemblage is having very nominal effect on displacement. Therefore, it can be suggested that size of podium can be restricted and some structural elements can be introduced in podium to limit tower displacement and reduce strutting forces.

Case VI – Podium with Outriggers in 9th and 10th floors at Podium-Tower Junction:

Outriggers are improvised form of frames which are very deep beams of single storey height between two columns. These are very effective in controlling drifts of tall buildings. As the study is about interface diaphragm, so the outriggers are introduced on 9th and 10th storeys of podium at podium-tower junction as shown in Figure 2.18. Size of podium is restricted to 17.5 m width.

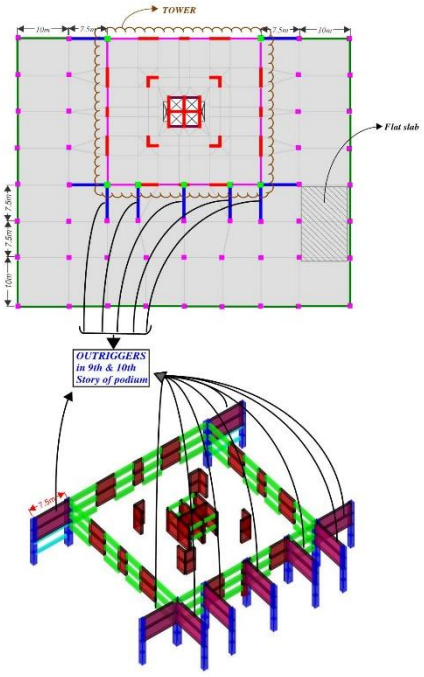

Figure 2.18

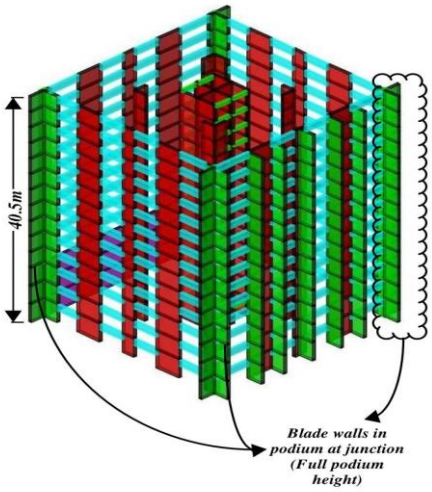

The analysis results from Table-19 revealed that the outriggers are very effective in controlling tower drift as it percentage contribution is around 32%, which is even not satisfying the allowable limit of displacement for lateral wind load. On the other hand, this podium configuration with outriggers has reported tremendous increase in in-plane strutting forces at interface level slab, which is 50% more than that of same podium size without outriggers as discussed in Case – III (Option – iv).

Table-19: Case VI

	F22 for Wy (kN/m)	504

Case VII – Podium with Extended Blade Walls at Podium-Tower Junction

This case is studied by introducing structural walls in podium at podium-tower junction to minimize strutting forces in podium-tower interface level diaphragm and also meet the allowable tower displacement. These are extended walls from either columns or existing walls as shown in Figure 2.19. As these are extended, we can call it as extended blade walls. These walls are extended up to 3.5 m length away from tower in perpendicular direction to the face of podium casted right from base to last storey of podium.

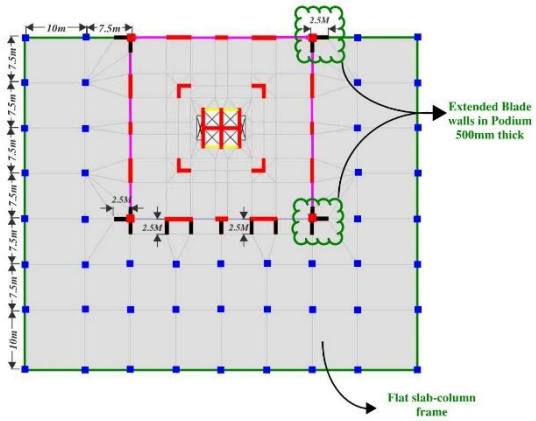

Figure 2.19

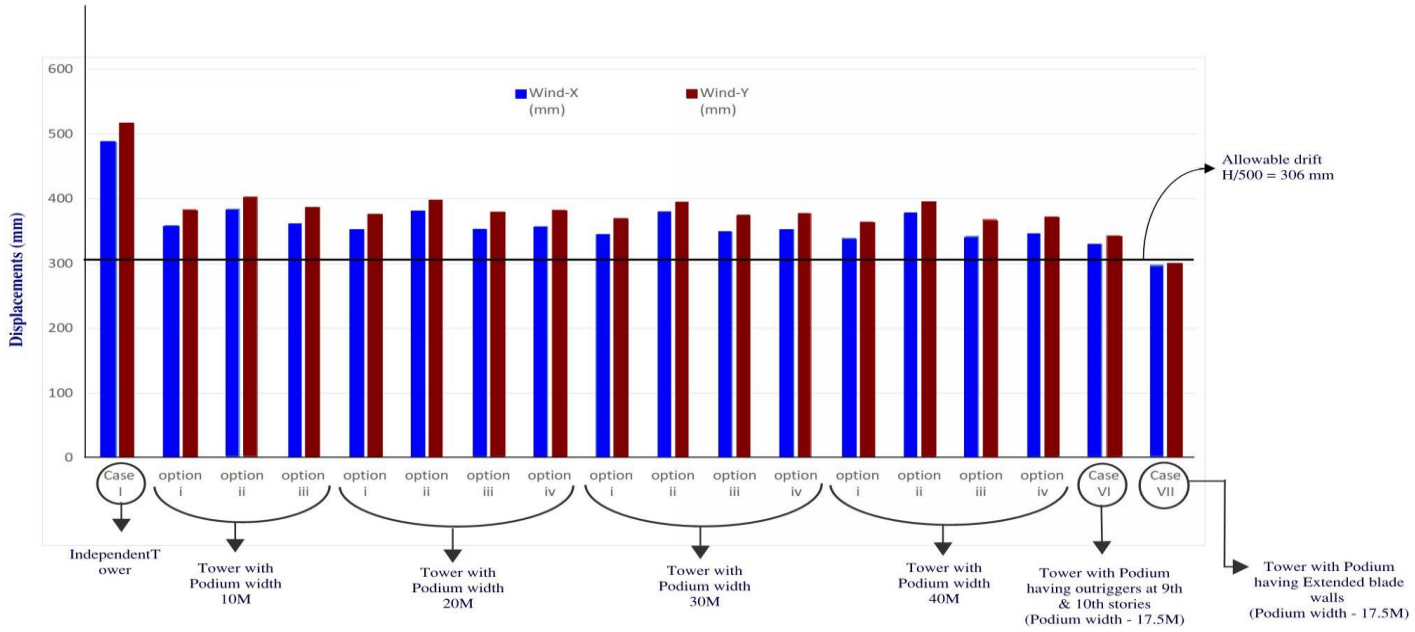
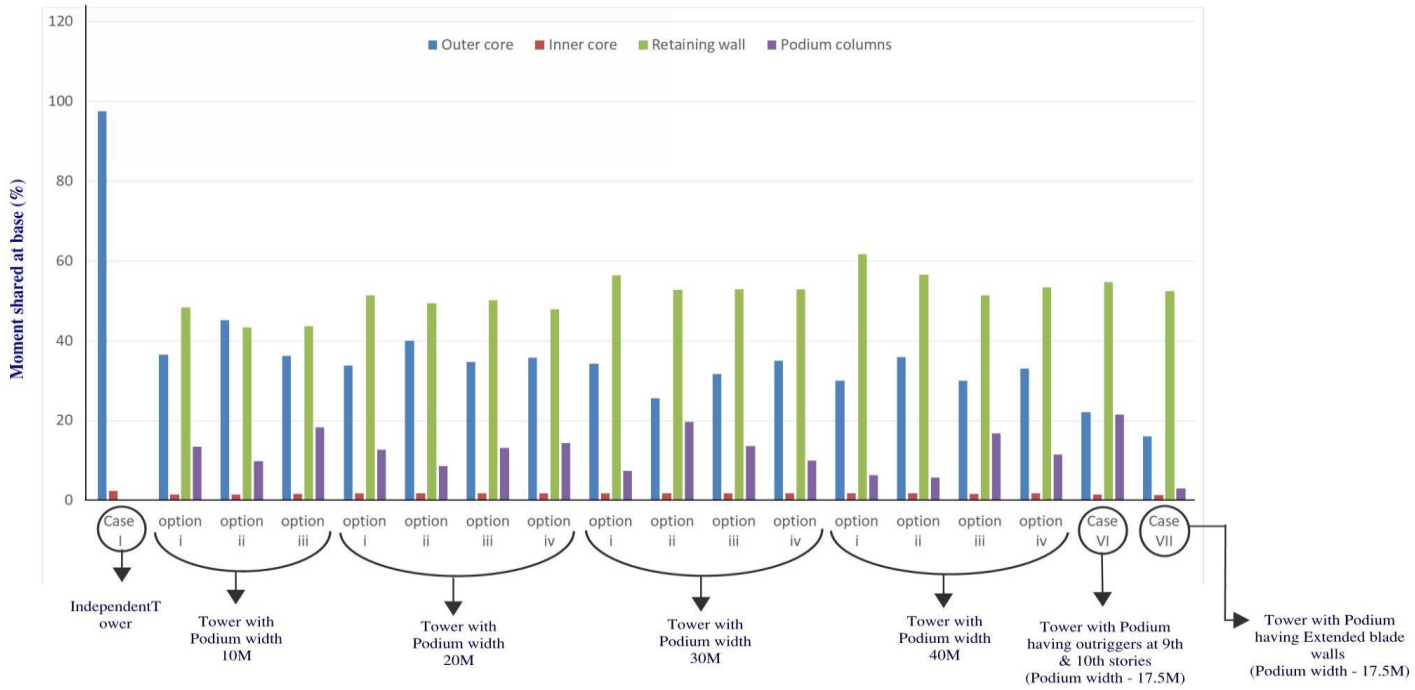
Table-20: Case VII



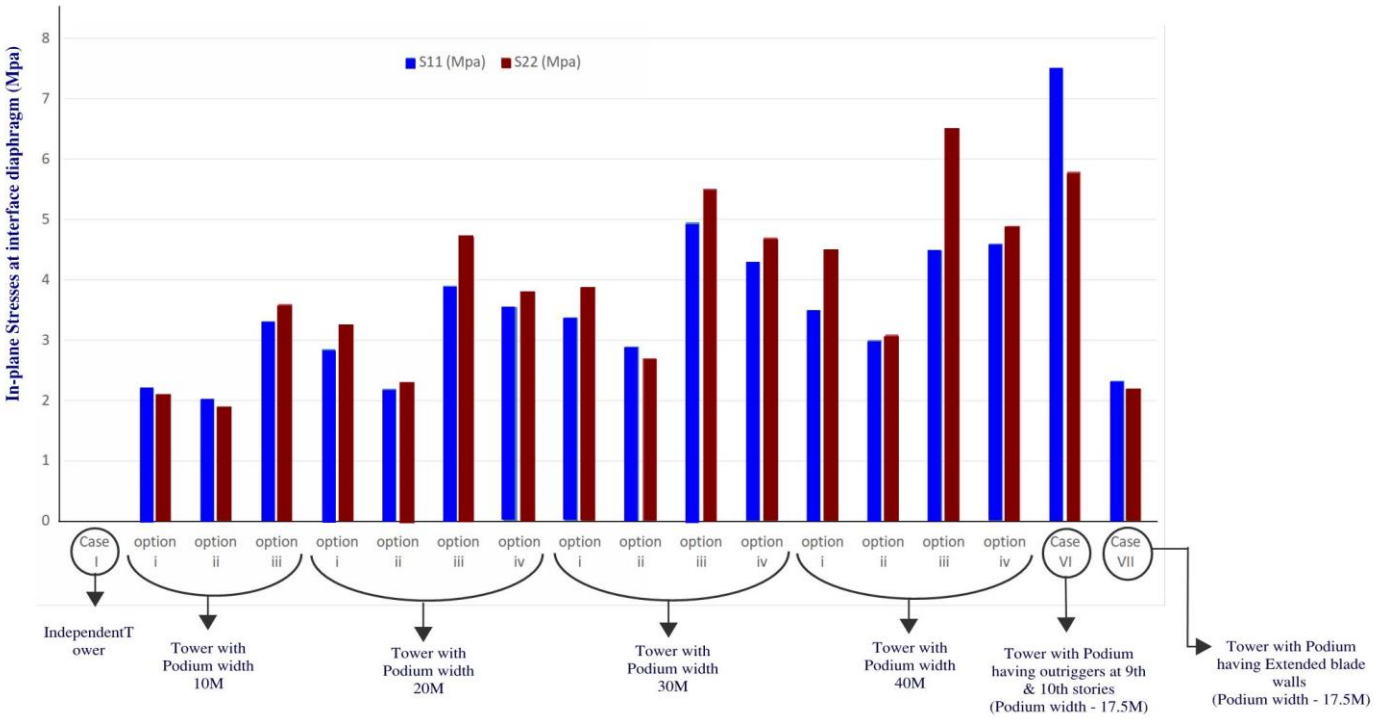
Displacements (mm)	Wind X	299
	Wind Y	301
	Allowable (H/500)	306
	% reduction for Wind X	-41.7
Total moment	My for Wx (kN-m)	1833706
	Mx for Wy (kN-m)	1857792.00
Moment contribution (Wind X)	Outer core (kN-m)	387518.2
	%	21.13
	Inner core (kN-m)	61510.6
	%	3.4
	Retaining wall (kN-m)	645814.7
	%	35.2
	Podium columns (%)	14.5
	Blade walls (%)	25.8
Moment contribution (Wind Y)	Outer core (kN-m)	297726.6
	%	16.03
	Inner core (kN-m)	26575.0
	%	1.4
	Retaining wall (kN-m)	974819.1
	%	52.5
	Podium columns (%)	3.1
	Blade walls (%)	27
Stresses in podium diap.	S11 for Wx (MPa)	2.33
	S22 for Wy (MPa)	2.2
Moments in podium diap.	M11 for Wx (kN-m)	30
	M22 for Wy (kN-m)	32
Axial forces in podium diap.	F11 for Wx (kN/m)	155
	F22 for Wy (kN/m)	135

The analysis results from Table-20 are satisfying both parameters, drift at top of tower and strutting forces at interface diaphragm. Tower displacement is under allowable limit and diaphragm forces are less comparatively with all the cases studied so far.

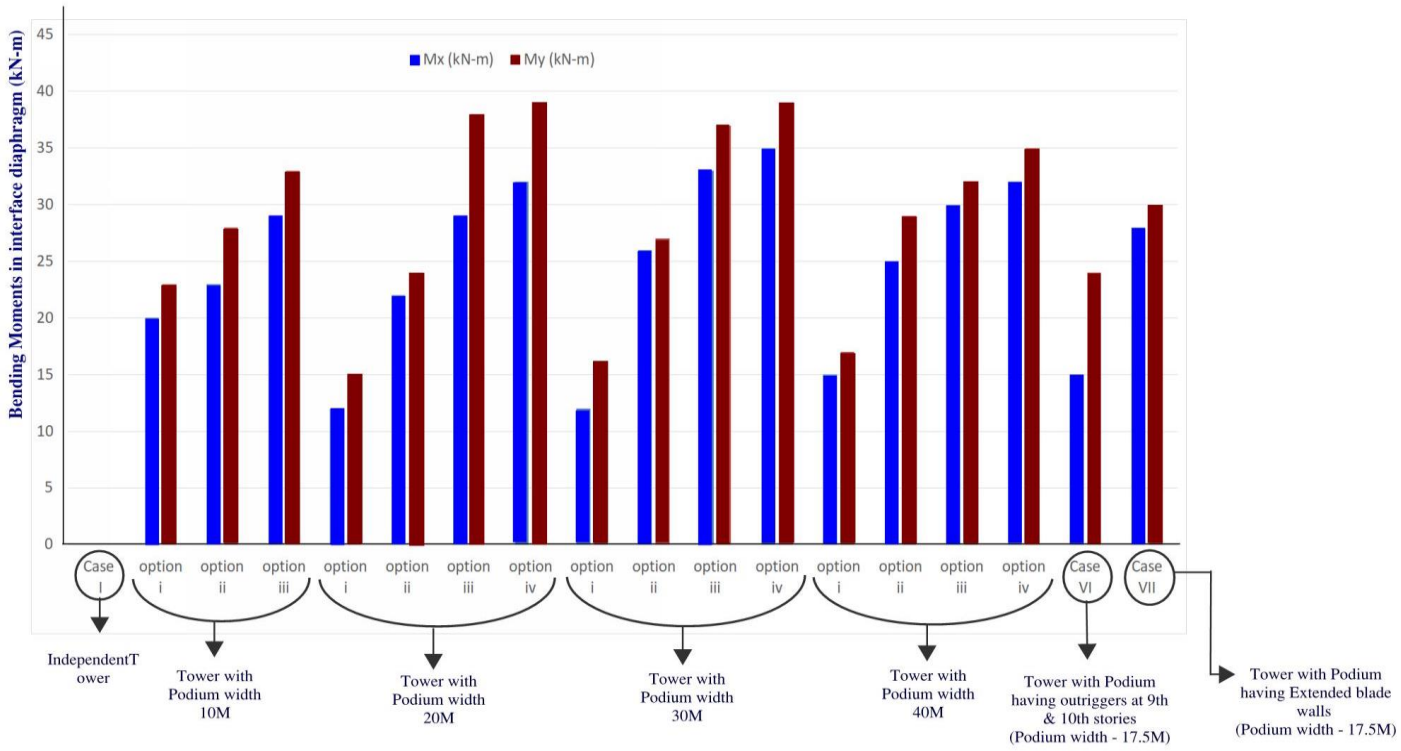


3. COMPARATIVE RESULTS

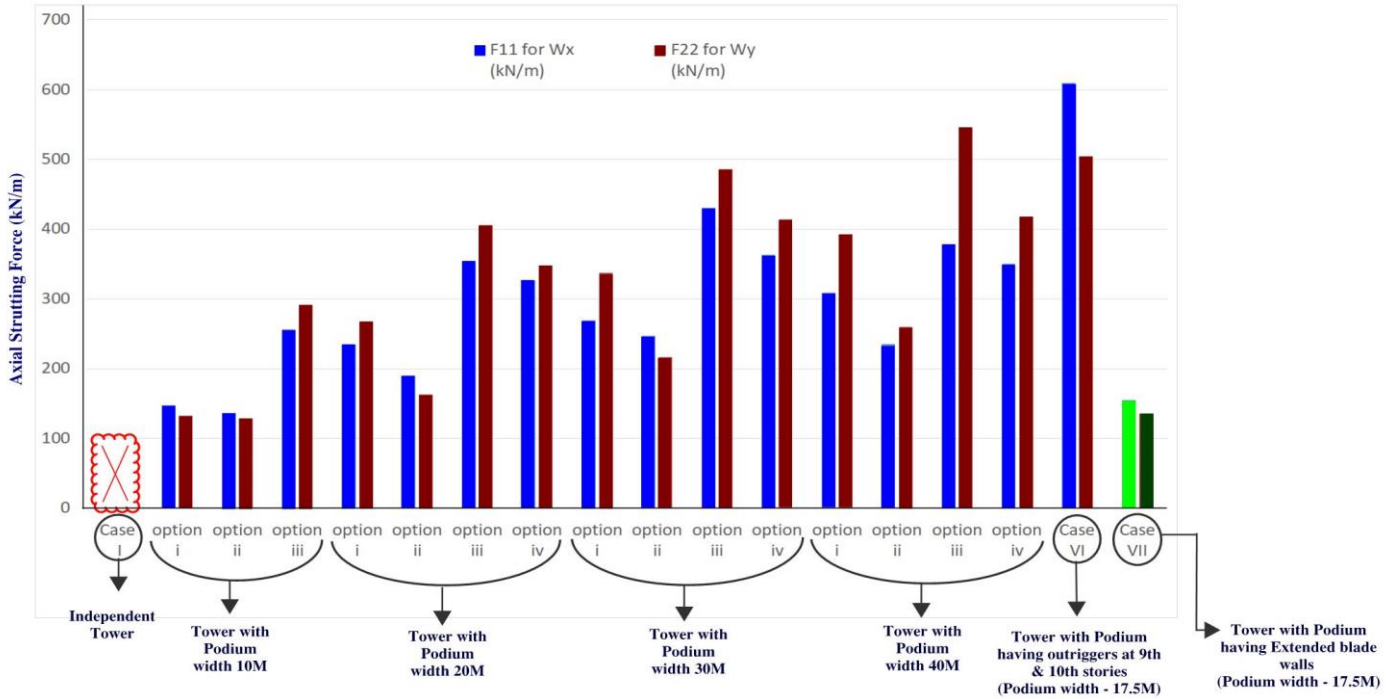
The comparative results after performing sensitivity analysis of podium-tower interaction emphasizing on podium structure are discussed in subsequent sections.



3.1 Comparison of displacements at top of tower



3.2 Moments shared at base of building



3.3 Comparison of stresses at interface level

3.4 Bending moments in interface diaphragm

3.5 Comparison of axial strutting forces in slab at podium-tower interface

4. CONCLUSIONS

The conclusions drawn from the numerical studies on podium structures are shown below. The results of linear analysis are varying from non-linear analysis, but the percentage difference of these results from model to model in linear analysis are almost similar to that of the non-linear analysis. Therefore, the specific conclusions are drawn from non-linear analysis, as it is recommended for tall buildings.

i. Podiums do contribute in reducing tower displacements. Almost 90% of this contribution is associated with its first bay around the tower.

ii. The increase in size of podium has nominal impact on tower drift. For Wind-Y tower displacement is 516 mm. Addition of first bay of podium reduced it to 384 mm (about 26.2%) and addition of next four bays reduced it to 360 mm (about 30.3%) which is 4% more reduction for 40 m wide podium.

iii. The strutting forces in podium diaphragm increase with increase in framing action. When columns are at 10 m distance the strutting forces are 260 kN/m and for 5 m distance it is 546 kN/m which is about 50% more.

iv. The flat slabs have less framing action than beam-slabs. Therefore, the flat slab system contributes less in control of tower displacement and also reports less strutting forces than the beam-column systems.

v. The outriggers in podium has reduced 32% of tower drift but increased strutting forces by 50%. This is due to increase in framing action.

vi. The extended blade walls in podium at podium-tower junction are very effective in controlling the tower drift to allowable limit (41.7% of displacement is reduced) and minimizing the framing actions at the same time, resulting in very less strutting forces of 135 kN/m at interface diaphragm.

vii. The moments shared by retaining walls at the base due to lateral loads is around 50%, which is more than any other structural element in the building for all cases.

viii. The podium columns in assemblage with outriggers exhibit more moment contributions at base than all other cases, which is around 22%.

Investigation and Approach of G+8 Building with Contrast the Results by using Staad.Pro and Etabs

K. Rajitha[1], G. Krishnarao[2]
[1, 2]*Civil Engineering Department, Malla Reddy Engineering College, Hyderabad*

Abstract: ***Structural analysis (calculating load coming on every member) is one of the most difficult and time consuming process. One single error can lead to life and money loss. STAAD. Pro and ETABS helps in analysis and designing (choosing size of member for coming load) of structures with very less time. Etabs is good for the designing a reinforced concrete structure. The user interface is easy and the analysis values of RC structures are better and we get economical steel data from etabs. Staad Pro is good for the analysis of steel structures frames as the codes and user interface is better integrated in staad pro. In this project we analyzing the G+8 building for finding the shear forces, Base shear, Bending moments, deflection and reinforcement. This project mainly deals with the comparative analysis of the results obtained by designing of a regular and a plan irregular (as per IS 1893) multi storey building structure designed separately using STAAD. Pro and Etabs softwares.***
Keywords: Sructural analysis, Regular and irregular, frame work, staad.pro, etabs.

I. INTRODUCTION

During an earthquake, failure of structure starts at elements of weak point. This weakness develops because of stoppage in mass, strength and also geometry of structure. The structures having this deduction are described as uneven frameworks. Uneven structures add a large portion of city framework. Upright irregularities are just one of the substantial variables of failings of structures throughout earthquakes. For instance a structure with soft floor was among one of the most significant frameworks which collapsed. So, the result of up and down abnormalities in the seismic effectiveness of structures winds up being really essential. Height-wise adjustments in stiffness in addition to mass render the vibrant attributes of these structures various from the regular framework. IS 1893 definition of Backwards and forwards unequal frame work. The abnormality in the structure frameworks could be due to irregular blood circulations in their mass, toughness along with tightness along the altitude of framework. When such frameworks are created in high seismic areas, the analysis and additionally design winds up being far more challenging. There are 2 types of irregularities.

1) Plan irregularities
2) Vertical Irregularities

A. Plan Irregularities

To offer first rate all-natural light and air float and to have an exceptional out of doors view from all the spaces, the designers set up very complex strategy shapes with re-entrant corners, floor slab reduce-outs, and additionally asymmetry These abnormalities are desirable to confined degree, however name for specific factor to remember in evaluation in addition to format, that's generally in no way made. In case of RC systems, now not just the method should be of ordinary shape, the arrangement of lateral load withstanding vertical additives ought to additionally be symmetrical.

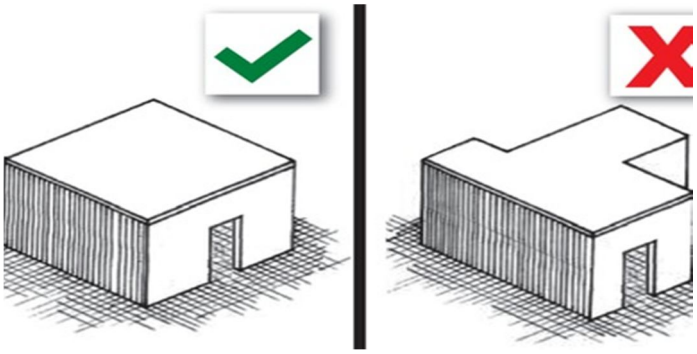

Figure1.1: Plan irregularities

©IJRASET: All Rights are Reserved

B. Vertical Irregularities

Vertical Abnormalities are especially of five kinds-.

1) *Stiffness Irregularity:* Soft Storey-A tender ground is one in which the lateral pressure is much less than 70 percent of the storey above or less than eighty percentage of the commonplace side stiffness of the three flooring above.
2) *Stiffness Abnormality:* Extreme Soft Storey-An immoderate smooth storey is one wherein the lateral pressure is much less than 60 percent of that in the floor above or much less than 70 percentage of the typical tightness of the 3 flooring over.
3) Mass irregularities
4) Vertical geometric irregularity

Figure1.2: Mass irregularities

II. OBJECTIVE OF THE STUDY

The following objectives are set in this study:

A. To accomplish modeling as well as assessment of G+ 8 R.C. framed frameworks utilizing STAAD-PRO & ETABS.
B. To Design ass per IS-456 & IS-1893:2002, a regular and irregular multi-storey structure.
C. To calculate shear forces, bending moments and reinforcing details for the buildings structural components (beams and columns) and compare the results.
D. To determine the economic section of the G+8 structure with both software.

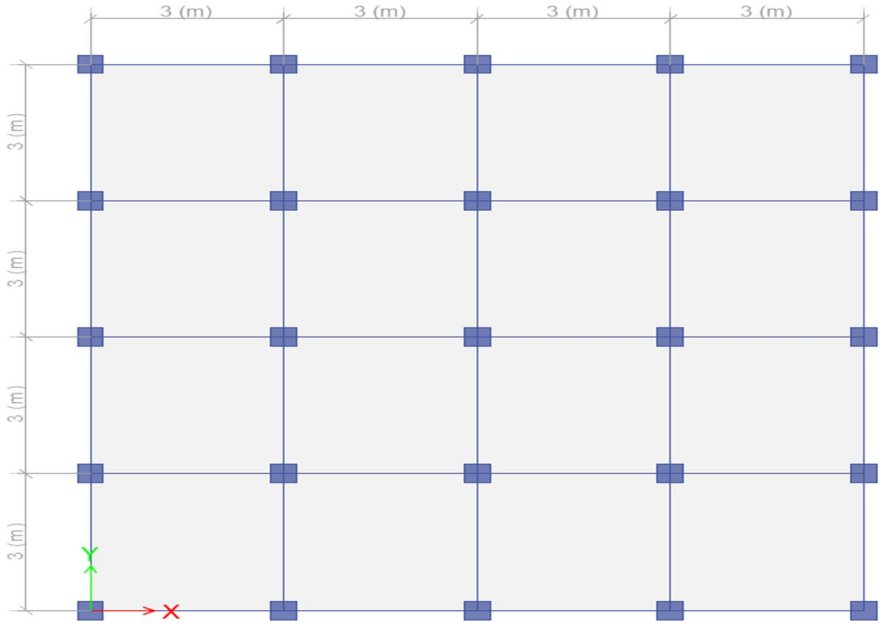
III. MODELLING OF G+8 STRUCTURE

In the recent time, Civil and Structural softwares analysis is more affectively used in analysis and design of different civil engineering. In this work we are using Staad Pro and Etabs softwares and analyzed structures as per IS 1893:2002. The following steps are adopted:



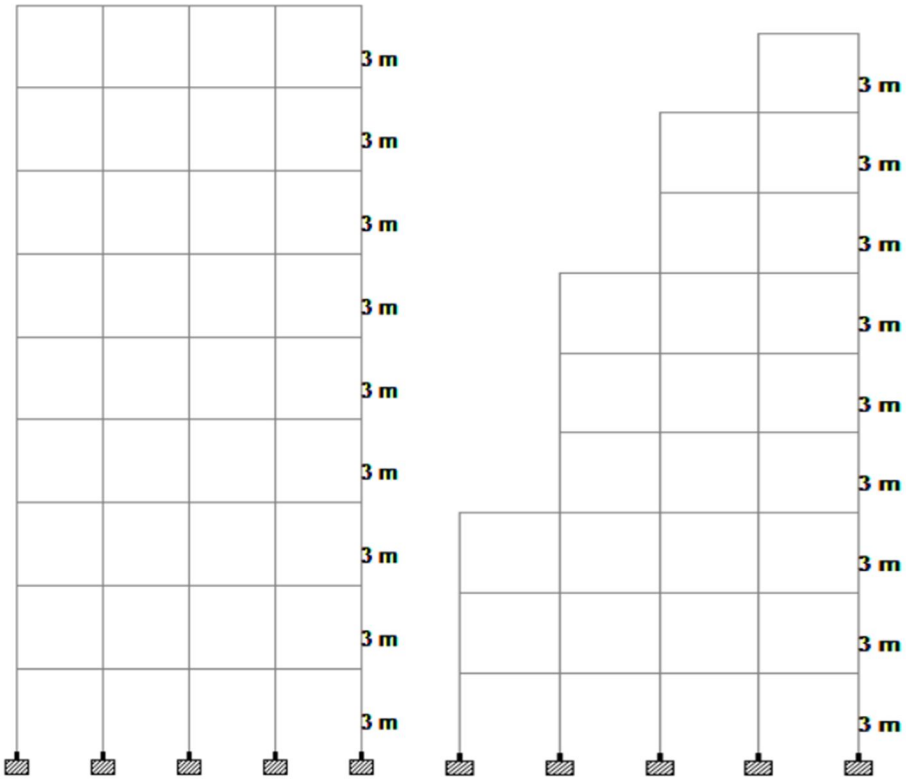


Figure2.1: Plan of G+8 Building

Regular Structure Irregular Structure

Figure2.2: Elevation of 2-Models

A. Preliminary Data

Type of frame :Ordinary RC moment resisting frame fixed at the base, Seismic zone :II , Number of storeys:9, Floor height:3m , Plinth height:1.5m, Depth of Slab:125 mm, Spacing between frames:3m along both directions, Live load on floor level:3 KN/m^2, Live load on roof level:1.5 KN/m^2, Floor finish:1.0 KN/m^2, Terrace water proofing:1.5 KN/m^2, Thickness of infill wall :230mm (Exterior walls),Thickness of infill wall:150mm (Interior walls), Density of concrete:25 KN/m^2, Density of infill:20 KN/m^2,Type of soil: Rocky , Response spectra :As per IS 1893(Part1):2002, Damping of structure:5 %

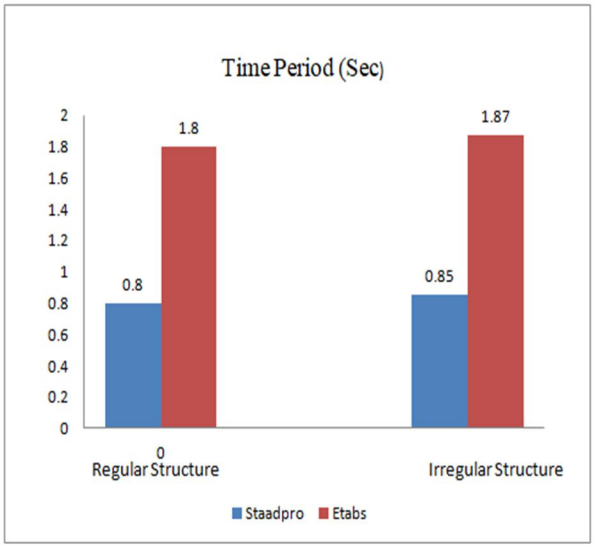
B. Material Detail and Section Properties

Beam of lighting: 230 mmx400mm, Columns: 400mmx400mm, Material homes of the shape resemble M20 grade of concrete, FE415 metal and also 13800 N/mm2 of modulus of elasticity of block stonework within the homes.

Live load on floor level and roof level are taken from IS-875 (Part-) considered RC framed buildings as residential usage.

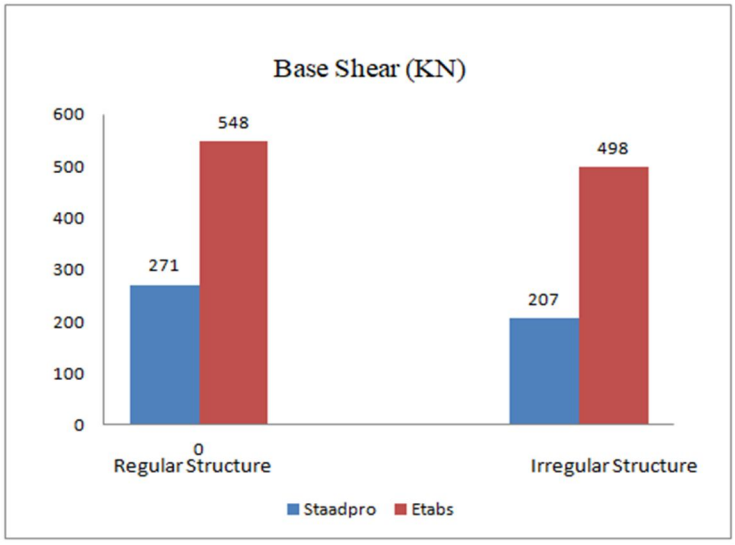
IV. RESULTS AND DISCUSSION

A. General



The results obtained in this work were discussed in this paper. The building models are subjected to dead load , live load, seismic forces and load combinations in order to understand the behavior of the G+8 building and their responses are observed. Time period and base shear for static loads were parameters studied. Similarly, bending moment, shear force and descriptions of reinforcement are studied.

B. Comparison of Base shear and Time period



The static analysis is done for three forms of models. The Table1 indicates variations within the Base shear and Time period for the 2models.

Table1 Comparison of Base shear and Time period

Model	Softwares	Base Shear (KN)	Time Period (Sec)
Regular	Staad Pro	272.40	0.80
Irregular		270	0.85
Regular	Etabs	549	1.80
Irregular		499	1.87

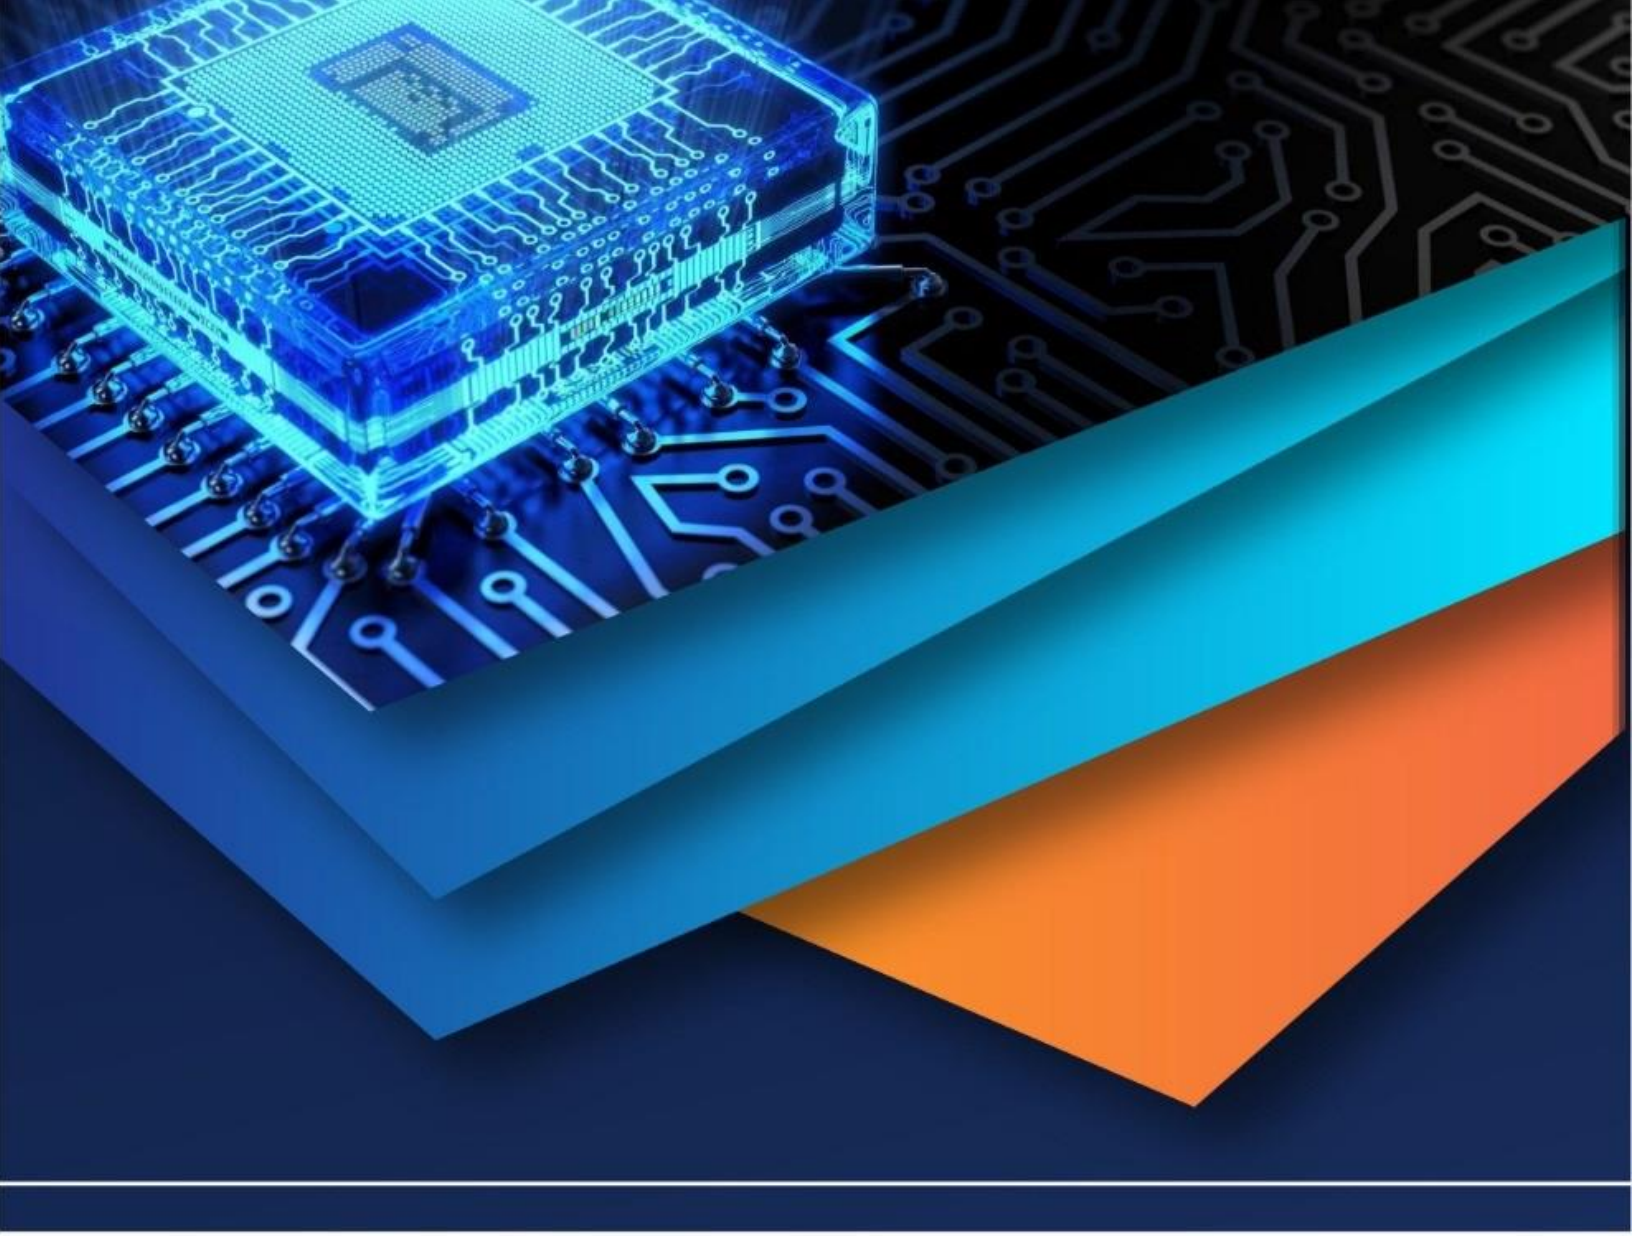
V. CONCLUSION

The analytic study is carried out in order to compare the behaviour of regular structure with irregular structure by using STAAD.PRO & ETABS. The structures are designed using IS: 456:2000 and IS 1893:2002 codes. From the study the following conclusions are obtained.

Compared to the ETABS software, STAAD.Pro software is more flexible to work. This is because ETABS has many input requirements that in the initial stage might be difficult to understand.

From the Beams, Columns design results, we can conclude that Staad pro gave less required area than Etabs.

The frame elements of regular structure showed maximum bending moments, shear forces and axial force among the two structures considered (Regular and Irregular structure).



In building design using both STAAD.Pro and Etabs analysis the quantity of provided steel is same.

Economic section are developed using Staad.pro and Etabs through the comparative analysis and design analysis of G+8 building.

Performance of the Building in Different Seismic Zones

M Afrin[1], VLS. Banu[2]
[1, 2]*Civil Engineering Department, Malla Reddy Engineering College, Hyderabad*

Abstract: ***Earthquake, any sudden shaking of the ground caused by the passage of seismic waves through earth's rocks. Seismic waves are produced when some form of energy stored in Earth's crust is suddenly released Hundreds of thousands of people have been killed by earthquakes despite scientists being able to predict and forewarn in advance and engineers construct earthquake-safe buildings.Non-linear analysis is necessary to evaluate the seismic demand of the proposed or existing structure, as linear analysis is inadequate in assessing the seismic demand under severe earthquakes. Pushover analysis is an analysis method to efficiently evaluate the post yield behaviour of the structure. In this article non-linear static analysis (pushover analysis) has been done to understand the behaviour of G+10 multi-storeyed residential building located in different seismic zones (II, III, IV, V) of India having similar geometrical properties using ETABS 2013. The behaviour of multi storied building has been investigated in terms of force-displacement relationships, inelastic behaviour of structure and sequential hinge formations etc. Plastic hinge formation gives real behaviour of the structure.***
Keywords: Non-linear static analysis, different seismic zones, shear, displacement, drift, hinge formation.

I. INTRODUCTION

An earthquake is a trembling or a shaking movement of the ground, caused by the slippage or rupture of a fault within the Earth's crust. A sudden slippage or rupture along a fault line results in an abrupt release of elastic energy stored in rocks that are subjected to great strain. This energy can be built up and stored over a long time and then released in seconds or minutes. Strain on the rocks results in more elastic energy being stored which leads to far greater possibility of an earthquake event. The sudden release of energy during an earthquake causes low-frequency sound waves called seismic waves to propagate through the Earth's crust or along its surface.

Hundreds of thousands of people have been killed by earthquakes despite scientists being able to predict and forewarn in advance and engineers construct earthquake-safe buildings.

Earthquake analysis and design principles are developed due to the earthquake consequences and damage of the structures. Earthquake analysis methods are divided into following four categories

1) Seismic coefficient method (Equivalent linear static analysis)
2) Response spectrum method (Linear dynamic analysis)
3) Pushover method (Non-linear static analysis)
4) Time history analysis (Non-linear dynamic analysis)

Linear static analysis or seismic coefficient method is a conventional elastic design method which doesn't give realistic values when the earthquake is severe.

Non-linear analysis is necessary to capture the response of structures under moderate to extreme earthquakes.

Nonlinear dynamic analysis (Time history analysis) requires site specific ground motion studies. The evaluations of dynamic earthquake parameters are inevitable and on the other hand it is computational, complex, time consuming and not feasible for most of the practical applications.

It is generally believe that the conventional elastic design analysis method cannot capture many important aspects that control the seismic performance of the building.

The capacity of building to undergo inelastic deformations governs the structural behavior of building during seismic ground motions.

For that reason, the evaluation of building should consider the inelastic deformation demanded due to seismic loading.

To estimate seismic demands for building, the structural engineering profession is now using the nonlinear static procedure, known as pushover analysis. It is a commonly used technique, which provides acceptable results.

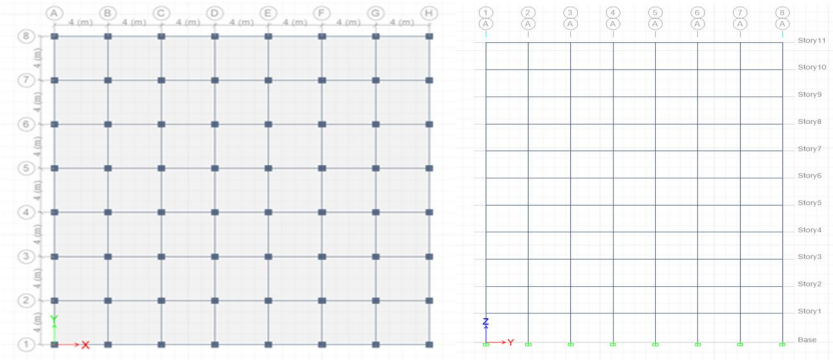
II. BUILDING MODELLING ANALYSIS

A G+10 reinforced concrete building is modelled, analysed and studied. The study is carried out in all the seismic zones of India and conclusions are drawn. The input data required for the design of G+10 building are presented in the tables below. Table 1 show the building details such as plan size, total height of the building, floor height and location details such as zone, soil type etc. The factors such as importance factor, response reduction factor values are taken from IS 1893 (Part 1): 2002. Table 2 shows the material properties and section properties. Table 3 shows the loading details on the building for designing.

Table 1 Building & location details



Building type	G+10
Plan size	28m x 28m
Building height	33.2mm
Zone	II, III, IV & V
Soil type	Medium
Damping	5%
Storey height	Ground floor 3.2m, remaining floors 3m.

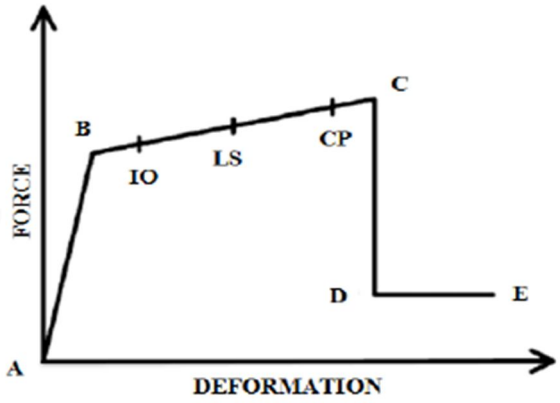
III. OBJECTVES AND NEED OF STUDY



A. Pushover Analysis

The pushover analysis of a structure is a static non-linear analysis under permanent vertical loads and gradually increasing lateral loads. The equivalent static lateral loads approximately represent earthquake induced forces. A plot of the total base shear versus top displacement in a structure is obtained by this analysis that would indicate any premature failure or weakness. The analysis is carried out upto failure, thus it enables determination of collapse load and ductility capacity. On a building frame, and plastic rotation is monitored, and lateral inelastic forces versus displacement response for the complete structure is analytically computed. This type of analysis enables weakness in the structure to be identified. The decision to retrofit can be taken in such studies.

B. Purpose Of The Structure

Pushover analysis is an analysis method to efficiently evaluate the post yield behaviour of the structure.
Pushover Analysis in the recent years is becoming a popular method of predicting seismic forces and deformation demands for the purpose of performance evaluation of existing and new structures.

C. Building Performance Level

1) Point A is the original state (OL) of Structure.
2) Point B represents yielding. No deformation occurs in the hinge up to point B.
3) Point C represents the ultimate capacity/Limit for pushover analysis.
4) Point D represents a residual strength limit in the structure. After this limit Structure initialize collapsing.
5) Point E represents total failure of the structure. After this point hinges breakdown.

©IJRASET: All Rights are Reserved

a) *Operational level (OL):* As per this performance level building are expected to sustain no permanent damages. Structure retains original strength and stiffness. Major cracking is seen in partition walls and ceilings as well as in the structural elements.

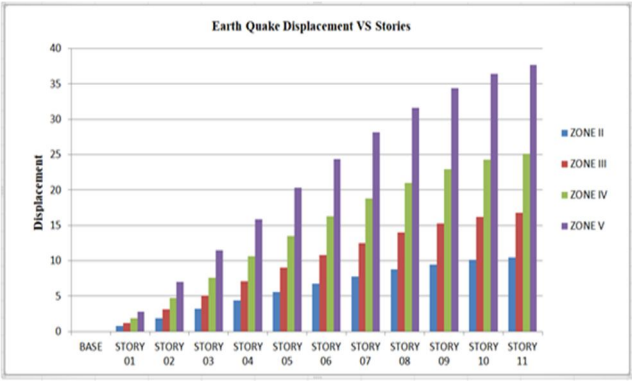
b) *Immediate occupancy level (IO):* Buildings meeting this performance level are expected to sustain no drift and structure retains original strength and stiffness. Minor cracking in partition walls and structural elements is observed.

c) *Life Safety Level (LS):* This level is indicated when some residual strength and stiffness is left available in the structure. Among the non-structural elements failing hazard mitigates but many architectural and mechanical and mechanical systems get damaged.

d) *Collapse Prevention Level (CP):* Buildings meeting this performance level are expected to have little residual strength and stiffness, but the load bearing structural elements function such as load bearing walls and columns. Building is expected to sustain large permanent drifts, failure of partitions infill and parapets and extensive damage to non-structural elements. At this level the building remains in collapse level.

IV. RESULTS & DISCUSSIONS

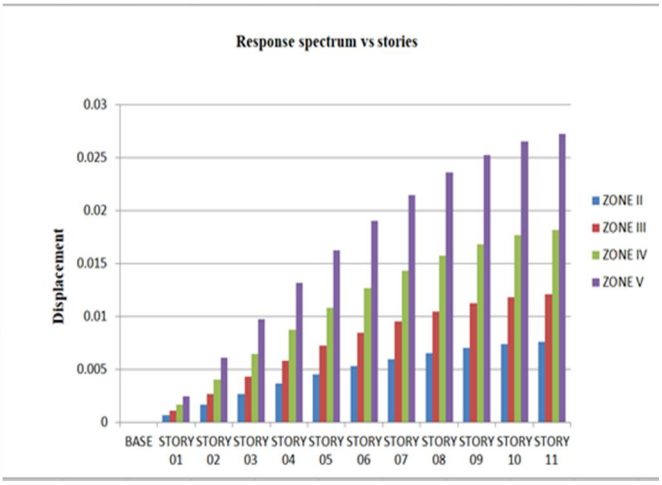
A. General



The selected building models are analyzed using pushover analysis. Pushover analysis was performed first by considering response spectrum analysis for defining gravity load case for different seismic zones (II, III, IV& V) and then a lateral pushover analysis was performed in a displacement control manner for zone V.

B. Results from Response Spectrum

Seismic analysis carried out by the help of ETABS and the results of Story Shear, story displacement and story drift from Response spectrum analysis.



C. Displacement Values for Earth Quake

V. RESULTS FROM PUSHOVER ANALYSIS:

Performance point in the zones IV for the considered building. Performance point is explained in the form of Spectral displacement Vs. Spectral acceleration graphs. Performance point gives the global behaviour of the building. The results will obtain in the form of capacity and demand curves. Formation of plastic hinges gives real behaviour of structure and their elements. Capacity curve was shown in green colour where as demand curve was shown in red colour. The intersecting point of both the curves gives performance

VI. CONCLUSIONS

The pushover analysis is a simple way to explore the nonlinear behavior of the buildings. The results obtained in terms of pushover demand, capacity spectrum and plastic hinges the real behavior of structure.

From the pushovr analysis results the target displacement of the building is 420mm, then building performance point is 261mm so that my building is in safe .

From the the hinge results my building status is A> B & B>IO

Story displacement : The displacement of building models increases with the increasing of seismic Zones. The displacement is very high at roof and very low at the base. The displacement for ZONE II is 10.5mm and ZONE IV is 37.7. This means base shear increases by more than 27% if seismic ZONE changes from II to V.

Story displacement results from Resonse Spectrum analysis increases with the increasing of seismic zones. The dispalcement for ZONE II is 0.007573mm and ZONE V is 0.02726mm.

It is concluded that the storey drift increases with the increasing of seismic zone factor. And the maximum storey drift is available at ZONE V for the max. The storey drift at 3rd floor for ZONE II is 0.000414 and storey drift for ZONE V is 0.001491m. This means the storey drift is increased when compared to ZONE II to ZONE V.

The Storey Shear is decreased as the building height increased and reduced at top floor in all the building models subjected to seismic loads considered. The storey shear is maximum at the base.The storey shear for ZONE II at the first floor1053 and at top floor 240 & for ZONE V at first floor 3792 and at top floor 867 This means the storey shear is increases when compare to ZONE II to ZONE V.

***Abstract*- Structural safety and integrity has become a great challenge to engineers. With advancement in technology the problem to design the structure for most complex loads have been solved easily. Though, the design of important and high rise structures have been restricted to seismic loads only. In recent years, terrorism has shown its impacts on buildings. Due to these effects the importance to design the structure against blast loads also increased. Blast explosions releases large pressures and heat into air. This phenomenon though it lasts for only milli seconds but have adverse effects on the structures. This paper shows blast resistant analysis and design of a G+7 commercial structure with and without shear walls for a charge weight of 50kg and 100kg TNT at 30m distance in ETABS 2016.**

Index terms- Blast loads, Standoff Zone, Time History, Shear walls

1. INTRODUCTION

Blast can be defined as an explosion which is a very fast chemical reaction during which rapid amount of hot gases and energy gets released. This phenomenon lasts only some milliseconds and results in production of high temperatures and pressures. When a detonation takes place a blast wave containing large amount of energy gets released and moves faster than the speed of the sound. Blast wave is assumed to be spherical and the energy reduces as the wave prolongs further. Blast loads are dynamic loads and have to calculate carefully similar to earthquake and wind loads. Blast loadings are short duration loads hence they can be taken as impulse forces.

2. EXPLOSIVES

Understanding the types and charge weights of the explosives are important for better designing of a structure to resist explosion loads. Explosives are taken in terms of TNT equivalent since it resembles blast characteristics of most of the solid explosives. The overall damage of the structure can be predicted based on the size of the explosion, distance between the explosion and the structure.

Table-1 Estimated quantities of charge weights of explosives in various vehicles

Vehicle type	Charge mass/kg
Compact car trunk	115
Trunk of a large car	230
Closed van	680
Closed truck	2.27
Truck with trailer	13.610

Table-2 various explosives in TNT equivalent

Types of Explosives	TNT equivalent in kg
TNT	1000
RDX	1185
Nitroglycerin	1480
Gelatin	1000
C4	1340
Nitroglycerin dynamite	600

3. STAND OFF DISTANCES

It is one of the most important parameter for the design of blast resistant structures. The distance between point of detonation (source) and the point under consideration (target) is known as standoff distance or standoff zone. From previous studies it has been proved that by an increase in the distance the blast energy

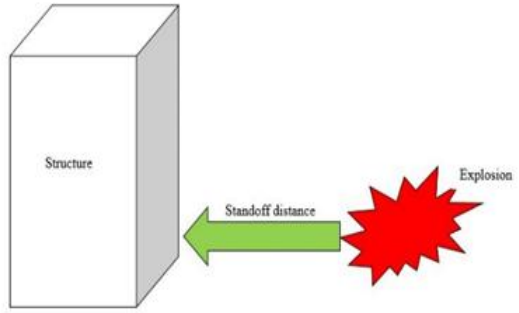

Fig.1 standoff distance

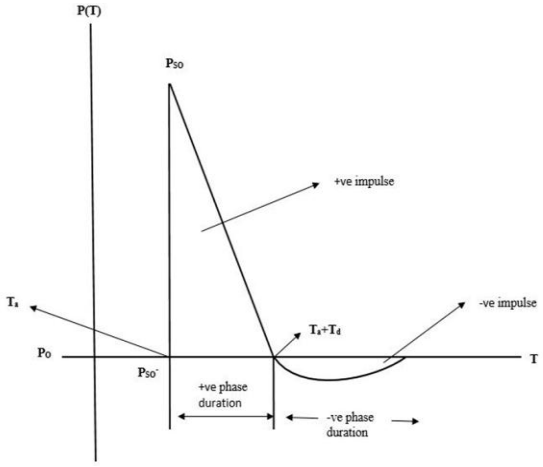

4. BLAST PHENOMENON

When an explosion occurs the pressure initially equal to ambient pressure (Po) will undergo to an instantaneous increase to a peak pressure (Pso) at the arrival time (Ta).

After reaching the peak value, the pressure decreases with an exponential rate until it reaches ambient pressure this phase is called positive phase duration (+ve).

After positive duration the pressure become smaller than the ambient pressure. This phase is known as negative phase duration (-ve).

The negative phase is longer than the positive phase and is neglected in design since their values are very small.

During negative phase the structures are subjected to suction force.

The minimum pressure is denoted as (Pso-) and its duration as (To-).

The pressures below the ambient pressures are considered if the overall performance of the structure is of concern.

5. BLAST LOADINGS

Blast loads are calculated from scaling laws as per IS 4991:1968.

To understand the effect of distance on blast characteristics scaling laws are used. These laws scales the parameters which were defined through experiments in order to be used for varying values of distance and charge energy release.

$$\textit{Scaled distance } x = \frac{\textit{Actual distance}}{W^{1/3}}$$

$$\textit{Scaled Time } t_0 = \frac{\textit{Actual Time}}{W^{1/3}}$$

Here,

W = yield of explosion in equivalent weight of reference explosive measured in tonnes i.e.,(weight of the charge in TNT).

x = scaled distance for entering the table1 from IS: 4991 for reading peak values.

t0 = scaled time read from table 1 from IS:4991 against scaled distance.

Actual distance is measured from the ground zero to the point under consideration and actual time is time after explosion.

6. BLAST ANALYSIS AND DESIGN

Blast analysis can be performed using a time history analysis in which the blast load is applied using a triangular function. The function should start with zero initially and ramp up over a small time step then vary linearly from full value to again zero.

Blast pressures act upon a unit area of the member by multiplying these pressures with the corresponding areas gives the required blast loads for a particular stand off distance.

Blast load obained is applied as point loads at one side only.

6.1 MODELLING OF THE STRUCTURE:

The structure is modelled in ETABS 2016 software which is a G+7 commercial building. Initially the structure is designed as per IS456:2000.Dead loads and loads are calculated as per IS875 part-1&2.

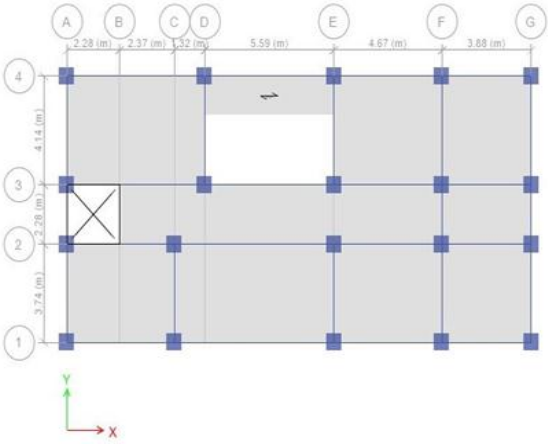

Fig. 3 plan view

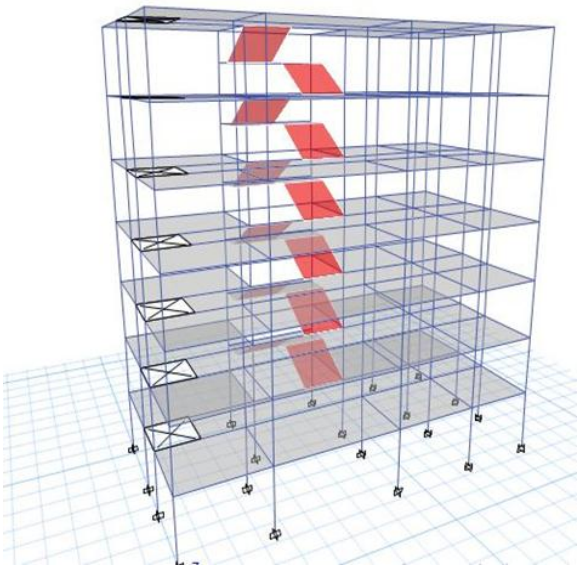

Fig.4 3D view

6.2 MATERIALS AND PROPERTIES OF THE STRUCTURE:

Material	Concrete M30
Steel	FE415
Beam size	250*400mm
Plinth beam	230*230mm
Column sizes	Ground storey: 650*650mm Other storeys: 530*530mm
Slab thickness	200mm
Height of each storey	3m
Dead loads	Slab:1.12 kn/m^2
	Beam(inner walls):3.5 kn/m^2 Beam(outer walls):4 kn/m^2
Live loads	Slab:10 kn/m^2
Load combinations	1.5(Dead load + Live load). 1.2(Dead load + Live load). 1.5(Dead + Live + Blast loads).

6.3 CALCULATION OF BLAST LOADS:

Assume a source point from where the blast occurs which is taken as (0, 1.5, 0) from the center of the building

Using two point formula the distance between source and the target is calculated which is as follows.

$X=\sqrt{(x_2-x_1)^2+ (y_2-y_1)^2+ (z_2-z_1)^2}$

Table-3 Distance between source and target for 30m

SLAB	COORDINATE POINTS			DISTANCE BETWEEN SOURCE AND TARGET
1	30	1.5	0	30
	30	1.5	3.74	30.23
	30	1.5	2.28	30.08
	30	1.5	4.14	30.24
2	30	4.5	0	30.14
	30	4.5	3.74	30.38
	30	4.5	2.28	30.23
	30	4.5	4.14	30.43
3	30	7.5	0	30.59
	30	7.5	3.74	30.82
	30	7.5	2.28	30.67
	30	7.5	4.14	30.87
4	30	10.5	0	31.32
	30	10.5	3.74	31.54
	30	10.5	2.28	31.42
	30	10.5	4.14	31.57
5	30	13.5	0	32.31
	30	13.5	3.74	32.52
	30	13.5	2.28	32.39
	30	13.5	4.14	32.57
6	30	16.5	0	33.54
	30	16.5	3.74	33.74
	30	16.5	2.28	33.61
	30	16.5	4.14	33.79
7	30	19.5	0	34.98
	30	19.5	3.74	35.18
	30	19.5	2.28	35.08
	30	19.5	4.14	35.22

Using the above distances scaled distances are calculated and peak reflected pressures are calculated from table-1 of IS 4991:1968.

Here, the blast loads are calculated for the front face of the building

Since, most severe loadings on any face of the structure is produced when the structure is oriented with face normal to the direction of propagation of the shock front. However, as the orientation for any explosion cannot be known before. Hence, every face of the structure is considered to be a front face.

Table-4 Blast pressures for 100kg TNT

SLAB	SCALED DISTANCE (x) m	Pro (KN/m2)	AREA (m2)	FORCE (KN)	Td (milli seconds)

Beam sizes:
Plinth beam: 450*650mm
Others: 500*650mm
Column sizes:
Ground and 1st storey: 750*750mm
Other storeys: 650*650mm

7. ANALYSIS AND RESULTS

The structure is considered as SDOF and Nonlinear dynamic time history analysis was done with a step size of 100 and output time as 0.05sec.
The structure is also analyzed with shear walls placing at different positions and compared

7.1 ANALYSIS WITHOUT SHEAR WALLS:

For 100kg TNT:
The maximum displacement is 0.94mm for 0.05sec at top storey.

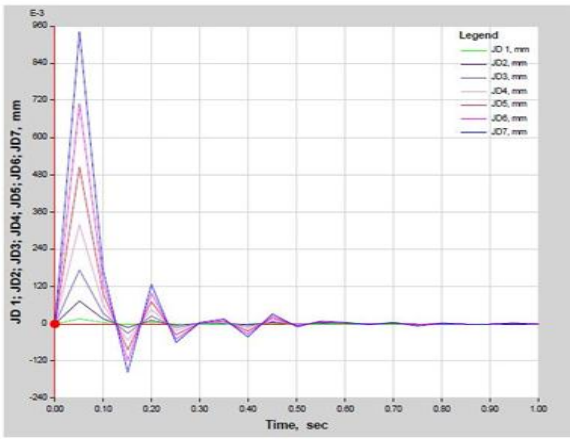

Fig.5 Time history displacements plots for 100kg TNT

The story force is 12915.6KN at ground and 2183.92KN at top storey.

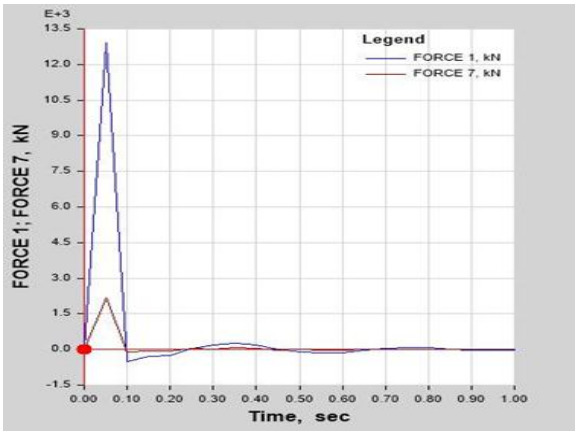

Fig.6 Time history storey forces for 100kg TNT

This graph shows joint displacements for different storey levels upto a time of 1 sec which is least at storey 1 and highest at storey 7 and also as the time increases the displacements are decreased.

The above graph shows storey forces for storey 1 and 7 with storey 1 having the highest peak and lowest peak for storey 7.It can be understood that the blast wave decreases as it propagates from bottom to top storeys.

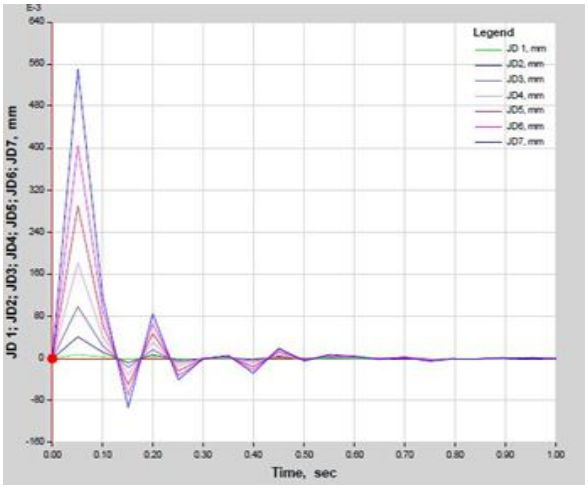

Fig.7 Time history displacement plot for 50kg TNT

For 50kg TNT:

The maximum displacement is 0.550mm for 0.05sec at top storey.

The storey forces are 13447.38KN at ground and 2283.57KN at top storey for 0.05sec.

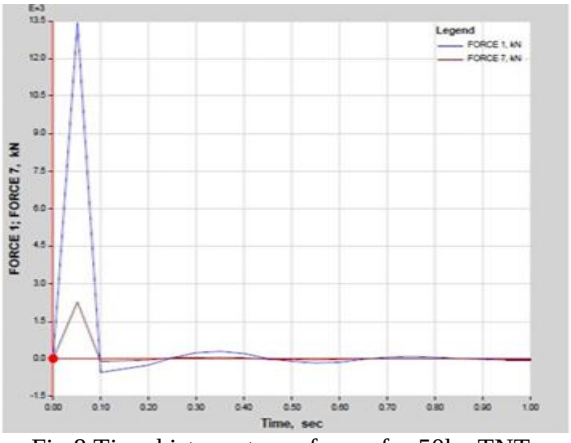

Fig.8 Time history storey forces for 50kg TNT

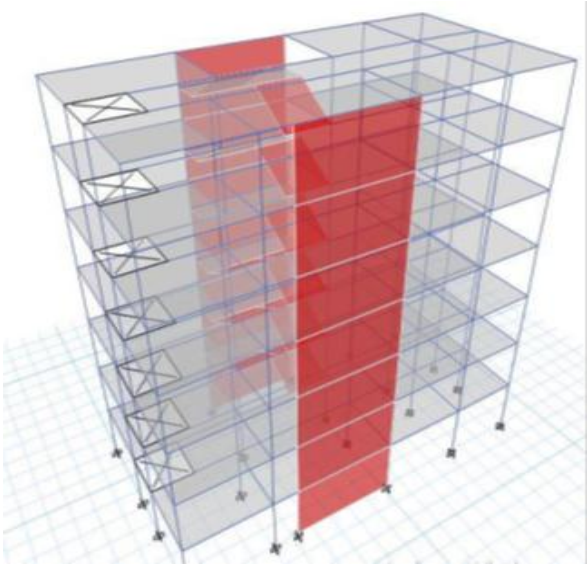
This graph shows joint displacements for different storey levels up to a time of 1 sec which is least at storey 1 and highest at storey 7 and also as the time increases the displacement peaks are decreased and when compared to 100 kg TNT the blast wave remains for very short time.

The above graph shows storey forces for storey 1 and 7 with storey 1 having the highest peak and lowest peak for storey 7.It can be understood that the blast wave decreases as it propagates from bottom to top storeys. When compared to 100 kg TNT storey forces are more in this case.

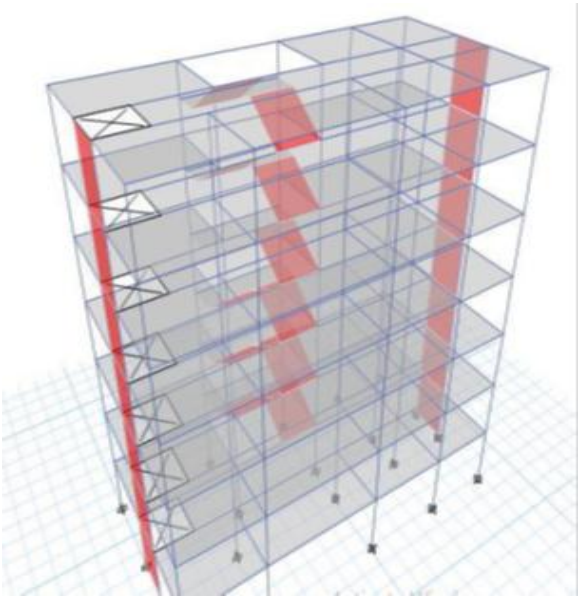
7.2 ANALYSIS WITH SHEAR WALLS:

In this paper analysis of the Structure is studied under three



Different positions of shear walls.

Thickness of the shear wall is taken as 230mm.



Case (a): Shear walls placed diagonally at the corners of the structure

Case (b): Shear walls placed at opposite sides of the structure along x-direction

Case (c): Shear walls placed at opposite sides of the structure along y-direction

For 100kg TNT:

Case (a): The maximum displacement is 0.631mm at top storey for 0.05sec.

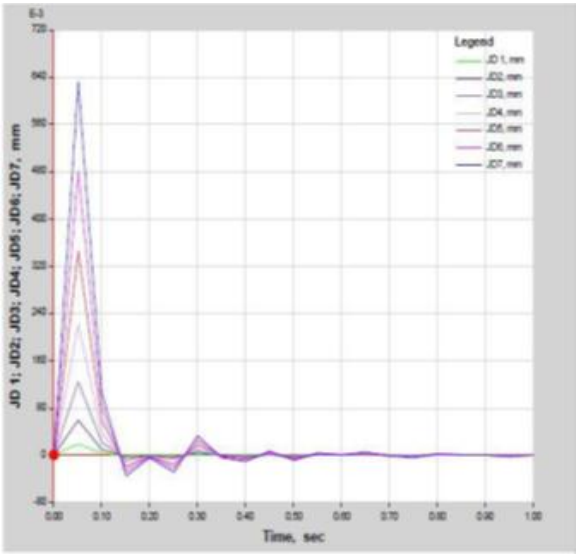


Fig.9 Time history displacement plot with Shear wall for 100kg TNT

The above graph shows joint displacements for different storey levels up to a time of 1sec when shear walls are placed diagonally at the corners of the structure which is least at 1st storey and highest at storey 7.

Case (b): The maximum displacement is 4.017mm at top storey for 0.05sec

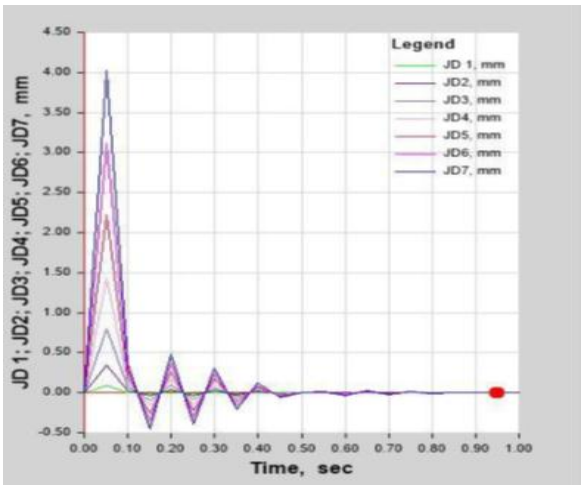

Fig.10 Time history displacement plot with Shear wall for 100 kg TNT

The above graph shows joint displacements for different storey levels up to a time of 1 sec when shear walls are placed along x-direction of the structure which is least at 1st storey and highest at storey 7.when compared case(a) this shows displacement peak of high value.

Case (c): The maximum displacement in this case is 0.576mm at top storey for 0.05 sec

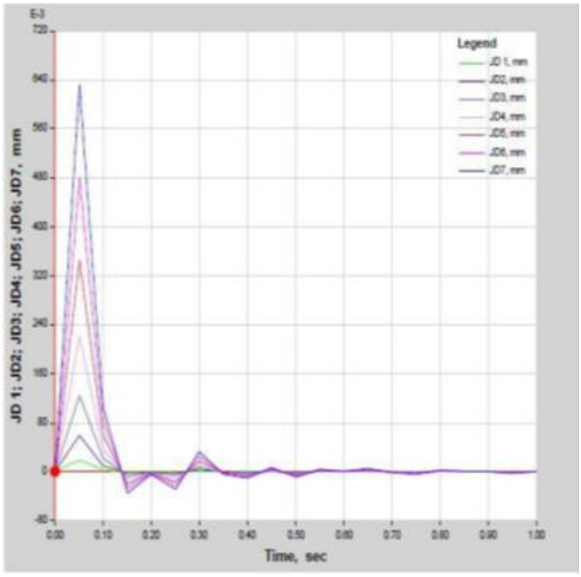

Fig.11 Time history displacement plot with shear wall for 100kg TNT

This graph shows joint displacements for different storey levels up to a time of 1 sec when shear walls are placed along y- direction of the structure which is least at 1st storey and highest at storey7.when compared case(a) and case(b) this shows displacement peak of less value.

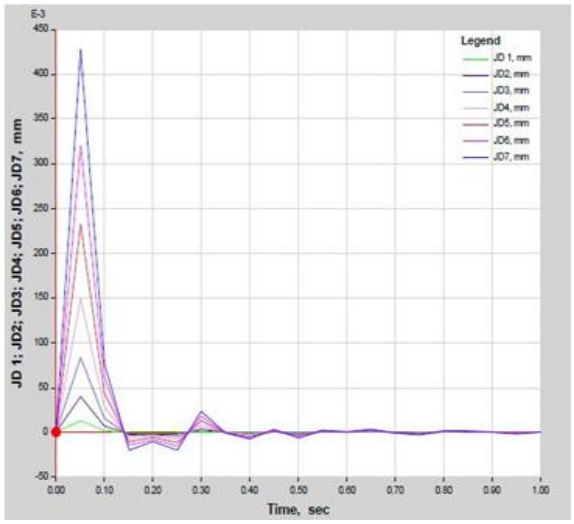

Fig.12 Time history displacement plot with Shear walls for 50kg TNT

Case (a): The maximum displacement is 0.428mm at top storey for 0.05sec.

The above graph shows joint displacements for different storey levels up to a time of 1 sec when shear walls are placed diagonally at the corners of the structure which is least at 1st storey and highest at storey 7.

Case (b): The maximum displacement is 2.593mm at top storey for 0.05sec.

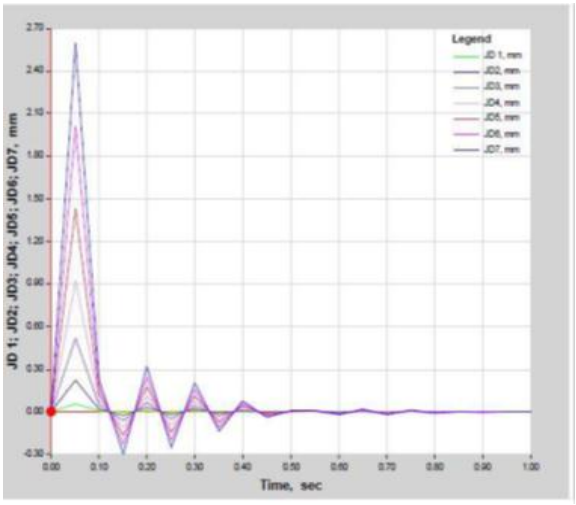

Fig.13 Time history displacement plot with shear walls for 50kg TNT

The above graph shows joint displacements for different storey levels up to a time of 1 sec when shear walls are placed along x-direction of the structure which is least at 1st storey and highest at storey 7.when compared case (a).

Case (c): The maximum displacement is 0.308mm at top storey for 0.05sec.

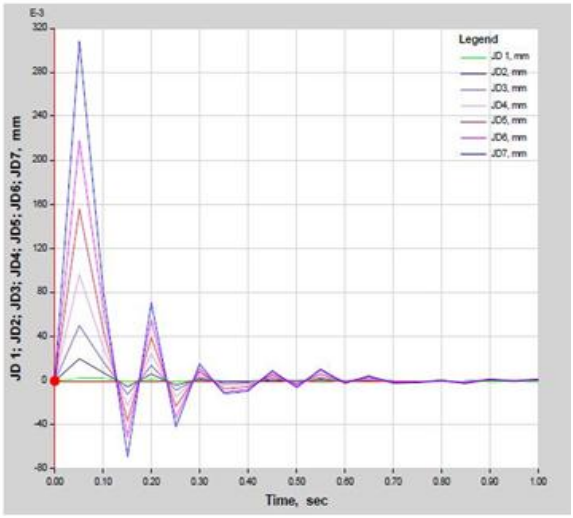

Fig.14 Time history displacement plot with Shear walls for 50kg TNT

This graph shows joint displacements for different storey levels up to a time of 1 sec when shear walls are placed along y-direction of the structure which is least at 1st storey and highest at storey7.when compared case(a) and case(b) this shows displacement peak of less value.

7. CONCLUSION

From time history analysis it is observed that displacements decreases with decrease in the storey levels and storey forces are more at bottom level which decreases with increase in storey height.

By placing shear walls small amount of displacement and forces have been reduced.

For the given plan with 50kg and 100kg TNT at 30m the best position of placing shear wall is along the y-direction of the structure.

It has also been observed that as the charge weight increases the impact on the structure also increases.

Increasing the size of the members also showed significant effect on the structure in resisting blast loads.

Hence, from above observations it can be concluded that by providing moment resisting frames such as shear walls and maintaining appropriate standoff distances maximum damage to the structure can be avoided and also gives time for the occupants to escape from the building.

Abstract:Self-compacting concrete (SCC) was first developed in Japan in the late 1980's as a concrete that can flow through congested reinforcing bars with elimination of compaction, and without undergoing any significant segregation and bleeding. In recent times, this concrete has gained wide use in many countries for different applications and structural configurations. The difference of strength at failure for accelerating and normal curing is 1.77MPa for 3days. The difference of strength at failure for accelerating and normal curing is 6MPa for the 7days. The difference of strength at failure for accelerating and normal curing is 7.5MPa for the 28days The percentage increase in strength between accelerated curing and normal curing for 3 days 15.93%. The percentage increase in strength between accelerated curing and normal curing for 7 days 33.33%. The difference at strength failure for accelerating and normal curing is 6MPa. The percentage increase in strength between accelerated curing and normal curing for 28 days 28.30 %. The difference at strength failure for accelerating and normal curing is 7.5MPa Split tensile strength for normal curing is 1.27MPa and for the accelerated curing is 1.54MPa. The percentage increase in strength between accelerated curing and normal curing for 3 days 21.25%. Split tensile strength for normal curing is 1.98MPa and for the accelerated curing is 2.54MPa. The percentage increase in strength between accelerated curing and normal curing for 7days 28.28%. Split tensile strength for normal curing is 2.26MPa and for the accelerated curing is 2.84MPa. The percentage increase in strength between accelerated curing and normal curing for 28 days 25.26 %.

Introduction

SELF-COMPACTING CONCRETE

Such innovative concrete requires high slump which can be achieved by the addition of super plasticizer. To avoid segregation on super plasticizer addition, the sand content is increased by 4% to 5%. When the volume of coarse aggregate in the concrete is excessive, the opportunity of contact between coarse aggregate particles increases greatly, causing interlocking and the possibility of blockage on passing through spaces between steel bars is also increased.

Ground Granulated Blast Furnace Slag (GGBS):

Ground granulated blast-furnace slag is a non-metallic powder consisting of silicates and aluminates of calcium and other bases. The molten slag is rapidly chilled by quenching in water to form glassy sand like material. The chemical composition of blast furnace slag is similar to that of cement clinker. The performance of slag depends on the chemical composition and fineness of grinding. The quality of slag is governed by IS: 12089-1987 (Specification for Granulated Slag for Manufacture of Portland Slag Cement).

Super plasticizer (SP):

Super plasticizer (SP) is a chemical compound used to increase the workability, without using any additional water. The super plasticizer used in the present work is the commercially available brand, plaxem

Accelerated curing:

Accelerated curing is any method by which high early age strength is achieved in concrete. These techniques are especially useful in the prefabrication industry, wherein high early age strength enables the removal of the formwork within 24 hours, thereby reducing the cycle time, resulting in cost-saving benefits.[1] The most commonly adopted curing techniques are steam curing at atmospheric pressure, warm water curing, boiling water curing and autoclaving.

ISSN- 2394-5125 VOL 7, ISSUE 11, 2020

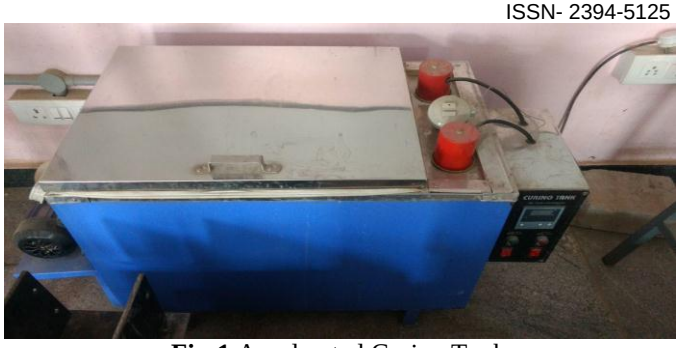

Fig:1 Accelerated Curing Tank

Normal curing:

Curing is the maintaining of an adequate moisture content and temperature in concrete at early ages so that it can develop properties the mixture was designed to achieve. Curing begins immediately after placement and finishing so that the concrete may develop the desired strength and durability. Portland cement consists of several complex chemical compounds. In preparation of concrete.

As the early strength of concrete is supportive towards the ultimate strength of concrete achieved, we should do proper curing according to the environment condition, type of member etc. The most effective method for curing concrete depends on the materials used, method of construction, and the intended use of the hardened concrete. For most jobs, curing generally involves applying curing compounds, or covering the freshly placed and finished concrete with impermeable sheets or wet burlap. In some cases, such as in hot and cold weather, special care using other precautions is needed.

Fig: 2 Normal Curing on Concrete

Objectives:

- Faster construction
- Reduction in Site manpower
- Better surface finish
- Easy placing
- Improved durability
- Due to high early age strength enables the removal of the formwork within 24 hours.

Scope of present work:

- The effect of different curing methods on mechanical properties of self-compacted concrete is studied i.e. effect on Compressive, Splitting tensile.
- Effect of natural climate factors such as sunlight, ambient temperature and humidity during self-curing on the properties may be studied.
- GGBS can replace a significant part of the necessary filler when used into a self-compacting concrete composition.

ISSN- 2394-5125 VOL 7, ISSUE 11, 2020

- The elimination of vibrating equipment improves the environment protection near construction precast sites where is being placed, reducing the exposure of workers to noise and vibration.

Table:1 Shows the Properties of Cement

S.No:	Characteristics	Values obtained	Standard values
1	Normal consistency	33mm	33 to 35 mm
2	Initial setting time	40 min	Not be less than 30 mins
3	Final setting time	300 min	Not be greater than 600mins.

L-box	Passing ability	0.8-1.0	0.90	Ok
U –box	Passing ability	0-30mm	25	Ok

Compressive strength test:

The compressive strength (in MPa), of the specimen is calculated by dividing the maximum load carried by the cube specimen during the test by the cross-sectional area of the specimen.

The compressive strength was determined at different ages 7 and 28 days. Some materials fracture at their compressive strength limit; others deform irreversibly, so a given amount of deformation may be considered as the limit for compressive load. Compressive strength is a key value for design of structures.

Fig 3 Compression testing machine

Split tensile strength of concrete:

The tensile strength of concrete is one of the basic and important properties. Splitting tensile strength test on concrete cylinder is a method to determine the tensile strength of concrete. Tensile testing is most often carried out at a material testing laboratory. The ASTM D638 is among the most common tensile testing protocols. The ASTM D638 measures plastics tensile properties including ultimate tensile strength, yield strength, elongation and Poisson's ratio.

The concrete is very weak in tension due to its brittle nature and is not expected to resist the direct tension. The concrete develops cracks when subjected to tensile forces. Thus, it is necessary to determine the tensile strength of concrete to determine the load at which the concrete members may crack.

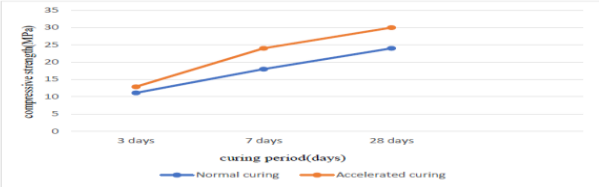
Mix Proportioning:

The mix proportion obtained for the present work by adopting the said method

Mix constituent	GGBS based SCC(kg/m3)
Cement	200
Powder	403.95
Fine aggregate	743
Coarse aggregate	961
Total water	224.90
Super plasticizer	10.87

Table 3 Mix proportioning (kg/m3)



RESULTS AND DISCUSSION

Compressive strength:

In this method of mix proportioning of SCC, the quantity of the powder used in the concrete is mainly dependent on the consistency and the specific gravity of the powder itself. It is observed that the consistency is more than that of GGBS. Whereas the Compressive strength of GGBS based SCC after 3days, 7 days and 28 days are 11.11MPa, 18 MPa and 22.5 MPa, for normal curing Whereas the Compressive strength of GGBS based SCC for accelerating curing after 3days, 7 days and 28 days are 12.88MPa, 24 MPa and 30 MPa. Which clearly indicates that the GGBS based SCC with accelerating curing gives better strength than normal curing-based SCC.

ABSTRACT: Now a day's Self-Compacting Concrete is the most common used concrete for construction now a day, Preparation of Self Compacting Concrete by addition of SP gives good results. Self-Compacting Concrete helps in reduction of man work at site. The void space in the concrete will not be reduced by using the SCC. For this purpose, partial replacement of Cement by NS Powder into the SCC helps in reducing the Void Space and concrete density will be increase. So, by the increase in concrete density and Strength of the concrete will also increases.

The present work deals with additions of nano-silica powder to Cement as a partial replacement to Cementous material as dosage by pf 2.5%,3%,3.5% respectively by the gauged cement and based on early research M20 grade concrete has been taken for the present study. Optimum Composition containing of SCC+ nano-silica powder was taken, in which compressive strength were increased to 6% respectively compared to the Nominal concrete. The advance of nano material is clearly seen in the Scanning Electron Microscope images showed in this journal paper. And the analysis has been taken and the presence of nano-silica and with particle shape and size are mentioned, nano-silica Powder is introduced into the concrete improves the interfacial surface transition zone area in between the Cementous material particles. The density of the concrete optimum specimens was decreased by 0.5% relative to the Nominal Concrete.

Therefore, Imbedding nano-silica powder to nominal Cement show a significant increase in compressive strength. SEM (scanning Electron Microscope) analysis evidence the direct involvement of nano-silica in the region of specimen.

KEYWORDS: self-compaction concrete, compressive strength, nominal concrete, void space, (SEM) Scanning electron Microscope, density, nano-silica Powder.

I. INTRODUCTION

Nominal Concrete is a composite material mixture of cement, fine aggregates, coarse aggregates and water sometimes its mixed with admixtures like accelerators and retarders. Self- compaction concrete was first introduced in the year of early 1988 to achieve self-compaction by its using its own weight and reducing the void space in between the particles and increasing the durability in concrete structures. Since then, the advancement in innovation and investigations have been carried out in Self-compaction concrete, this type of concrete has been used in practical in large, mass concrete structures in Japan, Investigations was carried out to establishing the standard mix-design method and self-compatibility methods. Self-Compaction Concrete has higher compressive strength due to closely packed particles present in the concrete, due to this nature the construction industry focusing on the time and optimized solution for the faster in casting and achieving better results comparing with nominal concrete and have greater impact in the concrete era. Therefore, keeping economics in picture SCC in cumulative is more economical, strength and durability building structures. The use of large portion of cement results in increases in CO_2 emissions and risk in duplation of ozone layer and increases in green house effects. By using nano silica partially to reduce the cement content in concrete mix. In the previous literature implies the European Federation of Specialist Construction Chemicals and Concrete

ISSN- 2394-5125 VOL 7, ISSUE 13, 2020

systems. SCC can be defined as well as concrete that is able to flow under its own self weight under the gravitational force and completely fill the formwork without any voids, even in the high and heavy dense reinforcement without any external compaction like pin vibrator or surface vibrator ect., and maintaining the homogeneity of the concrete in every section

of casting. SCC It is also called Super-Workable Concrete and high workability Concrete SCC and can be controlled by appropriate and specific dosage of plasticizer and superplasticizer.
In this study imbedding nano-silica in to the concrete, partially replacing cement to the nano silica and concrete prepared. In this study the properties of nano-silica are mentioned the results are compared with that nominal or traditional concrete. The compression has been done by the Compressive strength of both nominal and SCC. and concrete with addition of nano- silica were determined and compared with results of nominal or traditional concrete of M20. The principle stresses are compressive cube samples were obtained and tested in compressive testing machine in order to meet the minimum compressive strength of prepared specimen. economic benefits are likely to more in Self Compacting Concrete when compared to nominal or normal concrete. Self-Compaction Concrete is economical due to the flowable in nature and it is easily compacted due to the super plasticizer in it and feasible technical solution present in it. The use of SCC result in less maintenance and durable life for the structure. To achieve these effective results from conventional or nominal concrete to self-compaction concrete.

CONCRETE AND SUSTAINABILITY

Concrete is a unique material and it is very easily casted and mounded in different shapes and sizes in construction. The current construction there is a biggest hassle with the well compaction concrete as we know 5% of voids reduces 30% of actual strength of the concrete so it's a biggest challenge for the skilled labor so by adopting this kind of technique like SCC we can achieve the complete compaction and in other hand we can achieve the targeted strength and practices are based on the consumption of building materials, resulting not wasting the resources, The sustainable development of the cement concrete structures.
Degree of dispersion of cement in water that is water cement ratio is largely depends on the flowable of concrete and excess of water can occur segregation in concrete, hydration of cement behavior and properties of the hardened cement. Factors such as water cement ratio, has early hydration, water reducing admixture agents and mineral admixture agents are added determine the degree of flocculation in the cement paste. As we understand the high strength concrete depends upon water cement ratio. The strength w/c ratio rule holds good for concrete strength that we can determine by workability test. Low water cement ratio is also required for low permeability of concrete and to give good strength results and to give good hold like short creating and which is vital for high durability. low water cement ratio ensures high strength and low permeability or high durability according to the IS code. to ensure the workability of concrete low water cement ratio will require high cement content as well as strength but very low in workability due to the more of compaction is required and more voids can be occurred.

SELF CONSTRICTING CONCRETE

The British Standard describes "SCC is the concrete that is capable to flow under its own weight and compacted by gravity, fill the formwork corners and reinforcement given covering to the section like beams and columns ducts, etc., Marinating the homogeneity of the concrete. SCC exhibits following properties in its plastic state. It has the ability to flow into every corner of the formwork and completely all spaces in the dense reinforcement and while maintaining homogeneity and ability of concrete mix to pass through obstacles like narrow sections in form work like curved section zig Zac section, closely spaced reinforcement without getting blocked by interlocking of course aggregate particles. Segregation resistance of self-compaction concrete is its capability to retain homogeneity in the distribution of ingredient in fresh concrete mix in both static and dynamic moving condition i.e., workability during mixing, transportation and placing and finishing.
The mechanism behind the SCC when water is added into the cement the past becomes cohesive in nature the particals attracts each other. The super plasticizer is used. It's a special type of chemical that reputation action takes place and the Cementous particles and that losses its cohesive in nature and the cement particles ripples to each other, then the sticky nature changes into the form cohesionless past this phenomena occurs due to the agents are added into the Cementous particles due to this the cement starts loses its shape and starts flow like a liquid this is called flowing or compacting by its own weight this turn into self-compaction concrete.

NANO TECHNOLOGY IN CONCRETE

Nanotechnology is rapidly becoming the Industrial revolution of 21st century. It is known that "Nano" is a Greek word and means 'dwarf'. It's a common word for everything which is smaller than 1Micron or 1 Million of a millimeter where 1 Micron is 1000 Nanometer. Nano technology helps in provide the filling in between the Cementous material that can increase the density in the form of siliceous material and strength to the concrete by adding the agent. Cement is primary structural material by addition of Nano Technology it helps as a smart

ISSN- 2394-5125 VOL 7, ISSUE 13, 2020

functional material. Nano-silica has been added in order to increase the compressive strength, low permeability and reduces shrinkage. Cement particle size range bigger than few nano-meters to a maximum of about one hundred micro meter. In the case of Nano silica its ranges from 5 micro meter. the Properties of ordinary Portland cement like low shrinkage value, nano-silica powdered form reacts with liberated Calcium hydroxide from the hydration of cement that is OPC to form additional hydrated products like calcium silicate hydrate. Calcium silicate hydrate is main product of OPC it is primarily responsible for strength of bougs compounds comes in picture in cement-based materials. Chemical composition of OPC contains 17 to 27% of Silica. So, by addition of 2 to 3% of Nano Silica powder may help in increase in the strength of the concrete. Incorporation Nano silica powder in concrete mix leads to several benefits such as improves in Compressive strength, durability of concrete, chemical attack resistance, segregation resistance, permeability and water absorption. of cement's reaction with water as a function of temperature, water/cement ratio, and grain size because the reactions occur in the Nano-scale pores of the cement.

II. OBJECTIVE OF PRESENT STUDY

The objective of present study is to find out the influence of the imbedded of Nano silica partially replacing cement. Nano silica is added in different dosages to study the variation in the compressive strength of concrete. 2%, 3% of Nano silica are adopted as replacement by weight according to the mix design of M20 grade. Cube moulds are casted for the purpose of testing. Specific objective of the study is:

To find the workability aspects of Self Compacting Concrete and Nano Silica Powder concrete.

To decrease the permeability and to reduce the shrinkage in self compacting concrete and finding out the right workability for construction work.

To reduce the shrinkage in Self Compacting Concrete.

- To know the influence of Nano Silica Powder on the Strength Characters of Self Compacting Concrete.

Scope

The scopes of present work is increase the density as well as increase the compressive strength of the self-compaction concrete by adding nano-silica. Effect of Nano silica on the compressive strength of the self-compacting are studied and further modifications can be done. Mix design of M20 grade is chosen to increase its strength and reduce shrinkage. Comparison of compressive strength between ordinary self- compaction concrete with SCC of Nano silica powdered form is down.

Experimental Procedure

The present procedure deals with the evolution of self- compaction concrete using Nano-silica powder. It also involves the study of properties of concrete compressive strength. Cement is partially replaced with Nano-Silica powder of dosages in standard grade of M20, which was designed in accordance with IS:10262-2009 (For Nominal Concrete) and Nansu Method following EFNARC Guidelines for SCC. We have chosen mix design of M20 Grade, in order to increase the compressive strength of the self-compacting concrete. The study involves Casting and Testing of specimen's cubes. The concrete lab available at St. Martin's Engineering College is used for the project. The workability test equipment's are used for filling ability and passing ability.

Procurement of Materials

- Cement
- Fine Aggregates
- Coarse Aggregates
- Water
- Admixture (super plasticizer)
- Nano-Silica Powder

Table:1 Properties of Fine Aggregates

S.No.	Property	Result
1	Specific gravity	2.61
2	Fineness modulus	2.8
3	Bulk density(loose)	15.75KN/m^3
4	Grading of sand	ZONE-II

Coarse Aggregate

Coarse aggregates of nominal size 20 mm,12 mm, 10mm and 8mm, obtained from the local quarry confirming

ISSN- 2394-5125 VOL 7, ISSUE 13, 2020

to IS: 10262:2009. The properties of coarse aggregates are shown in Table No.2.

Observation and Calculations:
Fineness of cement = W1+W2+W3/ avg x10= weight retain on sieve/total weight

Table 4 Fineness of Cement

S.No	Weight of cement (gms)	Weight of residue formed (gms)	Fineness of cement (%)
1	300	20	6.67
2	300	30	10
3	300	30	10

Table:2 Properties of Coarse Aggregate

S. No.	Property	Result
1	Specific Gravity	2.6
2	Bulk Density	15.8KN/m^3
3	Water Absorption	0.3%
4	Fineness Modulus	7.2

Admixture
Admixture plays a vital role which makes SCC possible. The admixture used in this experiment is conplast SP430 (a polycarboxylate based superplasticizer).

Features & Benefits:
- Reduces setting time depending on the dose and ambient temperature
- Improves the workability of the concrete
- Reduces water cement ratio less of segregation
- Helps to achieve high early strength, hence reduces setting time required for removal of shuttering in time
- Ordinary Portland cement can be used thereby reducing cost

Table:3 Total Number of Specimens to cast

S. No.	Mix Designation	No. of cubes	
1	Nominal Concrete	3	3
2	SCC(without nano silica)	3	3
3	SCC 2.5%	3	3
4	SCC 3%	3	3
5	SCC 3.5%	3	3
6	Total Specimens	15	15

Fineness of Cement= (10+6.67+10)/3 = 8.89%

ISSN- 2394-5125 VOL 7, ISSUE 13, 2020

The finesse of cement is 8.89%, which is less than 10%.

Observations and Calculations:

Table:5 Normal Consistency

S. No.	Weight of cement (gms)	% of water Added ml	Penetration
1	250gms	27 X (250/100)	33
2		28 X (250/100)	25
3		29 X (250/100)	15
4		30 X (250/100)	10
5		31 X (250/100)	7

The percentage of water for normal consistency for the given sample of Cement is 31.67%.

Observation:

Quantity of cement = 250 gms.

Water for standard Consistency = 31.67%

Flow Table

Flow table test is performed to determine the consistency of flow the concrete mix on the table. To perform the test, the apparatus is first made wet and then placed on a level, firm surface. Then a cone is placed on the flow table, concrete is filled into the cone in two layers. As it is a self-compacting concrete, compaction is not needed. Wait for 30seconds and remove the cone gently at a height of 40mm, allowing the concrete to flow on the table. confirming to IS: 1199-1959. The measured diameter of flow of concrete are as follows:

Table:11 Flow Table Results

S.No	Description	Diameter of Flow	
1	SCC	48	48.5

IV. CONCLUSIONS

The main conclusions of this project are:

- As we compare with nominal concrete Compressive strength with NS dosage of 7% has increased for 7 and 28 days respectively compared to normal.
- As we compare with nominal concrete The workability of the concrete along with Nano- silica powder has decreased.
- As we compare with nominal concrete ,Due to Decrease in the quantity of cement, the concrete becomes economical and eco-friendly.
- Trial and error method was been used to design the SCC mix because there is no standard method for SCC in any institutes and concrete mix plants.
- As we compare with nominal concrete SCC do not depend in a single test, but it depends in all of the four tests and it must pass all of them to be called Self-compacting concrete.
- As we compare with nominal concrete When compared with normal concrete self compaction concrete shows a significant increase due to well compacted as density increases in concrete strength also increases.
- SEM results shows that Nano-Silica helps in filling the voids spaces between the cement particles and helps in increasing the density of the concrete.
- If the density of the concrete increases then the compressive strength of the concrete also increases.

COMPARATIVE STUDY OF BLACK COTTON SOIL STABILIZATION USING COPPER SLAG AND FLY ASH FOR PAVEMENT CONSTRUCTION

Pradeep Kumar Goudappnor*, Dr. Srinivas Gupta, J S S K Vasa*** , Vipparthi Rajesh******

Assistant Professor, Civil Engineering Department, Malla Reddy Engineering College (A), St Martins Engineering College Hyderabad*****

Abstract: Soil is the basic foundation for any civil engineering structures. It is required to bear the loads without failure. In some places, soil may be weak which cannot resist the oncoming loads. In such cases, soil stabilization is needed. Numerous methods are available in the literature for soil stabilization. But sometimes, some of the methods like chemical stabilization; lime stabilization etc. adversely affects the chemical composition of the soil. In this study, fly ash and copper slag were mixed with Black cotton soil to investigate the relative strength gain in terms of unconfined compression, bearing capacity and compaction. The effect of fly ash and copper slag on the geotechnical characteristics of clay-fly ash and clay-lime mixtures was investigated by conducting standard Proctor compaction tests, unconfined compression tests, CBR tests and permeability test. The tests were performed as per Indian Standard specifications. The black cotton soil used for these experiments was brought from bowrampet village ,near Bachupally, Hyderabad, Telangana. The physical properties of the soil were determined as per IS specifications. Fly ash for the study was brought from Dundigal (Hyderabad). It is finely divided residue resulting from the combustion of ground or powdered coal from electric generating plants. It has high water absorption capacity. Copper slag was brought from SRI SRINIVASA METALIZERS (Phase II, IDA, Cherlapally, HYD) Copper slag is a by-product extracted during the process of smelting. In the process of smelting, the impurities become slag and floated in the top surface of the molten metal which will be quenched in water produces angular granules and disposed as wastes. In this test programmer, without additives clay was tested to find the optimum moisture content, CBR value, plasticity index and unconfined compression strength. Fly ash and Copper slag were added in varying percentages and that fraction for which maximum strength is obtained was found out.

Key words: BC Soil, copper slag, fly ash, Compaction, CBR.

INTRODUCTION

Emerging trend of using waste material in soil stabilizing or soil strengthening is being operational all over the world in the present days. The main reason behind this trend is the excessive production of waste like fly ash, plastics, rice husk ash (RHA) which is not only hazardous but also creating deposition/disposal problems. Using some of these waste materials in construction practice will reduce the problem to a great extent.

The history of stabilization of soil has a long background with hundreds of research results. Several research results with waste materials such as fly ash, plastics; rice husk ash has also be published with their benefits Stabilized Sub-Grade Soil containing Copper slag and fly ash and Sensitivity Analysis of Sub-Grade Soil CBR.

The naturally occurring materials are fast depleting because of their over exploitation to meet the huge demand for construction of infrastructure projects. To study behavior of fly ash & copper slag with black soil, samples are collected from Hyderabad.

At present India is in the phase of development and huge investments are being made in the up gradation of existing roads under national highway development programme (NHDP) and construction of new roads under Pradhan Mantri Gram Sadak Yojana (PMGSY).

Therefore the naturally occurring materials are fast depleting because of their over exploitation to meet the huge demand for construction of infrastructure projects.

In a recent years there has been a growing emphasis all over the world towards promoting the use of marginal materials in road construction in order to effect cost saving reduce pressure on good quality aggregates and also protect environment.

FLY ASH

Fly ash is a coal combustion by-product – a finely divided residue resulting from combustion of coal in power plants. In the thermal power stations, coal is pulverized into fine powder and pumped into the boiler along with compressed air. Coal

ISSN- 2394-5125 VOL 7, ISSUE 11, 2020

powder is fired to generate heat, which in turn produces steam to run the turbine. After burning, the coarse ash or 'bottom ash' gets collected below the boiler. The finer particles of coal are collected in the Electro-Static Precipitators (ESP).

Fly ash, also known as "pulverized fuel ash" in the United Kingdom, is a coal combustion product that is composed of the particulates (fine particles of fuel) that are driven out of coal-fired boilers together with the flue gases. Ash that falls to the bottom of the boiler is called bottom ash.

Physical properties and chemical composition of fly ash

Physical Properties	
Specific gravity	2.27
Loss on ignition	11.8%
Chemical Composition	
Silica (SiO2)	58.3%
Alumina (Al2O3)+Iron oxide (Fe2O3)	26.3%
Calcium oxide (CaO)	2.2%
Magnesium oxide (MgO)	0.3%

COPPER SLAG:

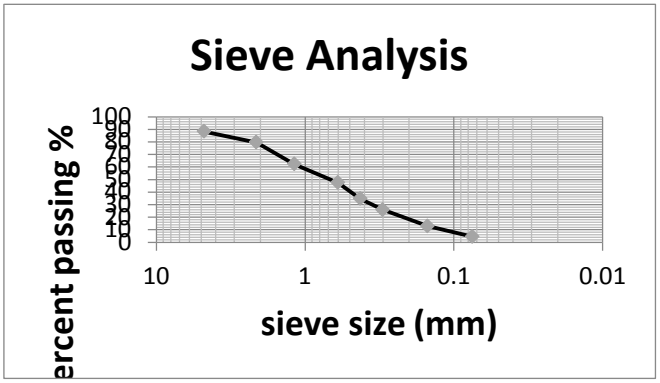
Copper slag is a by-product extracted during the process of smelting. In the process of smelting, the impurities become slag and floated in the top surface of the molten metal which will be quenched in water produces angular granules and disposed as wastes. Copper slag is in black color and granular in shape has less than 1% moisture

The specific gravity of slag was 3.2 and the grain size mostly between 2.36 mm to 1.18 mm which very closely matches with sand property. Mostly the composition of copper slag contains oxides of copper, iron and silica.

Copper slag was brought from SRI SRINIVASA METALIZERS (Phase II, IDA, Cherlapally, HYD) Copper slag is a by-product extracted during the process of smelting. In the process of smelting, the impurities become slag and floated in the top surface of the molten metal which will be quenched in water produces angular granules and disposed as wastes.

Fig 2: Curtailment of Reinforcement in RCC Section Beams

Beam was cast with circular moulds to provide the opening in the transverse direction. These moulds were removed after 24 hours. Beam was unmolded and surface curing was done for 28 days.



METHODOLOGY

Index tests on the natural laterite soils were carried out in accordance with the procedures obtained in IS 2720, step percentages of bitumen emulsion and coconut shell and egg shellby dry weight of soil (5,10 and 15%) was introduced into the soil.

The following tests were carried out on the Laterite soil

- Natural moisture content test
- specific gravity (Density Bottle method)•Compaction test (Standard proctor test)
- California bearing ratio test
- Compressive Strength test
- Direct shear test

ISSN- 2394-5125 VOL 7, ISSUE 11, 2020

CONCLUSION:-

The investigation that has been performed on black cotton soil with different admixtures such as fly ash and copper slag gives wide variety of results on several issues from which the following qualitative conclusions can be drawn:-

1. The strength of the black cotton soil without any admixtures is up to 28%.

2. At a 5% of fly ash, copper slag and mixture of the both fly ash and copper slag with black cotton soil, CBR value is increased up to 29.32%, 19.32% and 38.6%.

3. At a 10% of fly ash, copper slag and mixture of the both fly ash and copper slag with black cotton soil, CBR value is increased up to 31.4%, 21.41% and 39.01%.

4. At a 15% of fly ash, copper slag and mixture of the both fly ash and copper slag with black cotton soil, CBR value is increased up to 32.7%, 22.8% and 42.1%.

5. At a 20% of fly ash, copper slag and mixture of the both fly ash and copper slag with black cotton soil, CBR value is increased up to 33.5%, 23.3% and 45.3%.

6. At a 25% of fly ash, copper slag and mixture of the both fly ash and copper slag with black cotton soil, CBR value is increased up to 38.3%, 23.9% and 45.7%.

7. It is clearly observed from the above points that the strength of the soil stabilized using fly ash gives more strength compared to copper slag.

Scope for future work:

Large area of **Bowrampet village** near **bachupally**, **Hyderabad** is covered with black cotton soil, which has low strength and not so suitable as a sub grade material. To improve the strength characteristics of soil, the following further studies can be carried out.

- A detailed review of stabilizing weak soil of **Bowrampet village** near **bachupally**, **Hyderabad.**
- Field performance of different types of admixtures such as Fly ash and copper slag.
- Performance of admixtures for pavement constructions.
- Optimization of layer thickness of admixtures in the sub base layer of soil for reducing the fill thickness in roads.

Abstract

A-pillar is a vertical section, preliminary from footing level also shifting weight to the base. Hanging or stub section similarly a precipitous element which closes (as of model design/site condition) on its base level, lies on level part i.e., beam (horizontal section). Such sections (hanging or stub) where the burden was mulled over using point load. Present examination on G+12 model with/without hanging section is studied by applying response spectrum & time history procedures beneath quake load at zone two also differentiates with storey shears, lateral burden, storey relocations, storey drifts by using Etabs. From the final output, it was clear that storey shears, lateral burden, storey displacements, storey drifts are increased for the model without hanging sections concerning model with hanging section.

Keyword : storey shear, lateral burden, storey displacements, response spectrum, ETABS

I. Introduction

Innumerable capital (city) multi-storey constructions in India these days has first storey open as a predictable lookout. It is predominantly implemented for house stopping, gathering risk rooms at the essential storey. There were many structures where hanging sections are being used, mainly above the level of the ground. Wherever distribution beams are being used, with the objective that undeniably clear zone available at ground floor. Hanging sections were satisfactorily expert to get hold of gravity mass, nevertheless, distribution beams must have suitable dimensions with a minor deflection. Distribution beams must design prudently, particularly at quake

occurrence zone. Configuration elements of the model which was affected due to quake force should be kept away if not, configuration elements must limit. So, houses previously built with discontinuous sections must jeopardize at seismic tremor zones. Those constructions cannot be crushed, instead, the examination must carry out strengthen the structure or scarcely any recuperating features can propose.

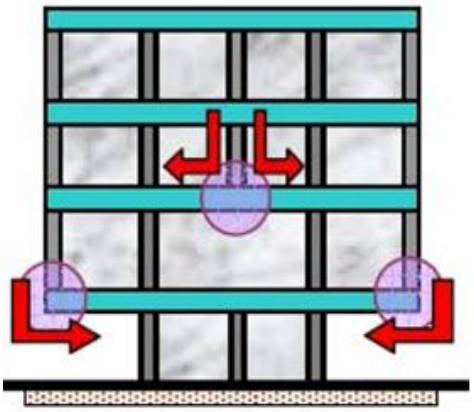

Fig. 1: Hanging column structure

II. Methodology

Response Spectrum Technique:

Response spectrum is a chart of highpoint and constant state reaction of the arrangement of an accelerator of fluctuating frequency which remained inhibited to movement via identical vibration, shake. It is a procedure to find the quake reaction of the model by using vibrational mode shapes. Computer investigation can be applied for guessing out modes of model. By utilizing the design spectrum each mode reaction can be known. After understanding the modal mass & frequency they remained combined on the certain approximation of absolute reaction of the model. In this, we have to figure the consequence of force at Y, X, Z direction and formerly observe the effects on the structure. Integrate approaches contain the following:

Absolute peak method
CQC method
SRSS method

The procedure of SRSS is utilized when the distance among eigenvectors or eigenvalues have more gap then we use this method. CQC procedure is utilized when eigenvalues are in the locale of ten per cent then we follow this method. Therefore, the entire reaction on every floor that has extreme values doesn't happen on a similar period, at a similar period immediately they can't remain added. So, for the accomplishment of the entire reaction 2 procedures were used.

Time history method:

Time history practice contains a stage-by-stage evaluation of model reaction, applying discretized data which was recorded/planned seismic records by way of ground wave input. A couple of ground-level motion records intended for coetaneous study along all flat axis of model essential to remain constant. Steady couples remain regular waves predictable on a specified location mainly depend upon alike seismic tremor. In time history practice, the reaction of the model towards ground level expansion is determined at time-space & wholly phase statics are subsequently sustained. In the situation wherever the model is extremely uneven, extremely elevated, Response Spectrum is not appropriate besides advanced complicated technique is desirable.

III. Modelling

Loads and Intensities:

Live load of the floor- 3 kN/m^2

wall load- 3.9 kN/m^2

Finishing off the floor- 1.5 kN/m^2

Parapet load- 1 kN/ m^2

Building details of modelled structure:

Storey height of Bottom story- 3.0 m

Storey height of typical storey- 3.0 m

Height of structure- 36 m.

Plan area- 8.5 m x 8.5 m

Structure type- Symmetrical and regular

Structure Frame system- O.M.R. F

No. of storeys- G+12

Support- fixed

Seismic Properties:

Seismic zone- II

Time history function- Elcentro seismic tremor data

Soil type- Medium

Damping ratio- 0.05

Response reduction factor- 5%

Zone factor- 0.10

Importance factor (I.F)- 1

Properties of Materials:

Reinforced concrete (R.C) density- 25 kN/m^3

Young's modulus (E_s)- 2 x 10^8kN/m^2

Steel Grade- Fe415

Young's modulus (Ec)- 27386127.87 kN/m^2

Concrete Grade- M30

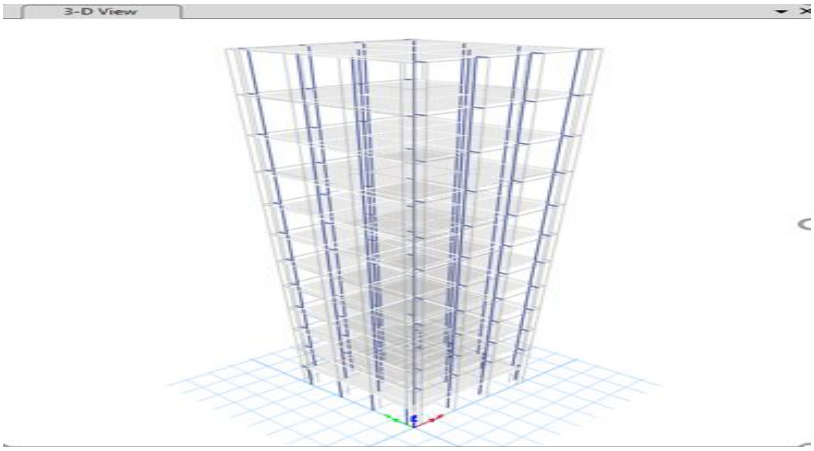

Fig..2: Elevation view of G+12 structure with hanging columns

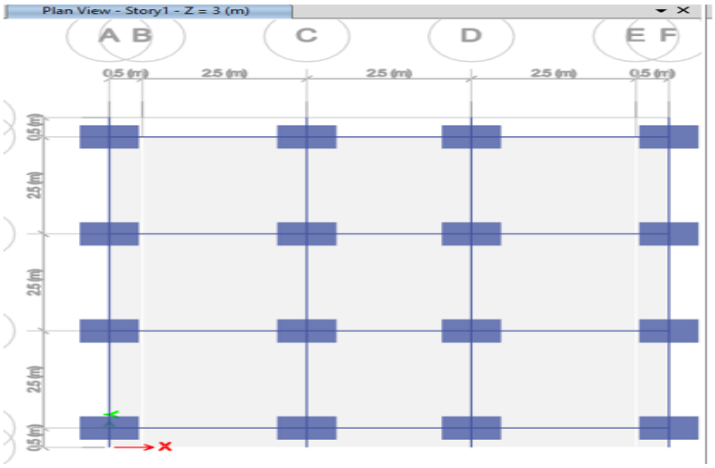

Fig. 3: Plan view of story 1 of G+12 structure with hanging columns

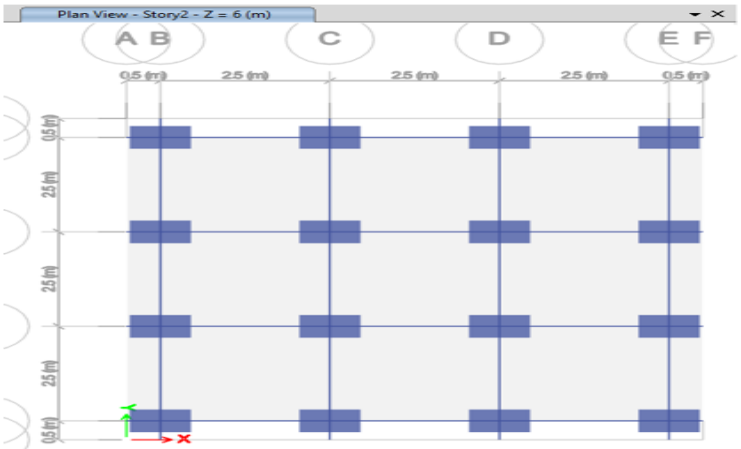

Fig. 4: Plan view of story 2 of G+12 structure with hanging columns

From figure 3&4 Insertion of hanging column exposed clearly.

IV. Results and Discussions

Results of G+12 structure with hanging columns

Lateral loads:

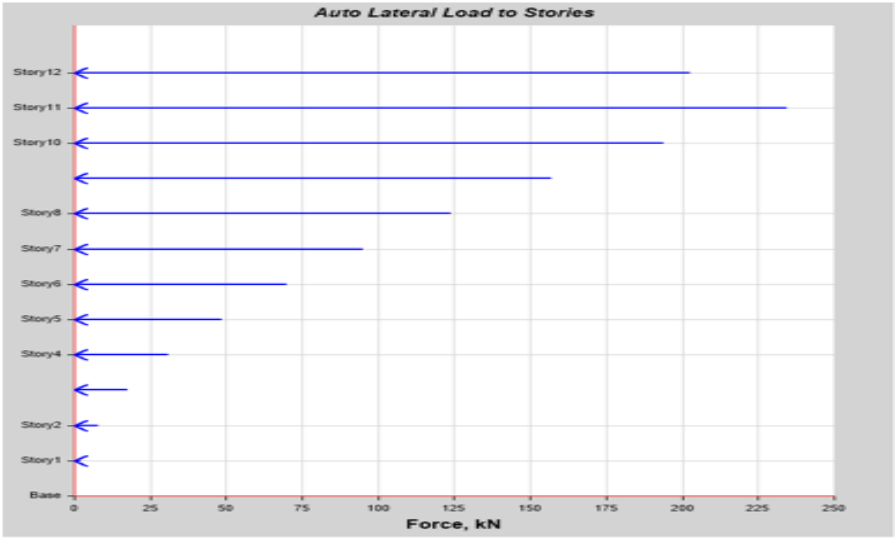

Fig. 5: The lateral burden in direction X at a storey of structure with hanging columns

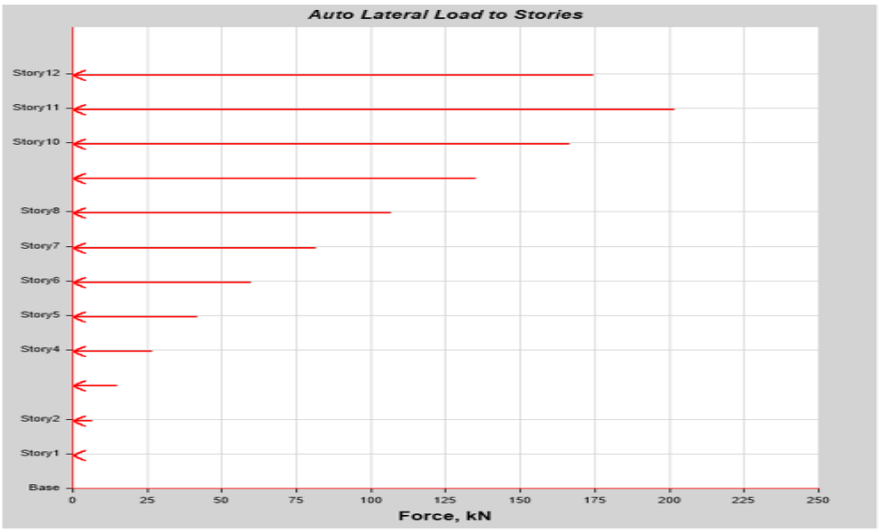

Fig. 6: The lateral burden in direction Y at a storey of structure with hanging columns

The lateral burden is Live loads that were acted parallel to the level of ground i.e., they remain flat forces applied on a model. It was seen that lateral weight for the model with a hanging column in direction X is greater w.r.t direction Y as shown in figure 5&6. lateral weight on model with the hanging column is lesser than the model without hanging column.

Storey shear:

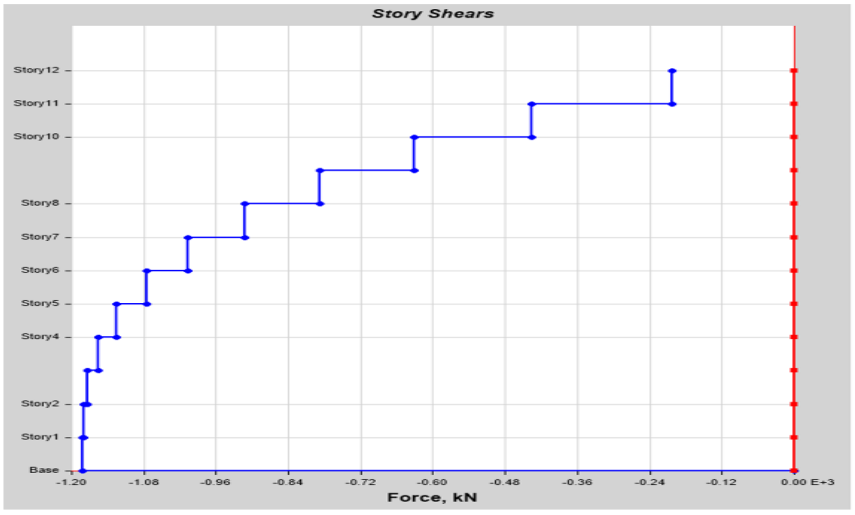

Fig. 7: Storey shear in direction X at a storey of structure with hanging columns

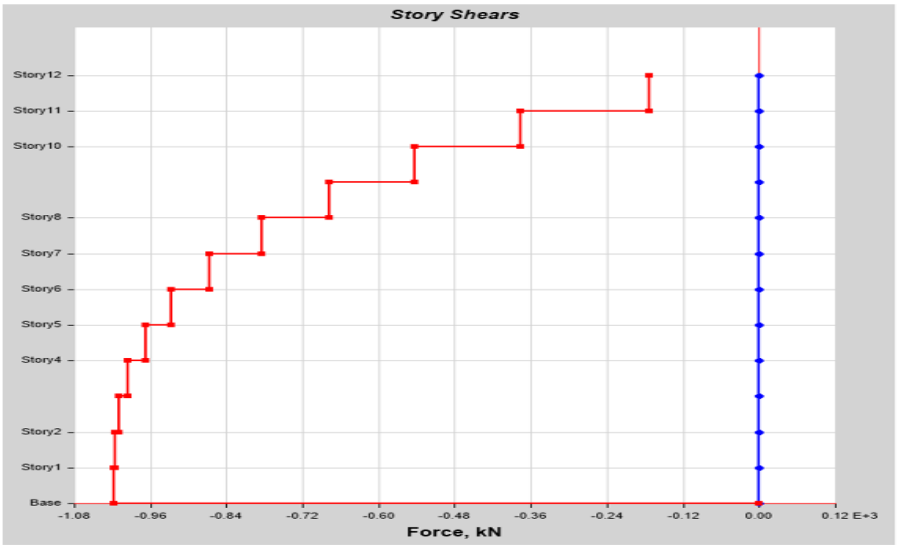

Fig. 8: Storey shear in direction Y at a storey of structure with hanging columns

In storey shear we can imagine conceivable leading lateral burden at a particular storey in a specified path and this determination will help to empathetic and examine where wind governs over quake in a particular direction. It was seen that storey shear for the model with a hanging column in direction Y is lesser w.r.t direction Y as shown in figure 7&8.

Storey drift:

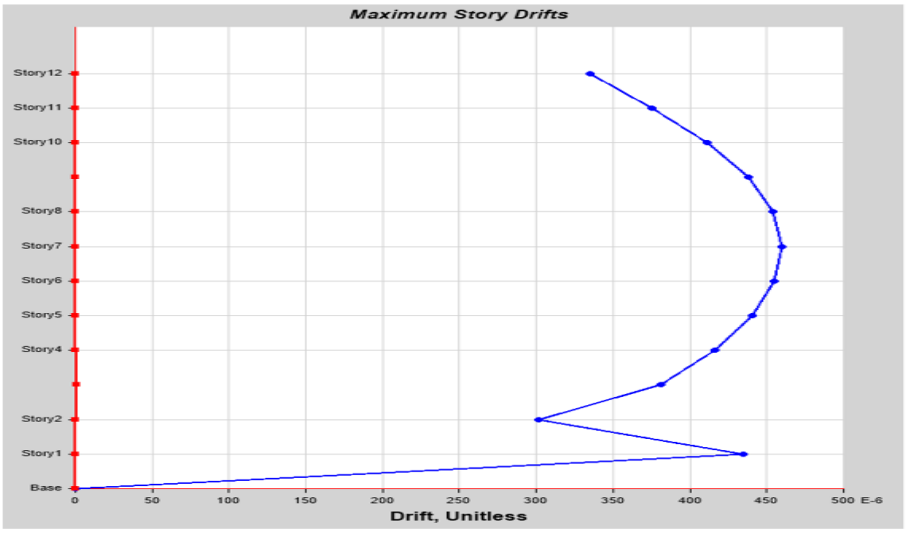

Fig. 9: Storey drift in direction X at a storey of structure with hanging columns

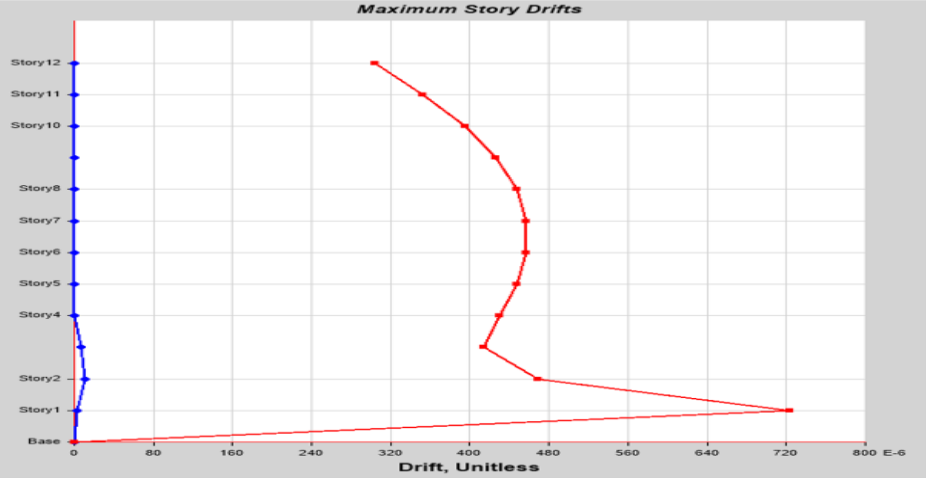

Fig. 10: Storey drift in direction Y at a storey of structure with hanging columns

Storey drift is the dislocation of one floor w.r.t the other floor it was seen that storey drifts for structure with a hanging column in direction X are decreased w.r.t direction Y as shown in figure 9&10.

Results of G+12 structure without hanging columns:

Storey Displacements:

Fig. 11: Storey displacements in direction X at a storey of the structure without hanging columns

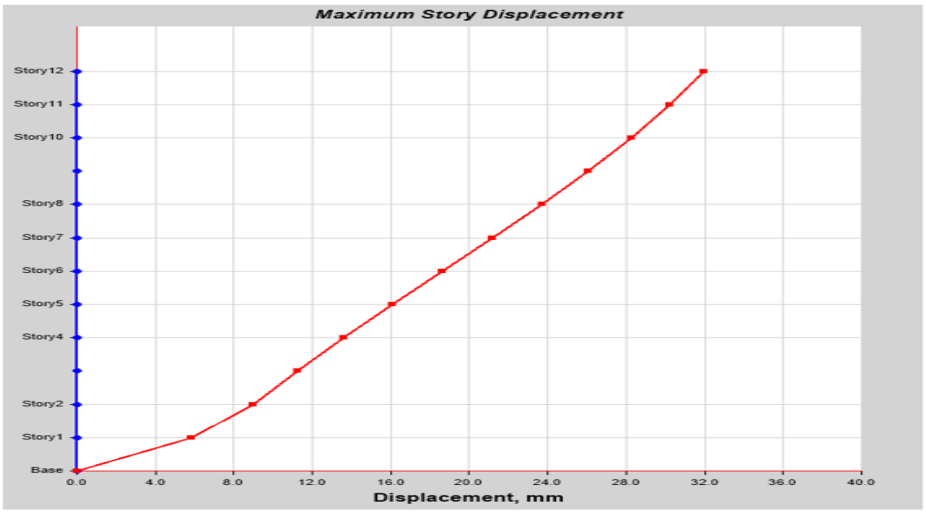

Fig. 12: Storey displacements in direction Y at a storey of the structure without hanging columns

Storey displacements are the dislocation of a floor w.r.t ground level of a structure. it was clear that displacements for the model without hanging column in direction Y is greater than direction X as shown in figure 11&12.

For different periods base shear of a structure:

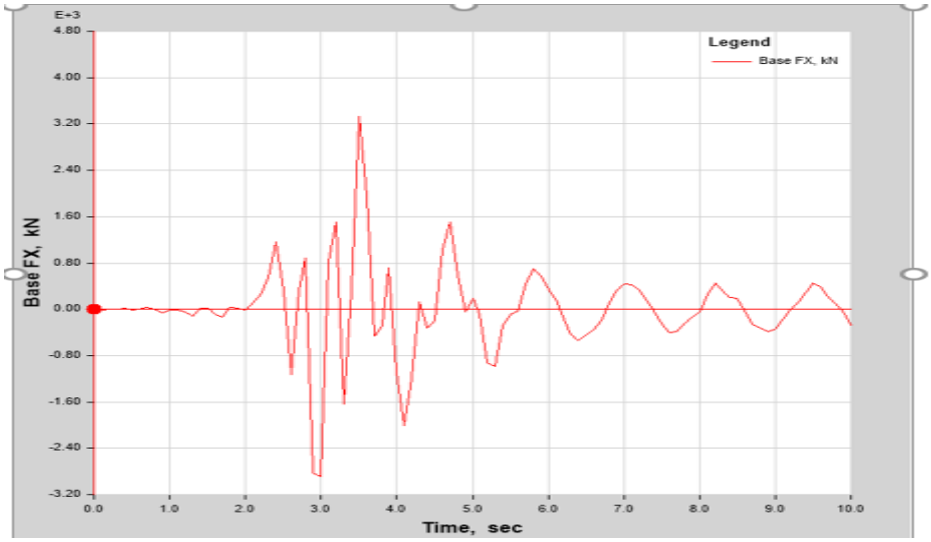

Fig. 13: Base shear for a structure without hanging columns at various periods.

It was demonstrated that with 3333.6 Kilo newton highest base shear befallen for a structure without hanging column at 3.5 seconds as shown in fig.13.

V. Conclusion

The response of high rise structure with and without hanging column is analysed under various earthquake excitation. The finite detailed model was created for observing dynamic conduct of multi-storey frame. Free vibration and static results acquired by utilizing present finite component code which was approved and it was finalized that.

1. The storey shear of structure with a hanging column in X-direction is more concerning Y-direction. The storey shear of structure with hanging columns is 48 per cent decreased than the structure without hanging columns.
2. The storey drifts for structure with hanging columns in Y-direction is more concerning X-direction. The storey drift of structure with hanging columns is 60 per cent decreased than the structure without hanging columns.
3. By increasing the ground floor column maximum displacement, base shear, overturning moment storey drift values are decreasing.
4. The horizontal loads on structure with hanging columns are 45 per cent decreased than structure without hanging column.
5. It has been seen that structure with the hanging column is stiffer than structure without hanging columns.
6. It has been seen that structure with hanging column has increased period as compared to the structure without hanging columns.
7. The storey displacement of structure with hanging columns in X-direction is more concerning Y-direction. The storey displacement of structure with hanging columns is 50 per cent decreased than the structure without hanging columns.
8. It has been seen that structure with hanging column has decreased base shear concerning the structure without hanging column. The maximum base shear occurred in structure with the hanging column is -283.42 Kilonewton at five seconds and the maximum base shear occurred in structure without hanging columns is 3333.6 Kilonewton at 3.5 seconds.

VI. Future Scope

This research can be extended by keeping the hanging columns at various storeys and various locations. We can examine in severe seismic tremor zones by keeping the seismic tremor resistant structural elements to the structure with hanging columns.

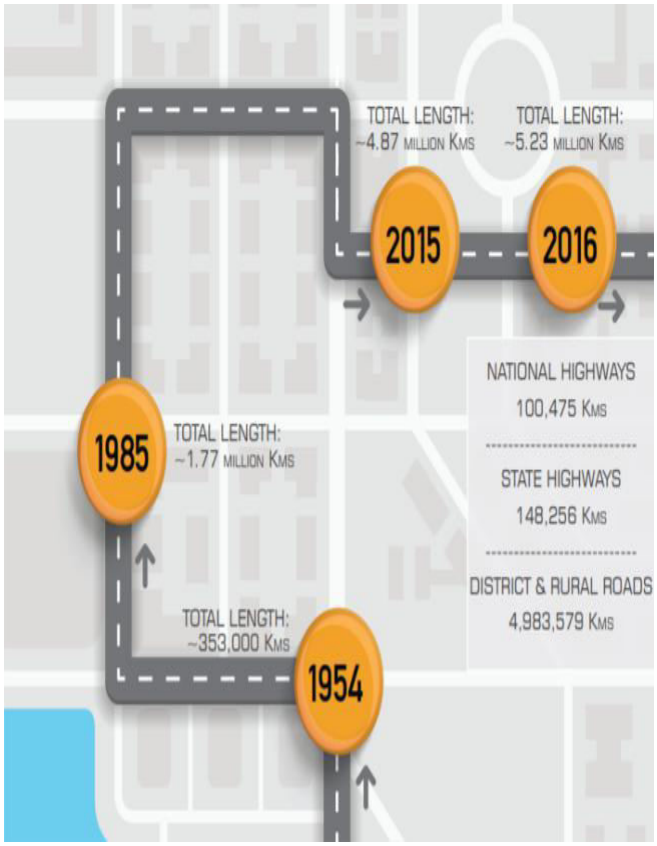
Mode Selection and Route Layout of Internal Transportation In Industrial Enterprises

MS. POOJA SRI REDDY, MS. NAGA PRASUNA

Malla Reddy Engineering College (Autonomous)
Department of Civil Engineering

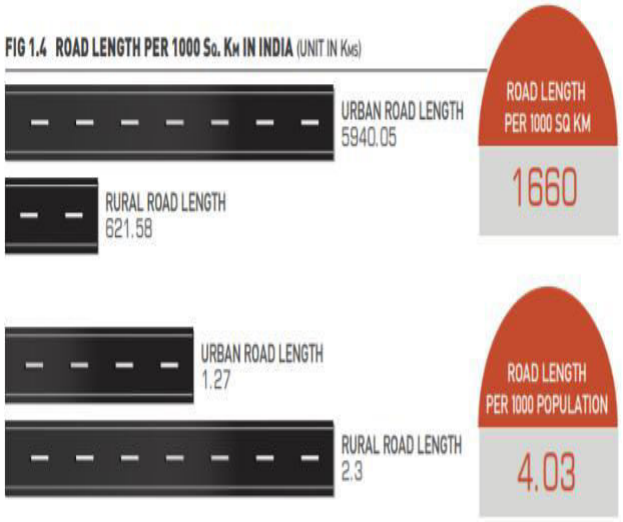


ABSTRACT

Transport is an essential component with which people not just connect with each other, but also progress. To fulfill the increase in demand for safe, reliable, environmental friendly, economical and efficient transport system, road infrastructure becomes crucial. With an increase in types of motor vehicles, there has been a gradual transition from rail-dominated transport to road-dominated transport over last few decades. The share of railways in passenger/km has decreased by ~60%. Transport of passengers and goods is vital to satisfy the mobility needs, which is commensurate with today's lifestyle characterized by social interactions and reliable goods distribution nationwide.Internal transportation means the process transportation in industrial enterprises. It is an extremely important aspect of General layout, the continuation of production and the core of enterprise logistics. Any modern industrial enterprise can operate successfully based on reasonable mode selection and route layout to meet the plan need of business, workshops and team section, to meet the need of handling work and other work, and to improve the relationship between public transport in which the material and technical, labor, consumption of energy and wealth is the minimum. By analyzing characteristics of different transportation, the factors of selecting transportation modes are concluded, focusing on the layout elements of road, rail and pipeline transportation routes to achieve maximum benefit in this paper.

INTRODUCTION

Starting from 1960's, Indian road network has developed in several stages and it is largely influenced by different political, technological, environmental and social factors. Total length of motor able roads in India in 1954 was estimated to be ~353,000 kms, which was meagre for any country of size of India, and its population. In 1985, the total motor able road length increased to



1.77 million kms and 208,938 villages were connected by the new roads. The problems related to urban transport became increasingly complex due to massive increase in road network, increased economic activities on the one hand and shortage of resources on the other hand. Due to unprecedented growth in population and unchecked migration from rural areas to urban areas and metropolitan cities, population pressure increased in urban areas and metropolitan cities. Today, India has one of the largest road networks in the world aggregating to ~5.23 million kms as of November, 2016. Roadways still remains the dominant mode of transport in India, carrying >75% of total traffic, out of which, road carries >57% freight traffic and >85% passenger traffic. There are several indicators, which are the indicators of development of road infrastructure. These include total road length, passengers carried i.e. billion passenger kilometres (BPKM), vehicles per km of road, passenger cars per 1000 people etc. Road network density of India's highways is 0.66 km of road per square kilometre of land, which is almost similar to that of the USA (0.65) and greater than China's (0.16) or Brazil's (0.20) highway network density[3]. Indian road network face numerous challenges such as overcrowding, congestion, pollution, overloading and poor maintenance of the available infrastructure. 33% of Indian villages still do not have access to all-weather roads. The figure 1 shows the evolution of roads as well as the current share of different types of roads in Indian Road network.

Road network needs to be strengthened with new roads, especially connecting remote areas. Last mile connectivity still remains a dream in many areas and needs to be provided. Road quality needs to be improved, especially considering the deterioration in road quality, especially during the rainy seasons. It is suggested that

appropriate concrete or hot mix technology should be used to construct good quality roads. India transports >57% of its total freight by road, compared to ~22% in China and ~37% in USA. In contrast, the share of freight transport by railway is ~36%, compared to ~47% in China and ~48% in USA, which is more energy efficient mode of freight transport.Despite the fact that a large part of India's freight traffic comprises transporting bulk material over long distances, which can be served efficiently by railways and waterways, the share of shipping through waterways.

Infrastructure connectivity is an important link in integrating economic activities and basic services amongst countries in any geographical region and is a prerequisite for future growth of that region. It also opens up rural areas for development and makes cities internationally competitive. Undoubtedly, the evolution of transport will offer many challenges, the biggest of which is providing sustainable transport at the lowest social cost possible. The government policies play a critical role in determining the most likely pathway into the future.

The concept of connectivity via the development of regional infrastructure to link one country to another is not new to Asia. In India, poor rail and road connectivity affects cargo movement and concept of intermodal transport is evolving rather slowly. There is great scope for improvement in rail-road connectivity with major ports. Maritime infrastructure greatly facilitates international trade and economic growth. Therefore a major port performance indicator is intermodal connectivity. Intermodal connectivity is relevant, because many ports can handle a larger share of the volumes with the seamless assistance of intermodal transport methodology. A higher share of intermodal transport requires better connectivity between ports and intermodal terminals in the hinterland. Sea ports in India handle roughly 70% of all container volumes. Cargo handled at the 12 major

ports in India has increased to >400 million tons. Government of India has emphasized on development and modernization of the port infrastructure, in order to become globally competitive.

PROPOSED METHOD

The level of connectivity controls reliability and transit time. Any impediment that slows or halts the flow of traffic creates a bottleneck. The symptoms of bottlenecks are usually congestion, slowdown of vehicular movement, queue formation or shipping delays, which not only have negative impact on economy but also causes environmental pollution. Bottlenecks may be due to lack of infrastructure or due to unfavorable regulatory causes and in some cases, dysfunctional supply chain.

Intelligent Transport System (ITS) is defined as "the use of modern communications, computer and control technologies and systems to improve mobility and transportation productivity, enhance safety, maximize utility of transportation facilities, save energy, and protect the environment". ITS is a term used to refer to several inter-dependent transport modes and road technologies, and offers to check congestion, air pollution and road safety using intelligent communication systems. Information and communication technology (ICT) plays an important role in revolutionizing the ITS. Intelligence can be embedded at all levels of the systems e.g. in the vehicles and its subsystems, in the surrounding infrastructure, in the energy supply, in the traffic management systems and in the services delivered by the system. ITS is not restricted to road transport alone, but also plays an important role for other modes of transport like rail, water, air and MMTS. Internet of Things (IoT) makes these communications amongst different sub-system components possible, thereby enabling a new realm of optimization and automation.

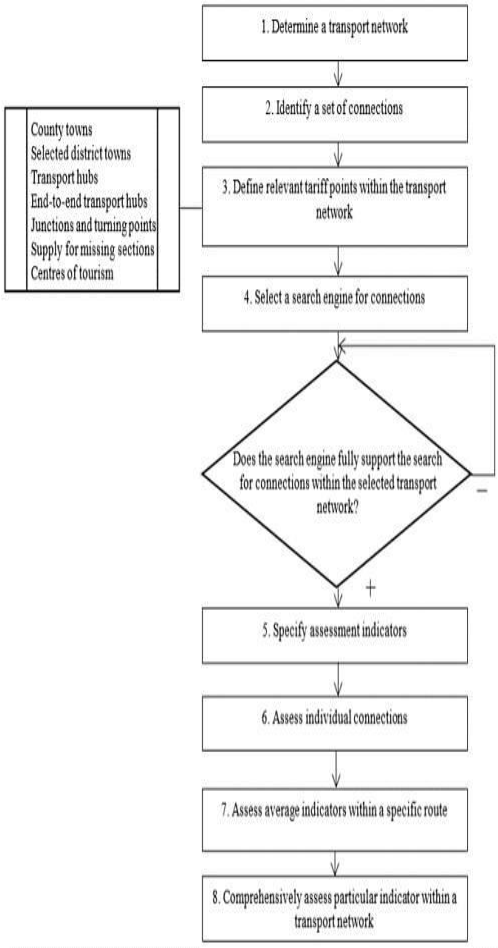
METHODOLOGY

Any new methodology for the comprehensive assessment of the quality of network connectivity should be based on predetermined and well-defined steps. The interconnection of individual indicators must enable the assessment of connectivity, and therefore the quality of transport, on equal terms. This implies that all connections within a selected network must be taken into consideration. The assessment procedure itself includes individual steps as follows:

1. Determining a transport network;

2. Identifying a set of transport connections;

3. Defining the relevanttariff points on a defined transport network;



4. Selecting search engines for transport connections;

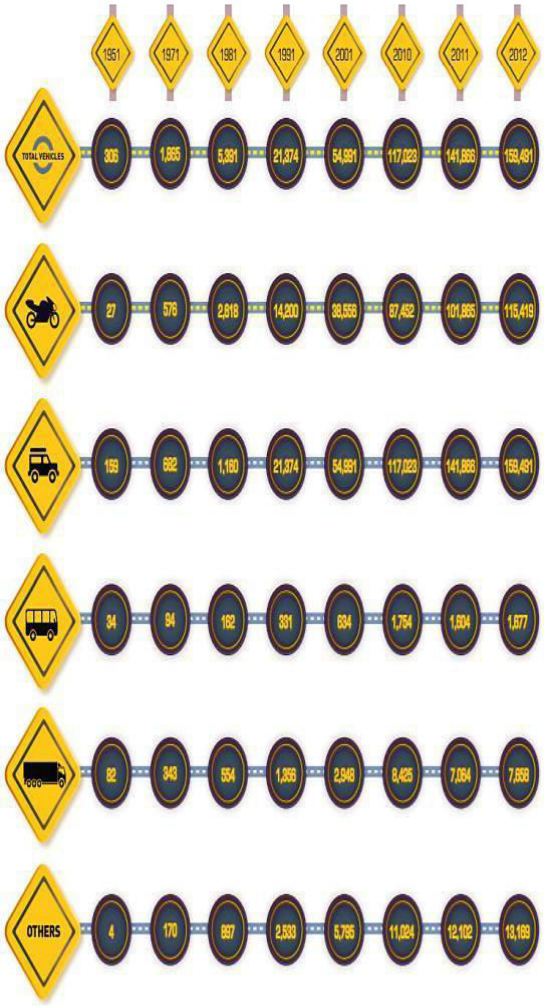
5. Specifying the assessment qualitative indicators;

6. Assessment of individual connections;

7. Assessment of average indicators within a specific route; and

8. Comprehensive assessment of a particular indicator within a transport network

Flowchart for assessing the quality of transport network connectivity



DATA CONTENTS

The traffic in Indian cities has mixed transport modes. There are various modes of road transport in India including 2-wheelers, Cars, SUVs, Jeeps, Buses, Mini Vans, Buses, Vans etc. Urban road transport is increasing significantly per capita however availability of road space per vehicle is declining rapidly, adding to urban congestion woes. As on March 2011, twowheelers account for the largest share

(72%) amongst the total registered motor vehicles of the country, followed by Cars, Jeeps and Taxis (14%), other vehicles (8%), goods vehicles (5%) and buses (1%). The lag in investment in the transport infrastructure has a detrimental effect on the booming car ownership, because available road space per car is continuously shrinking. Congestion leads to higher fuel use per km travelled, leading to significantly higher emissions.

CARRIER KEY ASSUMPTION

Automotive industry in India is one of the largest industry and is one of the key drivers of the economy. Automotive industry comprises of automotive manufacturing units encompassing commercial vehicles, passenger cars, two-wheelers, three-wheelers, tractors etc., and auto-component manufacturing units. Personalized vehicles (mainly two wheelers and passenger cars) account for more than four-fifth of the motor vehicle population in India compared to their share of little over three-fifths in 1951 (Figure 1.7). The total number of registered motor vehicles on Indian roads increased from 0.3 million in 1951, to 115 million in 2008-09, to 182 million in 2013. This has also led to an increase in the number of registered vehicles from ~25 in 2007-08 to ~33 in 2011-12 per km of road, further adding to congestion.

CONCLUSION

According to the different characteristics of transport modes and general layout of industrial enterprises, transportation mode can be selected and transportation routes can be arranged rationally to achieve maximum benefit.

Abstract- In this study, decomposition of two methylated chloro phenols - 4chloro3methylphenol (4C3MP) and 2chloro5methyl phenol (2C5MP) are investigated using various UV mediated oxidation processes- Fenton, UV/H_2O_2, UV/Fenton and UV/TiO. Among all the processes, Fenton accelerated with UV is observed to be efficient in decreasing the COD with a maximum removal rate of 98.5% for 4C3MP and 95.2% for 2C5MP. First order equations were used in evaluating the Kinetic constants. Photo mediated Fenton process is observed to have maximum kinetic constants of 5.1×10^{-3} for 2C5MP and 8.3×10^{-3} for 4C-3MP. Among the two chloro substituted cresols, decomposition of 4C3MP is observed to be higher than 2C5MP i.e., 95.2% for 4CMP and 86% for 2C5MP.

Key words: *Compound reduction, substitution, deactivating, oxidation & kinetic constants.*

1. Introduction

With industrialization and urbanization, large number of chemical industries sprouted worldwide. These industries consume huge amounts of water for production purpose and at the same time release wastewater at an alarming rate. Since the treatment cost of these wastewaters was high compared to production cost, these industries started releasing wastewaters in to the nearby water bodies. Many of these wastewaters contain non-biodegradable compounds of significant concern. Among them, cresols constitute a significant fraction of hazardous waste especially the methylated chloro phenols because of their chronic effects at 12 mg/L. The two model compounds of the present study 4-chloro and 2-chloro methyl phenols (4C3MP & 2C5MP), pose significant health threat when discharged into the environment due their carcinogenic and refractory nature.

4C3MP is used as a stabilizing agent in paint, textile, and cosmetic industry. It is also a chemical intermediate in the manufacture of some pesticides. 4C3MP is toxic to aquatic flora and fauna and can become persistent in some species of fish. 2C5MP is widely used in pharmaceutical industry. Effluents generated from these industries contain excess of methylated chloro phenols.

Many traditional treatments are available for the removal of such non-biodegradable compounds like adsorption or by membrane filtration [1]. However, some of these methods are either too expensive or involve only transfer of pollutants from one phase to another phase without complete removal. Under such conditions, Photo mediated Oxidation process seem to be an alternative for the treatment of methylated chloro phenols. These methods involve reaction of hydroxyl radical (*OH), with refractory compounds converting them to less toxic compounds. Many AOPs result from the combination of UV radiation with oxidants, like H_2O_2, catalyst like TiO_2 and Fenton reagent.

There have been some studies on the decomposition of 4C3MP using pressurized hot water/supercritical oxidation [2] and temperature activated fenton decomposition and 2C5MP using sonication , but no studies have been carried out using UV mediated oxidation processes. Hence, the main objective of this paper is to estimate the potential of photo mediated oxidation processes such as photo mediated catalytic oxidation (UV/TiO_2), photo mediated chemical oxidation (UV/H_2O_2), fenton, and photo mediated fenton oxidation (UV/H_2O_2–Fe) in degrading the methylated chloro phenols. For a greater efficiency of the treatment processes, operational factors such as pH, initial strength of peroxide, initial strength of iron and catalyst dosage effect are all monitored. Further, tentative degradative pathway of the two model compounds is also proposed.

2. Materials & methods

2.1. Chemicals

Analytical grade 4C3MP & 2C5MP were purchased from Sigma Aldrich. P-25 TiO_2 powder, a gift from Degussa Corporation (Pune, India) contains 80% anatase. Analytical grade chemicals like Ferrous Sulphate, Sulphuric acid, Sodium hydroxide are all procured from Merck while H_2O_2 solution is from Lobachem. For the entire study, Glass distilled water is being used.

2.2. Reactor set-up

A 1.0L cylindrical photo reactor with diameter 12cm and height 13.3cm is used for all the experiments. A quartz tube encases the whole reactor to prevent contact with the solution flowing between the inner and the external wall of the quartz tube. The reactor has provision of inlets and outlets for reactants and withdrawing samples along with ports for temperature measurement. A Teflon painted magnetic mixing bar is placed at the bottom for homogenous mixing of compounds. A 16W mercury vapor lamp is the source of UV light (λmax at 270nm) which is placed in the center and immersed in the phenolic solution. The samples are collected with an air tight syringe at regular intervals (Figure 1).

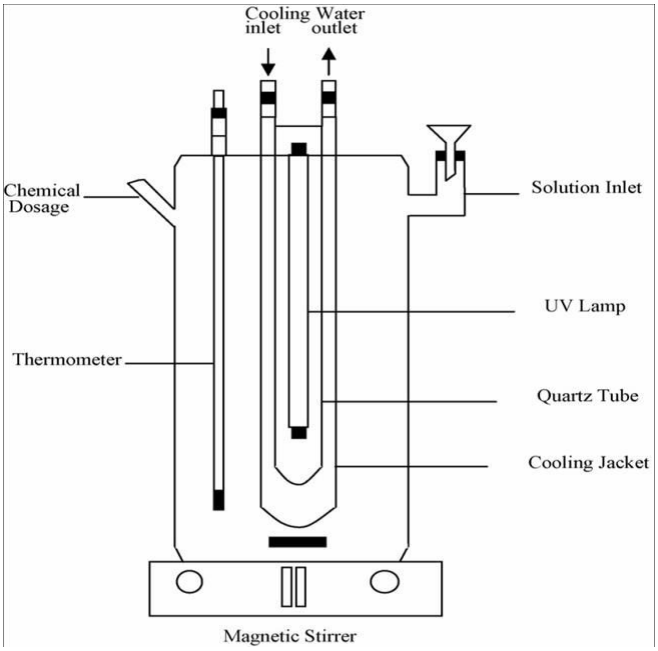

Figure 1 Photo Reactor with 16W UV lamp

2.3 Experimental procedure

Stock solution of methylated chloro phenols with a shelf life 1 week are prepared by dissolving them in methanol solution. Prior to experiments, all the dilutions from stock solution and other standards stored in dark are brought to room temperature. To validate the treatment process and check for any loss on volatilization, control samples are run for every experiment. pH studies are done by adjusting the pH with H_2SO_4 or NaOH (0.1 N /1.0N).

All the experiments are performed in batch mode with varying concentrations of H_2O_2 and Fe^{+2} (10:1) in Fenton and photo mediated Fenton, while 1:1 ratio is maintained for experiments with UV/H_2O_2. In UV/TiO_2 experiments, TiO_2 dosage ranging from 0.1g – 0.5g is varied at an interval of 0.1g. The reaction mixture is introduced in to the photo reactor after homogenization for 15min by magnetic agitation. After collection at regular intervals, the samples are centrifuged and sepearted through 0.25µm syringe filters (mdi, India type SY25NN). The seperated samples are submerged with Na_2SO_3 (10%) solution to stop further oxidation process after the treatment and stored in dark for further analysis.

2.4 Analytical procedure

The decomposition of methylated chloro phenols is evaluated with UV-Vis Spectrophotometer (Systronics-1272 wavelength 234 nm).

COD experiments were performed according to STANDARD METHODS of examination of H_2O and wastewater (1989), 21st edition**.** Systronics pH meter is used for measuring the pH. All the samples were diluted with 1:1 ratio for analysis.

3. Results and discussion

The present section deals with the results obtained in different oxidation methods in degrading methylated chloro phenols. The performance of these methods is evaluated in terms of decomposition of methylated chloro phenols and also reduction in COD.

3.1 UV Photolysis

3.1.1 Initial pH Optimization

Figure 2 & 3 represents the effect of pH in UV photolysis on the decomposition of 2C5MP & 4C3MP. At 250ppm of 2C5MP & 4C3MP, the experiments are performed at pH ranging from of 3 to 11. The decomposition of methylated chloro phenols are significantly affected by initial pH values which directly influences ˙OH radical generation. A 36 % of 2C5MP decomposition is observed at pH 3 which then decreased gradually at increased pH. It decreased to 17.9 % and 14% at pH 7 and 11. At a pH of 3, 59% decomposition is achieved in case of 4C3MP similar to previous studies. The decomposition decreased at higher pH (pH>3) to 26%.

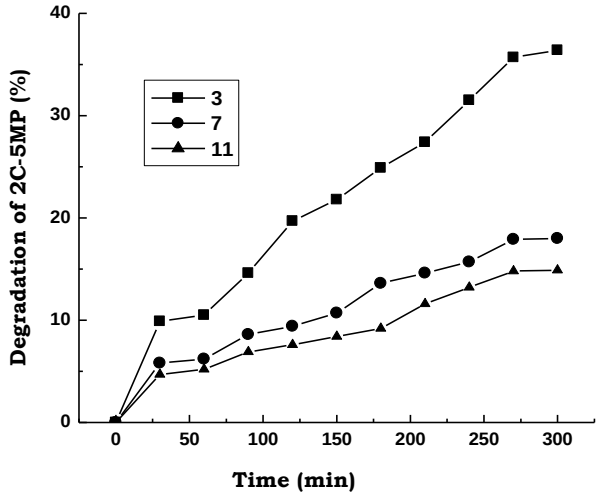

Figure 2 Initial pH Optimization of 2C5MP in UV photolysis

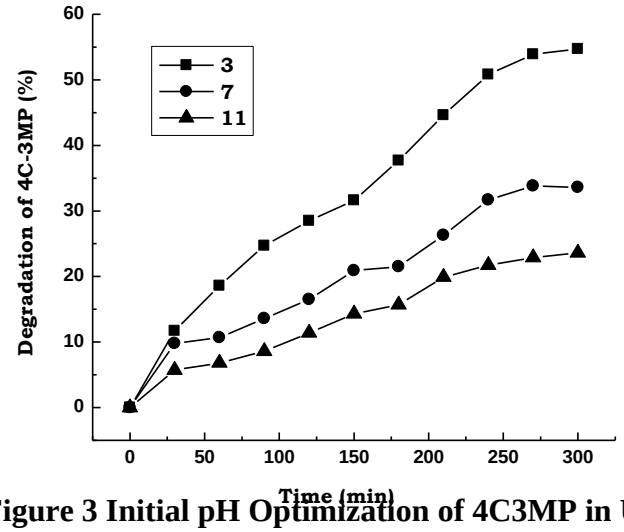

Figure 3 Initial pH Optimization of 4C3MP in UV photolysis

3.1.2 Initial strength Optimizaion

The optimization of initial strength of 2C5MP & 4C3MP in photo mediated experiments is studied with in a range of 50–750ppm at fixed pH of 3. It is observed from figure 4 and 5 that 64% of 2C5MP and 76% of 4C3MP decomposition is achieved with an initial strength of 100ppm of both the compounds. At higher concentrations, the decomposition decreased significantly (17.9% for 2C5MP and 18.6% for 4C3MP). Hence, in all further experiments, 100ppm of methylated chloro phenols is used as the optimum compound concentration.

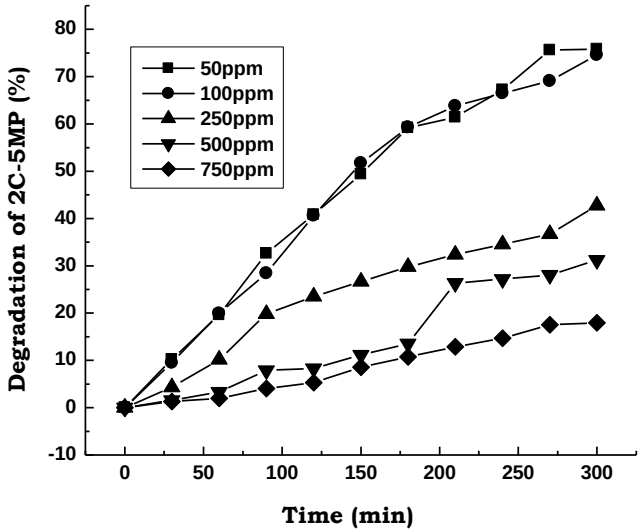

Figure 4 Initial 2C5MP strength optimization in UV photolysis

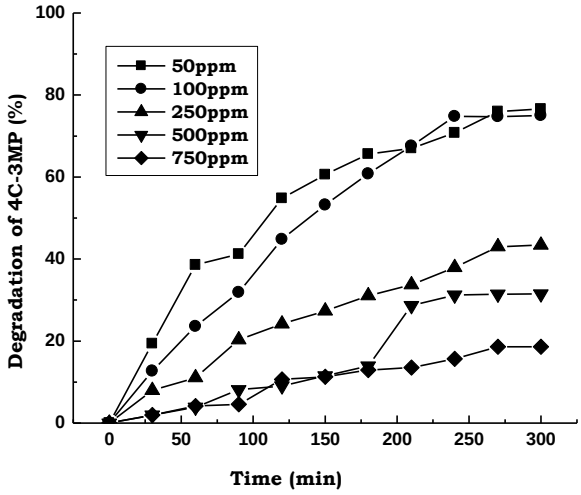

Figure 5 Initial 4C3MP strength optimization in UV photolysis

3.2 UV/H_2O_2 process

3.2.1 Initial H_2O_2 strength Optimization

The peroxide effect on 2C5MP & 4C3MP decomposition is observed by differing the strength of H_2O_2 from 50–500ppm (Figure 6 & 7). At 100ppm of initial peroxide, 48% of 2C5MP decomposition is observed with gradual decrease in the decomposition at higher concentration. The decomposition rate is observed to be high initially (from 50 to 100ppm) which might be due to the generation of more hydroxyl radicals at high peroxide strength. However, 2C5MP decomposition rate slowed down when H_2O_2 strength increased above 100ppm

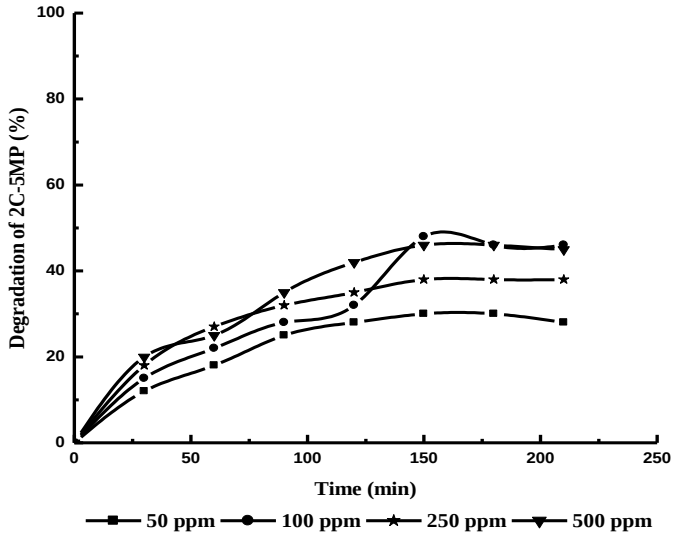

Figure 6 Initial H_2O_2 strength optimization on the decomposition of 2C5MP in UV/H_2O_2 system

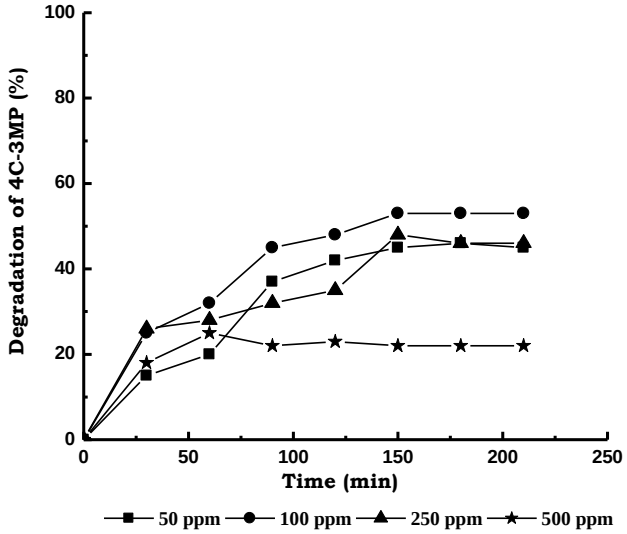

Figure 7 Initial H_2O_2 strength optimization on the decomposition of 4C3MP in UV/H_2O_2 system

As the peroxide strength is increased from 50-100ppm, the decomposition of 4C3MP also increased and it reached to a maximum of 53% at 100ppm of peroxide within 150min. But above this strength (>100ppm), 4C3MP decomposition decreased significantly [3] which might be due to the cleaning effect of ˙OH radicals at high peroxide strength. Therefore, in further studies 100ppm of peroxide is taken as optimum.

3.2.2 Initial pH Optimization in UV Peroxide system

In UV mediated peroxide system (UV/H_2O_2), initial pH was varied from 3-11 to study 2C5MP & 4C3MP degradation. It is found that at pH of 7, 48% of 2C5MP (Figure 8) and 55% of 4C3MP (Figure 9) decomposition is achieved. At lower pH (<7), the decomposition was less effective while at high pH (>7) only 10–15% decomposition is observed.

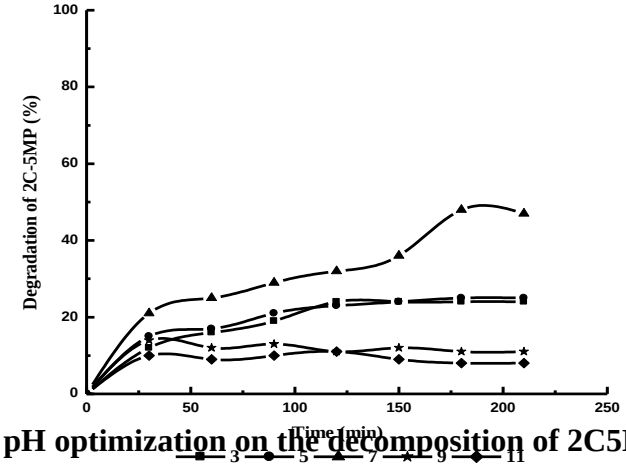

Figure 8 Initial pH optimization on the decomposition of 2C5MP in UV/H_2O_2 system

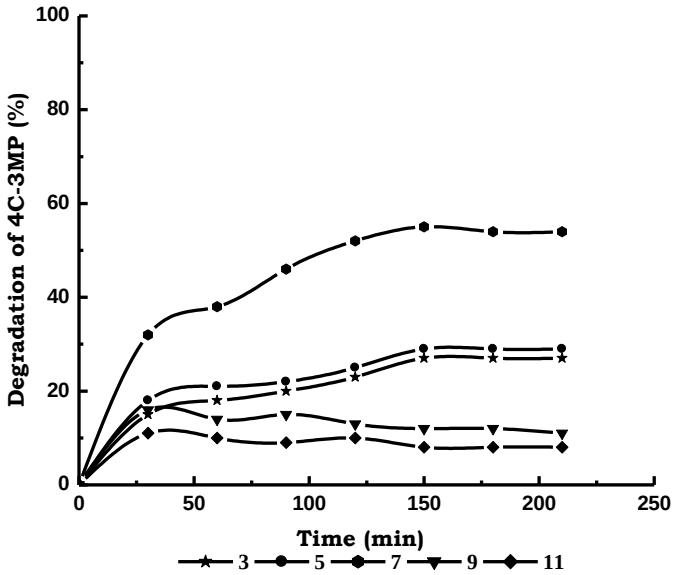

Figure 9 Initial pH optimization on the decomposition of 4C3MP in UV/H_2O_2 system

3.3 Fenton & Photo Fenton process

3.3.1 Initial Fe^{+2} strength Optimization

To find out the effect of Fe^{2+} ion on 2C5MP & 4C3MP decomposition in Fenton and UV mediated Fenton, iron strength was varied at pH 3 from 10 to 50ppm (Figures 10 & 11). The decomposition of 2C5MP was observed to be less than 60% at 10ppm iron strength and it increased gradually due to excess generation of ˙OH radicals [4]. Within 150min, 86% decomposition is observed in photo mediated Fenton while 73% is achieved in Fenton at 20ppm of Fe^{+2}.z

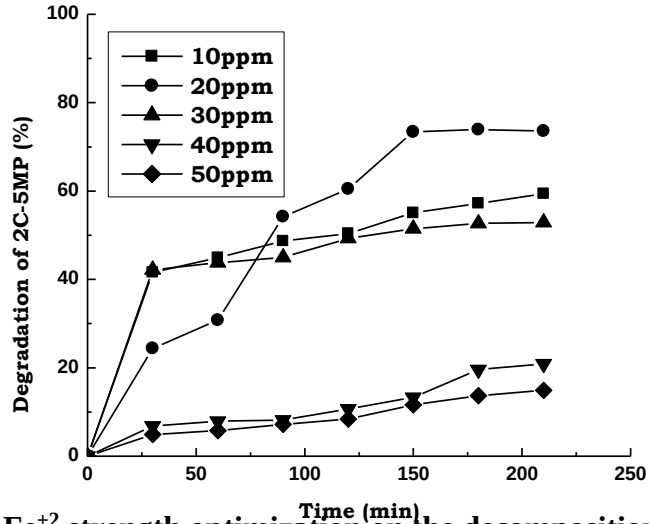

Figure 10 Initial Fe^{+2} strength optimization on the decomposition of 2C5MP in Fenton's oxidation

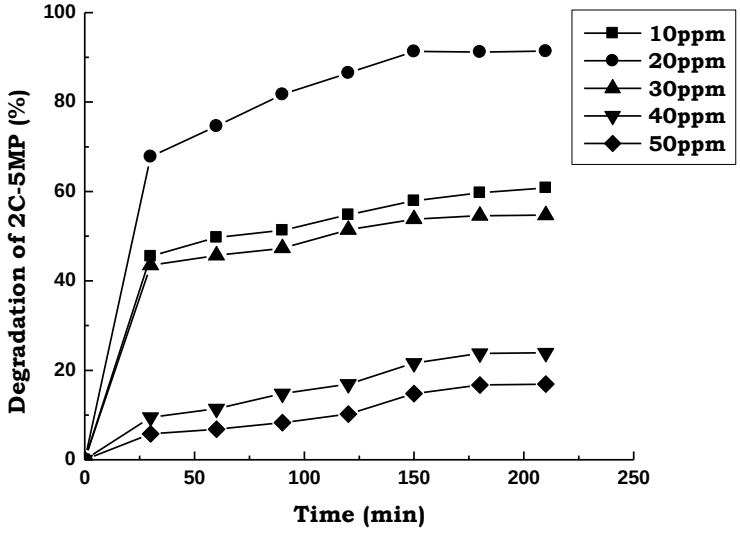

Figure 11 Initial Fe^{+2} strength optimization on the decomposition of 2C5MP in Photo mediated Fenton's oxidation

With an increase in the dosage of iron, significant decomposition of 4C3MP is observed (Figures 12 & 13). In Fenton procedure, adding of Fe^{+2} from 10-20ppm enhanced the degradation of 4C-3MP and attained to. An increase of 79.5% decomposition of 4C3MP is observed with the increase in dosage of iron from 10-20ppm, which is due to rapid formation of hydroxyl radicals catalyzed by ferrous ion. Photo mediated Fenton reaction increased the decomposition of 4C3MP leading to a rapid decomposition compared to Fenton process [34]. In Photo mediated Fenton process, 95% decomposition is observed at 20ppm of iron strength with in 150min (Figure 13). However, an increased iron strength (>20ppm) did not increase the decomposition which might be due to side reactions of hydroxyl radical with iron ions.

$$Fe^{+2} + {}^{\bullet}OH \longrightarrow Fe^{+3} + OH$$

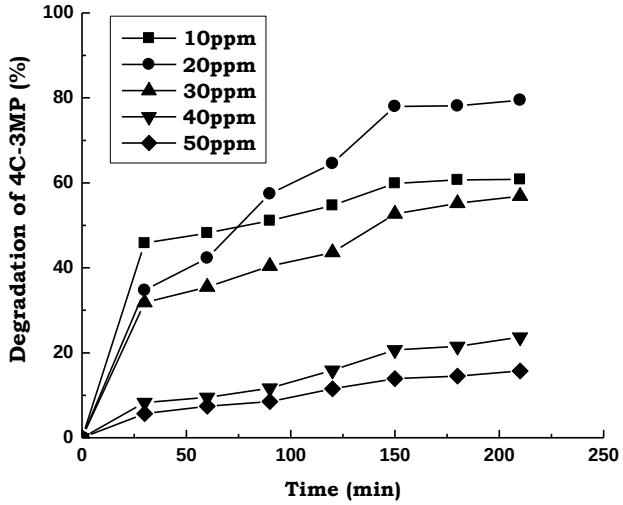

Figure 12 Initial Fe^{+2} strength optimization on the decomposition of 4C3MP in Fenton's oxidation

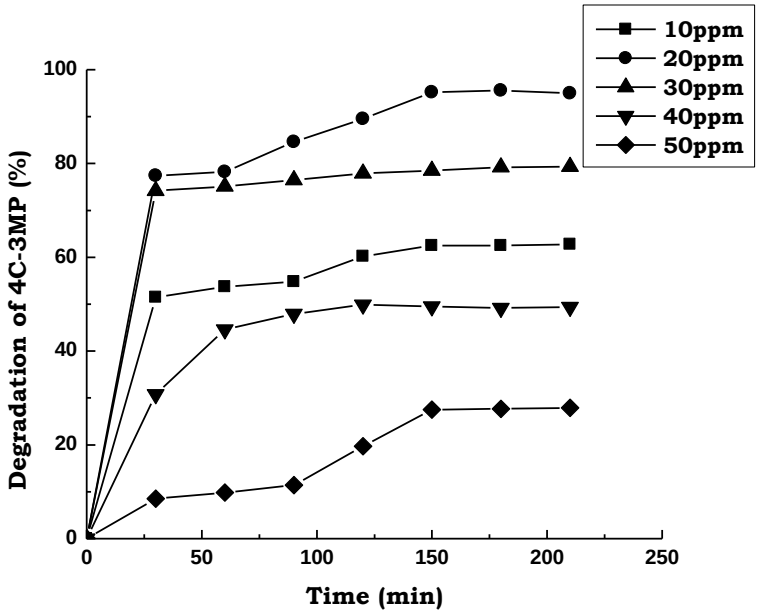

Figure 13 Initial Fe^{+2} strength optimization on the decomposition of 4C3MP in Photo Fenton's oxidation

3.4 Photo mediated decomposition using TiO_2 as catalyst

3.4.1 Initial pH Optimization

To study the pH effect with 0.2g of TiO_2 on 2C5MP & 4C3MP degradation, experiments are conducted by varying the pH from 3-11. It is observed that the decomposition of the compounds was high at neutral pH compared to basic and acidic pH. Basic medium with pH values >7.0 enhance carbonate ion formation, which scavenge hydroxyl ion generation that are responsible for oxidation reaction.

At pH 7, 58% and 70% decomposition of 2C5MP and 4C3MP respectively is observed within 180min (Figure 14 & 15). TiO_2 is amphoteric in nature with a point zero charge around pH 6-7 [5] and hence oxidation reaction is found to be effective at this pH.

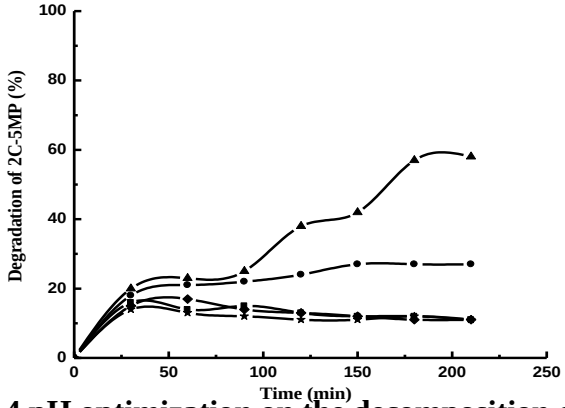

Figure 14 pH optimization on the decomposition of 2C5MP in UV/TiO_2 system

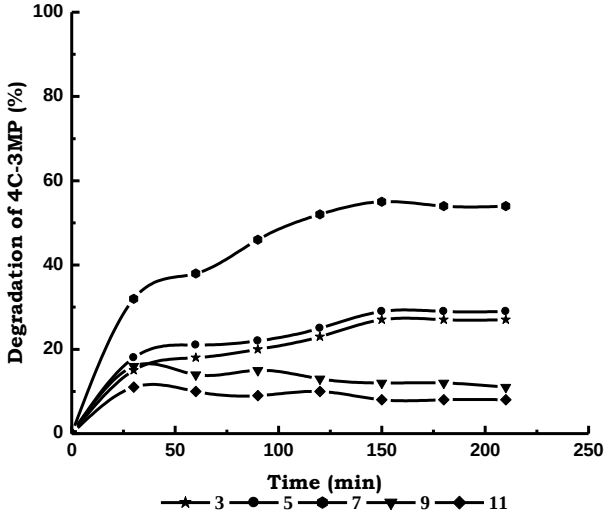

Figure 15 pH optimization on the decomposition of 4C-3MP in UV/TiO_2 system

3.4.2 TiO_2 dosage Optimization

TiO_2 dosage variation (0.1, 0.2, 0.3, 0.4 and 1.0 g) is studied for 2C5MP & 4C3MP at neutral pH (Figure 16 & Figure 17). At 0.3g of dosage of TiO_2 and within 180min 72% and 75% decomposition of 2C5MP & 4C3MP is achieved. The high reaction efficiency at this dosage may be due to increased active sites for oxidation process.

When the dosage of the catalyst was increased above 0.3g, the reaction efficiency decreased due to loss of interaction between photons and catalyst. While at low catalyst dosage, the efficiency decreased due to non-availability of active sites for oxidation process to occur.

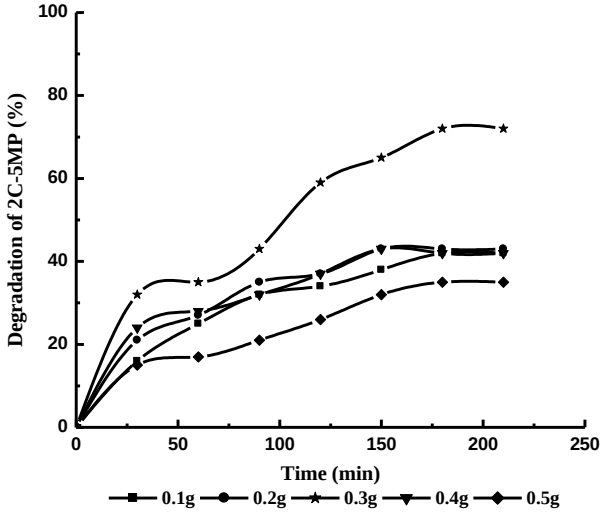

Figure 16 TiO_2 dosage optimization on the decomposition of 2C5MP in UV/TiO_2 system

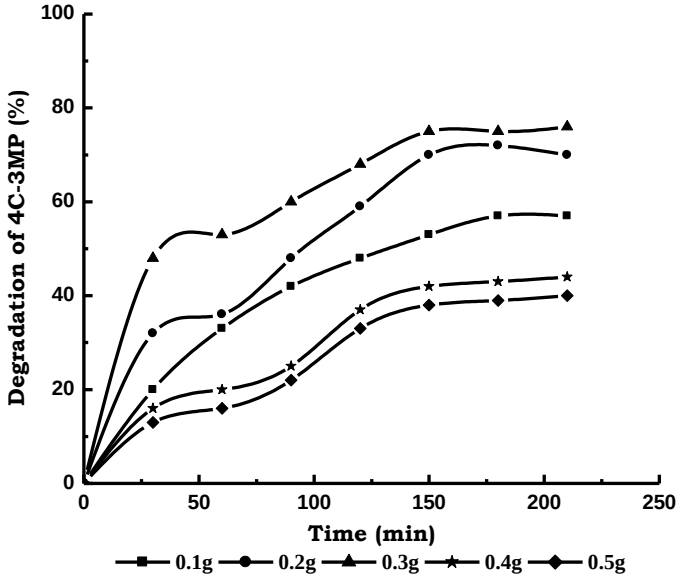

Figure 17 Effect of TiO_2 dosage on the decomposition of 4C-3MP in UV/TiO_2 system

3.5 Comparative study of various treatment systems

3.5.1 COD reduction

The decomposition of 2C5MP & 4C3MP with advanced treatment systems is evaluated using reduction in COD and compound. In COD reduction experiments of 2C5MP (figure 18), it was observed that 20.1% reduction in COD could be achieved with UV alone but very slowly. The COD reduction is found to increase (38%) when peroxide is added to the system with increased free radical formation. In Fenton process, COD reduction increased to 58.7%. The COD reduction rate increased to 85% when the catalyst TiO_2 is used along with UV. The optimum COD decrease of 95.2% is achieved with photo mediated Fenton process.

With 4C3MP (Figure 19), the COD reduction was found to be highest (98.5%) in photo mediated Fenton reaction. In UV/TiO_2, the COD reduction was observed to be 88.4%. While UV alone could reduce the COD to 25.6%, it was further enhanced to 65.2% when peroxide was added to the system. In Fenton system, COD reduction of 68.5% is observed.

The order of reduction in COD in both cresols is found to be:

UV/Fenton > UV/TiO_2 > Fenton > UV/ H_2O_2 > UV

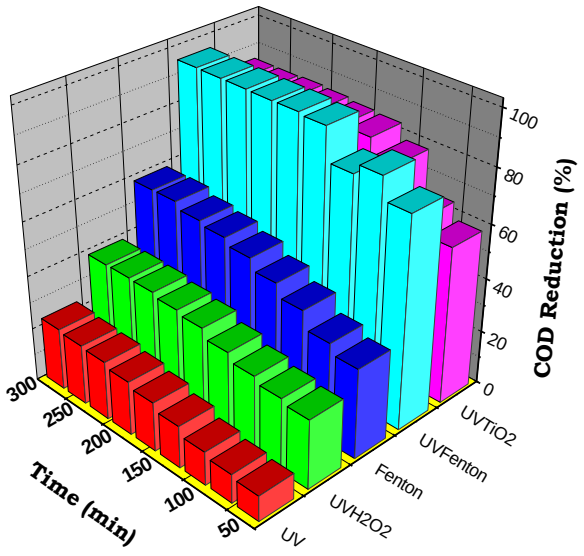

Figure 18 COD Reduction of 2C5MP with different oxidation systems

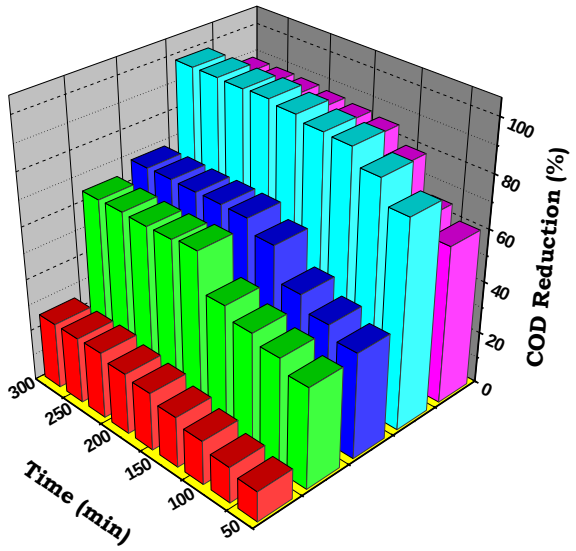

Figure 19 COD Reduction of 4C3MP with different oxidation systems

3.5.2 Compound reduction

UV process is observed to be a very slow method in degrading the compound with 36% of 2C5MP and 58% of 4C3MP. The decomposition of both the compounds is enhanced with 48% and 64.3% decomposition of 2C5MP & 4C3MP when peroxide is added to the system. In Fenton and UV/TiO_2, systems, 73 & 72% decomposition of 2C5MP and 79.5% & 75% decomposition of 4C3MP is observed. Photo mediated Fenton showed high efficiency among all the treatment system with 86% of 2C5MP and 95.2% of 4C3MP degradation.

3.5.3 Decomposition rate

2C5MP & 4C3MP decomposition rates with time for various treatment systems is observed to follow the pseudo first order kinetics (Figure 20 & 21) which is expressed as:

$$ln\ C_t / C_0 = -k^* t$$

Where C_0 and C_t represent 2C5MP & 4C3MP strength at times (minutes) 0 and t, while k* represents pseudo first order rate constant.

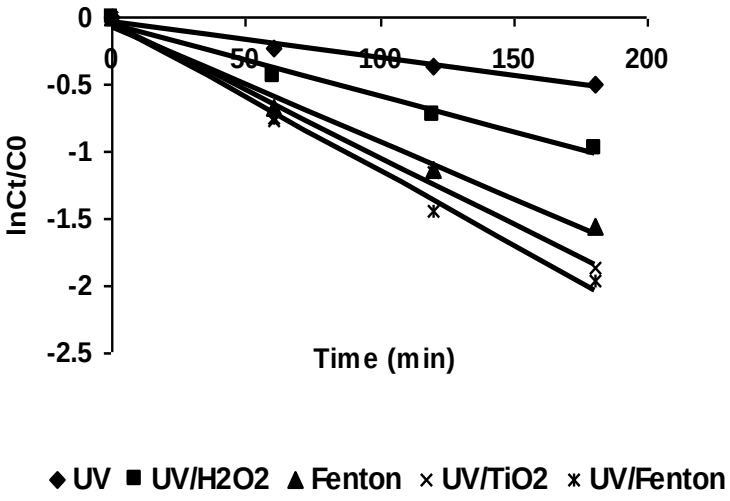

Figure 20 Kinetics showing the decomposition of 2C5MP with various treatment systems

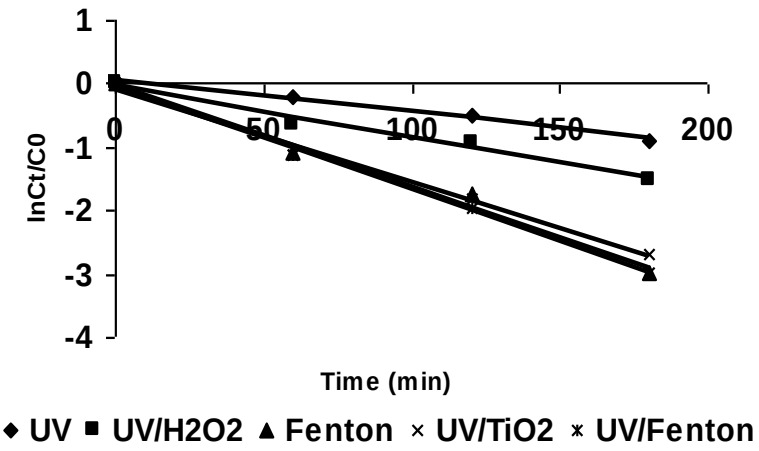

Figure 21 Kinetics showing the decomposition of 4C3MP with various treatment systems

S.No	Oxidants	K (min^{-1})	r^2
1.	UV/Fenton	5.1×10^{-3}	0.99
2.	UV/TiO_2	4.2×10^{-3}	0.98
3.	Fenton	4.3×10^{-3}	0.98
4.	UV/ H_2O_2	2.1×10^{-3}	0.98
5.	UV	1.4×10^{-3}	0.97

Table 1 2C5MP - rate constants

S.No	Oxidants	K (min^{-1})	r^2
1.	UV/Fenton	8.3×10^{-3}	0.99
2.	UV/TiO_2	7.8×10^{-3}	0.99
3.	Fenton	6.6×10^{-3}	0.98
4.	UV/ H_2O_2	5.6×10^{-3}	0.98
5.	UV	4.9×10^{-3}	0.98

Table 2 4C3MP – rate constants

Table 1 & 2 shows the rate constants obtained with linear regression analysis confirming the efficiency of photo mediated Fenton oxidation in the decomposition of 2C5MP & 4C3MP. All the treatment processes studied followed pseudo first order equation with highest rate constants of 5.1×10^{-3} & 8.3×

10^{-3} for 2C5MP & 4C3MP in photo mediated Fenton oxidation. However, a slight deviation from linearity (r^2 =0.97) is observed in UV system attributing to its low efficiency in degrading the cresols.

3.5.4 Degradative pathway

Among the two model compounds studied in the present paper, 4C3MP decomposition is observed to be very fast compared to 2C5MP. The OH group present in both the methylated chloro phenols is highly reactive and directing in electrophilic aromatic replacement of direct hydroxyl charged particle attack on electron rich positions. Since the hydroxyl radical attack is on electron rich chloro group, there is a considerable reduction in the stearic effect on 4C3MP making it more vulnerable to decomposition process. Figure 22 shows the tentative degradative pathway of 4C3MP & 2C5MP.

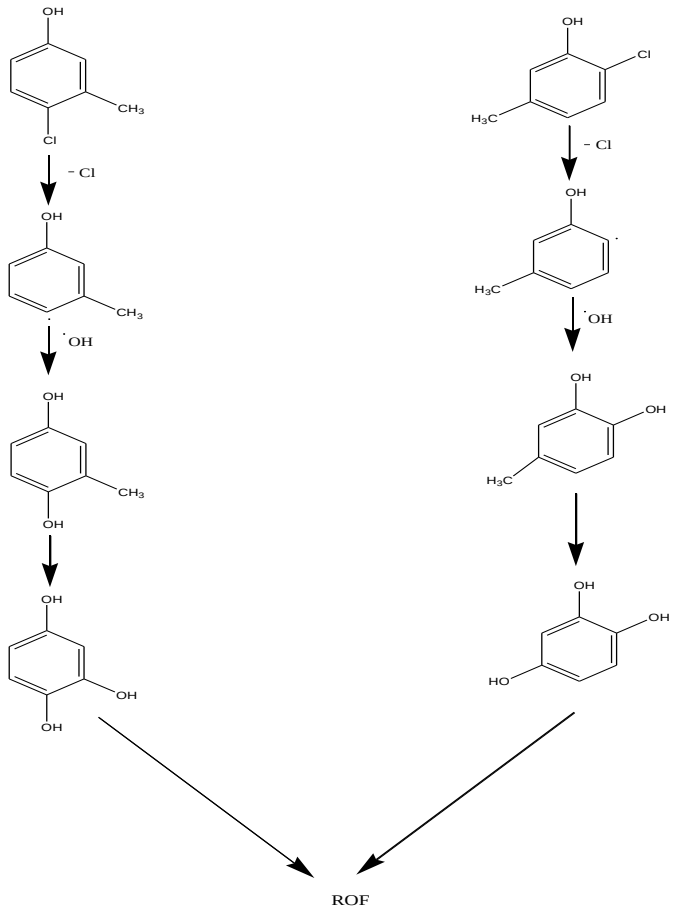

Figure 22 Tentative Degradative pathways of methylated chloro phenols

4. Conclusions

Photo mediated Fenton system is found to be efficient in degrading the cresols compared to other treatment systems.

- UV alone was found to be less efficient in the decomposition of cresols.
- UV peroxide was observed to enhance the treatment system but it required longer reaction time.
- Photo mediated Fenton process was efficient in achieving maximum COD as well as compound reduction.
- This was confirmed by kinetic studies which showed linearity in all the treatment systems except for UV that slightly deviated showing its least efficiency in the decomposition of cresols.
- 4C3MP decomposition is much faster compared to 2C5MP due to the position of active chloro group.

***Abstract*—** Pharmaceutical industrial wastewater is hazardous in nature so it needs to be treated before it is discharged in to any water body or on to soil. This paper, deals with the study of the treatment of pharmaceutical wastewater using different coagulants. Experimental investigations are carried with different operational parameters such as pH variation (2-10) and coagulant dosage variation (1-5g/500ml). Alum, Iron sulphate and Moringa oleifera are used as coagulants. Treatment is done for turbidity removal and COD reduction. Among all the coagulants studied, the natural coagulant Moringa oleifera is observed to be efficient in the treatment of pharmaceutical wastewater.

***Keywords*—** *Phamaceutical wastewater; Alum; Iron sulphate; coagulation.*

INTRODUCTION

Rapid industrialization and subsequent urbanization have increased the rate of environmental pollution [1]. Depleting water resources have seriously impacted industrial growth and also the standards of urban dwellers. Major problems are due to wastewater containing high SS concentration, COD and BOD. There is a constant search for finding new methods for the treatment of wastewater.

Pharmaceutical industry is considered as one of the highly polluting industry, generating a huge amount of wastewater [2]. Pharmaceutical products are manufactured in batch mode and this leads to a wide variety of pollutant production from different stages of manufacture. Pharmaceutical compounds enter into potable water through two different sources: Production processes and through usage of the same by human beings [3]. A plethora of toxic compounds are present in pharmaceutical effluents. Reuse of water also contributes towards contamination [4]. To overcome contamination, as well as to cater to the needs of the urban dwellers optimized methods of removal are the need of the hour [5].

Chemical coagulation is usually accomplished with coagulants such as Aluminium sulphate- or Ferrous sulphate. Natural coagulants can also be used to reduce the secondary pollution loads [6].

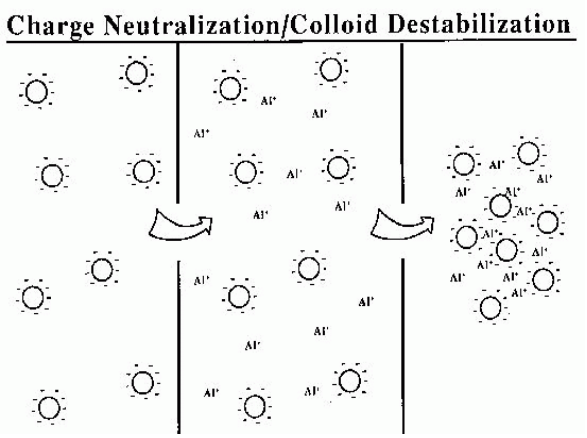

Fig.1 Charge Neutralization and Colloid Destabilization Mechanism

The focus of this work is to study the efficiency of wastewater treatment using suitable coagulants and to determine the values of optimum pH and dosages of FeSO4, Al(SO2).12H2O and Moringa Oleifera for the treatment.

MATERIALS AND METHODS

2.1 Materials

*2.1.1 Wastewater***:** The wastewater used in the present study is obtained from a reputed pharma industry. Initial turbidity, pH, COD and other parameters are to be investigated in this work.

2.12. Chemicals: Alum & Ferrous sulphate are purchased from Sigma Aldrich and Moringa oleifera is collected from nearby local market, Hyderabad.

2.1.3 *Preparation of Moringa oleifera coagulant:* the common name of Moringa is drumstick. The Moringa Oleifera plant seeds are sun dried and ground to fine size (fig.2).

Fresh drumsticks

Sundried drumsticks

Dried seeds of drumstick

Powdered Moringa

Fig.2 Preparation of Moringa coagulant

2.2 Methodology:

Wastewater sample is collected from a reputed pharmaceutical industry to which initial characterization is done. Experiments are run in a batch mode using Jar Test and the total volume of the sample taken is 500ml for each experiment. Optimization of parameters such as effect of pH and

dosage of the coagulant are being studied. pH of the pharmaceutical wastewater [7] is adjusted using diluted Sodium hydroxide (NaOH).The dosage of coagulant is varied from 1g to 4g (1g,2g,3g & 4g). Experiments are run for 30 min, after which they are allowed to settle down [8]. The supernatant is filtered and further analysis such as COD and Turbidity are done for the filtered sample to check the treatment efficiency.

% removal of COD/Turbidity = $\{(C_i-C_f)/ C_i\}X100$

Where,

C_i - initial concentration of COD/Turbidity

C_f - Final concentration of COD/Turbidity

3. Results and Discussion:

The studies of effects of pH and coagulant dosage with different coagulants are conducted in order to investigate the efficiency of Coagulation process in the treatment of Pharmaceutical wastewater. COD of wastewater is a good indicator of the strength of pollutants. Also the physical parameters like turbidity of wastewater are estimated.

3.1 Characterization of wastewater: The initial characteristics of the wastewater from pharmaceutical industry are as follows:

S. NO	**Parameters**	**Characteristics of the wastewater**	**Standards for disposal (mg/l**
1	pH	3.	6.5 – 8.5
2	BOD	45	10
3	COD	105	25
4	TS	149	210
5	TS	59	10
6	TD	98	10
7	Chloride	10	25
8	Alkalinity	20	60
9	Acidity	46	20
10	Turbidity	46	40

3.2 Effect of pH: pH of wastewater changes surface charge of coagulants and affects stabilization. pH value plays a prominent role in solubility of pollutants in wastewater. The study of pH plays a prime role in working of wastewater treatment system. At a coagulant dose of 2g/L, rapid mixing was done at a rate of 250 rpm for 10 minutes and slow mixing was done at a rate of 30 rpm for 20 minutes. Later, the solution was allowed to settle for about 30 minutes. The results obtained were analyzed by plotting the parameters and is presented in Fig.3.The range of pH tested was between 3 and 10, which indicates vthe effects of pH on percentage of COD. The initial turbidity and COD are observed to be 460NTU and 1050 mg/l respectively [9]. At an acidic pH 3 and basic pH 10 the removal % found very low. At the pH studied, pH 8 showed maximum removal efficiency of turbidity of 81, 11, 85% and COD of 78, 2.8 and

85% with Alum, Iron sulphate and Moringa (Fig.3) respectively. So, the maximum pH value by using alum as coagulant is 8.

S. No	Types of coagulant	Reduction in COD (%)	Cost in (Rs)
1	Alum	81.9	150.00
2	Ferrous sulphate	1.33	300.00
3	Moringa olefeira	**87**	**5.00**

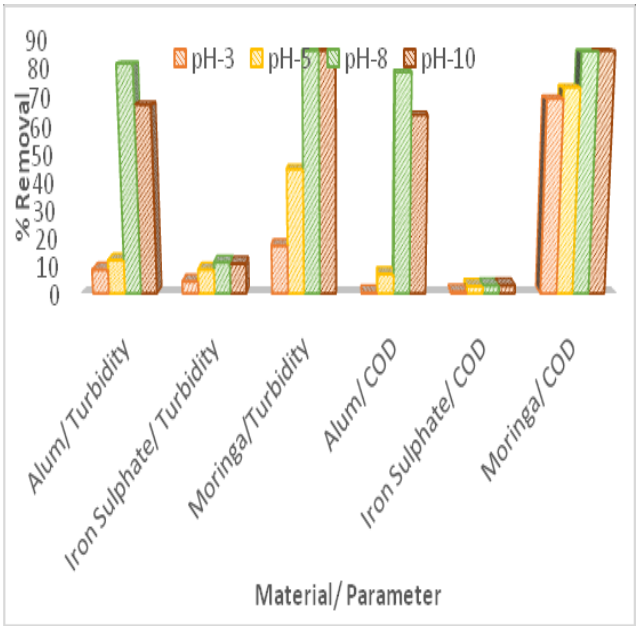

Fig.3:Influence of initial pH on turbidity and COD. Volume of sample = 500ml, pH

variation = 3, 5, 8, 10, Dosage of the coagulant =2g

3.3 Influence of dosage of coagulant

The impact of coagulant range on the treatment of pharmaceutical wastewater is studied by varying the dosages from 1g-5g at a constant pH of 8 (fig.4). From the figure, it is clearly observed that with an increase in the dosage of coagulant, there is an increase in the percentage removal of turbidity and COD. Maximum percentage removal of turbidity of 83, 86, 86.8 and COD of 81, 2.3, 87 is observed with Alum, Iron sulphate and Moringa compounds. The removal efficiency of turbidity stabilized and in case of COD, it decreased when the dosage of alum is increased above 3g.

3.3 Effect of dosage of coagulant

The effect of coagulant dosage on the treatment of pharmaceutical wastewater is studied by varying the dosages from 1g-5g at a constant pH of 8 (fig.4). From the figure, it is clearly observed that with an increase in the dosage of coagulant, there is an increase in the percentage removal of turbidity and COD.

Maximum percentage removal of turbidity of 83,
86, 86.8 and COD of 81, 2.3, 87 is observed with
Alum, Iron sulphate and Moringa compounds. The removal efficiency of turbidity stabilized and in case of COD, it decreased when the dosage of alum is increased above 3g. It can be due to reversal of charge. Hence, the optimum dosage of alum for the treatment system is 3g (9).

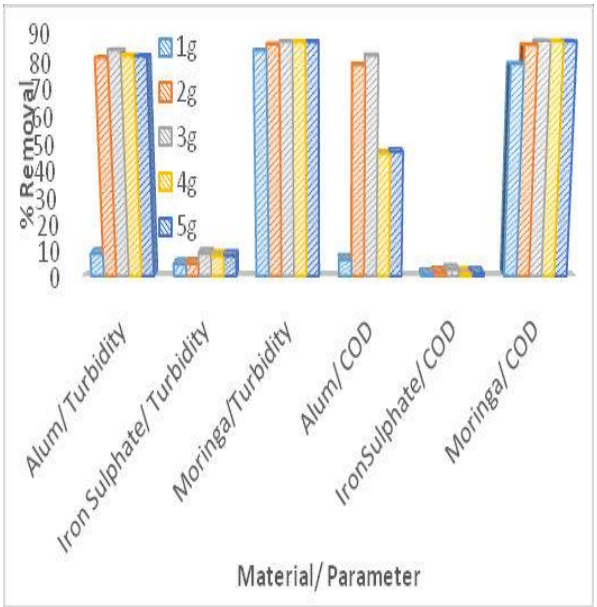

Fig.4: Influence of coagulant dosage on Turbidity and COD removal from pharmaceutical wastewater Conditions: Volume of sample = 500ml, pH =
8, Dosage variation= 1g, 2g, 3g, 4g & 5g

3.4 Comparative study: In this section, a comparative study is done between the different types of

coagulants on the treatment of Pharmaceutical wastewater in terms of percentage reduction in COD and also cost of operation. Among all the coagulants studied, ferrous sulphate is found to be the least efficient in the removal ofCOD while alum showed much higher removal efficiency than ferrous sulphate. However, huge amounts of sludge is formed which is again a problem for disposal as it is a chemical sludge and nonbiodegradable. In the present study, as shown in table 2, the natural coagulant Moringa oleifera is observed to be more efficient. A maximum of 85.7% COD reduction is achieved with this coagulant. In terms of cost also, this coagulant is found to be economically feasible. Moreover, less amount of sludge is formed which is easily biodegradable.

Table 2 Comparative study of various coagulants studied

The final characteristics of the pharmaceutical wastewater are given in table 3. It shows both initial and final characteristics of the wastewater with Moringa oleifera as the coagulant. All the parameters are found to be within the standard limits of disposal. Hence, Moringa oleifera can be effectively used as the coagulant for the treatment of industrial wastewaters.

Table 3 Characteristics of the pharmaceutical wastewater before and after the treatment with Moringa oleifera as coagulant

S NO	**Parameters**	**Initial (mg/l)**	**Final (mg/l)**	**Standards for disposal (mg/l)**
1	pH	3.0	8	**6.5 – 8.5**
2	BOD	450	85	**100**
3	COD	1050	135.4	**250**
4	TS	1490	180	**2100**
5	TSS	590	100	**100**
6	TDS	900	80	**100**
7	Chloride	100	35.4	**250**
8	Alkalinity	200	354	**600**
9	Acidity	460	150	**200**
10	Turbidity (NTU)	460	60.4	**100**

Note: all the parameters are given in mg/l except for pH and turbidity (NTU)

4. Conclusions:

- Pharmaceutical wastewater has the initial characteristics of pH-3, Color-milky white, COD- 1050 mg/l and turbidity- 460 NTU, also the remaining parameters are found to be above permissible limits.

- The optimum pH in coagulation process for Alum, Ferrous sulphate and Moringa oleifera seed powder is found to be 8.
- The optimum dosages of Alum, Ferrous sulphate and Moringa oleifera seed powder as coagulant are found to be 3g/500ml, 3g/500ml and 2g/500ml respectively at an optimum pH of 8.
- Of all the coagulants used in the present analysis, optimum turbidity decrease is found to be 86% and optimum COD decrement is 87% with Moringa Oleifera

Therefore, we can interpret that as compared with remaining coagulants, Moringa Oleifera is the best coagulant in removal of pollutants from pharmaceutical wastewater.

Abstract- The road building agencies in India are promoting construction of concrete pavements in a big way due to its ability in handling complex stresses from vehicle loads and temperature. As per the Indian Road Congress guidelines for design of concrete pavements, M40 grade concrete is to be used for the concrete slab and accordingly, the approximate slab thickness shall be varying between 250mm to 320mm. Higher the concrete grade results in further reduction of pavement thickness, temperature stresses and depth of joints. Therefore, in this study, to increase the grade of the concrete, VacuumDewatered Concrete (VDC) technology is adopted in place of conventional method of pavement construction. The properties of concrete such as compressive strength, flexural strength and split tensile strength were found in both the methods and compared. The test results depicted that all the properties discussed above are higher in case of VDC method as compared to the conventional method of construction.

Key words: Design mix concrete, Conventional concrete, Vacuum Dewatered concrete, Rigid pavements, cost comparison.

1.0 Introduction:

To maintain the workability of concrete, it is necessary to add water content above the optimum which is required to attain the strength. The excess water evaporates and left the pores in the concrete which leads to reduction in strength of the concrete. Water above the

optimum could be removed after placing the concrete that is the role of workability completes and this will help in attaining the higher strength. To remove the excess water, generally vacuum pressure is applied and therefore, this method is named as Vacuum Dewatered Concrete (VDC). It is an alternative method of pavement construction in which water is removed from the concrete through vacuum pressure after the laying**(Academy, 2011)**. With the help of VDC technique, it is possible to achieve the concrete with higher strength with less cementitious materials and hence, it is cost effectiveness. A pavement constructed with VDC technique is found be more abrasive resistance, less shrinkage, less permeability, high durability and can resist higher traffic loads**(Bolat and Çullu, 2016; Jacobs *et al.*, 2012; Ebensperger and Torrent, 2010)**.Using VDC technique, it is possible to reduce the water content approximately by 15-25% in the concrete **(Feng, Sun and Feng, 2018)**.

The present study is aimed to achieve the high-strength concrete pavement with less cementitious materials. Accordingly, two test sections were constructed with conventional and VDC technique methods. For the test sections, same proportions of materials and water-cement ratio were maintained. While constructing the conventional pavement, testing specimens were casted at the site to check the compressive strength, flexural strength and split tensile strength. In case of VDC technique, cores were extracted after construction to check its properties. These specimens were tested in the laboratory to find the 7 days and 28days strengths and compared the results with both the methods. The results show that the VDC technique has given the better strength and performance as compared to the conventional method of concrete. In addition, cost estimates were carried out to check which method is economical and presented here.

2.0 Materials and methods:

Conventional Portland cement of 53 grades is used. River sand locally available in the market is used. Crushed granite aggregate of 20 mm nominal size produced from local crushing plants are used. Water is the cheapest but the most important constituent of concrete. Generally water fit for drinking called "wholesome water" or potable water is used**(Saeed and Ezzulddin, 2014)**.

To study the parameters, one pavement was constructed by conventional method, and another one using vacuum dewatering method. From the conventional concrete cubes of 150x150x150mm were casted and tested for 7 and 28 days compressive strength. And another pavement casted by vacuum dewatering method is tested for 7 and 28 days compressive strength by taking core samples. The results are compared for both the pavements. And also the cost involvement in the construction for both types of pavements is worked out and comparative studies carried out with these results and conclusions have been made.

3.0 Results and Discussion

3.1 Compressive strength

From Fig 3.1 it can be observed that as design mix concrete, conventional concrete and vacuum de-watered concrete are cured and hardened, vacuum de-watered concrete has attained a considerably high amount of compressive strength with progress of time. Also it can be seen that vacuum de-watered concrete attained stability quicker. The mix proportions of design mix concrete, conventional concrete and Vacuum dewatered concrete for investigating compressive strength are presented in Table 3.1., Table 3.2 and Table.3.3 respectively.

TABLE – 3.1

3.2 Flexural strength

From Fig 3.2 it can be observed that as design mix concrete,conventional concrete and vacuum de-watered concrete are cured and hardened, vacuum de-watered concrete has attained a considerably high amount of compressive strength with progress of time. Also it can be seen that vacuum de-watered concrete attained stability quicker. The mix proportions of design mix concrete, conventional concrete and Vacuum dewatered concrete for investigating flexural strength are presented in Table 3.4., Table 3.5 and Table.3.6 respectively.

The following aspects were included in estimating the cost of conventional concrete:

Table. 3.10 shows the detailed cost analysis of Normal concrete for 1 m^3 of concrete work. From this table, it can be observed that the cost of vacuum de-watered concrete is a little bit higher compared with conventional concrete by a margin of just Rs. 271 or by a mere 3%. But the benefits accrued far surpass the marginal increase in cost. Therefore it can be said considering the compressive strength and cost analysis that vacuum de-watered concrete is invariable better.

Table.3.10: Cost estimate of conventional concrete

Total					7969.56
Add 15 % for contractor's profit and overheads					1195.43
Cost per 1.00 cum					9164.99
Say					9165

Table. 3.10 shows the cost estimate of conventional concrete and Table. 3.11show the cost estimate of vacuum dewatered concrete. It can be observed from these tables, that with just an additional cost of Rs.271/- per Cu.m, exorbitant benefits such as increase in compressive strength, lower consumption of cement etc can be achieved.

4.0 Concluding remarks:

It can be arrived that there is a considerable enhancement in compressive strength, flexural and split tensile strength and on usage of vacuum de-watered concrete. With a marginal increase in cost of construction, good benefits such as overall increase in all the three strength parameters, reduction in cement consumption, early utilization of pavement, reduction in maintenance cost etc, are possible by using this technology.

Abstract: Pedestrian crossing and the behavior of pedestrians in different conditions especially at uncontrolled crossings is a subject which needs in depth study and analysis. At uncontrolled junctions, the pedestrians and their behavior, safety of pedestrian crossing is neglected and no measures are taken to systematize pedestrian crossings at these junctions. Therefore a practical study of the pedestrian road crossing data is made in this study and statistical analysis of the data is done at uncontrolled crossing junctions in mixed traffic conditions of Indian scenario. The main objective of study is to analyze the pedestrian road crossing behavior at uncontrolled junctions. Adopting multiple regression technique the various parameters which effect the behavior of pedestrian. Vehicular gap, driver yielding behavior, frequency of attempts to cross, age and condition of pedestrian , rolling gap are some of the parameters that decide the pedestrian crossing time and other requirements. The surveys have been conducted at all junctions between Bowenpally to Kompally on national highway manually and analysis is made. The survey and statistical analysis concluded that at almost all junctions, the vehicular gaps and pedestrians behavior is not up to mark and the parameters considered indicate there is scope of accidents if suitable measures are not taken. It is concluded that counselling pedestrians and drivers for change of their behavior is very important. Providing visible marks for pedestrian crossing is to be done at all junctions. Traffic control devices are to be installed where ever possible. Considering the volume of pedestrian traffic all along the city, safe crossings for pedestrians has to be given.

Key words:*PedestrianCrossing-speed, Gap-acceptance, Delay, Safety, Mid-block crossing*

I. INTRODUCTION

A person walking on road is called pedestrian. They are required to cross the roads to go to other side. Foot paths and crossing facilities like Zebra crossings, foot over bridges are to be provided for them, to safe guard their lives and make them move safely without any fear, or hurdle to their destinations. It is responsibility of the Government and authorities to ensure their safety. On their behalf, the drivers

and pedestrians should behave properly and follow the traffic rules correctly. To achieve this objective, a study of behavior of drivers and pedestrians is very important. This paper makes such study.

A convergence is characterized as an at-level intersection of at least two streets. Convergences are the most bustling spots in the street way. Safety for pedestrians is very important in designing any traffic control system. Several necessities make people walk. Walking for health and good health is now considered as prime necessity. If a person has to go to his friends house which is nearby he will walk. A person requiring some goods to purchase for his daily needs will also walk. Persons having no vehicular support will walk for all their requirements even for long distances. Whenever a need arises in these endeavors, they have to cross the roads. When no traffic signals are available at near places, they will try to cross seeing the vehicular gaps. It is very difficult to predict the vehicle gaps in mixed traffic conditions. Therefore the pedestrians may try to run or behave improperly to cross roads in hurry leading to accidents. At intersections, this is very problematic as vehicles come in all directions.

1.1 Need for Present Study

Several problems like darting, dashing, age, intoxication of both pedestrians and drivers, lighting darkness, fog, are associated with pedestrian crossing. Each problem has its own effect on pedestrian crossing. Therefore multiple regression analysis is done on the data collection. Each road and city has got specific problems of pedestrian crossing and is to be studied separately having its own uniqueness. Therefore the problem of National highway 44(NH44) from Bowenpalli to Kompally is studied in this analysis and conclusions are drawn.

1.2 Objective and Scope of the Study

This study has been directed towards accomplishing the following goals:

- To study the walker crossing offices at convergences in Hyderabad City.
- To study passerby development design at some chosen crossing points and foot over scaffolds in our City.
- To recognize the issues related with person on foot crossing at convergences.
- To assess the need of restrictive walker signal stage at signalized convergence.

2. LITERATURE REVIEW

Only a few studies were done in the Hyderabad city, regarding pedestrian problems.

These investigations are chiefly centered around review of the summed up issues related with people on foot. In any case, none of them has estimated the condition of people on foot at convergences. To have better comprehension on the conceptualization on the issue, data identified with the exploration

were gathered from various accessible existing books/diaries, unpublished proposition, course papers, magazines, papers and so forth.

The different studies made on this issue are presented below to understand the problem and to serve as guide for our study.

ChaudhariAvinash[a]ShahJiten[b]ShriniwasArkatkar[a]JoshiGaurang[a]ParidaManoranjan, 2018.

This work explains the impact of encompassing elements on common intersection in various urban communities of India, explores the impact of person on foot qualities on strolling speed, hole acknowledgment conduct and deferral and it suggests 50th percentile (1.15 m/s) speed as configuration speed for mid-block intersections, especially for developing countries like India. A normal 6.2 s is suggested as mean speed for plan of walker office at mid-block crosswalks under blended traffic conditions, A normal 8 s is suggested where female or senior people on foot are available.

Saha et al. 2011;Pa sha et al. 2015;Ma lik et al. 2017;Anciaes and Jones 2018.

Dread of heights (Opdyke et al. 1995;Juan and Pérez 2009) and the nonattendance of sufficiently planned flights of stairs (Mutto et al. 2002;Rizati et al. 2013) essentially influence the rationale of the walkers toward utilizing raised offices. Walkers across various Asian urban areas generally favored utilizing at-grade offices instead of utilizing underpasses or bridges because of security concerns.

Malik et al. 2017;Saha et al. 2011;Das and Barua 2015;Pasha et al. 2015;Sinclair and Zuidgeest 2016.

Past investigations indicated that in any event, when such isolated offices were given, walkers were hesitant to utilize them and crossed unlawfully utilizing accessibility at-grade middle openings. Analysts over the globe had contemplated distinctive intersection offices to comprehend factors that prompted the utilization or non-utilization of such isolated offices.

Pasha et al. (2015)

Even the presence of merchants, diminished the compelling walkway width, which was further liable for the decrease in the utilization of the pedestrians, and this was as per the findings announced by Pasha et al. (2015). During the review, a lot of criticisms were acquired from respondents which additionally affirmed that the portability contact happened significantly.

TRB, National research council, Washington

A study was made by TRB, National research council Washington on pedestrian flow, speed, capacity relationships and gave their own equations. The level of service aspects was also studied.

Di Pietroand King& V. Himanen, R. Kulmala

Dr. pietroand and others studied decision making process and explained the same with a gap acceptance theory.

D.Sun, S.K.Ukku suri, R.F. Bene kohal, et al.

D. Sun et.al studied the gap acceptance theory and suggested suitable modeling for assessment of gap acceptance by pedestrians.

Transportation Research board meeting,2003.

The motorist-walker association at uncontrolled block cross sections was studied by TRB in 2003 and recorded during their 82nd proceedings and studies continued up to 2006.

C. Holland, R. Hill

The pedestrian, vehicular and roadway characteristics which influence the pedestrian crossing behavior was studied by Holland and others and concluded that gender and age influence the behavior to a large extent. The driver status will also influence the crossing behavior in risky situations.

G. Tiwari, S. Bangdiwala, A. Saraswat, et al.

Tiwari et.al concluded that Females will wait for longer time than males while crossing the road.

J. Oxley, B. Fildes, E. Ihsen, et al.

The studies on age were done by J. Oxley et.al and it was concluded that the elderly and old peoples crossing behavior is more safe compared to young people. This behavior is more predominant in roads without dividers and with small dividers.

Himanen and Kulmala, 1988.

The behavior of pedestrians and car drivers on pedestrian crossings was analyzed by Himanen and Kulmala, in 1988. And an application of logical models was developed.

3. METHODOLOGY

Information from just one source has been utilized for this examination. This study keeps up the stringent standards for the accomplishment and effective achievement of the proposed targets of the work. Field overview has led to distinguish the current walkers crossing offices beginning at Bowenpally Police Station and ends at Kompally X-Roads, Hyderabad on NH44. Existing walker crossing dat has been gathered physically. Walkers information has been gathered by manual checking some chosen crossing points where traffic interest and passerby exercises are exceptionally high. Heading passerby crossing information has been gathered for 7 sequential days starting from 7AM toward the beginning of the day till 7PM at night. Information investigation has been performed using MS Excel. Walkers data has been correlated with manual perception. From this perception, issues related with passerby crossing at convergences and mid-blocks have been recognized. Some signalized crossing points have been chosen to present selected walkers.

3.1 Data collection

The data on the parameters like driver behavior, pedestrian behavior, road condition was collected at all the junctions from Bowenapally to Kompally on National highway 44 and recorded with different teams. The data collection included the age, gender, condition of pedestrian, gap of vehicles, vehicle types, driver conditions, average speed, and number of vehicles. The data were recorded for a period of 7 days Starting from 7 AM to 7 PM on 7 consecutive days as explained above manually through different teams on all the parameters identified. A Proforma was furnished to the team and the team members were asked to collect the information and fill up the data in detail with remarks if any. They were advised to collect the information from different type of people like young, old male and female, pedestrians and drivers, traffic officials. They were also instructed to note down the road conditions

and existing facilities of pedestrian crossings at the junctions. The road sketch of the reach indicating the crossing locations where survey was conducted is shown in **Fig.1** below.

Fig.1: Intersections from Bowenpally P.S to Kompally X-Roads

The **Figure 1** shows the junctions between Bowenpally to Kompally on National highway 44.

The study is done through manual count. The following measureswere taken for manual count to get correct and accurate results.

- The time period(s) of count should cover the peak times of the pedestrian crossing activity of study. As counts are done from 7 AM to 7 PM, this is covered as peak time will be in the afternoon and noon times.
- A continuous period of 7 days were observed where there are no school holidays, no office holidays, no bank holidays, no early closing, and no special events were considered for this study.
- All the junctions were considered and selected which cover all strategic locations of the road stretch under consideration.
- The pedestrian facilities need to be provided to divert trips to walking, or increase the current pedestrian activities,at each junction were also studied.

3.2Data extraction

At the junctions, cameras are placed and the information of passerby crossings are recorded once in every 30 milliseconds. This data is extricated by utilizing AVS video editorial manager programming from each forward snap and is shown in Fig. 2. The manual tallying of data recorded by software at Dhulapally crossroads is shown in Fig 3. The traffic jams were usually not included in the data extraction process and the collected data are summarized in **Tables 1 and 2** for male and females respectively.

Fig 2: Data Extraction using AVS video

Fig.3: Dhulapally X-Roads Mid-Block Road Crossing
Morning Survey Timings - 7:00AM To 11:00AM

Table1: Time Vs number of persons crossing (extracted from camera)

TIME PERIOD (in Seconds)	Number of Persons crossing the road (Male)
10-20	5
20-30	18
30-40	24
40-50	11
50-60	25
60-70	13
70-80	2
80-90	1
90-100	6
100-110	17
110-120	26

Table 2: Time Vs number of persons crossing (extracted from camera)

TIME PERIOD (in Seconds)	Number of Persons crossing the road (Female)
10-20	12
20-30	17
30-40	21
40-50	26
50-60	15
60-70	8
70-80	3
80-90	8

The data points from manual counting are related to gap required for pedestrian crossing and the empirical equations are developed. These equations have demonstrated that age, gender and driver condition are most influencing factors.

4. CONCLUSIONS

Age, gender and driver condition effects the gap time required to be provided for pedestrian crossing and should be considered while fixing the pedestrian signals. Our Survey was based upon the pedestrians and the motorists.

In spite of the fact that traffic light gadgets can assist with traffic control, educating people on foot and drivers is principal to a safe control. Arrangement of noticeable cross stamping must be introduced in all the convergences. Considering the high thickness of walker traffic everywhere on the city, pedestrian foot crossing has to be provided. Middle Island with middle obstruction must be given in all the convergences to guarantee safe walker crossing. Road lighting around the intersection ought to be sufficient so that cross imprints are handily caught by the vehicle drivers to have halting sight separation to keep away from crash in evening. The executives of existing physical framework must be upgraded to empower more powerful utilization of crosswalks. Street marking signs, traffic lights, and channelization at convergences, turning limitations, partition hindrances, space for transport stops and leaving off of space for public vehicles should be given provision. Passerby intersection ought to be considered cautiously in rush hour gridlock designing and arranging of the convergences and mid squares. Strolling ought to be perceived as one of the predominant methods for movement all over Hyderabad city. Pedestrian wellbeing ought to be considred depending on traffic convergences, midblock plan contemplations, signal planning, sign boards, cross checking, isolated traverse paths, underpass and numerous other parameters. It is important to eliminate improper and illicit non-transport related traffic from the public traffic to ensure safety on the street. This may include the buildup of elective destinations. Demo-exercise activities ought to be taken to improve the capacity of passengers (drivers and walkers) to be more productive and more secure. Projects ought to be taken to adjust huhman mentalities and bring about eagerness among people to assist better traffic administrations. Set of traffic rules guarantee a more consistence compliance of conduct. Implementation activities can include formal policing to embrace traffic standards and code of conduct, ought to be incorporated into the common public. During foot crossings, vehicles are found to run with max throttle which poses a perilous danger to passersby. Therefore security must be beefed up and traffic police should adopt strict measures to control it. All the vehicles ought to be authorized appropriately to decrease speed at the zebra crossing in the whole signalized convergences.

5. RECOMMENDATIONS

A few suggestions are given considering modifications to encourage safe pedestrian transportation during strategy making. Restrictive passerby phase might be provided in some chosen convergences on pilot premise to improve pedestrian safety and give the walker a cordial ambience. These may be provided where passerby traffic volume is high and where pedestrians regularly violate crossing indiscriminately. Selective Pedestrian Phase (SPP) might be presented which will lessen vehicular movement in the convergences. Convergences, for example, in and around shopping zones and institutional zones are associated with higher volume of people on foot and therefore vehicular regulation time exerts a better flow of traffic. Pedestrian path regularization might be carried out in

different staging plans. At areas with hefty passerby volumes and weighty turning developments, it might be reasonable to give a select path to walkers. Unlawful stopping close to the crossings which obstruction walker crossing ought to be eliminated. Pedestrian regularization methods at intersection ought to be permitted through law. At grade crossing walkers should not be allowed to cross, aimlessly on account of profound traffic flood in most of the assemblies, considering high people thickness and high volume of traffic in the city. It will in general be communicated that introduction of prohibitive bystander signals and placards in the high business and shopping domains of the city will be prohibited.

6. FUTURE SCOPE

Colossal possibilities ought to be considered to suggest most ideal alternatives for determination of the convergence to the present EPP and propose for signal planning in setting of the whole stretch from Bowenpally P.S to Kompally X-Roads. Such exploration may improve the nature of traffic and assist policy makers of Hyderabad.

ABSTRACT-The behavior of accepting gap determines the capacity of an uncontrolled intersection.Intersection performance influences the critical gap. Gap and lag give better results. Studies reveal that developed countries exhibit good performance by adopting proper traffic rules. When a minor road intersects a major road critical gap is to be considered. Critical gap concerns the safety of traffic and pedestrians. In developed countries people follow traffic rules voluntarily. In some cities of India, due to heavy traffic regulation of the traffic is difficult at intersections with no control. Pedestrian safety is also of paramount importance. The aim of this paper is to calculatecritical gap and critical lag separately. In this work we used the clearing behavior of vehicles in connection with gap and lag. The clearing behavior of vehicles is studied along with lag and gap data procured from the local region at two legged and three leg controlled intersections. It was observed that the critical lag and critical gap values were dynamically changing with change in the volume of traffic and also pedestrians. Depending on the nature of intersections, the values of critical gap and lag were observed to be quite changing. The values of critical gapwere found to be more than critical lagin our study area.

Keywords:*Mixed traffic, Uncontrolled cross, Critical gap, Gap acceptance.*

1.0 Introduction:

Gap acknowledgment at convergence is generally viewed as where a little street meets an enormous street. A gap between two vehicles is to be deliberately kept up by drivers during blending and intersection [1]. The way of moving toward vehicles of the significant road vehicles bring about the production of delays of various spans. A gap between two vehicles is the separation between the back guard of the primary vehicle and the front guard of the subsequent vehicle and is typically estimated in a flash. Slack is the separation in time between the entering vehicle and the progressive vehicle in the significant stream.

An uncontrolled convergence is one in which the passage into the crossing point from any of the methodologies isn't constrained by an administrative (i.e., STOP) sign or a traffic light. "at the point when two vehicles approach or enter a convergence from various expressways at roughly a similar

time, the driver of the vehicle on the left will yield the option to proceed to the vehicle on the right." The driver should likewise respect any vehicle that is now legitimately in the convergence and any common in a checked or plain crosswalk. Uncontrolled crossing points are generally restricted to low-volume streets in rustic or neighborhoods, as outlined beneath.

The base sight separation (perceivability) relies upon the control that exists. For an uncontrolled convergence, drivers drawing closer from all headings ought to have the option to see the crossing point as well as the restricting minor road comes nearer from a separation that would be adequate for them to securely respond [2]. In the event that the convergence is constrained by a STOP sign, the driver drawing nearer on the significant street ought to have the option to see the crossing point from at any rate the halting sight separation. The base halting sight separation relies upon the plan speed of the street and is usually alluded to as the Green Book, the public plan manages streets and gives guidance on the best way to decide the proper halting sight separation for a given area.

Drivers don't have adequate perceivability of approaching vehicles on the two methodologies of the converging road to securely enter or cross the convergence. For convergences at which just the minor street approaches are stop-controlled, the minor street crossing point sight separation is the length obvious along the two methodologies of the significant road. Convergence sight separation is estimated utilizing approach sight triangles or takeoff sight triangles, contingent upon the control at the crossing point. The sight triangle is framed by the two legs of the contradicting roads and relies upon the working rate and the traffic light of the converging streets. The clients' view inside the triangle ought to be unhampered. There are a few situations that relate crossing point sight separation to the kind of control and vehicle maneouver.

Drivers are not given adequate data as signs or markings to recognize or explore the crossing point. At some unsignalized crossing points, the way or path of the driver ought to follow may not be self-evident, or the plan and arrangement may lead the driver into an off-base way. This is regularly the situation at bizarre crossing points, particularly if there are no asphalt markings depicting the paths. The absence of a Street Name sign at the convergence can likewise be viewed as insufficient direction.

The crossing point is powerless to visit close misses or clashes and coming about crashes between vehicles because of a mix of traffic volumes, working rates, and turning developments at or close to the convergence.

There are a few factors that can intensify the potential for clashes among vehicles at a convergence, for example, neighboring area uses and passageways (e.g., business carports in nearness to the crossing point), hefty through volumes and additionally turning developments, and high working paces on the methodologies.

Numerous analysts have dealt with the idea of gap acknowledgment during the previous hardly any years, yet the vast majority of them considered homogeneous traffic stream circumstances [3]. As indicated by accessible writings, a few strategies or models have been set up since the time of 1947 for the assessment of basic gap as unmistakably as conceivable [4] Thus, plainly written works with respect to gap acknowledgment wonder is rich. Larger part of literary works ordinarily think about the dismissed and acknowledged gaps as the vital boundaries for the basic gap assessment. "accordingly basic progress/gap can be assessed based on perceptions of the biggest dismissed and littlest acknowledged gap relating to a given transportation office.

Raff and Hart (1950) said that the expression "basic slack" as a significant boundary in the assurance of gap acknowledgment for a minor road driver ready to take a orientation development in an un-signalized convergence. Additionally the creator proposed a theoritical model where two aggregate conveyance bends identified with the quantity of acknowledged and dismissed gaps meet to yield the estimation of basic Lag .

Mill operator (1972) remedied the Raff's model and reasoned that the created model is appropriate for traffic however isn't satisfactory for substantial traffic conditions. The creator additionally confirmed that it gives good outcomes for gaps as that acquired for slacks. Further the creator recommended a gap acknowledgment to check the materialness of different techniques for basic gap assessment.

The targets of this work are to investigation the inhabitance season of various vehicles at unsignalized crossing point, to gauge the traveler vehicle unit for various vehicles at unsignalized convergence to decide the estimation of basic gap for various vehicles at unsignalized crossing point and to comprehend the accessibility of gap impact.

2.0 Materials and methods:

Information was gathered from three legged crossing points in Hyderabad city, Telangana state, India. Both the convergences comprise of two path isolated significant roads and one path unified minor roads. Crossing points were chosen with the end goal that there is an away from in the extent of hefty vehicles.

For convergence 1, extent of hefty vehicles is less contrasted with crossing point 2. The decision has been had to dissect the unmistakable effect between the gap acknowledgment conduct due to hefty vehicles and other vehicle types on the significant street. The video-realistic information was caught from raised situations for a time of three hours during non-weekend days on every area [5].

Gap acknowledged and dismissed, subsequent time for every vehicle type was extricated from the video. What's more, the impact of gap accessible for every vehicle type and with other vehicle types in

the transfer was separated from the data. characterization follow up progress as the time between the takeoff and flight of the following vehicle utilizing a similar major-road progress, under a state of constant lining on the minor road. The subsequent time is estimated from the field as the normal of the absolute readings.

The philosophy incorporates reasonable site choice for the field overview, assortment and extraction of field information, distinguishing proof and measurable investigation of components prompting gap acknowledgment. For gathering the gap acknowledgment information, blend of vehicles are ready for the significant stream traffic. The gap acknowledgment study is done uniquely for vehicles which are taking right abandon minor to significant stream.

Further, the significant stream vehicles are isolated into various blends. As the level of portion of , 3w, and 4w are higher, the mixes are readied. In basic gaps strategy, it is hard to gauge basic gap legitimately. Generally it tends to be assessed by acknowledged gaps and dismissed gaps. As referenced previously, there are numerous computation strategies for basic gap, for example, inhabitance technique, Acceptance bend strategy , slack strategy, Ashworth's technique, Raff's technique, Harders' technique, Logit methodology, and Greenshield technique.

Crossing points were chosen with the end goal that there is an away from in the extent of weighty vehicles.

For convergence 1, extent of hefty vehicles is less contrasted with crossing point 2. The decision has been had to break down the reasonable effect between the gap acknowledgment conduct in light of weighty vehicles and other vehicle types on the significant street. The video-realistic information was caught from raised situations for a time of three hours during non-weekend days on every area [5].

3.0 Results and Discussion:

Occupancy time analysis for combined traffic for 3 hours from minor to major road.Table.1, shows Occupancy time analysis for minor right vehicle.

Table.1: Occupancy time analysis for minor right vehicle

Type of vehicles	**Number of vehicles**	**Time**
CS	19	6.9 sec
CB	6	7.3 sec
TWO WHEELERS	44	1.5 sec
LW	32	9.2 sec
HCV	40	12 sec

AUTOS	3	5.2 sec

Maximum occupancytime was 1.7sec and minimumoccupancy time was0.4sec whereas the averageoccupancytime was found to be3.42sec. Theaverage occupancy time of individual vehicleon3.5mwide traffic lane was7.01 sec. The passenger car unit value which is combined from occupancy method is 4.47sec. Theaverage criticalgapby raff's method is 3.1 sec. Theaverage criticalgapby lag method is 3.89 sec from the collected data design of signals was proposed atunsignalized intersections.

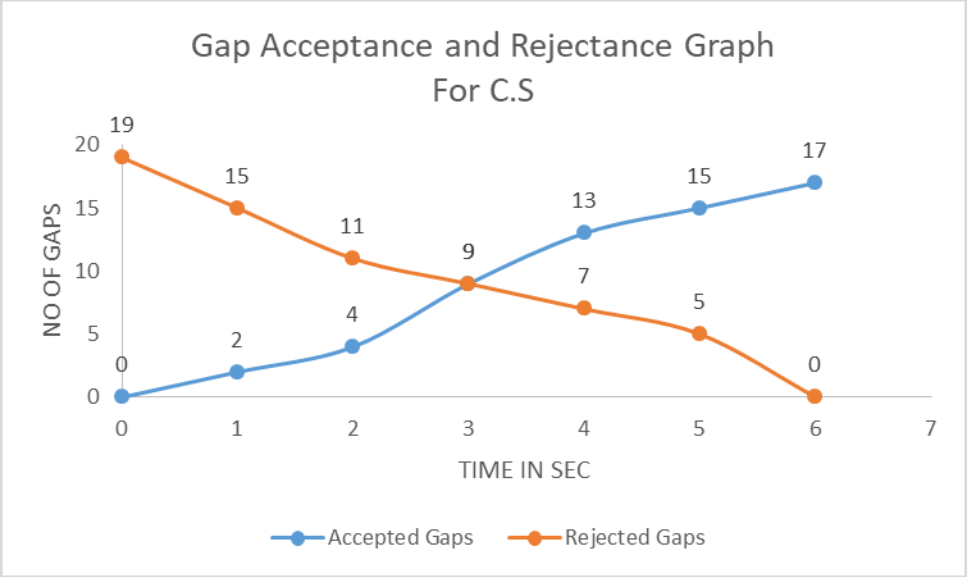

Fig.1: True average of the critical headway

Average critical gap : 3.0 sec .9.5-acceptance gap less than 3.0sec. 9.5-rejected gap greater than 3.0 sec.Pcu=average of individual vehicle by occupancy method / pcu factor [6]. Fig.1 shows the The average value of the headway is found. Table.2 shows the Consistency and homogeneity of drivers and it does needs predefined programs of critical gap and theories connect to the uniformity and equality of drivers.

Table.2: Consistency and homogeneity of drivers

Length of gap t(sec)	Number of allowable gaps	Number of rejected gaps
0.0	0	116
1.0	2	103

2.0	12	66
3.0	32	38
4.0	57	19
5.0	84	6
6.0	116	0

From experimental and hypothetical contemplations, if the reliant variable is a parallel variable, the state of the reaction capacity will be curvilinear. Table.3 shows gap acknowledgment conduct of ward factors of this reaction bend are the aggregate likelihood of tolerating a gap of a particular length.

Table.3: Gap acceptancebehaviour

TIME		**TURNING LEFT**			**TURNING RIGHT**		
FROM	TO	Two wheelers	Autos	CB	Two wheelers	Auto s	CB
8.3	9.3	44	25	10	55	11	10
8.45	9.45	55	10	15	45	16	14
9	10 0	40	15	17	55	13	14

The x-value comparing to the 0.5 probabilities might be characterized as a basic gap size. The primary disadvantage of this philosophy is that the improvement of acknowledgment bend predisposition (or slack acknowledgment inclination) delivers a pretty much misshaped. This predisposition is presented when information from drivers that reject numerous gaps are incorporated.

4.0 Conclusions:

The traffic surveys wereconductedat Kompally, by using the video recording technique:

- Passenger car unit:
  -Minimum for small cars = 1.4
  -Maximum forheavy commercial vehicles = 5
- Theaverage occupancy time of individual vehicle on3.5m wide traffic lane is7.01 sec.
- The passenger car unit value which is combined from occupancy method is4.47sec.
- Theaverage criticalgapby raff's method is 3.1 sec.
- Theaverage criticalgapby lag method is 3.89 sec
- From the collected data:
  -design of signals atunsignalized intersection.
  -Provision ofsignals for pedestrians.
  -Design ofroad as per traffic conditions.

Abstract- India delivers yearly around 960 MT of solid waste, which poses major natural and biological issues in addition to posing huge risk of diseases. In spite of the fact that numerous lab cycles, items and advances have been created dependent on agro-modern squanders, non-adequacy of the other option and recently created items among clients because of absence of mindfulness and certainty is to be eliminated. Be that as it may, climate well disposed, energy-productive and savvy elective materials created from strong squanders will show great market potential to take into account individuals' needs in country and metropolitan regions. So as to augment the utilization of elective structure materials created from various kinds of strong squanders and to expand the creation limit of lab scale measures, innovation empowering focuses are should have been set-up to encourage business visionaries for successful commercialization. Toughness and execution of the fresher items and spread of advances underlining costs-benefits examinations and life cycle evaluation report will essentially add to fruitful commercialization of inventive cycles. Consideration of mechanical waste-based more up to date assembling materials, accentuating their ecological criticalness in the educational program at advanced education level and pragmatic uses of squanders in development area will offer fillip to such innovation advancement. The logical progression in reusing and utilizing mechanical and agrarian cycles for using squanders will prompt a superior utilization of world's assets. The new and elective structure development materials created utilizing agro-mechanical squanders have adequate degree for presenting new structure parts that will diminish to a degree the expenses of building materials.

1.0 Introduction:

Waste might be characterized as an undesirable material produced after the assembling cycle of mechanical, or from agrarian, or from house hold action. It is the disposed of material which fundamental prerequisite of removal. Squander causes numerous aggravations in the climate. It produces numerous sorts of viral or bacterial contamination for the human and creature which make awful impact on wellbeing.

During various mechanical, mining, horticultural and homegrown exercises, India creates every year around 960 MT of strong squanders as results, which posture major natural and environmental issues other than involving an enormous territory of land for their capacity/removal [1]. Looking to such gigantic amount of squanders as minerals or assets, there is huge extension for setting up auxiliary ventures for reusing and utilizing such strong squanders in development materials. Despite the fact that numerous lab cycles, items and innovations have been created dependent on

agro-modern squanders, non-agreeableness of the other option and recently created items among clients because of absence of mindfulness and certainty is to be taken out. Nonetheless, climate agreeable, energy-productive and practical elective materials created from strong squanders will show great market potential to oblige individuals' needs in rustic and metropolitan territories [2]. So as to boost the utilization of elective structure materials created from various sorts of strong squanders and to build the creation limit of lab scale measures, innovation empowering focuses are should have been set-up to encourage business visionaries for viable commercialization. Sturdiness and execution of the fresher items and spread of advancements stressing costs-benefits investigations and life cycle evaluation report will fundamentally add to effective commercialization of imaginative cycles. Incorporation of modern waste-based fresher structure materials, accentuating their natural noteworthiness in the educational plan at advanced education level and pragmatic utilizations of squanders in development area will offer fillip to such innovation advancement. The logical progression in reusing and utilizing modern and rural cycles for using squanders will prompt a superior utilization of world's assets. The new and elective structure development materials created utilizing agro-modern squanders have plentiful degree for presenting new structure parts that will diminish to a degree the expenses of building materials. The Endeavor, thusly, should be to support business visionaries and development organizations to grow new items and cycles utilizing every one of these losses as crude materials for setting up auxiliary enterprises and adding to decrease of green house gases and a dangerous atmospheric devation.

It was seen that sythesis of the examined changed after some time. During the relieving time frame, different hydration items were shaped. These new items impact the breadths of the pores and their appropriation inside the composite, diminishing the extent of huge pores, while expanding the volume of miniature pores, in this way debilitating water availability to the fused poisons, and catching them in the composite network [3]. Underway of such composites reused totals can likewise be utilized, bringing about comparable low-quality materials, with a comparable mineralogical organization, which contrast basically because of the mineral arrangement of the additional reused total. All the composites concentrated inside the extent of this examination have the qualities of CLSM, and can be utilized as a development material primarily in the zone of every day or middle landfill covers, and the adjustment of street bases. Because of their properties they can likewise be utilized as low stream fills material, just as bedding material for lines and links, and for the refilling of utility channels. As to economical turn of events, the portrayed waste buildups the executives strategy speaks to an ideal e zero waste arrangement, bringing about the cleaner creation, while safeguarding characteristic assets, lessening CO2 emanations and bringing down the expenses of sewage muck the board. An investigation comprising of an ecological effect examination of the novel treatment of sewage muck and biomass debris with traditional treatment advances is on-going.

Landfill drain ate comprises of a wide range of disintegrated or suspended structure natural and inorganic mixes. These mixes, paying little mind to their inclination, have a potential contamination impact on neighborhood ground and surface waters. An extremely wide scope of treatment measures have been applied for the treatment of this exceptionally defiled waste stream.

The RO cycle is an elective filter ate treatment technique which is supported by districts in Europe and Turkey. RO measure doesn't give a last removal to landfill drain ate without a powerful RO concentrate treatment alternative. The utilization of RO just declines the measure of waste stream and expands the toxin focuses. The treatment of concentrate ought to be considered top to bottom. Concentrate distribution which is the generally utilized technique isn't an answer for this issue and furthermore prompts serious issues about filter ate treatment and landfill dependability. This examination demonstrated that all contaminations in drain ate concentrate can be cemented effectively. Also, eluate fixations agreed to the Turkish and EC guidelines [4]. Be that as it may, the utilization of zeolite as a total material didn't show huge contrasts. The critical factor for the evaluation of hardening/adjustment innovation is the utilization of set material as an eventual outcome. By the by, in the inscription of this examination the model for the utilization of hardened materials as significant item was not considered as an exploration subject. This subject was considered as a future exploration for the minimization of cementing/adjustment cost of concentrate removal.

2.0 Materials and methods:

The materials utilized in the solid blend configuration were dry slop, soil and fly Ash. Sifter investigation was done as follows: A reasonable amount of broiler dried dry slop was taken. . The mass of dry slime test needed for each test relies upon the most extreme size of material. The sifter to be utilized was gauged and the heaviness of each strainer and container were recorded. The strainers to have the biggest work size at the highest point of the stack. The dirt example was filled the top strainer and a cover was set. The sifter stack on the mechanical shaker was in a bad way down the cover and the dry ooze test was vibrated for 10 minutes.

The stack was weighed again and each sifter and the base container with the dirt example division were held on it. Delegate compaction test and explicit gravity trial of dry ooze investigation were done according to standard methods referenced in code books. Weight was estimated utilizing weight cluster strategy. The form was set on a firm base and compacted to guarantee ejection of water.

Dry slop explicit gravity test was done as follows: The Pycnometer was washed, dried and weighted. Around 10 g of dry muck test was put in the Pycnometer. The container was weighed with the dry slime. Adequate water was added to cover the dry slime and it was associated with a vacuum siphon to eliminate all entangled air. The siphon was separated and topped with water off to the alignment mark [5]. The outside surfaces of the jug and Pycnometer were cleaned with a dry fabric and weighted. The container was cleaned once more. It was topped with refined water off to the imprint and its weight was recorded.

3.0 Results and discussion:

The weights of the blocks made, produced using distinctive blend of sludge are introduced in Table.1. It is demonstrated that various metallurgical squanders blended in with common earth and sand can be utilized for the creation of clay development materials. Substance of 50 wt% exhaust

dust in the underlying blend for earthenware production furnishes flexural quality of the examples with increment of dilatation coefficient and water ingestion.

Table.1 Weights of blocks made of sludge

S.no	Conventional bricks (gms)	10% sludge bricks (gms)	20% sludge bricks (gms)	30% sludge bricks (gms)	40% sludge bricks (gms)	50% sludge Bricks (gms)
1	3800	3211	2903	2674	2553	2203

Organizations with 35% fumes give residues marginally of higher quality, and water assimilation. Consequently, an ideal creation of beginning combination can be picked relying upon neighborhood accessibility of spent foundry sands and different parts just as on the requests to pottery's mechanical properties.

Notwithstanding the high substance of substantial metals in the crude materials, draining and dissolvability trial of the new earthenware production show profitable qualities when contrasted with the Brazilian norms. The Weight of Bricks after Water Absorption is introduced in Table.2. The materials and innovations created might be profoundly beneficial considering the way that the utilization of normal modern squanders fundamentally lessens the expense of the final result in contrast with customary common materials.

Table.2 Weights of Bricks after absorbing Water

S.no	Conventional bricks (gms)	10% sludge bricks (gms)	20% sludge bricks (gms)	30% sludge bricks (gms)	40% Sludge bricks (gms)	50% sludge bricks (gms)
1	3950	3550	3280	3030	3000	2980

Wide use of this technology can result in an extended service life of the bricks and can also result in a reduction of waste generated. However, proper treatment and disposal are required to ensure environmental safety. Dry shrinkage involves expulsion of air from the voids. This results in shrinkage in the volume of the bulk of cement. This also enhances hydraulic pressure. Hydraulic pressure is reduced when the pore spaces get emptied. Pressure increases with increase in pore spaces. The Compressive Strength of Bricks observed is given in Table.3. During the curing period, various hydration products were formed. Different hydration bye-products have resulted out of the reactions.

Table 3: Compressive Strength of Bricks

No. of Brick	Conventional Bricks	10% Sludge Bricks	20% Sludge Bricks	30% Sludge Bricks	40% Sludge Bricks	50% Sludge Bricks

1	4	3.50	3.00	2.50	2.00	1.5

During the curing period, various hydration products were formed. Different hydration bye-products have resulted out of the reactions.

Fig. 1: Water Absorption of Bricks

Fig.1 shows the water absorption of bricks. Bricks were soaked in water for about 28 days and the water absorption was measured at regular intervals of time. It was observed that as sludge volume was increased there was an initial increase in compressive strength and later it gradually got decreased after a threshold.

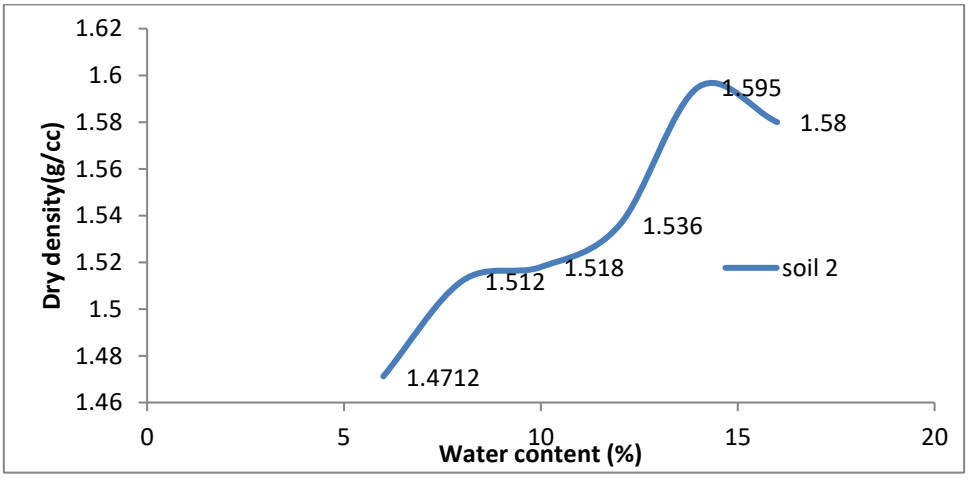

Fig.2 : Analysis of compaction Test of Soil

In Fig.2 the analysis of compaction of soil based on dry density is made. In order to use waste materials, they were used as a raw material for the manufacture of bricks. To agreeably use these hardships as an unpleasant material, filler, folio and added substance in making elective structure materials, wicked good physical-compound, arranging, warm, mineralogical and morphological properties of these squanders are to be studied and cautious information made open.

To develop the utilization of elective structure materials produced using various kinds of strong squanders and to develop the creation farthest reaches of lab scale measures, progression drawing in focuses are should have been set-up to help business visionaries for persuading commercialization. Toughness and execution of the more current things and scattering of degrees of progress underlining costs-benefits evaluations and life cycle appraisal report will all around add to profitable commercialization of innovative cycles.

4.0 Conclusions:

Dry sludge has no plastic limit. The cost of Dry sludge is very less. A 50% replacement of dry sludge by soil resulted in a tremendous increase in compressive strength. Water absorption is dependent on sludge characteristics. There is a significant reduction in weight of bricks on sludge replacement. Utilization of Dry Sludge in block can spare the ferrous and non-ferrous metal through ventures removal, land contamination, cost and produce a greener block for development. Ecological impacts from squanders and removal issues of waste can be diminished or controlled through this examination.

Abstract

The data required for the study was collected from YMCA road in Calicut city for frame based approach. Video-graphic technique was used for the data collection by the advantage over other data collection technique. For frame based approach video frames were taken approximately with a time lag of 3 s. From extracted data calculate the speed of vehicles, porous area, areal density, density and space headway of vehicles. From porous area data, pore space distribution function was determined by using easyfit5.5 software. The difficult was arises when extracting the traffic data from video frames. So for solving that problem on screen versus on ground distance graph was prepared. Best parameter to explaining the heterogeneous traffic system obtained as areal density rather than density measurement based on R-square value. The speed, areal-density model obtained was linearly decreasing relationship.

Effect of Plate Curvature on Blast Response of Structural Steel Plates

Lakshmi Shireen Banu Veeredhi, N. V. Ramana Rao & Vasudeva Rao Veeredhi

Journal of The Institution of Engineers (India): Series A **99**, 463–471 (2018) | Cite this article

220 Accesses | Metrics

Abstract

In the present work an attempt is made, through simulation studies, to determine the effect of plate curvature on the blast response of a door structure made of *ASTM A515* grade 50 steel plates. A door structure with dimensions of 5.142 m × 2.56 m × 10 mm having six different radii of curvatures is analyzed which is subjected to blast load. The radii of curvature investigated are infinity (flat plate), 16.63, 10.81, 8.26, 6.61 and 5.56 m. In the present study, a stand-off distance of 11 m is considered for all the cases. Results showed that the door structure with smallest radius of curvature experienced least plastic deformation and yielding when compared to a door with larger radius of curvature with same projected area. From the present Investigation, it is observed that, as the radius of curvature of the plate increases, the deformation mode gradually shifts from indentation mode to flexural mode. The plates with infinity and 16.63 m radius of curvature have undergone flexural mode of deformation and plates with 6.61 and 5.56 m radius of curvature undergo indentation mode of deformation. Whereas, mixed mode of deformation that consists of both flexural and indentation mode of deformations are seen in the plates with radius of curvature 10.81 and 8.26 m. As the radius of curvature of the plate decreases the ability of the plate to mitigate the effect the blast loads increased. It is observed that the plate with smaller radius of curvature deflects most of the blast energy and results in least indentation mode of deformation. The most significant observation made in the present investigation is that the strain energy absorbed by the steel plate gets reduced to 1/3 rd when the radius of curvature is approximately equal to the stand-off distance which could be the critical radius of curvature.

Abstract

Long-term consumption of water containing excessive fluoride can lead to fluorosis of the teeth and bones. Electrocoagulation is an electrochemical technique, in which a variety of unwanted dissolved particles and suspended matter can be effectively removed from an aqueous solution by electrolysis. Semi continuous flow experiments for fluoride removal were undertaken to investigate the effects of the different parameters such as: applied voltage (10–20 V), flow rate (150–450 mL/min), initial pH (6–8), and initial fluoride concentration (2–10 mg/L) at lowest cost with novel rector. The maximum of 8 mg/L fluoride treated up to World Health Organization drinking limits within 30 min residual time at a flow rate of 300 mL/min, with an applied voltage of 15 V at influent pH 7. The results obtained, showed that this novel semi continuous flow electrocoagulation reactor is an effective for defluoridation of ground water supplies at lower cost.

Abstract

This paper has been investigated the effect of steel and polypropylene fibres addition in concrete and evaluating the mechanical properties of concrete. In this research work has focused on concrete specimens for compression and flexural rigidity prepared with steel fibres and polypropylene fibres along with the different percentage of SCBA for various moist curing. The experimental test results were proved a better improvement in strength gain up to16.37% and 27.01% for 7 and 28 days respectively when the dual fibre combination of 1.5% of steel (by volume fraction) along with 0.2% of polypropylene fibres along with 20% of SCBA. Also, there was an increase in flexural strength up to 57.14% in concrete with steel and polypropylene fibre combinations than compared to conventional concrete.

Preface: Everything Flows, but Circularity is the Solution

There is nothing more essential to life on Earth than water. Yet, there is a global water crisis. People are struggling to access the quantity and quality of water they need for drinking, cooking, bathing, hand washing and growing their food. Rapid industrialization, population growth and unplanned urbanization have contributed to severe land and water pollution. The main sources of freshwater pollution can be attributed to direct discharge of untreated toxic industrial wastes and dumping of various industrial effluents. More than 40% of the world's population resulted affected by water scarcity, and this problem is also featured in the UN Sustainable Development Goal 6 (SDG 6), "clean water and sanitation". Currently, about 3 in 10 people lack safe drinking water and 6 in 10 lack inadequate sanitation systems. Globally, 844 million people lack access to clean water resulting in families and communities being locked in poverty for generations. Access to clean water as a stepping stone to development changes everything. Safe, secure, affordable and equitable access to clean water in particular for the poor is among the most relevant challenge to be faced in the next years. In 1993, the UN General Assembly designates March 22 as World Water Day and recognizes the importance of addressing the global water crisis each year with an amazing progress in making clean drinking water accessible to 2.6 billion people in developing countries from 1990 to 2015. There are still opportunities to multiply the benefits of clean water through improved sanitation and hygiene education.

The wastewater contains contaminants such as metal ions and organic compounds impacting the environment severely. This aspect will be further exacerbated in the next years by the increase in urbanization, in particular in developing areas, leading to the use of more of Earth's dwindling resources. In recent years, nanotechnology has introduced a myriad of novel nanomaterial that can have promising outcomes in environmental clean-up and remediation. Thus, it is highly needed now to recycle and reuse water resources in a sustainable manner. Effluent discharged in water bodies contributes to eutrophication, pathogen growth and emission of nitrous oxide and methane with GHG potential of about 300 and 21 times higher

vivekvardhan2@gmail.com

than CO_2, respectively. Untreated effluents have impacts three times higher than the treated ones representing a key factor of paramount importance for safe and environmentally sustainable urbanization. Among the multiple pollutants like fluorides, heavy metals, dyes, oils, etc., several new emerging components, such as endocrine-disrupting compounds, pharmaceuticals, personal care products and other bioactive organic compounds, are also present in the wastewaters.

The conventional wastewater treatment processes such as ion exchange, electrocoagulation, membrane filtration and adsorption are used. Adsorbents from renewable resources like tamarind seed, agricultural waste materials, Bermuda grass, rice husk and tea wastes are used nowadays. Carbonaceous materials are being used widely nowadays, which include hydrochar, biochar and activated carbon. These adsorbents are environmentally sustainable and available from waste products like MSW and domestic wastes. Various low-cost sorbents including waste/by-products from industries and agricultural operations, natural materials and microbial and non-microbial biomass have been identified and documented as effective dye-removing agents. Synthesizing cellulose nanofibres from agricultural lignocellulosic wastes is a novel approach for the production of a material from a cheap renewable resource. Recent development of membrane separation technologies, nanomaterial-based waste separation processes and advanced oxidation processes like combinations of ozone, UV light and H_2O_2 could be the alternative to these problems. Private and public sectors should invest in infrastructure to create the conditions for the transition to a circular use of resources bringing about social, economic and environmental benefits. Implementation of circular economy in this sector, including the safe reuse of water and the energy neutrality, can have also positive consequences on water quality and water security.

The 8th IconSWM 2018 received 380 abstracts and 320 full papers from 30 countries. A total of 300 accepted full papers have been presented in November 2018 at Acharya Nagarjuna University, Guntur, Andhra Pradesh, India. After thorough review by experts and required revisions, the board has finally selected 25 chapters in this book, "Recent Trends in Waste Water Treatment and Water Resource Management", dealing with the application of synthesized nanocellulose material, defluoridation of water, removal of hexavalent chromium, methylene blue dye, lead, chloride and different iodine species, sustainable sewage treatment process, utility of bacteria for detoxification of textile dyes, utilization of activated carbon, anaerobic co-digestion of sewage sludge and animal by-product and many modern techniques of wastewater treatment.

The IconSWM movement was initiated focusing better waste management, resource circulation and environmental protection since the year 2009. It helps in generating awareness and bringing all the stakeholders together from all over the world under the aegis of the International Society of Waste Management, Air and Water (ISWMAW). It established a few research projects across the world involving the CST at Indian Institute of Science, Jadavpur University, and a few other institutions in India and experts from more than 30 countries in the research project on circular economy. Consortium of Researchers in International Collaboration (CRIC) and many other organizations across the world help the

vivekvardhan2@gmail.com

IconSWM movement. IconSWM has become one of the biggest platforms in India for knowledge sharing and awareness generation among the Urban Local Bodies (ULBs), government departments, researchers, industries, NGOs, communities and other stakeholders in the area of waste management. The primary agenda of this conference is to reduce the waste generation encouraging the implementation of 5Rs (Reduce, Reuse, Recycle, Repair and Remanufacturing) concept. The conference provided holistic pathways to waste management and resource circulation conforming to urban mining and circular economy.

The success of the 8th IconSWM is the result of effective contribution of the government of Andhra Pradesh, several industry associations, chamber of commerce and industries, the AP Higher Education Council, and various organizations and individuals in India and abroad. Support of the UNEP, UNIDO and UNCRD and delegation from European Union and other foreign organizations was significant. 8th IconSWM 2018 was attended by nearly 823 delegates from 22 countries. The 9th IconSWM 2019 will be held at KIIT, Bhubaneswar, Odisha, during 27–30 November 2019, expecting nearly 900 participants from 30 countries.

This book will be helpful for the educational and research institutes, policy-makers, government implementers, ULBs and NGOs. We hope to see you all in 9th IconSWM 2019 in November 2019.

Acknowledgements

We thank the Hon'ble Chief Minister and Hon'ble Minister of MA&UD for taking personal interest in this conference.

We are indebted to Shri. R. Valavan Karikal, IAS; Dr. C. L. Venkata Rao; Shri. B. S. S. Prasad, IFS (Retd.); Prof. S. Vijaya Raju and Prof. A. Rajendra Prasad, VC, ANU, for their unconditional support and guidance for preparing the platform for successful 8th IconSWM at Guntur, Vijayawada, AP.

I must express my gratitude to Mr. Vinod Kumar Jindal, ICoAS; Shri. D. Muralidhar Reddy, IAS; Shri. K. Kanna Babu, IAS; Mr. Vivek Jadav, IAS; Mr. Anjum Parwez, IAS; Mr. Bala Kishore; Prof. S. Varadarajan; Mr. K. Vinayakam; Prof. Shinichi Sakai, Kyoto University, JSMCWM; Prof. Y. C. Seo and Prof. S. W. Rhee of KSWM; Shri. C. R. C. Mohanty of UNCRD; members of Industry Associations in Andhra Pradesh; Prof. P. Agamuthu, WM&R; Prof. M. Nelles, Rostock University; Dr. Rene Van Berkel, UNIDO; Ms. Kakuko Nagatani-Yoshida and Mr. Atul Bagai of UNEP and UN Delegation to India for their active support.

IconSWM-ISWMAW Committee acknowledges the contribution and interest of all the sponsors, industry partners, industries, co-organizers, organizing partners around the world, the government of Andhra Pradesh, Swachh Andhra Corporation as the principal collaborator, the vice chancellor and all the professors and academic community at Acharya Nagarjuna University (ANU), the chairman, vice chairman, secretary and other officers of AP State Council of Higher Education for involving all the universities in the state, the chairman, member secretary and the officers of the AP Pollution Control Board, the Director of Factories, the Director of Boilers, the Director of Mines and officers of different ports in Andhra Pradesh and the delegates and service providers for making a successful 8th IconSWM.

I must specially mention the support and guidance of each of the members of the International Scientific Committee, CRIC members, the core group members and the local organizing committee members of 8th IconSWM who are the pillars for the success of the programme. The editorial board members including the reviewers, authors and speakers and Mr Aninda Bose and Ms Kamiya Khatter of

vivekvardhan2@gmail.com

M/s. Springer India Pvt. Ltd deserve thanks who were very enthusiastic in giving me inputs to bring this book.

I must mention the active participation of all the team members in IconSWM Secretariat across the country with special mention of Prof. H. N. Chanakya and his team in IISc Bangalore; Ms. Sheetal Singh and Dr. Sandhya Jaykumar and their team in CMAK and BBMP; Mr. Saikesh Paruchuri; Mr. Anjaneyulu; Ms. Senophiah Mary; Mr. Rahul Baidya; Ms. Ipsita Saha; Mr. Suresh Mondal; Mr. Bisweswar Ghosh; Mr. Gobinda Debnath and the research team members in the Department of Mechanical Engineering and ISWMAW, Kolkata HQ, for various activities for the success of the 8th IconSWM 2018.

I express my special thanks to Sannidhya Kumar Ghosh, being the governing body member of ISWMAW supported the activities from USA. I am indebted to Mrs. Pranati Ghosh who gave me guidance and moral support in achieving the success of the event. Once again, the IconSWM and ISWMAW express gratitude to all the stakeholders, delegates and speakers who are the part of the success of 8th IconSWM 2018.

Anaerobic Co-digestion of Sewage Sludge and Animal by-Product

Ahmad Reza Salehiyoun, Maria Francesco Di, Mohammad Sharifi, Omid Noroozi, Hamid Zilouei and Mortaza Aghbashlo

Abstract The management of animal by-products (ABP) is a crucial issue since the relevant economic and environmental consequences that this practice involves. Anaerobic digestion (AD) is indicated as a suitable process for addressing such issue. AD facilities resulted already largely implemented in existing wastewater treatment plants for sludge stabilization but operated a quite low organic loading rate ($kgVS/m^3$). For this reason, thence digestion of ABP with SS in existing facilities can be considered a solution to a double problem: efficient treatment of ABP at reduced investment costs; increase in energy efficiency of existing digesters. In this study, the effect of different ABP to sewage sludge ratios on AD performances was investigated by batch runs. Best results were achieved for a ratio of 40% w/w leading to a biomethane yield of 730 L/kgVS with a VS reduction of 70%. No significant inhibition phenomena occurred during the runs.

1 Introduction

Due to the high nutritional value of meat, meat consumption has increased in the world and its production has exacerbated centralized activities, causing large animal by-product (ABP) in slaughterhouses (Moukazis et al. 2018). Approximately, between 20 and 50% of weight of a live animal is not edible for human (Pagés-Díaz et al. 2014).

In the only EU area, the amount of deadweight of animals generated by slaughterhouses is of about 39 M tonnes. Of these 6.3 M tonnes are represented by bovine and 17.5 M tonnes by swine. At the Italian level, the total amount of dead weight of animals processed in slaughterhouses is of about 3.77 M tonnes of which 1.1 M tonnes are bovine and 1.4 M tonnes swine. According to European Union legislation for slaughterhouse by-products management (EC 2009), animal waste is divided into three categories, namely Category 1, 2 and 3, based on the reduced risk of utilization. Majority of the slaughterhouse waste (SHW) belongs to Category 2 and 3 of ABP, which can be used in various ways under certain conditions, provided that not be hazardous to animal and human health.

Different methods for management of ABP have been proposed including incineration (for energy), aerobic digestion (composting), alkaline hydrolysis and anaerobic digestion (AD) (Moukazis et al. 2018). Anaerobic digestion is one of the best options for slaughterhouse waste treatment which produce energy-rich biogas, reducing greenhouse gases emissions and effectively control the pollution in abattoirs. Category 2 and 3 can be used as a feedstock to AD after completing a series of pretreatment including crushing, pressure sterilization (heating in 133 °C, 3 bar for 20 min) and pasteurization (size reduction below 6–12 mm and heating to 70 °C for 60 min) (Ortner et al. 2014).

AD of solid and pasty slaughterhouse waste fractions is much more difficult, and in contrast to wastewater, only a few industrial applications are established (Ortner et al. 2014). Anaerobic digestion of solid slaughterhouse waste is engaged several problems owning to its high nitrogen and sulfur concentration. The anaerobic treatment of these wastes as mono-substrates often leads to the accumulation of ammonia, volatile fatty acids (VFA) and long chain fatty acids (LCFA). These may inhibit methanogenesis and thereby lead to instability, lower biogas production and, at higher concentrations, lead to complete inhibition (Di Maria et al. 2016; Hejnfelt and Angelidaki 2009; Pitk et al. 2013). Dissolved free ammonia (NH_3) and sulfides are most responsible for process imbalances, causes, e.g., reduced methane yields and the inhibitory effects of intermediate substances (Chen et al. 2008). For successful operation of anaerobic digestion at high concentrations of ammonia, measures such as adjustment of C/N ratio by adding high-carbon substrates, acclimatization of microflora to higher ammonia concentrations, control and modification of pH, reduction in ammonia concentration by stripping or membrane technique, and two-stage anaerobic digestion have been proposed (Rajagopal et al. 2013). The most problems often occurred in non-appropriate C/N ratio. Many studies proposed in the literature investigated the possibility of increasing the performance of these existing

vivekvardhan2@gmail.com

digesters by co-digestion with other substrates. Co-digestion can supply macro- and micro-nutrient, vary in bacteria consortium, balance C/N, improve buffer capacity and process stability, dilute inhibitors and supply water resource for process and increment biogas production with respect to mono-digestion (Karthikeyan and Visvanathan 2013).

A relevant sector in which AD is currently fully implemented is the wastewater treatment plant (WWTP). In this sector in the only EU, there are about 36,000 WWTPs. Despite the development of many AD treatment plants in Italy, most of the designed anaerobic digesters have exceeded the required capacity, so organic loading rates in their digesters are low, which results in the digester to operate in an inefficient and non-economic way. For this reason, in the present work the possibility of co-digestion of ABP with sewage sludge for an existing Italian WWTP was investigated.

In this research, the effect of adding the total stream of slaughterhouse waste originated from a small-scale bovine-pig abattoir in Italy to the sewage sludge (SS) was investigated in different proportions in batch assays. The results of this research will contribute to assess the sustainability of the exploitation and management of ABP by an integrated approach strongly related to human bean basic needs as food and wastewater.

2 Materials and Methods

2.1 Slaughterhouse Waste and Inoculum

The slaughterhouse waste was prepared from a pig and bovine slaughterhouse in the city of Marsciano, Italy, which slaughtered 15,000 pigs, 2000 cows and a limited number of sheep per week. The bovine slaughterhouse waste was selected and collected in all sections of categories 2 and 3 according to the European standard (EC 2009). Each section was first grinded with industrial meat grinder up to 6 mm and then was homogenized in a large blender (Fimar, Italy) and was finally stored in a freezer at −20 °C until it was consumed. Prior to consumption, the pasteurization operation was performed at 70 °C for 1 h in an oven in a sealed container.

Municipal sewage sludge was prepared from a WWTP of 90,000 population equivalent in the town of Foligno (Italy). The sludge sample was sampled after a concentrator including primary and waste activated sludge. Sewage sludge was stored at 4 °C. The inoculum was sampled from the anaerobic digester of the WWTP and acclimatized at 37 °C for 2 weeks. When necessary the total solids (TS) concentration of the sludge was increased by settling operation.

vivekvardhan2@gmail.com

2.2 Experimental Setup

Experiments in batch mode were carried out in 0.5-L glass digesters at mesophilic conditions (37 °C ± 1 °C) by an incubator (Fig. 1a). Different SHW to SS ratios were used: $R1 = 0\%$; $R2 = 2\%$; $R3 = 40\%$; $R4 = 60\%$ (Borowski and Kubacki 2015; Pitk et al. 2013). Experiments were performed at 4% TS. The volume of the reactor fluid was filled with 400 g of the feed and inoculum. The ratio of inoculum to feedstock was set to 1:3 on VS basis. When necessary, TS concentration was adjusted by deionized water. Before starting, each reactor was flushed with nitrogen gas for 2 min. Control samples were also activated to determine the amount of biogas produced from inoculum. Reactors were shaken manually once a day, and all the runs were activated in triplicate.

Biomethane volume was determined directly by measuring the displaced water volume (Fig. 1a) and expressed at standard pressure and temperature (273 K and 1 atm) (Kafle and Kim 2013). The percentage of methane was measured via extraction of a 10 ml sample by syringe from the reactor head and injecting and passing through a 3 molar solution to remove carbon dioxide and hydrogen sulfide (Fig. 1b).

The weighted average was used to calculate the average methane percentage (El-Mashad and Zhang 2010). The experiments were stopped when the daily biogas production reached less than 1% of cumulative one (VDI standard 2006).

Analysis of variance (ANOVA) was carried out using the SPSS18 in order to find a significant difference between the treatments in a completely randomized design (one-factor ANOVA) for biomethane yield, methane content and VS destruction. The significant difference between results was considered when p-value was lower 0.05 at a probability level of 5% ($\alpha = 0.05$).

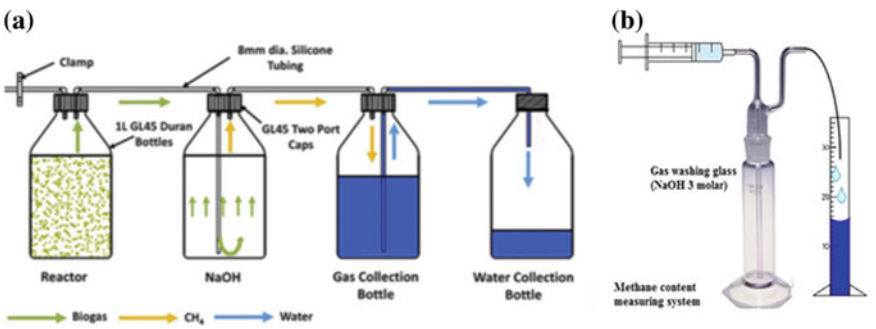

Fig. 1 Schematic of the batch laboratory-scale reactors (Ware and Power 2016) (**a**), and gas scrubber for determining of methane content (**b**)

vivekvardhan2@gmail.com

2.3 Chemical Analysis

The total solid content was determined by placing the wet samples in an oven at 105 °C for 24 h. The dried samples were then milled and combusted to determine the VS percentage at 550 °C in a muffle furnace until it reached a constant weight (APHA 2004). The pH of the feedstock and inoculum was measured by a PH meter METTLER TOLEDO. The total amount of organic carbon (TOC) was determined in the percentage of TS according to APHA's 5310 standard (APHA 2004). The amount of total Kjeldahl nitrogen (TKN) was assessed using an autokjeldahl device and subsequent titration with 0.1 normal sulfuric acid according to ISO 1871 standard (ISO 1871: 2009 (E); ČSN, 2010). To measure the total ammonium nitrogen (TAN) and total volatile fatty acids (TVFA), the HACH Lange DR 3900 Spectrophotometer was used. The digestate samples were first centrifuged at 6000 rpm for 10 min and then filtered through 45 μ paper. Total volatile fatty acids equivalent to mg/L of acetic acid and ammonium were measured by LCK 365 kuvet and LCK 303 kuvet, respectively. The amount of VS degradation as an indicator of anaerobic degradation efficiency in converting materials and reducing its contamination load was calculated by measuring the VS of each reactor after digestion and comparing it with VS before the process.

3 Results and Discussion

3.1 Feed Characteristics

The characteristics of the SHW and municipal SS are presented in Table 1. For the former, TS and VS were 25.6% and 95.6%, respectively, very similar to those reported in the study of Hejnfelt and Angelidaki (2009), with high degradable VS. C/N ratios resulted much higher than those reported in other studies, in the range of 6–10 (Borowski and Kubacki 2015), given that total carbohydrate wastes (ruminal

Table 1 Characteristics of slaughterhouse waste and inoculum

Particular	SS		SHW		INO	
TS	1.73	0.01	25.6	0.18	2.97	0.15
TS/VS	78.6	0.17	95.6	0.04	48.5	0.93

Alkalinity ratio	–		–		0.14	

vivekvardhan2@gmail.com

and intestinal contents) and digestive tract are considered as a mixture with the waste flow (Pitk et al. 2013). Therefore, there is a better balance in terms of preventing the ammonia inhibition.

3.2 Batch Experiments

Mean results of the batch runs are summarized in Table 2. The cumulative BMP (L/kg VS) per day, as well as the daily production of methane, is represented in Fig. 2.

Table 2 Biogas production results in a 4% TS batch experiment

Parameter	4% TS							
	0% (sewage sludge)		20% ABP		40% ABP		60% ABP	
Temperature	37		37		37		37

T90% (day)	16.2		12.8		13.1		12.6	

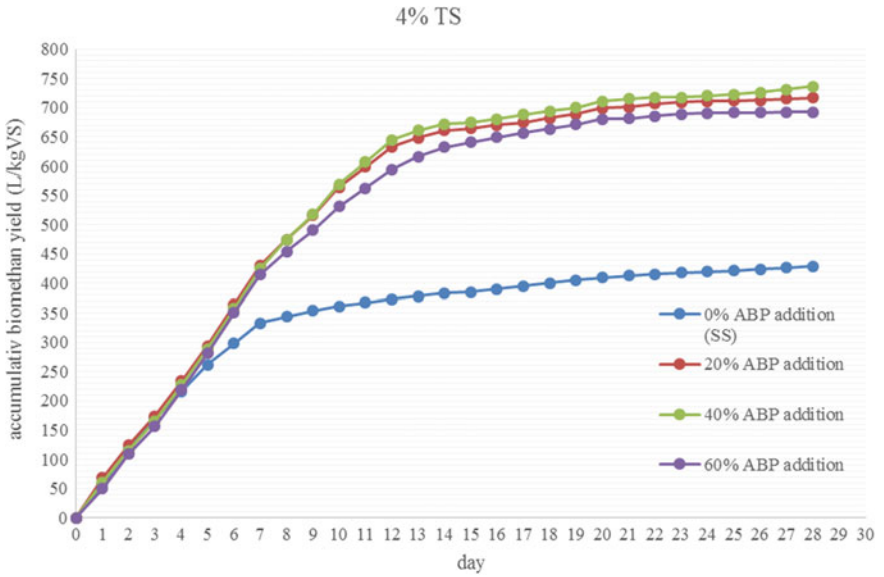

Fig. 2 Co-digestion of slaughterhouse waste and sewage sludge in BMP tests

vivekvardhan2@gmail.com

The results of ANOVA test showed mixer had a significant effect on biomethane production ($p > 0.05$). As seen in Fig. 2, the co-digestion has doubled the production of biomethane potential indicating the presence of synergic effects. There is no significant difference between R2, R3 and R4 treatments, but the highest methane yield was obtained for R3 treatment, 736.4 L/kgVS. Anaerobic digestion of single feed wastewater has been reported in the range of 200–350 L/kgVS (Luostarinen et al. 2009; Pitk et al. 2013; Wan et al. 2011), whereas in this study achieved 470 L/kgVS, which is significantly higher. Biomethane potential for co-digestion of SHW with other substrates reported in the literature was quite in line with those of the present study. Borowski and Kubacki (2015) reported 832.9 L/kgVS for the co-digestion of SHW from pig, whereas Moukazis et al. (2018) reported values of about 855 L/kgVS. Hejnfelt and Angelidaki (2009) reported a value of 620 L/kgVS. For sterilized and cooked slaughterhouse waste (at 133 °C and 3 bar for 20 min), the best results were obtained for 5% adding to SS by 618.9 L/kgVS in semi-continuous reactor, that was equivalent to a 60% TS share and approximately 65% VS in the feedstock mixture as reported by Pitk et al. (2013). By adding 14% of grease trap sludge from a meat processing plant with 25.4% TS to SS, Luostarinen et al. (2009) reported a biomethane yield of 788 L/kgVS in a batch digestion test. The synergistic effect of ABP co-digestion with SS was superior to other organic waste supplementation, such as agricultural waste. In the Pagés-Díaz et al. study (2014), the BMP, in a 2L batch test, was obtained 613 L/kgVS for bovine slaughterhouse waste with animal fertilizer, 647 L/kgVS with the organic fraction of municipal solid waste and 461 L/kgVS with agricultural wastes (various crops, i.e., straw and fruit/vegetable waste). The relatively high nitrogen content, the high total solid (TS) content, often excludes the possibility of treating animal by-products in their original undiluted form. Therefore, dilution is typically necessary or, as a more attractive option, co-digestion with less concentrated organic waste types, such as manure or municipal wastewater (Hejnfelt and Angelidaki 2009).

Analysis of variance for methane content indicated that methane percentage was significantly affected by feed mixture. According to Table 2, an increase in the proportion of ABP has led to a significant increase in methane composition. This is due to the increased share of fat waste because lipids produce higher methane percentages than carbohydrates and proteins (Wellinger et al. 2013). However, there is no significant difference between R2, R3 and R4 treatment.

The effect of ABP:SS proportion was significant on VS degradation. The VS removal for co-digestion treatments were about 36.7%, while for SS was about 32.6%. In the AD of alkaline pre-treated mixed slaughterhouse waste, a 47% VS reduction was obtained under mesophilic conditions (Flores-Juarez et al. 2014). Although VS degradation is usually higher for AD of easily biodegradable wastes, such as food and vegetable waste, addition of slaughterhouse waste to SS reduced the effective process time (T90%) (Table 2) to an average value of about 13 days instead of the about 16 days detected for the mono-digestion of SS. The effective digestion time or technical digestion time is an important parameter that provides primary information of hydraulic retention time (HRT) for continuous anaerobic digestion (Kafle and Kim 2013). This figure resulted higher than the HRT reported

vivekvardhan2@gmail.com

Table 3 Characteristics of digestate at the end of the batch tests

Component	4% TS			
	0%	20%	40%	60%
pH	7.27 (0.06)	7.32(0.07)	7.32 (0.10)	7.33 (0.07)
TVFA (mg/L)	141 (7)	167 (0)	167 (12)	156 (12)
TAN (mg/L)	444 (20)	564 (18)	473 (88)	587 (41)
COD (mg/L)	605 (174)	738 (230)	741 (218)	744 (219)

by Moukazis et al. (2018) that resulted in the range of 6–8 days. One of the reasons of this result can be found in the presence of fiber-containing and lignocellulosic parts such as ruminal content in the ABP composition, leading to an increase in the T90.

All the runs showed a final pH similar to the one of the mono-digestion of SS (Table 3). The final COD value for SS was only 605 mg/L. For the co-digestion runs, it ranged from 736 to 744 mg/L. The initial COD content of the sewage sludge was 2038 mg/L. Thus, an average COD removal of about 70% occurred for the runs with co-digestion of ABP and SS. Also these values resulted in line with those reported by other authors (Moukazis et al. 2018). The total amount of volatile fatty acids resulted quite low, <170 mg/L indicating the absence of specific inhibition risks. In their works, Flores-Juarez et al. (2014) and Moukazis et al. (2018) reported for AD after alkaline pretreatment of SHW a TVFA concentration of 555.5 mg/L and of 420 mg/L, respectively. No sing of ammonia inhibition was observed and TAN was in the stable spectrum, i.e., <1500–7000 mg/L (Hejnfelt and Angelidaki 2009).

4 Conclusion

Co-digestion of animal by-product and sewage sludge resulted to be an effective solution for matching two different aspects: environmentally sound management of ABP; increase the amount of energy recoverable. In particular, the large presence of wastewater treatment plant already equipped with anaerobic digester for the sludge stabilization represent an interesting opportunity also as a consequence of the reduced costs for investment, just limited to the necessary improvements for the introduction of the ABP in the existing digesters. Even at high ABP rates, the biological processes occurred with quite high efficiency and practically absence of inhibition phenomena.

Application of Synthesized Nanocellulose Material for Removal of Malachite Green from Wastewater

Lopamudra Das, Niladri Saha, Papita Das Saha, Avijit Bhowal and Chiranjib Bhattacharya

Abstract A method associated with nanocellulose material derived from sugarcane bagasse as bio-adsorbent in order to decolorize Malachite green dye was carried out through batch process. Objective of this study was to appraise the performance of SB nanocellulose, was synthesized using bleaching treatment of sugarcane bagasse as agro-waste followed by alkaline hydrolysis, acid hydrolysis (using 50% sulfuric acid at 50 °C for 3 h), and freeze drying. The synthesized cellulose was characterized by Fourier transform infrared (FTIR) spectroscopy. The absorbance of the supernatant solution was measured at 617 nm in UV visible spectrophotometer. Adsorption process was carried out by varying the pH value (2, 4, 6, 7, 8), initial dye concentration (1, 5, 10, 15, 20, 25, 50 mg/L) contact time (15, 30, 45, 60, 120, 180 min), temperature (25, 30, 35, 40 °C), and adsorbent doses (2, 4, 6, 8 g/L). In case of SB Nano cellulose, percentage of dye removal with initial 20 mg/L dye solution was 98.35% at normal condition. The adsorption efficiency of the SB cellulose is still over 80% after four times of recycling. Adsorbent has some beneficial features like, it is renewable, inexpensive, high surface area, unique chemical composition, and top of it all these adsorbents exhibit high removal capacity in dye solution.

Keywords Adsorption · Malachite green dye · Sugarcane bagasse (SB) · SB nanocellulose

1 Introduction

With the improvement of technology, most of the countries have boosted their economy through industrialization, and by virtue of increasing industrialization, waste disposal and pollution concern become more and more important. Most industries require large amounts of water for their work. Effluents of these industries are either disposed into bare oceans or rivers, which seriously hampers our ecosystem. Dyes are widely used in the textile, cosmetics, printing, leather, paper, and electroplating industries (Hu et al. 2013). Effluents of those industries contain large amount of untreated synthetic dyes which are often difficult to biodegrade due to its xenobiotic

vivekvardhan2@gmail.com

properties and complex organic structures (Ma et al. 2012). The discharged dye staff wastewater from those industries can cause great threat to marine life as well as human health due to its toxicity and carcinogenic nature (Attallah et al. 2013). For example, Malachite green (MG) is one of the common types of dye in waste disposal, widely used in the textile industry. Up to now, the main conventional methods for dye removal from wastewater have been used such as membrane filtration, ion exchange, adsorption, chemical coagulation, reverse osmosis, ozonation, and ultra-filtration. (Nada and Hassan 2003; Singh et al. 2011; Silva Filho et al. 2013).

However, the adsorption technique is considered as most efficient, easy operating, inexpensive, and eco-friendly technique for wastewater treatment (Mittal et al. 2010). Carbonaceous material and nanomaterial having high surface area, high adsorption capacity, microporous structure, low cost, and special surface reactivity for the organic compound shows great efficiency in adsorption process.

Cellulose is the most ubiquitous biodegradable renewable natural polymer (Salas et al. 2014). Cellulose nanomaterials (CNs) can be isolated from various natural resources like plant, animal, or mineral plants. Two general type of cellulose nanomaterials (CNs) are commonly known as cellulose nanocrystals (CNCs) and cellulose nanofibrils (CNFs). Carbon nanocrystal particles are highly crystalline in nature (at least one dimension should be equal or less than 100 nm) (Kumar et al. 2014). It can be used as a cheaper adsorbent for removing dyes from aqueous solution directly (Ren et al. 2013; Zhou et al. 2014). Nanocellulose having high surface area, high mechanical strength, chemical inertness, and hydrophilic surface makes it a very efficient material in membranes and filters, for adsorbing impurities from industrial effluents and drinking waters. Due to intrinsic hydrophilicity property nanocellulose has organic fouling and bio-fouling reducing capacity (Tashiro and Kobayashi 1991; Šturcová et al. 2005; Mansouri et al. 2010).

India is one of the agricultural countries in the world. A large number of agro-based industries, such as jute, cotton, and sugar produce large quantities of agro-waste which hamper in proper waste disposal management and environmental ecosystem. In recent years, researchers are giving attention for questing toward maximizing the efficiency of the use of raw materials and minimizing the accumulation of waste by reusing agricultural residues. Sugarcane bagasse is fibrous matter that left after crushing the sugarcane stalks to extract the juice commonly available from the sugar and industry. Sugarcane bagasse contains about 40–55% of cellulose, hemicellulose as much as 26–35% (Wulandari et al. 2016; Mandal and Chakrabarty 2011; Jacobsen and Wyman 2002). In the present research work, sugarcane bagasse has been used as raw material for the extraction of microscopic crystal cellulose and nanocellulose obtained by delignification with sodium chlorite followed by alkylation. Interestingly, an acid hydrolysis treatment of SB has been done to get the more pure cellulose fractions (Sun et al. 2004). To generate nano-cellulose acid hydrolysis of isolated SB cellulose with 50% sulphuric acid was carried out (Wulandari et al. 2016). Characterization of nanocellulose has been made by analyzing of Fourier transform infrared spectroscopy (FTIR) (Wulandari et al. 2016). Additionally, desorption and recycling experiment provided to investigate its good cycle performance. We also discuss on the MG dye adsorption process onto SB cellulose. Thus, this study

vivekvardhan2@gmail.com

assessed the suitability of cellulose, extracted from sugarcane bagasse in removal of dye from aqueous solution.

2 Materials and Methods

2.1 Raw Bagasse

Sugarcane bagasse (SB) was obtained from the local juice center, near Jadavpur University, Kolkata, West Bengal. It was washed followed by drying in the electric oven at 120 °C for overnight. After that, the SB were ground and sieved to at range 80–100 μm. The adsorbent was stored for further use in batch adsorption.

2.2 Isolation of SB Cellulose

For each gram of raw sugarcane bagasse (SB), 50 ml of 0.75% sodium chlorite (Merck Life Science private limited) solution was used to bleach SB and it was kept for 1 h at 45 °C with continuous stirring. The treated mass was filtered, washed with distilled water until it reached to pH 5 and put into 2% sodium hydrogen sulfite (Merck Life Science private limited) solution for 30 min. It was then filtered and washed with distilled water. The dried mass was then treated with 17% NaOH (Merck Life Science private limited.) solution for 15 min to remove hemicellulose. Finally, this chemically treated mass was filtered and washed with distilled water to remove the alkali until to neutral pH.

2.3 SB Nanocellulose Preparation

Hemicellulose and lignin-free cellulose were acid hydrolyzed for 3 h at 50 °C with constant stirring. For each gram of cellulose, 20 ml of 50% H_2SO_4 (w/w) solution (Merck Life Science private limited) was used for acid hydrolyzation. After that, excess acid was washed with distilled water until it was reached to neutral pH. Hydrolysis process was followed by centrifugation and freeze drying.

2.4 Dye Solution Preparation

In this study, Malachite green (MG) dye (Loba. Chemie.) Stock solution of 1000 ppm concentration was prepared and solutions of different concentrations ranging from 1

vivekvardhan2@gmail.com

to 50 mg/L were made by further dilutions. The absorbance of solution was measured using UV-V is spectrophotometer (Perkin Elemer—L365).

2.5 Characterization

Fourier transform infrared spectra (FTIR) of SB cellulose sample was analyzed on an instrument (PerkinElmer) in the range of 4000–450 cm^{-1} at a resolution of 4 cm^{-1}. Samples were grounded and blended with KBr. Mixture was then pressed into ultra-thin pellets. Various functional groups present on SB cellulose adsorbent have been shown by The FTIR spectrum with respect to their peak value.

2.6 Batch Adsorption Experiment

The batch adsorption study on MG dye was performed in a BOD shaker (GB Enterprises, India) at different experimental condition such as pH (2–8), initial dye concentration (5–25 mg/L), adsorbent mass (2–8 g/L), and temperature (25–40 °C). The pH of the dye solution was adjusted using 0.1 M NaOH (Merck Life Science private limited) and 0.1 M HCl (Merck Life Science private limited) solution. The isotherm study was done by varying the concentration of dye solution keeping temperature constant and agitated at 120 rpm. The kinetic study was investigated with different contact time. Thermodynamic study was done with varying temperature. The sample mixture solution was withdrawn from the shaker followed by centrifugation. After that, concentration of MG dye was determined by UV-VIS spectrophotometer (Perkin Elmer—L365). The dye removal efficiency of SB cellulose adsorbent and adsorbent capacity (mg/g) was derived according to the following equations:

$$\text{Removal efficiency} = \left(\frac{C_0 - C_t}{C_0}\right) \times 100$$

$$q_e = \frac{(C_0 - C_t) \times V}{m}$$

where C_0 is represented as the initial dye concentration and C_t (mg/L) is indicated as the dye concentration at time t, respectively. q_e is denoted as the amount of adsorbed dye (mg/g) per gram of adsorbent. V is referred to the volume (L) of the dye solution and m is denoted as adsorbent weight.

vivekvardhan2@gmail.com

3 Result and Discussion

3.1 Adsorbents Analysis—FTIR

By analyzing FTIR spectroscopic spectrum of raw SB and extracted SB cellulose, different characteristics of absorption peaks were analyzed. The peak centered at 1035.57 cm^{-1} for SB is attributed to C–O stretching. Absorption band at 1728.37 cm^{-1} is attributed to the C=O stretching associated with the acetyl and uronic ester groups present in pectin and hemicellulose (Sain and Panthapulakkal 2006; Sun et al. 2005). The peaks at 1603.51 and at 1514.39 cm^{-1} are assigned to the aromatic C=C present in lignin (Garside and Wyeth 2003; Wang et al. 2009). The peak at 1242.56 cm^{-1} as present only in spectra of SB is assigned to the C–O stretching vibration of the aryl group present in lignin (Troedec et al. 2008). The broadband around 3500–3200 cm^{-1} with the maxima centered at 3332.64 cm^{-1} is attributed to the free O–H stretching present in cellulose molecules. The spectra of both samples showed C–H stretching vibration around 2898.75 cm^{-1} (Khalil et al. 2001). From spectra of raw SB, it was observed that the absorption band at 3329 cm^{-1} is attributed to the O–H stretching and that of 2899.95 cm^{-1} is attributed to the C–H stretching vibration. The peak at 1316.29 cm^{-1} is assigned to the C–H bending and C–C stretching. The peak at 1157.17 cm^{-1} arises from C–O stretching. The peak at 1026.8 cm^{-1} is attributed to the C–O–C vibration due to the presence of pyranose ring skeletal. A band at 895.61 cm^{-1} is associated with the C–O–C stretching at *b*-glycosidic linkage between glucose present in cellulose. Remarkably, the absence of the band at 1514.39 cm^{-1} in the spectra inferred that the prepared cellulose are free of residual lignin.

3.2 Effect of pH

As shown in Fig. 1, pH plays an important role for MG removal on SB cellulose. Initially, the pH of the dye solutions was adjusted pH range from 2 to 8 by adding HCl and NaOH solution. With increasing pH value from 2 to 8, dye adsorption efficiency

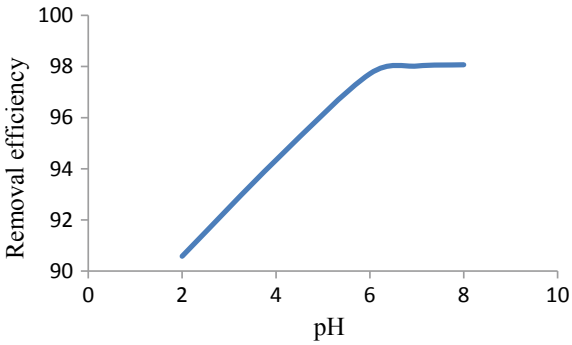

Fig. 1 Effect of pH on % removal

vivekvardhan2@gmail.com

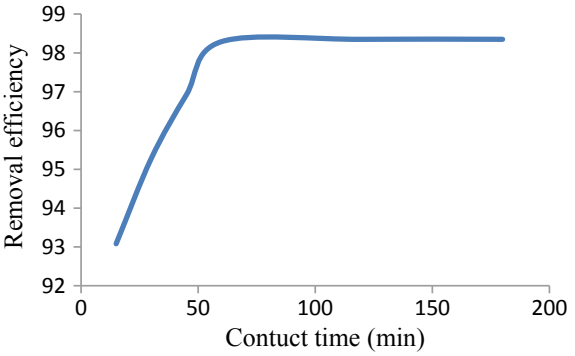

Fig. 2 Effect of contact time on % removal

increases from 90 to 98%. Cationic dyes are favorably adsorbed on negatively charged surfaces (Saliby et al. 2013). Protonation increases in strong acidic solutions. Due to the presence of excess H^+ ion in lower pH solution and having small ionic radius, it can be adsorbed more easily than cationic MG onto SB cellulose surface. With increasing pH, more negative charged adsorption sites will be vacant. For this reason, electrostatic attraction between SB cellulose surface and cationic dye becomes easier (Yagub et al. 2014; Song et al. 2015).

3.3 Effect of Contact Time

Variation in contact time plays significant role in determining the MG dye removal efficiency of SB cellulose. Batch equilibrium studies were conducted at 30 °C by adding 8 g/L of SB cellulose adsorbent to 20 mg/L MG dye of 50 ml solution at neutral pH. The flasks were agitated in BOD shaker at 120 rpm for 2 h. Samples were taken at different time intervals (15, 30, 45, 60, 120 min) and concentration was analyzed by UV-VIS spectrophotometer. The adsorption capacity increases till the contact time increases up to 1 h and then it attained saturation condition after 2 h. It was observed that agitation time increased from 15 to 60 min, and MG dye removal efficiency of SB Cellulose increased from 93.08 to 98.35% (Fig. 2).

3.4 Effect of Adsorbent Mass

The removal efficiency was increased as the adsorbent masses were increased from 2 to 8 g/L at 50 ml of MG dye solution on equilibrium time of 2 h. It was observed that removal of MG dye changes from 88 to 98.34% with increasing adsorbent mass. From Fig. 3, it is readily estimated that by increasing the amount of adsorbent, the number of active adsorption sites on adsorbent surface was increased; therefore, dye

vivekvardhan2@gmail.com

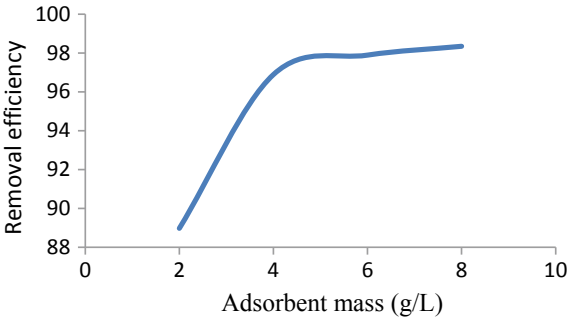

Fig. 3 Effect of adsorbent mass on % removal

removal efficiency was increased. So, in this project work, adsorbent dose of 8 g /L was kept constant for further investigation.

3.5 Effect of Initial Dye Concentration

Figure 4 shows the influence of initial dye concentration on the MG dye removal efficiency by SB cellulose. The effect of initial MG dye concentration (5–50 mg/L) on removal efficiency was conducted in a BOD shaker at 120 rpm while adsorbent dose was constant at 8 g/L. It was found that the dye adsorption efficiency gradually decreased with increasing dye concentration until the adsorption equilibrium condition was reached. The MG removal efficiency on SB cellulose decreased from 99 to 96%. The equilibrium condition was reached within 1 h. Figure 4 showed the plot between initial dye concentration and the percentage of MG dye removed.

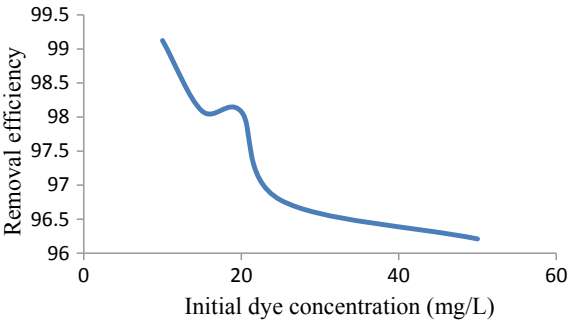

Fig. 4 Effect of initial dye concentration on % removal

vivekvardhan2@gmail.com

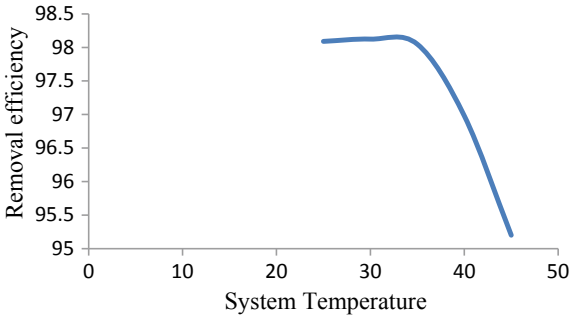

Fig. 5 Effect of system temperature on % removal

3.6 *Effect of Temperature*

In general, the dye removal efficiency increased with the increasing system temperature. In our project work, it was found that the removal efficiency decreased from 98.14 to 95% with the increasing temperature from 25 to 45 °C. Figure 5 showed that maximum MG dye adsorption on SB cellulose was 98.14% at 30 °C. It is well known that the motility of dye molecules may be enhanced by raising the system temperature and it may also reduced active sites on adsorbent surface. At high temperature, uncontrolled molecular movement facilitated desorption process (Ghorai et al. 2014) which reduced the adsorption efficiency.

3.7 *Adsorption Isotherm*

Commonly used equilibrium adsorption isotherm models, Langmuir and Freundlich (Ghorai et al. 2014; Metin et al. 2013), were used to determine the adsorption data of MG on the SB cellulose. Empirical expression of the Langmuir model is given by following equation.

$$C_S/q = 1/(k \times Q_0) + C_s/Q_0$$

where q (mg/g) is represented as the amount of adsorbed dye per unit mass of adsorbent and C_s (mg/L) is denoted as the unabsorbed dye concentration in solution at equilibrium condition. Q_0 is indicated as the maximum monolayer capacity at equilibrium condition and k presented as Langmuir constant (L/mg).

Mathematical expression of the Freundlich isotherm is given by following equation.

$$\log q = \log k_F + (1/n) \log C_s$$

vivekvardhan2@gmail.com

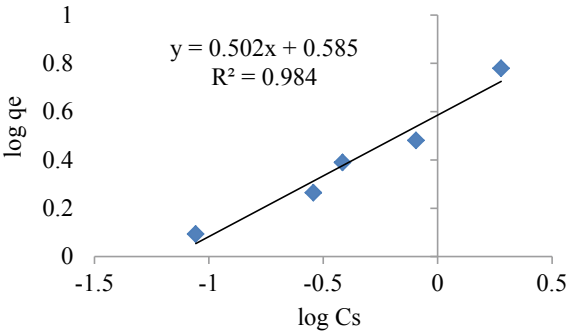

Fig. 6 Adsorption isotherm by using Freundlich model

Table 1 Calculated parameters of Langmuir Isotherm

Temp (°C)	k (L/g)	Q_0 (mg/g)	R^2
30	1.133173	8.161	0.9082

Table 2 Calculated parameters of Freundlich Isotherm

Temp (°C)	K_F (L/mg)	n	R^2
30	3.851	1.989	0.984

where k_F and n are Freundlich constants. The value of K_F (mg/g(L/mg)$^{1/n}$) is indicated the adsorption capacity of the adsorbent. Values of $n > 1$ is indicated the condition of adsorption favorability (Ncibi et al. 2007).

Figure 6 showed Freundlich isotherm model for MG adsorption by SB cellulose. Calculated parameters for Langmuir isotherms and Freundlich isotherm models are shown in Tables 1 and 2. The adsorption of MG dye on SB cellulose fitted the Freundlich model very well with the correlation coefficient $R^2 = 0.984$, better than the Langmuir Isotherm with $R^2 = 0.9082$. Malachite green dye adsorption system process using SB Cellulose well fitted by Freundlich isotherm due to heterogeneous distribution of surface active side on SB cellulose (Vimonses et al. 2009). A value of 1.989 obtained for n indicates the condition of favorable adsorption process (Hameed 2009).

3.8 Recyclability Study

In evaluation of economy in adsorbent application, recyclability and reuse are important factors. Experiment on the recyclability of the SB cellulose adsorbent was done at 30 °C. 8 g/L of SB cellulose adsorbents were added into 50 mL of 20 mg/L dye solutions for 60 min and then taken out from the solutions. After adsorption, the MG dye adsorbed SB cellulose was added into 0.1 M NaOH or 0.1 M HCl solution and was stirred for 60 min at 30 °C. Then, The SB cellulose was washed with deionized

vivekvardhan2@gmail.com

water two times to remove the residual NaOH or HCl solution. Then, it was dried by vacuum dryer at 80 °C and reused for adsorption. By this process, generated adsorbents were reused for another adsorption process in the subsequent cycles. The adsorption efficiency of the SB cellulose for MG removal was still over 80% after the fourth cycle.

4 Conclusion

Extraction of cellulose from sugarcane bagasse was performed successfully. Malachite green dye removal efficiency on cellulose obtained from sugarcane bagasse was also investigated by adsorption study. It was observed that the removal efficiency depends on the parameters, as in: adsorbate concentration, adsorbent mass, contact time, pH, temperature, and rotational speed. The maximum MG dye removal efficiency of SB cellulose was observed as 98% for 20 mg/L dye solution using 8 g/L of adsorbent within 60 min at 30 °C and neutral pH. Modeling of experimental data was evaluated through two isotherm models: Langmuir and Freundlich isotherm model. It was found that Freundlich isotherm model fitted well for this adsorption process on SB cellulose than Langmuir isotherm model because of heterogeneous surface active side distribution on adsorbent surface. FTIR spectra of SB cellulose indicated the presence of hydroxyl groups, lignin structure, and hemicelluloses structure on the surface of adsorbents. From the results, it can be concluded that extracted SB cellulose was a stable and efficient adsorbent for removal of MG dye from their aqueous solution.

Acknowledgement The authors would like to thank the Dalmia Holding Groups for the financial support and also thankful to the Department of Chemical Engineering, Jadavpur University for great facilities and support.

Status of Sewage Treatment in Bihar and Needs for Improvement

Prabhansu, Krishna Kant Dwivedi, Malay Kr Karmakar and Pradip Kr Chatterjee

Abstract With the ever increasing growth in population across the nation, there is a need for proper disposal of solid waste of households. A comprehensive literature survey was conducted to study the status of sewage treatment plants (STP) in different states of India. More emphasis was laid on its status in different districts of Bihar. Existing plants are incapable of handling huge inflow of wastes through sewage pipe lines. If properly developed, STP could not only remove the problem of waste management but it will also provide financial gains. Biogas produced in most of these plants from the digesters is flared off and are not being stored, if done will certainly reduce the cost of cooking fuel. Only primary and secondary treatment of the plants is being done in most of the sewage treatment plants. If tertiary treatment is also provided, this might help in solving the problem of safe drinking water. Conventionally, these left over sludge from the digester still contains a lot of carbonaceous content which can be harnessed by converting them in the form of powders and be utilized in different gasifiers and pyrolyser to produce clean combustible gas. Several districts do not even have a single sewage treatment plant and people are forced to use pit latrines. It was found that districts like Buxar, Muzaffarpur and Bhagalpur are having very old STP which date back to 1885 AD and are insufficient to handle the load of rapidly increasing population. Government initiatives are required not only to properly manage it but also to utilize it in a more effective manner.

1 Introduction

The main purpose of sewage treatment plants construction is to transform the household sewage into an easily manageable waste and the secondary purpose is to retrieve and to re-use the water after treatment of sewage. Untreated sewage contains water; nutrients that are mainly nitrogen and phosphorus; solids, pathogens that includes bacteria, viruses and protozoa; helminthes such as metals, different gases and Oil Street dust parking lots and buildings with toxic chemicals and chlorinated organic.[1] Untreated sewage that comes from rivers and oceans creates threat for human beings and environmental issues.[2] They cause acute illnesses including dysentery, diarrhoea, typhoid, cholera, and hepatitis A in human while direct sewage discharge in river and oceans leads to eutrophication and algal blooms reducing the oxygen content in water.[3] The sewage treatment plant should produce water that is safe for human consumption, to get water that can be used for the consumer with reasonable cost.

2 Current Status of STPs Across the Globe and in India

Latest technologies for water treatment are being used by some of the advanced nations of the world. The ozone technology is being used by United States, whereas AAO and oxidation ditch methods are commonly used in China.[4] In Germany, Federal Water Act (WHG) restricts wastewater discharge into river bodies which leads to that European country which has the highest waste water reprocessing and recycling rate. In Germany, more than 96% of the sewage waste water from households and public facilities are discharged into nearby STP for treatment.[5] Treated waste-water is widely used for irrigation, particularly in the Gulf countries. Currently, an average of 700,000 cubic meters per day is being used to meet irrigation and industrial demand in the countries such as Kuwait, Oman, UAE and Saudi Arabia.[6]

According to Pollution Control Board of India, 816 STPs are located in different States/UTs in the country, out of which only 522 STPs are operational. Table 1 describes the current status of STPs in different states, where inference can be drawn that Maharashtra and Gujarat have the maximum capacity of municipal STPs. It can also be correlated that the developed states are having more number of STPs, so STPs also act as growth parameter, which is quite obvious by the fact that wastes are more recycled and utilized in these states.

3 Current Status of STPs in Bihar

Bihar is one of the states that are facing worst condition as evident from the Table 1. In the entire state, only 06 STPs are installed. These STPs are very old and dates back to British rule in India. Prominent towns & cities have been considered for studying the status of STP, out of which Bhagalpur, Begusarai, Hajipur, Buxar and Patna are the prominent ones.

3.1 Sewage Project, Bhagalpur

Water supply system is very poor and identified as a major problem for Bhagalpur town. The current water treatment plant (WTP) in Barari, commissioned in 1885 has design capacity of 17.3 million liters per day (MLD) but it operates only at 12 MLD due to deterioration of the plants and machineries. Underground sewerage network is completely absent in Bhagalpur town. About 70% of the households are using septic tanks, but still around 20% are forced to use pit latrines. The remaining 10% have no other choice but to do open defecation. Wastewater management system in Bhagalpur was built under Ganga Action Plan for reducing the pollution level of the holy river. The total quantity of sewage water that reaches the sewage treatment plant is about 8.25 MLD. No reuse of the treated effluent is performed. Government is planning for the installation of sewage treatment of 47 MLD, funded through the World Bank.[7]

3.2 Sewage Project, Begusarai[8]

Sewerage system does not exist in this town. People are forced to perform open defecation. Households that are having sufficient area and in some of the newly developed colonies, septic tanks are used for waste water disposal and effluents arising from these septic tanks are discharged in open drains which further gets collected in local ponds. A sewage utilization plant with 17 MLD capacity of waste has proposed of 105 km length. Begusarai museum and the Gayatri shakti peeth are the sights for the two pumping stations. The proposed treatment process shall be Activated Sludge process which will be based on Sequential Batch Reactor technology. The STP site will be south east of the town near Wajidpur and the after treatment, effluent shall be allowed to get discharged in river Ganga.

[7] http://igemportal.org/Resim/Wastewater%20Treatment%20Technologies_%20A%20general%20rewiev.pdf.

[8] http://chinawaterrisk.org/resources/analysis-reviews/8-facts-on-china-wastewater/.

vivekvardhan2@gmail.com

3.3 Sewage Project, Buxar and Hajipur[9]

Bihar government launched different Sewerage projects such as Buxar, Hajipur and Begusarai near Ganga river for improvement this project and financial support. The main objective of this project is rejuvenation of Ganga water quality by preventing from municipal sewage into the river.

The authority board of Ganga river has decided that municipal sewage and industrial waste would be enters Ganga river after 2020 for the project clean Ganga mission. Total Rs. 15,000 crore investment is needed for coming 10 years for the necessary treatment and sewerage infrastructure.

3.4 Sewage Treatment Plant, Patna

Next is the capital of Bihar state, Patna which is the second largest city in eastern India, after Kolkata. Sewerage system was first introduced in Patna town during the year 1936-39 under which a STP of 4.5 MLD was constructed in the year 1937 at Saidpur. At present, the Municipal limits of PMC from Patna Urban Agglomeration Area. The PMC cover an area of 100 km^2 with the present population of 16.83 lakhs as per 2011 census. Patna city covering an area of 100 km^2 is subdivided into 6 Sewerage Zones: Digha, Beur, Saidpur, Kankarbagh, Pahari and Karmali Chak. Saidpur zone covers the central part of Patna City. In this area, the population is very dense therefore, the sewage generation is high. The old Saidpur Zone of Patna as per the existing sewerage scheme is now divided in two zones namely Zone-III & IV A (N). This zone have a STP within its boundary at Saidpur STP (45 MLD plant) site.[10] At present, Saidpur zone has an existing ASP based STP capacity of 45 MLD which is catering a load of 33 MLD with primary and secondary level of treatment which is proposed to be augmented for treatment of 60 MLD. For proper maintenance of the sewerage system, provision has been made for one jetting cum suction machine, submersible dredger pump, safety equipment, and sewer cleaning machine of power bucket type which will help to collect the sludge and will disposed on identifies PMC waste disposal site regularly by packed tractor trolley, mounted tanker and other environmental friendly collection and disposal sources. At present, the technology used is Conventional Activated Sludge Process (ASP). The merits of this method are that the land requirement is less compared to others. Also better control is possible with reduced flies and odour nuisance. At the same time it involves high capital cost, high power requirement and skilled labour. With the present population of 3.64 lakhs which generates sewage discharge of 43.69 MLD, open drains are acting sewers during the dry weather flow.

[10] http://biomasspower.gov.in/document/download-lef-tside/Biomass%20gasification.

vivekvardhan2@gmail.com

3.4.1 Problems Identified

As per the visit of the Saidpur Sewage Treatment Plant, some problems with the typical plant of Bihar are identified as under:

- The methane gas produced as a result of decomposition of the sludge is completely flared off into the atmosphere. This can be brought up into use by collecting it in a gas dome but there was no mechanism for that.
- Since the plant is under construction for the expansion of capacity, area which has to be used for sun drying is now being occupied by the government for infrastructure development. Now the digested sludge cannot be sun dried and is now left over in the tank itself which produces risks of blockage of channels.
- The water even after treatment could not meet the requisite standards. This is due to workers' inefficiency and lack of proper reviewing policy.
- Lack of flow of sewage in the absence of sufficient sewer length in the drainage system.
- Power shortage is one of the factors which is being faced by the existing STPs.
- Shortage of manpower both skilled and unskilled type has led to mismanagement.
- Government is not providing enough funds for the basic requirements i.e., repair of machines, etc.

3.4.2 Recommended STP Technology

This SBR based project effluent can be beneficial for utilization for non-domestic purposes such as house flushing, gardening and floor cleaning. The effluents from sewage can be dried and the separated from sewage. After drying, pretreatment process can be applied and that processed sewage sludge may be used as biomass for the gasification plants. Gasification of biomass is a well-known technology and for this different gasifier is available with different designs and capacities according to the requirements. A biomass gasifier is similar as other renewable sources like solar energy and wind energy means it can produce power when required.[11] Whereas large thermal power plants and solar and wind based units are very location specific, Sewage sludge gasifier based systems can be set up at almost any place. Sewage sludge is a CO_2 neutral fuel and, therefore, unlike fossil fuels such as diesel does not contribute to net CO_2 emissions, which makes biomass based power generation systems an attractive option in mitigating the adverse effects of climate change.[12]

[11] https://energypedia.info/wiki/Biomass_Gasification_(Small-scale).

[12] https://en.wikipedia.org/wiki/Gasification.

vivekvardhan2@gmail.com

4 Conclusions

Bihar state has very few STP and the existing ones are in very poor condition. It can be concluded that the Saidpur STP is working well but still needs some major modifications. The plan of expansion of capacity of the plant from 45 MLD to 60 MLD has affected the regular working to a large extent. There are definitely some implementation shortages which needs an eye by the officials. The overall operations at various stages are its fine screen channels, PSTs or secondary sedimentation tanks needs more labor concern as the final treated water was not up to the set standards. The biomass gasification technology of sewage sludge is theoretically an interesting option for rural development. Dangerous threats exist to the environment and health due to carcinogenic waste involved in the sewage waste. Therefore, at present the application of the gasifier technology for small-scale electricity production in developing countries seems to be justifiable. Each new plant would be a unique tailor-made facility.

Effluent Water Treatment: A Potential Way Out Towards Conservation of Fresh Water in India

S. Bej, A. Mondal and P. Banerjee

Abstract In modern age, rapid industrialization catalyses the steady magnification of the adverse effects. Released wastewater from various industries is of deepest concern which is highly responsible for aquatic pollution especially in India. An estimated amount of ~61,754 million litres per day (MLD) effluent water is produced in foremost metropolitans in India; however, the sewage management facility is only of ~22,963 MLD (approximately 37% of industrial effluents), and the remaining is disposed of untreated (according to the 2015 report of the Central Pollution Control Board 2015). The unscientific way of disposal causes severe diseases, responsible for environmental and ecological imbalance. This aquatic pollution is heading towards moderate to severe water shortages, brought on by the simultaneous effects of agricultural growth, industrialization and urbanization. In the forthcoming decades, the crisis of freshwater may lead to a major societal problem and political instability, if not the new option is found to supply the clean water. The development of cost-effective and eco-friendly wastewater management technologies and recycling could be the best way to solve the problem of potable water scarcity. Several conventional treatment technologies, i.e. adsorption, chemical coagulation, activated sludge management, membrane filtration, etc., have been implemented to eliminate the pollutants from effluent waters. In addition, it is straightforward, with good effectiveness and ability for degrading contaminants. This paper emphasizes the recent advancement and simultaneous use of wastewater treatment technologies in India to remove pollutants from wastewater like halogenated hydrocarbons, heavy metals, dyes and pigments, pesticides, herbicides, etc., which correspond to the main pollutants in wastewater. Movements like Swachh Bharat Mission (SBM), which has become the

largest movement towards cleanliness, highly emphasizes the treatment along with recycling of these effluent waters throughout India.

Keywords Effluent water · Water pollutants · Heavy metals · Toxicity · Natural adsorbents · International society of waste management · Air and water

1 Introduction

Rapid industrialization and urbanization have been adversely affecting the global environment in addition to that the quality as well as quantity of the potable water resources for the past few decades. Pollution by inappropriate industrial wastes management is one of the chief environmental problems in India. The basic technical knowledge required to cope up with pollution is already known to us, but unfortunately, less concern about the fact leads us towards self-destruction.

Access of clean water is immensely indispensible for growth and development, as water is a lifeline for all forms of life on this earth, and it is basically acquired from two principal usual sources, natural surface water like rivers, freshwater lakes, streams, etc., and groundwater such as borehole water and well water. So, contamination of these water bodies creates a real day crisis of freshwater. Generally, the industrial development occurring along the banks of rivers exerts pressure on the water resources causing the shortage and contamination of surrounding water bodies. Moreover, disposal of untreated wastewater directly into the water bodies causes the surface and groundwater pollution. Normally, wastewater consists of ~99.90% water and ~0.10% suspended or dissolved solids mainly bio-organic in nature (human waste, vegetable matter, paper, etc.), various toxic metals and pathogens which consume available oxygen from water bodies resulting in the increase of BOD and COD level. The contamination of water bodies by toxic metals is a severe problem for all living organisms. The metals get bio-accumulated in the nature and consecutively get biomagnified next to the food chain. Though metals like Cu, Fe and Zn are vital micronutrients, but excess accumulation leads to several lethal effects (Kar et al. 2008; Nair et al. 2010). The heavy metals such as iron, cadmium, lead, zinc, chromium, vanadium, nickel, copper, platinum, silver, titanium, etc., are commonly released from various industrial sectors like tannery, textile, leather, pigment and dyes, paint, petroleum refining industries, etc. Thus, treating the effluent water in the industrial premises before discharging it into the environment is of extreme importance. Table 1 shows the maximum contaminant level (MCL) standards for some heavy metals established by USEPA (Tripathi and Ranjan 2015).

The amplifying demand of freshwater for various domestic purposes is met by groundwater, which is presently at high jeopardy due to continuous withdrawal. Treated wastewater can be a substitute to the groundwater for some domestic uses. Therefore, mitigation of water pollutants from industrial effluent becomes compulsory before disposing it directly into the environment. A series of approaches have

vivekvardhan2@gmail.com

Table 1 The MCL values of the most hazardous heavy metals

Name of heavy metal	Toxicity	MCL (mg/L)
(i) Arsenic (As)	Skin manifestations, visceral cancers, vascular disease	5×10^{-2}
(ii) Cadmium (Cd)	Kidney damage, human carcinogen	1×10^{-2}
(iii) Chromium (Cr)	Headache, diarrhoea, nausea, vomiting, carcinogenic in nature	5×10^{-2}
(iv) Copper (Cu)	Liver damage, insomnia, Wilson Disease	25×10^{-2}
(v) Nickel (Ni)	Nausea, chronic asthma, coughing, carcinogen, Dermatitis	20×10^{-2}
(vii) Lead (Pb)	Damages the foetal brain, kidney diseases, circulatory system, nervous system	6×10^{-3}
(viii) Mercury (Hg)	Rheumatoid arthritis, kidney diseases, circulatory and nervous system	3×10^{-5}

been looked into such as coagulation, membrane technique, adsorption, foam flotation, reverse osmosis, catalytic degradation and other bio-techniques for the removal of contaminants from effluent water (Pontius 1990). Out of these processes, adsorption has come out to be one of the safest and cheapest alternative methods. Indian Government has already taken many steps to nurture the matter like 'Ganga rejuvenation' [a part of Swachh Bharat Mission (SBM)], according to the Environment Protection Act, 1986, as a planning, financing and monitoring for effective reduction of pollution and conservation of the river Ganga. This review article deeply concerns about the improper management of generated effluent water from industries in India and emphasizes the primary treatment systems available for treating wastewaters. To properly address the pollutants releasing from the industries, proper management of generated wastes and adoption of greener and cost-effective technology are being encouraged day by day.

1.1 A Historical Perspective

In the year 1900, scientist Louis Pasteur and other researchers showed that sewage-borne bacteria grow due to the contamination of human excrement and are responsible for severe infectious diseases (Henze and Harremoes 1983). Therefore, the contaminated water used to spread in large farms to be decayed by the action of micro-organisms. It was quickly investigated that the land converted to be 'sick' and unproductive. Later, attempts indulged direct disposal of effluents into the surface water which caused the aquatic pollution. But, it was soon realized that environment might not act as an unlimited dumping reservoir. Basic methods of effluent water treatment were first advanced in response to the adverse circumstances caused by the unscientific disposal of effluent water to the nature and public health. Furthermore, due to the urbanization, inadequate land was available for wastewater treatment

vivekvardhan2@gmail.com

and clearance. Moreover with population explosion, the quantity of effluent water produced per day increases rapidly and goes beyond the self-purification capacity (Spellman 1999; Rosen et al. 1998). Therefore, other treatment methods were developed and resulted an upliftment of the technologies from 1900 to the early 1970s that aims at-

(i) Removal of unwanted suspended materials from wastewater
(ii) Treatment of chemicals along with biodegradable organics (COD and BOD removal)
(iii) Inhibition of lethal pathogenic micro-organisms.

Major objective is to attain efficient and prevalent wastewater treatment technology to get better quality of water. Since 1990, effluent water treatment has been started by increasing scientific knowledge and various Government campaigns which are still continuing, but the emphasis has been shifted to the cause and removal of pollutants to improve the degree of treatment.

1.2 Distribution of Total Water on Earth's Surface

The circulation of total water on the Earth's surface is shown in Fig. 1, which states that only ~3% of water sources on the surface is fresh (among which, ~69% in glaciers, ~30% underground and ~1% in lakes, rivers and swamps); the remaining ~97% exists in the ocean. Hence, it is clear that only 1% of the water source on the surface of Earth is usable.

2 Category of Effluent Water

Effluent water is a side product of domestic, industrial, agricultural activities, surface runoff or any sewer infiltration (Tilley et al. 2016). The qualities of wastewater vary depending on the sources and the degree of contamination. It may be wastewater released from households, municipal wastewater (sewage) coming from societies or industrial wastewater from industrial sectors. Effluent water generally contains

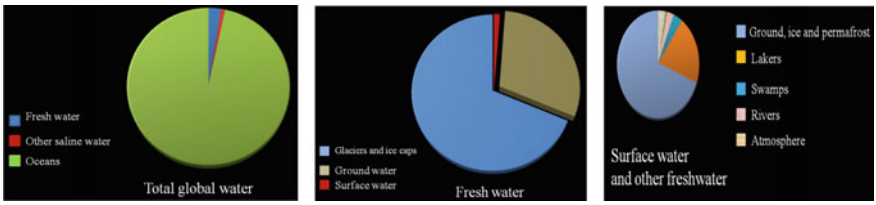

Fig. 1 Distribution of earth's water

vivekvardhan2@gmail.com

physical, chemical and biological pollutants. Basically, they are categorized into three broad classes: Black water, Grey water and yellow water (CPCB 2005).

2.1 Black Water

It is used to describe the effluents coming from the toilets, contaminated with various pathogens.

2.2 Grey Water

Grey water or Sullage is all kinds of effluent water generated from households or offices, except the wastewater from toilets. It contains lesser pathogens and therefore easier to treat and reuse for other purposes like sanitation, crop irrigation, etc. Reuse of grey water provides enormous benefits to reduce the demand of freshwater and minimizes the generation of wastewater.

2.3 Yellow Water

Water basically mixed with urine gathered from specific channels which are not polluted with either black water or grey water.

2.4 Sources of Effluent Water

Effluent waters originate from various sources like residences (household wastes), commercial sectors (schools, hospitals, offices, hotels, etc.) and industries. Apart from these, wastewaters are generated from non-pointed sources such as storm water, contaminated rainfall runoff from agricultural lands and entrance of the groundwater to the wastewater collection system. The resource of wastewater generally determines the qualities of the contaminated water, based on which the treatment procedures must be designed.

2.4.1 Domestic Sewage

This includes effluent water from homes and offices, typically contains contaminants such as vegetable, faecal matter, oil and grease, detergents, rags and sediment.

vivekvardhan2@gmail.com

2.4.2 Industrial Wastewater

Industrial effluent water is one of the prime sources of water pollution, includes toxic chemicals, organic and radioactive wastes, large amount of sediments, high-temperature waste or acidic/caustic waste. During the last century, a large amount of industrial wastewater was disposed directly into the environment without any treatment. The main concern is that the local farmers unconsciously use this raw sewage to irrigate their lands, and the agricultural products are marketed locally. Therefore, the pollutants may indirectly enter the food chain causing serious problems to the eco-system and human's life. In Durgapur industrial belt, severe incidents took place due to drastic consequences of wastewater pollution (Javed et al. 2013). Some of them are mentioned below:

(i) In 1973, thousands of fishes and frogs died, and ~240 hectares of cultivated lands were lost in the left bank irrigation canal at the Durgapur Barrage of the Damodar Valley Corporation (DVC).
(ii) In 1978, a huge number of cattle are died after drinking contaminated canal water.
(iii) In 1983, ~500 domestic animals died, and ~8000 quintals of processed crops were demolished. All the three catastrophes occurred due to the disposal of toxic chemicals into the Damodar canal water by the nearby small- and large-scale industries.

2.5 General Characteristics of Industrial Wastewater

A vivid idea of the chemical composition of wastewater is important since this helps to know the probable reactions with the organic and inorganic matters (Roila et al. 1994). Generally, the effluent water released from different industrial sectors can be separated into two broad categories: (i) inorganic industrial wastewater and (ii) organic industrial wastewater.

2.5.1 Inorganic Industrial Wastewater

This kind of wastewater is generated largely in the mining industries, nonmetallic minerals industries and metal surface processing industries (iron pickling, electro-plating plants, etc.).

2.5.2 Organic Industrial Wastewater

Organic industrial effluents are released from several organo-chemical industries, which mainly use organic materials for reactions and contain organic contaminants

vivekvardhan2@gmail.com

such as phenol, organic sulphur, volatile organic matters, surfactants, etc. Table 2 describes the general parameters of effluent waters coming from different industrial sectors (Kaur et al. 2012).

The large amount of produced effluent water destroys the eco-system, mainly marine lives. Hence, it becomes a burning issue to purify the wastewater properly. Therefore, we should be keen to control the production of the wastewater, consumption of clean water in different sectors and cost of the treatment of wastewater (Fig. 2).

Table 2 Categories of industrial effluent water

Industrial sector	General contaminants
(i) Steel and Iron	High BOD and COD, oil and grease, high pH, acids, phenols, cyanide, heavy metals like Mn, As, Hg, Cd, Ti, V, Sb, Th, Pb
(ii) Leather and textiles	High BOD, solids, sulphates
(iii) Paper and pulp	High BOD and COD, solids, chlorinated organic compounds
(iv) Refineries and petrochemicals	Mineral oils, BOD, COD, phenols, chromium
(v) Chemicals	Cyanide, carbon-based chemicals, heavy metal ions, SS, COD
(vi) Non-ferrous metals	Fluorine, suspended solids
(vii) Microelectronics	Organic chemicals, COD
(viii) Mining	Suspended solids, metals, acids, salts

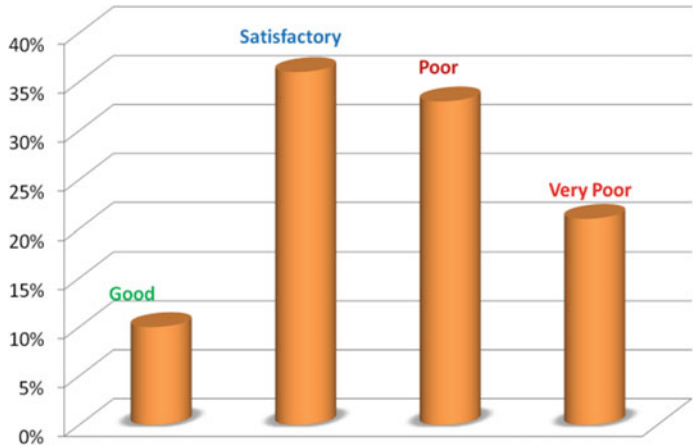

Fig. 2 Wastewater treatment plants in India under different grades

2.6 *Present Status of Effluent Water Conundrum and Treatment in India*

In India, climate alteration in the monsoon has huge implications on agriculture that makes India more vulnerable because >60% of countrymen are relying on cultivation for survival, and ~two-thirds of the nurtured terrestrial is fed by rain. Simultaneously, the government has launched ambitious programs like 'Smart City Mission', 'Swachh Bharat Mission', and the 'Make in India' campaign which needs to be reviewed from water and environmental aspects. Moreover in urban areas, freshwater resources are at high risk because of the increasing demand of freshwater. Apart from this, contaminants from various industrial sectors pollute the local water bodies making the freshwater endangered. Hence, a proficient solution is essential for viable water treatment. Therefore, reuse of purified effluent water would be of immense significance in achieving freshwater security and water conservation.

In India, a regular rainfall of ~1170 mm occurs corresponding to a yearly precipitation of ~4000 BCM (Billion Cubic Metre). However, based on the constraints like substantial variation in rainfall, evaporation throughout the year, etc., ~1123 BCM (690 from surface plus 433 (28%) from groundwater resources), gained from precipitation, is utilizable. Moreover, ~ 688 BCM of water is used for watering, which may upsurge to 1072 BCM in 2050. The average amount of ground water renewal is 433 BCM in a year, out of which ~212.5 BCM is utilized for watering, and ~18.1 BCM is spent in domestic and industrial usage (CGWB 2011). However, by 2025, the demand of water used in industrial and domestic purposes may rise to ~29.2 BCM (Fig. 3).

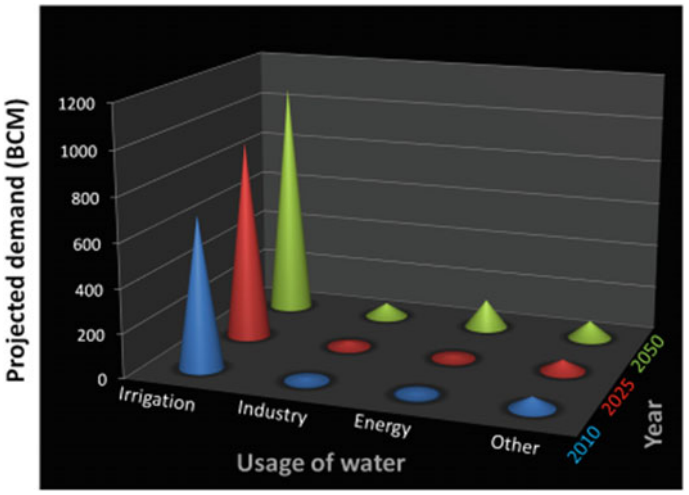

Fig. 3 Projected water demand at different sectors (CWC 2010)

vivekvardhan2@gmail.com

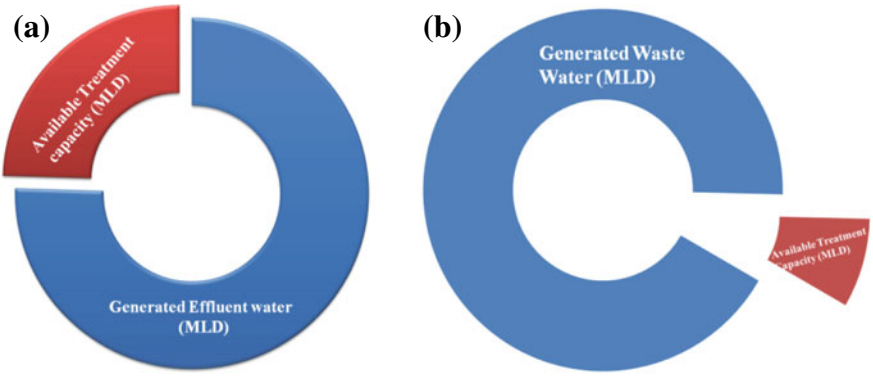

Fig. 4 Treatment capacity and sewage generation in class-I cities (**a**) and class-II townships (**b**) in India (CPCB 2009)

With rapid development of urbanization and domestic water usage, production of grey water is growing day by day. According to CPHEEO (The Central Public Health and Environmental Engineering Organization), ~70 to 80% of the water supplied for domestic usage transfers into wastewater. Survey reveals that wastewater production in class-I cities as well as class-II towns is ~98 lpcd (litres per capita per day). According CPCB (Central Pollution Control Board), the total generated wastewaters by 498 Class-I cities and 410 Class-II towns in India are ~35,558 and ~2696 MLD (millions of litres per day), respectively, while the installed sewage treatment capacity is just 11,553 and 233 MLD, respectively (Fig. 2). Five States in India, viz Delhi, Uttar Pradesh, Maharashtra, Gujarat and West Bengal are the foremost contributors of effluent waters (63%; CPCB 1999, 2007; CWC 2010). Further, according to WWAP and UNESCO (2006), it is anticipated that in 2050, ~48.2 BCM of wastewaters would be produced, which will further widen this gap (Bhardwaj 2005). Thus, entire study reveals that in near future, a double-edged problem will arise to deal with: reduced sources of pure water and increased effluent water production. Hence, there is an acute requirement for effectual water management (Fig. 4).

2.7 Wastewater Treatment Technologies

A host of new technologies for proper management of wastewater is being developed worldwide. However, new methodologies include natural procedures and are intended with feasibility. The techniques described below provide some basic idea on the miscellany, tractability and future utility.

vivekvardhan2@gmail.com

2.7.1 Physicochemical Treatment Technologies

Physicochemical technique (Gupta et al. 2012) may be described as a treatment process in which biological and physical-chemical processes are mixed to get a hybridized treatment technique (Fig. 5).

The primary treatment includes decontamination and elimination of unwanted toxic elements depending upon some physical methods like screening, sedimentation, coagulation, flotation, etc. Secondary treatment deals with the biological process as aerobic, anaerobic, etc.

In the tertiary treatment, wastewater is converted into freshwater by using methods like distillation/evaporation/solvent extraction/advanced oxidation/precipitation/micro- and ultrafiltration, etc.

Adsorption is the most efficient and a universal technique used in the elimination of a wide variety of contaminants like colour, odour and various organic and inorganic impurities. The main advantage of this process lies in its low cost, straightforwardness and less sludge generation. Apart from this, reverse osmosis processes a widely used wastewater purification technique, but contains comparatively high cost for maintenance.

2.7.2 Bio-chemical Treatment Technology

Bio-chemical technology (Seow et al. 2016) including biofilm technology, aerobic granulation and bacterial fuel cell are a few useful methods for wastewater purification. Biofilm, a cluster of micro-organisms, is devoted to an exterior part. Dental plaque, for example, is one of the biofilms, comprises ~500 microbial species (MSU Center for Biofilm Engineering, 2008). The various species in biofilms, like, fungus, algae, yeasts, protozoa, etc., form groups by creating an 'extracellular polymeric substance (EPS)'. The cells develop three dimensional, hardy communities by making sugary molecular strands which excrete glue-like material to permit them to stick to an exterior of nearly any kind.

The biological wastewater treatment is often carried out by conventional treated sludge systems, which require bulky surface areas for management and biomass segregation units because of the deprived settling nature of the sludge.

Aerobic granules, having compactness, regularity, smoothness and good settling ability, can self-immobilize flocks and micro-organisms into spherical and strong compact structures.

Microbial fuel cell (MFC), a bio-chemical device, uses bacteria as a biocatalyst to transform chemical energy present in biological matter into electricity. MFC shows high energy conversion efficiency due to direct conversion of chemical energy within substrate to electricity.

vivekvardhan2@gmail.com

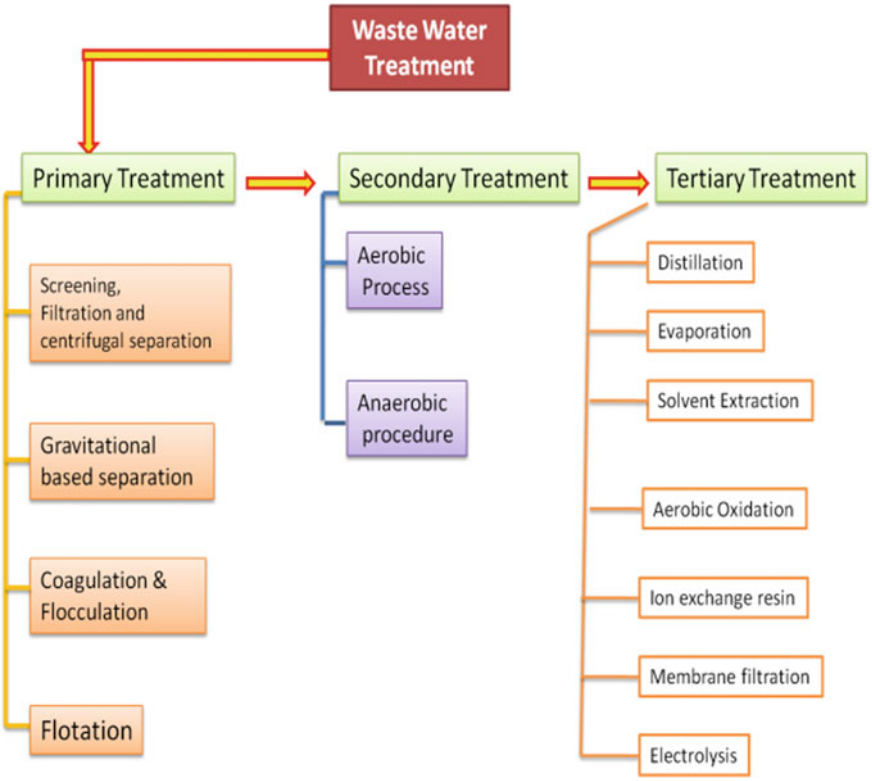

Fig. 5 Steps involved in chemical treatment methodologies are briefly demonstrated using a flow diagram

2.7.3 Bio Mediated Treatment Technology

Aquatic plant-based treatment systems (Dixit et al. 2011) using ponds or artificial wetlands are effective for purifying domestic and industrial drainage water. Biosorption is a proficient substitute of conventional techniques for elimination of noxious metals from effluents released from industries. Slower the flow and longer the retention time, greater will be the removal. Aquatic plants show remarkable absorption of metals (like N, P, S, Ca, Mg, Na, Fe, Mn, Zn, Cu, etc.) and nutrients. Removal of aquatic vegetation on timely basis is an important step; otherwise, died plants will decay releasing their absorbed nutrients to the water, thereby further degrading the water quality.

vivekvardhan2@gmail.com

2.7.4 Membrane-Based Treatment Technology

Membrane-based separation technique is presently used as a replacement of conventional wastewater treatment processes and is the main market driver (Hamingerova et al. 2015). These technologies provide membrane separation based on selective separation through apertures of various sizes and contain four core membranes: microfiltration, ultrafiltration, nano-filtration (CNT-silicon nitride membranes, Ag particles impregnated membrane) and reverse osmosis (CPCB 2007; Noy et al. 2007). Micro and ultrafiltration are used for unwanted particle removal, whereas nano-filtration and reverse osmosis are used for softening or desalination. Handling of organic and inorganic contaminants typically requires modified sludge treatment by using a dipped membrane.

2.8 Proposed Wastewater Treatment Prototype

Because of the growing demand of potable water supply in the domestic sectors, there is an urgent requisite to prepare an inexpensive, gravitational-based domestic wastewater purification system (Fig. 6) that would convert contaminated water to

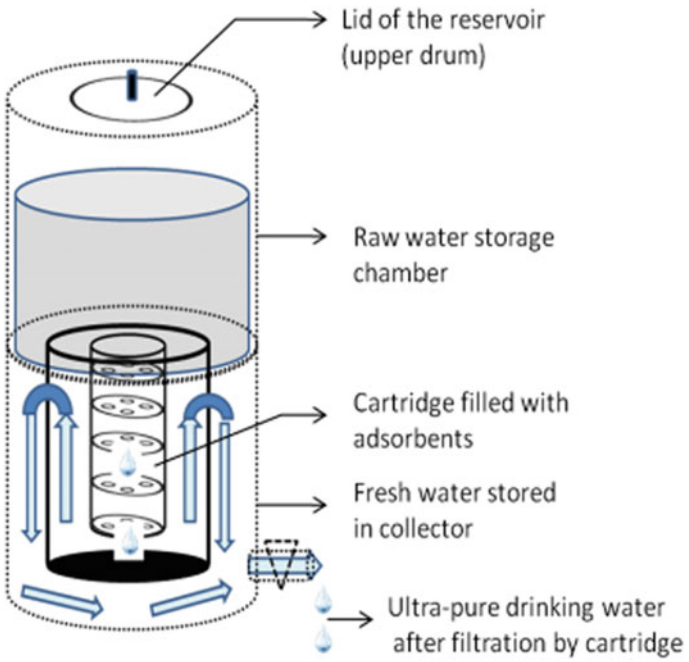

Fig. 6 Domestic wastewater treatment unit

vivekvardhan2@gmail.com

potable water. The emphasis in this regard is to use naturally abundant adsorbent materials (e.g. sand, gravels, brick dust, etc.) for treatment purposes. The treated water will serve the required domestic purposes like gardening, washing, etc.

2.9 Conclusion

Clean potable water is indispensable for human activities. The demand of healthy drinking water is enhancing proportionally with increasing population. Hence, there is a pressing requirement for an effectual water management and wastewater recycling technology. In this milieu, nanotechnology is fast replacing traditional concepts, which depend on the improvement of newer multi-functional materials with unique properties and specific attraction towards certain contaminants. But, these approaches are convoluted, tedious and costly. Therefore, exploration is going on to develop inexpensive, but effective water treatment techniques. In a developing and heavily populated nation like India, large amount of effluent water is being produced from different sectors. This review article draws attention about concerning issues and technological options connected to the wastewater collection followed by treatment systems.

Development of an Effective and Efficient Integrated Charcoal Filter Constructed Wetland System for Wastewater Treatment

V. V. D. N. G. Vidanage, A. K. Karunarathna, A. M. Y. W. Alahakoon and S. M. N. Jayawardene

Abstract Effective and efficient treatment of greywater from households and public places is an important and urgent issue to be solved in many developing countries. The higher capital investment of high-tech systems hinder the implementation, thus development of efficient yet affordable and compact wastewater treatment units for greywater treatment can solve the problem to a greater extend. This research developed a compact wastewater treatment system using commonly available construction and biomaterials. The proposed compact wastewater treatment system is consisted of three main components: up-flow anaerobic sludge blanket, charcoal granular media, and a subsurface flow constructed wetland system and is named Integrated Charcoal Filter Constructed Wetland (ICFiWet) system. In the vertical cylindrical reactor, the influent wastewater flows upward through an anaerobic chamber passes through the granular media to the subsurface flow wetland. The ICFiWet system was first tested at household scale (100 L capacity) fed with synthetic greywater. Water quality parameters such as pH, EC, TS, TSS, biological oxygen demand (BOD_5), nitrate N, and phosphate removals were estimated to evaluate the reaction kinetics and performances. The BOD removal was >66% and the system reduced the nitrate (1.77 ± 0.28) concentration by 15.3%. It was also revealed that the system decomposes the complex phosphorous substances to soluble P, leaving about 3 times increase of soluble P in effluent waters. The ICFiWet system was then up-scaled to 15.0 m^3 capacity to treat 5.0 m^3/day of flow. The ICFiWet system was installed in a larger public washroom to treat partially digested effluents. The results showed that the treated effluent achieved the water quality standard that comply with irrigation water quality. Thus, it was concluded that the ICFiWet system could effectively use for greywater treatment in household and public places while recovering the important nutrient phosphorus.

1 Introduction

Treatment of greywater from households and public places in developing countries is an urgent issue to be solved. Techniques of greywater treatment should fulfil five main criteria: hygienic safety, esthetic appearance, environment tolerance, technical and economic feasibility, and low cost, and the ability to easily maintain by unskilled workers (Nolde 2000; Gross et al. 2007). Implementation of greywater treatment systems has subsided due to economic and technical challenges (Ammari et al. 2014). Most of the available high-tech wastewater treatment systems are not affordable by the small wastewater generators, particularly households in developing countries because of high installation and maintenance costs (El-Khateeb and El-Gohary 2003). Therefore, greywater is generally disposed to the environment without any treatment as there is no any provision for its treatment (Katukiza et al. 2014).

Releasing wastewater to the environment without any treatment can cause various problems with regard to the environment and human health. Therefore, wastewater should be treated prior to discharge into environment. Generally, natural treatment systems are used for treating greywater as it is economically feasible and environmental friendly (Li et al. 2009; Boyjoo et al. 2013). The use of conventional low-tech wastewater treatment systems such as treatment wetlands and pond systems has gained limited attention due to space limitations in urban and semi-urban communities (Parkinson and Taylor 2003).

Wetlands and pond systems have gained limited attention due to space limitations in urban and semi-urban communities (Parkinson and Tayler 2003). Consequently, there is a demand for development of appropriate and innovative technologies for wastewater treatment and reuse for small communities (Bdour et al. 2009).

Constructed wetlands and granular filtration can be identified as extended natural greywater treatment systems which use natural media for biological degradation and filtration (Albalawneh et al. 2017). Among many small scale and low-cost alternatives (Kamal et al. 2008), constructed wetland system is one that highly preferred by small communities with limited funds. Those can be identified as the systems which have the ability to remove pollutants using interactions of plants and microorganisms (Li et al. 2004). Once the constructed wetlands are designed and established, maintenance costs are less. Also, they add an esthetic value to the environment (Lorion 2001). However, larger land footprint requirement and inability of conventional constructed wetlands to handle diverse range of wastewaters hinder the effective use of this affordable system.

Granular filtration achieves wastewater treatment through three main mechanisms: physical, chemical, and biological. Physical filtration, chemical transformation, and biological treatment due to microbial growth are occurred in granular filtration (Ciuk 2015). This technology is suitable for small communities in developing countries due to the low cost of construction, operation, and maintenance (Manz and Eng 2004). Cost effective and sustainable greywater treatment systems can be achieved by selecting locally available filter materials and using them in simple treatment

vivekvardhan2@gmail.com

methods (Nansubuga et al. 2015). Charcoal can be used as an effective filter material for greywater treatment (Dalahmeh et al. 2012).

Therefore, an attempt was made to integrate an up-flow anaerobic sludge blanket; a charcoal granular media and a constructed wetland system in one physical entity and developed a new concept: Integrated Charcoal Filter Constructed Wetland (ICFiWet) system. This study presents the design concepts, pilot-scale testing of the ICFiWet for synthetic greywater treatment, and preliminary results of the up-scaled design installed in a public place for secondary treatment of sewage wastewater.

2 Methodology

2.1 Pilot-Scale Design

The ICFiWet system consisted of three main components: an up-flow anaerobic sludge blanket, charcoal granular media, and a subsurface flow constructed wetland system. As shown in Fig. 1, three components were assembled vertically creating an updraft movement of wastewater through successive components.

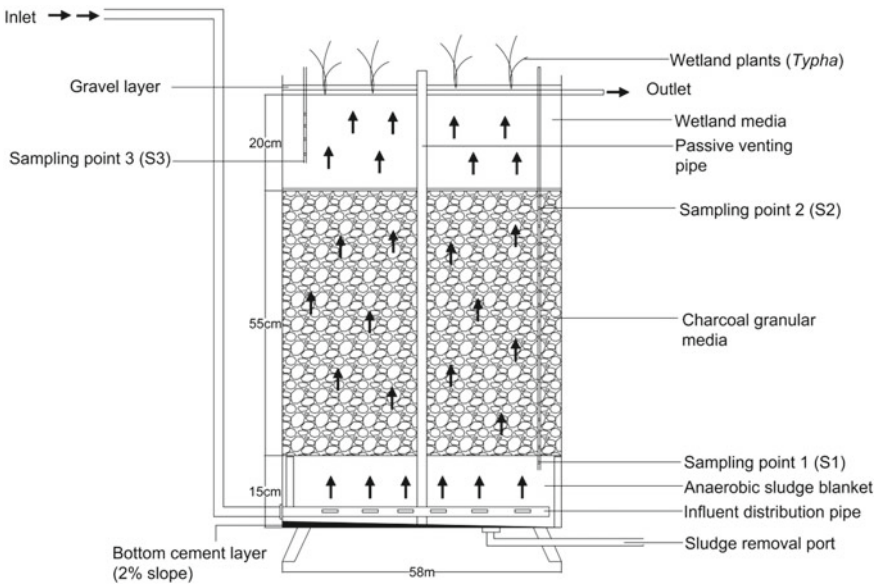

Fig. 1 Experimental setup of the pilot-scale reactor

vivekvardhan2@gmail.com

2.1.1 Fabrication of the System

The pilot-scale reactor was established using an empty HDPE plastic barrel container having dimensions of 58 cm internal diameter and 92 cm height. A sludge removal port was fixed on the outside wall of the bottom, and 5-cm diameter perforated PVC pipes were fixed on the bottom to evenly distribute the influent. A perforated 4 mm thick plastic baffle was fixed 15 cm above the bottom, leaving the first chamber to be acting as an anaerobic reactor. A layer of softwood charcoal granules with particle sizes in between 0.5 and 3 cm was filled above the baffled up to 70 cm from bottom which acted as the charcoal granular bed. The constructed wetland media was placed above the charcoal bed, separated by a similar plastic baffle as above. Wetland media was prepared with top soil, sand, and charcoal mixture with 2:3:2 weight ratios. The wetland media was planted with *Typha angustifolia* plants which were collected from a microcosm previously grown in a nursery and washed with tap water to remove debris and dead parts.

Perforated stainless steel tubes (5 mm diameter) were vertically inserted into each component allowing water samples to be collected from different compartments.

2.1.2 Influent Greywater Preparation and Flow Rate

The influent for the system was a synthetic greywater solution prepared by mixing 500 g of kitchen/food waste, 8 g of laundry powder, 10 g of pulverized bar soap, 2.5 g of vegetable oils, and 100 ml of kitchen effluent in 100 L of tap water (Travis et al. 2010). A 100 L synthetic greywater solution was supplied to the system with a gravity head as shown in Fig. 1. With this arrangement, 18.3 L day^{-1} of influent passed through the system with a nominal residence time of 5.5 days. In order to avoid depletion of quality, the synthetic greywater solution was replaced every other day.

2.2 Upscaling of the Integrated Charcoal Filter Constructed Wetland (ICFiWet) System

The system was up-scaled and installed at a public washroom (approximately 100 users/day) as a secondary treatment system to treat the partially digested effluents. In the system, the raw sewage first collected in a septic tank and secondly, flows into a soakage pit. However, the soakage pit often overflows due to overloading, thus, the overflowing wastewater pipeline was connected to the ICFiWet system. All components of the up-scaled ICFiWet system was an up-scale of the pilot design. The system was up-scaled to capacity of 15 m^3 to treat 5 m^3 of daily inflow by maintaining 3 days of hydraulic retention time in ICFiWet system. The system was having 3.0 m diameter and 2.8 m depth which included 0.6 m height anaerobic compartment,

vivekvardhan2@gmail.com

Fig. 2 Construction of the up-scaled ICFiWet system

2.0 m height charcoal granular bed, and 0.2 m deep treatment wetland. The up-scaled reactor was built using masonry bricks, reinforced concrete, and finished with cement rendering. Except 0.3 m of freeboard of the wetland, entire system was constructed underground (Fig. 2).

2.3 Water Quality Monitoring

2.3.1 Pilot-Scale System Monitoring

The pilot-scale Integrated Charcoal Filter Constructed Wetland system performances were monitored for 47 days in order to evaluate grey water treatability. The treatment efficiency of the system was measured in terms of pH, electrical conductivity (EC), total solids (TS), total dissolved solids (TDS) by measuring the water quality at the inflow, outflow, and different layers; sampling point 1 (S1) in the anaerobic sludge blanket region, sampling point 2 (S2) at the top of the charcoal granular media, and sampling point 3 (S3) within the constructed wetland (Fig. 1). Water quality parameters of BOD_5, nitrate and phosphate were measured for the inflow and outflow during the operational period. Greywater samples were tested for pH by probe method (Thermo Scientific, model Orion 2 star), Total Solids (TS) by oven dry method, EC and Total Dissolved Solids (TDS) by probe method (Thermo Orion, model 145A), biochemical oxygen demand (BOD_5) by Winkler Titration method, nitrate nitrogen and phosphate by colorimetric method (Jenway 6305 UV/Vis Spectrophotometer).

2.3.2 Up-Scaled System Monitoring

Sampling points were established in up-scaled system, similar to the pilot-scale system and preliminary treatment efficiency was measured in terms of pH, EC, TS, and total suspended solids (TSS), Salinity, BOD_5 for all five measuring points for a period of 18 days. Additionally, Nitrate Nitrogen and Phosphate were measured for inflow and outflow.

vivekvardhan2@gmail.com

3 Results and Discussion

3.1 *Performances of Pilot-Scale Integrated Charcoal Filter Constructed Wetland System*

Table 1 illustrates the water quality of the inflow, outflow, and the three sampling points during the operational period. The average pH value of influent wastewater was in slightly acidic range but improved to neutral pH while flowing upward through the three consecutive treatment systems. The pH improvement was greater in first anaerobic sludge blanket indicating acidogenic and methanogenic transformations. A neutral pH of 6.69 ± 0.29 facilitates the optimum conditions for acid-producing bacteria and methane-producing bacteria. As shown in Fig. 3a, the time-dependent average pH of the outflow effluent was varied from 6.71 to 8.04 (7.3 ± 0.30) which is in the environmentally acceptable pH range (between pH 6 and 8.5 for inland

Table 1 Quality of wastewater at inflow, outflow and sampling points in pilot-scale system (±standard deviation, $n = 47$ days)

Parameter	Inflow	S1	S2	S3	Outflow
pH	4.63 ± 0.39	6.69 ± 0.29	6.8 ± 0.29	7.58 ± 0.13	7.3 ± 0.30
EC (mS/cm)	0.37 ± 0.11	1.47 ± 0.72	1.47 ± 0.83	3.12 ± 0.91	1.54 ± 0.74
TS (mg/l)	1908 ± 384	1201 ± 46	1185 ± 633	2646 ± 1637	1208 ± 519
TDS (mg/l)	234 ± 59	719 ± 367	727 ± 428	1586 ± 482	735 ± 482

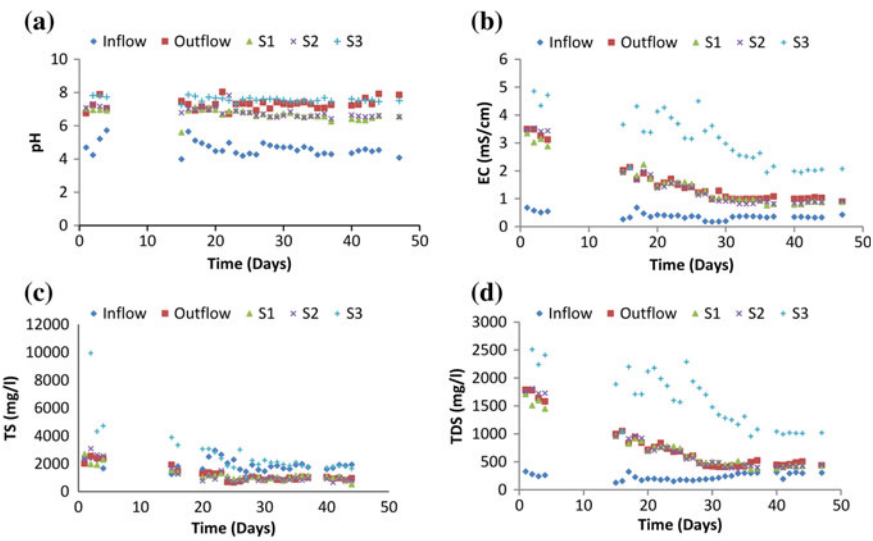

Fig. 3 Variation of **a** pH, **b** EC, **c** TS, and **d** TDS with time in pilot-scale ICFiWet system

vivekvardhan2@gmail.com

surface waters) of treated wastewater before discharging into the natural environment (National Environmental Protection and Quality Regulations, No. 1 of 2008).

The EC variation of different sampling points of the reactor during the study period is shown in Fig. 3b. The artificially prepared greywater (influent) was having low EC compared to outflow waters. The EC was increased through three consecutive treatment systems because of the consumption of complex organic materials by microorganisms and their breakdown within the sludge blanket. Nevertheless, EC within the wetland is relatively high due to the solubility of different ions included in the wetland filter materials (sand, soil, and charcoal). However, with the time EC within the wetland reduced with washing away of impurities and settlement of the filter materials. EC of outflow water is gradually decreased with time from 3.5 to 0.9 mS/cm during the sampling period.

Figure 3c shows the TS variation of the inflow, outflow and within the reactor. As illustrated in Table 1, influent contains 1908 ± 384 mg/l total solids and effluent contains 1208 ± 519 mg/l with a 45.09% of removal efficiency. As shown in Fig. 3d, TDS concentrations of outflow were higher than that of the inflow due to the microbial digestion and breakdown of complex organic substances.

As shown in Fig. 4a, during the first four days of operation, BOD_5 values of the outflow were greater than inflow due to the dissolution of organics in charcoal and wetland bed media substrates. A higher increase of BOD_5 can be observed during 15th day. Formation of microbial flocs due to prolong storage (3 days) of synthetic greywater was the reason for sudden fluctuation of influent waters. But, effluent water quality, particularly BOD_5 was maintained below 90 mg/l with a time-dependent average of 52 ± 33.11 mg/l with approximately 67% of removal efficiency.

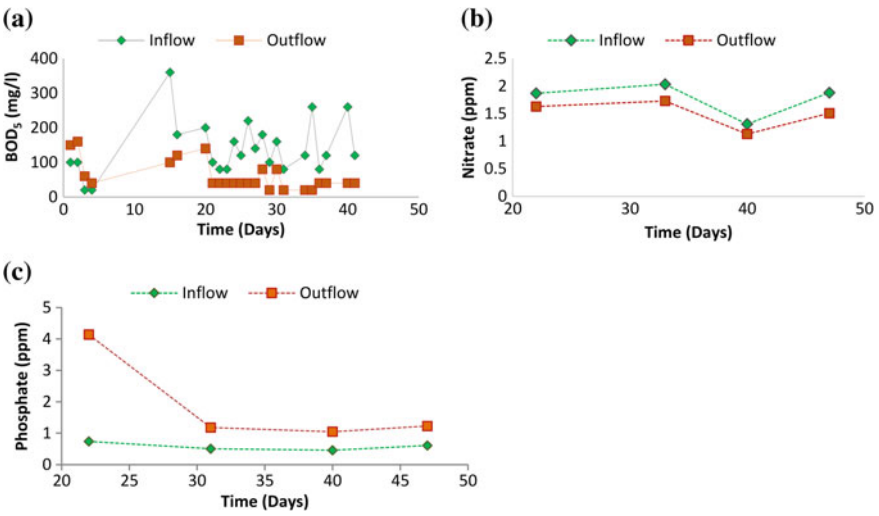

Fig. 4 Variation of **a** BOD_5, **b** Nitrate, and **c** Phosphate concentrations of influent and effluent with time in pilot-scale ICFiWet system

vivekvardhan2@gmail.com

Table 2 Time-dependent averages of the nutrient concentrations and their removal efficiencies

Parameter	Inflow	Outflow	Removal efficiency (%)
BOD_5 (mg/l)	156 ± 72.55	52 ± 33.11	66.67
Nitrate (ppm)	1.77 ± 0.28	1.50 ± 0.23	15.3
Phosphate (ppm)	0.58 ± 0.11	1.90 ± 1.3	−205.07

This reduction of BOD_5 can occur due to the aerobic and anaerobic degradation of complex organic materials by the microorganisms grown in the filter material surface (Vymazal and Kropfelova 2008; Rani et al. 2011).

Nitrate concentration ranges between 1.31 and 2.03 ppm in the influent wastewater and 1.13–1.73 ppm in the effluent with time-dependent averages of 1.77 ± 0.28 and 1.50 ± 0.23 at influent and effluent, respectively (Table 2). The system shows a 15.3% of nitrate removal efficiency. Nitrate removal is occurred due to biological processes such as denitrification which takes place under anoxic conditions. Anoxic conditions are expected to be present at wetlands except plant root zones and near the surface (Cooper et al. 1996).

Figure 4c illustrates the phosphate concentration variation during the experiment. The influent contains of 0.58 ± 0.11 ppm phosphate concentration which increases to 1.90 ± 1.3 ppm at the outflow as shown in Table 2. This is due to the various microbial activities within the reactor, and complex organic compounds are decomposed into simple forms which release phosphate to the system and limited fixing capacity by filter media and plant.

3.2 Performances of the up-Scaled ICFiWet System

Table 3 shows the preliminary data obtained from the up-scaled ICFiWet system by water quality analysis. While flowing through the three main compartments the

Table 3 Variation of time-dependent water quality parameters of up-scaled ICFiWet system (±standard deviation, $n = 18$ days)

Parameter	Inflow	S1	S2	S3	Outflow
pH	7.93 ± 0.09	7.81 ± 0.12	7.10 ± 0.16	7.06 ± 0.18	7.53 ± 0.16
EC (mS/cm)	3.12 ± 0.49	3.27 ± 0.36	2.00 ± 0.21	1.83 ± 0.30	2.37 ± 0.40
Salinity (‰)	1.72 ± 0.23	1.77 ± 0.16	1.07 ± 0.09	0.98 ± 0.15	1.27 ± 0.20
TS (g/l)	0.81 ± 0.21	0.82 ± 25	1.06 ± 0.35	1.01 ± 0.36	0.64 ± 0.28
TSS (g/l)	0.74 ± 0.36	0.64 ± 0.30	0.58 ± 0.26	0.40 ± 0.36	0.36 ± 0.23
BOD_5 (mg/l)	383 ± 23.5	215 ± 71.6	145 ± 44.7	64 ± 34.3	36 ± 12.0
Nitrate N (ppm)	0.19	–	–	–	3.34
Phosphate (ppm)	9.65	–	–	–	3.71

vivekvardhan2@gmail.com

BOD_5 of wastewater is reduced from 383 ± 23.5 mg/l to 36 ± 12.0 mg/l which is near to the standard water quality level for surface discharge.

The pH value shows a slight reduction while flowing through three consecutive compartments and it increases slightly at the outflow. However, the outflow pH is lower than the inflow pH and outflow pH is maintained at environmentally acceptable pH range to discharge to the natural environment. EC and Salinity show a similar variation like pH as shown in Table 3. Total solid content increases at S2 (charcoal granular media) region and S3 (wetland media) region due to mixing of filter material and other organic microorganism complexes with flowing wastewater. TSS is reduced gradually from inflow to the outflow through three consecutive treatment systems due to digestion of organic matter by microorganisms.

As this system was fed with a partially digested effluent from a public washroom system, the contribution of ammonia must be high; however, consequently converted to nitrate through nitrification according to data. The inflow of the up-scaled system contains high amount of phosphate (approximately 9.65 ppm) due to heavy usage of detergents for cleaning of public washroom system.

3.3 Conclusion and Recommendation

The pilot-scale Integrated Charcoal filter constructed wetland system shows 67% of BOD removal and the system reduced nitrate concentration by 15.3%. It was also revealed that the system decomposes the phosphorous complexes in influent leaving an increase in effluent phosphate, demonstrating that charcoal substrate and plants have limited capacity to fix phosphate, but recover nutrient for irrigation water use. Thus, it can be concluded that ICFiWet treated greywater can be used in irrigation and home gardening as it contains high amount of soluble phosphate; however, phosphorus adsorption substrate should be used in ICFiWet system if treated water to be discharged into natural waters. In perspective, Integrated Charcoal filter constructed wetland system can be used as a cost effective, efficient wastewater treatment system which can be constructed with locally available materials. High phosphate in outflow water gives an added advantage if the treated water to be used for irrigation/gardening, thus the system shall be coupled with home garden irrigation with treated water.

A Consolidated Stratagem Towards Defenestration of Coke Oven Wastewater Using Various Advanced Techniques—An Analogous Study

U. Pathak, D. D. Mandal, S. K. Jewrajka, Papita Das Saha, T. Kumar and T. Mandal

Abstract Coke oven wastewater produced from steel industry contains hazardous constituents like phenols, cyanides, ammonia, SCN^-, etc., which needs to be treated before expulsion to the environment. Therefore, pre-treatment of these large volume of wastewater is required for maintaining environmental standards. Simulated coke oven wastewater pertaining to effluent characteristics discharged by industrial sector was synthesized. Initially, treatment of wastewater was performed with ozone which was used in combination with activated carbon (AC) and H_2O_2 to increase the degradation of COD. The maximum degradation achieved in the O_3/AC was 76.8% while in with O_3/H_2O_2, the COD removal was 75.8%. The O_3/AC process was found more acceptable in terms of fast rate of COD degradation, time and economy efficiency suitable for handling large volume of wastewater. However, problems of sludge disposal and process hazards diverted the adoption towards microbial treatment using bacterial strain *Alcaligenes faecalis* JF339228 where phenol was degraded up to 80.88% in 76 h from the coke oven mixture. Due to the high toxicity level of coke oven wastewater, only biological treatment fails to treat them effectively. Combined microbial treatment as well as membrane-based separation process (thin-film composite—reverse osmosis membrane) for wastewater purification was also applied. Thin-film composite (TFC) RO membrane was used to treat this solution at pressure of 200 and 300 psi and at different pH of 5, 7 and 8, respectively. The maximum *quantity of* phenol *removed by TFC RO membrane* at 300 psi pressure and pH of 8

was 76%. Thus, an amalgamated approach of bioremediation and reverse osmosis was sustainable.

Keywords Coke oven wastewater · Ozone · Activated carbon · Alcaligenes faecalis JF339228 · Reverse osmosis

1 Introduction

With the inflation in demand for coal and coke, consumption of freshwater generates coke oven wastewater which results from various onsite operations like quenching, washing, cooling, processing and purification. Other prominent sectors responsible for discharge include petroleum refineries, explosive and phenolic resin manufacturing units, paint and varnish industries, pharmaceuticals plants, textiles units, organic dye processes, metallurgical operations, etc. The complex nature contains a diverse range of hazardous compounds like phenol, ammonia, cyanide, thiocyanate, oil and grease, etc. However, the concentration varies with the classification of coal and the operating conditions involved in the process. These pollutants find their way to surface and groundwater or to the nearby river and the low-level areas. Particularly, phenolic compounds are easily transmitted to the aqueous ecosystem due to their high solubility and volatile nature (Pal and Kumar 2014).

Suitable treatment strategies for coke oven wastewater include coagulation and flocculation, chlorination, chemical oxidation, adsorption, biological degradation and membrane process. Physico–chemical methods have been widely applied due to their high proficiency but cost involvement and evolution of secondary toxicants or dioxins becomes problematic (Kim et al. 2007; Minhalma and de Pinho 2002; Papadimitriou et al. 2006; Staib and Lant 2007). Biological methods are more economical and environmental friendly but cannot be considered initially to handle such extreme levels of toxicity. Biological treatment has been adopted due to its efficacy of degrading phenol and various pollutants into non-toxic end products with reduced operating costs (Lin and Weber 1992). Bioremediation of phenol eventuates through cleavage in the benzene ring by the enzyme secreted by micro-organism. But these bacteria behave disparately in different phenol concentrations and other process conditions. *Pseudomonas sp.* emanates as one of most popularly applied bacteria for bio attenuation of phenol where the latter acts as carbon source and desired energy for cell growth and metabolism (Bandhyopadhyay et al. 2001). Separation using membranes has also emerged to be a potential technology but the drawbacks of fouling have restricted its applicability at preliminary stage. Both physico–chemical and biological treatment techniques are being applied in full-scale industrial use, with satisfactory reports of abatement. Current trends have diverted the treatment technologies to hybrid process like electro catalytic degradation with simultaneous adsorption, solvent extraction, chemical oxidation or irradiation which poses several problems like high process expenses and production of virulent by-products (Bodalo et al. 2008; Spiker et al. 1992). Chemical oxidation process using Fenton's reagent

vivekvardhan2@gmail.com

Table 1 Characteristic features of four different membranes (Bódalo et al. 2009; López-Muñoz et al. 2010; Kislik 2010)

Membrane process	Membrane pore size (μm)	Applied pressure (kg/cm^2)	Rejected solute size (Å)	Permeates through membrane	Suspended particles
MF	0.2–5	<2	>1000	Water dissolved solutes	Suspended particles
UF	0.02–0.2	1–5	50–1000	Water small molecules	Large molecules
NF	0.002–0.01	5–15	5–75	Water monovalent ions	Multivalent ions
RO	<0.002	20–75	1–10	Water	All solutes

also improves the biodegradability of the wastewater. But the major disadvantage of Fenton's reagent appears to be large consumption of $H_2O_2/FeSO_4$ and generation of sludge (Mandal et al. 2010). Agenson et al. (2003) utilized five different membranes for eradication of alkyl phenols (initial concentration-0.05 mg/L) and achieved removal of 90%. For absolute elimination of complex pollutants, simultaneous advanced oxidation and RO process can be applied. Though membranes have elevated rejecting salt levels, they often demonstrate low rejection for some organic molecules (Kucera 2010). Therefore, their pre-treatment with adsorption processes has been executed. The characteristics of the different membranes are expressed in Table 1.

Kumar et al. (2017) implemented ozone as the oxidizing agent where two sets of experiments—one in combination with activated carbon and the other purged with H_2O_2. In continuation to this study, the eradication of phenol in presence of cyanide and ammonia by an isolated bacterial strain *Alcaligenes faecalis* JF339228 from coke processing wastewater has been attempted in combination with TFC RO membrane.

2 Experimental

2.1 Materials

Phenol, ammonia and cyanide standards were purchased from Merck, India to prepare synthetic coke oven wastewater. For the membrane preparation polysulfone and dimethyl formamide (DMF) were procured. Trimesoyl chloride (TMC, Sigma Aldrich) and *m*-phenylenediamine (MPD, Sigma Alrich) are used for preparing TFC RO membrane. All the solvents and salts were purchased from SRL, India.

vivekvardhan2@gmail.com

2.2 Preparation of Coke Oven Wastewater

Feed solution was prepared containing 600 ppm of phenol, 200 ppm of ammonia and 60 ppm of cyanide. The pH of feed solution was 7. Cyanide and ammonia stock solutions were synthesized from 1000 ppm standard solution following serial dilution technique. Phenol stock solutions were developed by dissolving requisite amount in deionized water.

2.3 Microbial Culture and Acclimatization

Alcaligenes faecalis JF339228 was isolated from the drainage effluent of Durgapur steel plant and maintained on nutrient agar plates/slants at 30 °C and pH 7.4 sub-cultured every 30 days for further usage. Sterilization experiments were carried out with the autoclave. Acclimatisation of the microorganism was executed in minimal media to adapt to the toxic environment for essential utilisation. For *Alcaligenes faecalis* JF339228 temperature required for growth is 32–35 °C. The plates were kept in the incubation chamber for 10–12 h. Similar conditions were also maintained for liquid nutrient media. The bacterial growth curve was studied over 0–76 h. The collected samples were centrifuged at 10,000 rpm for 10 min to separate the cell pellet from the supernatant part. The cell pellet was used for measuring the OD in UV—visible spectrophotometer at wavelength 600 nm. Supernatant part was utilized for phenol measurement at 270 nm.

2.4 Synthesis of TFC RO Membrane

PSf casting solution contained dissolved PSf in DMF (15% w/v) at 70 °C. Semi-automated casting machine was used to prepare PSf membrane supported on nonwoven polyester fabric of thickness 100 μm by phase inversion method. The membrane thickness was 30–40 μ. Temperature and humidity of the casting assembly were maintained between 33–35 °C and 13–14%, respectively. PSf-supported fabric was exposed to a gelation bath at a temperature of 24–25 °C containing sodium lauryl sulphate (0.1% w/v) in aqueous DMF (4% w/v).

To prepare TFC membrane with MPD, the PSf support membrane adhered on glass slide was plunged into MPD (2%, w/v) aqueous solution comprizing of glycerol (0.5% w/v) and DMSO (1% w/v). After removing the soaked membrane, its surface was then rubbed to eliminate bubbles formed during the wetting process. Further the MPD-rinsed membrane was immersed into the TMC (0.125% w/v) solution in hexane that formed thin-film coating over the PSf layer. The final material was subjected to heat treatment at 70 °C for 2 min. The humidity and temperature were retained at 62 ± 7% and 30 ± 3 °C, respectively. The synthesized membrane was washed

vivekvardhan2@gmail.com

with water and preserved in aqueous glycerol (10% w/v) solution (Peterson 1993; Kesting 1985; Peterson and Cadotte 1990).

The feed solution was transmitted through these membranes for the removal of phenol from the coke oven mixture at applied pressure of 200 psi and 300 psi, respectively. Each experiment was conducted in triplicate. The permeate flux (J) was calculated as:

$$J = \frac{V}{At}$$

J denotes permeate flux (L m^{-2} h^{-1}) in permeate time, t (h), V signifies permeated water volume (litre, L), A stands for membrane cross-sectional area (m^2). The rejection (R %) was evaluated as:

$$R\% = \left(1 - \frac{C_p}{C_f}\right) \times 100$$

where C_f and C_p are the feed and permeate concentrations, respectively.

2.5 Anatomisation

Scanning electron microscopic analysis was performed with a LEO 1430 VP instrument. Atomic force microscopic measurements were executed in semi-contact mode using a Ntegra Aura, (made by Nt-MDT, Moscow) instrument, involving 'Nova' software for image perusal. Images were captured from different zones of the sample. ATR-IR spectroscopy was conducted using an Agilent Cary 600 series.

3 Results and Discussion

3.1 Treatment of Coke Oven Wastewater Using Ozone in Combination with Activated Carbon and Hydrogen Peroxide

The results obtained by Kumar et al. (2017) depicted that COD removal of 76.79 and 75.8% could be achieved by integrated systems like ozonation conjugated with adsorption by activated carbon and ozonation with hydrogen peroxide. Here, hydroxyl radicals serve a prominent role in eradication of pollutants. Though the cost of ozone consumption is a hindrance, but the catalytic property of activated carbon enhances COD removal. Similarly, incorporation of hydrogen peroxide with ozone

vivekvardhan2@gmail.com

augments hydroxyl radical generation which favours the removal of pollutants. The combination of Ozone–activated carbon was more preferable in terms of economy, effective COD removal and less consumption of ozone and reaction time.

3.2 *Microbial Treatment of Coke Oven Wastewater*

Figure 1 shows the growth of *Alcaligenes faecalis* JF339228 with time in presence and absence of coke oven wastewater along with degradation of phenol (mg/l). Results indicate that with time, the microbial biomass increases up to 60 h in the minimal nutrient media where glucose is the only carbon source. This amount was continuously reduced to replace the medium with phenol, cyanide and ammonia. When development of microorganisms occurs in presence of two substrates or carbon sources, it has a tendency to exhaust the more reliable one that can support maximum growth. Similar observations are noted in this study where the glucose is consumed prior to the phenol. Earlier, Mandal et al. (2013) have reported that about 2100 mg/l of phenol could be degraded completely in 90.8 h incubation time. This study reveals that 80.88% of phenol could be degraded in a time period of 76 h. The current work suggests that *Alcaligenes faecalis* JF339228 have the potency to degrade phenol under the inhibitory effect of ammonia and cyanide through the enzymatic activity phenol hydroxylase (Jiang et al. 2007).

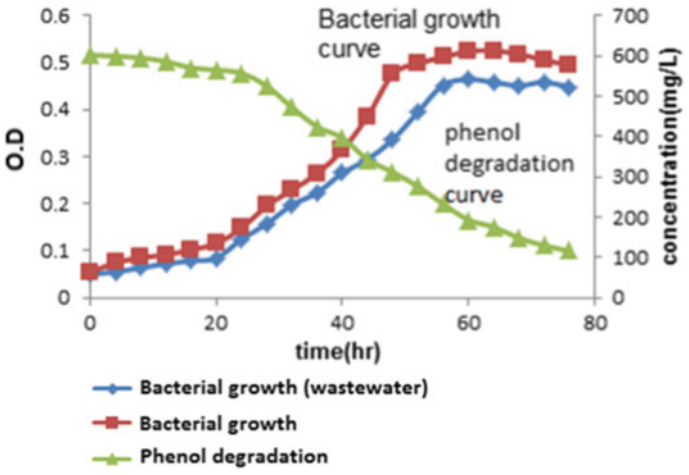

Fig. 1 Bacterial growth curve in absence and presence of coke oven wastewater and phenol degradation curve

vivekvardhan2@gmail.com

3.3 *Removal of Phenol from Coke Oven Wastewater by TFC RO Membrane*

Initially, the phenol rejection efficiency of the prepared TFC RO membrane was tested with 100, 200, 400 and 600 ppm phenol feed solutions. The pH of the solution was 7. Results depicted from Fig. 2 that the rejection of phenol was almost similar and did not vary marginally with feed concentration. The rejection of phenol was much lower than NaCl rejection capacity of the membrane. Since, TFC RO membrane is negatively charged in nature and the phenol is slightly acidic, the rejection of phenol is governed predominantly by the size exclusion and not by electrostatic repulsion (Srinivasan et al. 2009). Observations also reveal that the concentration of phenol increases with the decrease in permeate flux. At pH 10, the rejection of phenol is higher due to the dissociation nature of phenol into phenolate ions at pH > 8.

From Fig. 3, at an applied pressure of 200 psi, the phenol rejection and the permeate flux by the membrane were lower than 300 psi. The rejection of phenol and flux at pH 8 were higher than that of feed solution of pH 5 and pH 7. Arsuaga et al. (2008) performed experiments with a similar thin-film composite nano-filtration membrane (NF-90) with the phenol feed concentration in the range of 100–500 mg/l. The pH was varied between 2.8 and 5.3 and temperature 20–41 °C. Results revealed that initial organic concentration and operating pressure have a considerable effect on

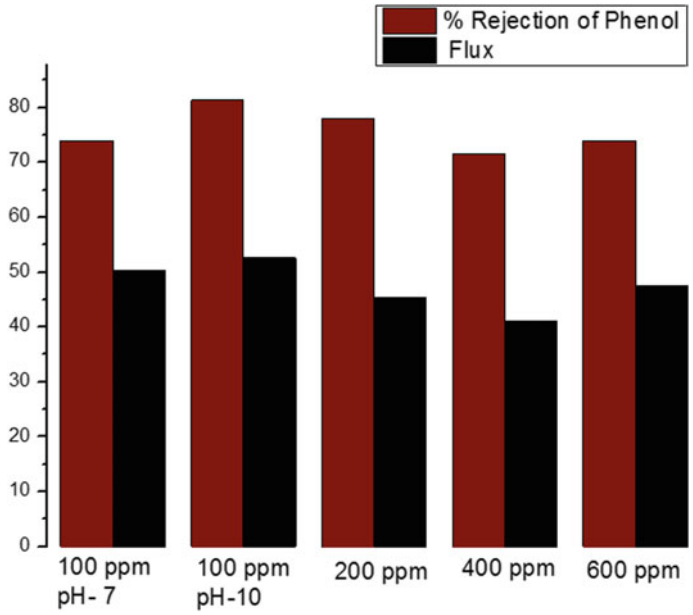

Fig. 2 Percentage rejection of phenol from coke oven wastewater and flux at different concentration

vivekvardhan2@gmail.com

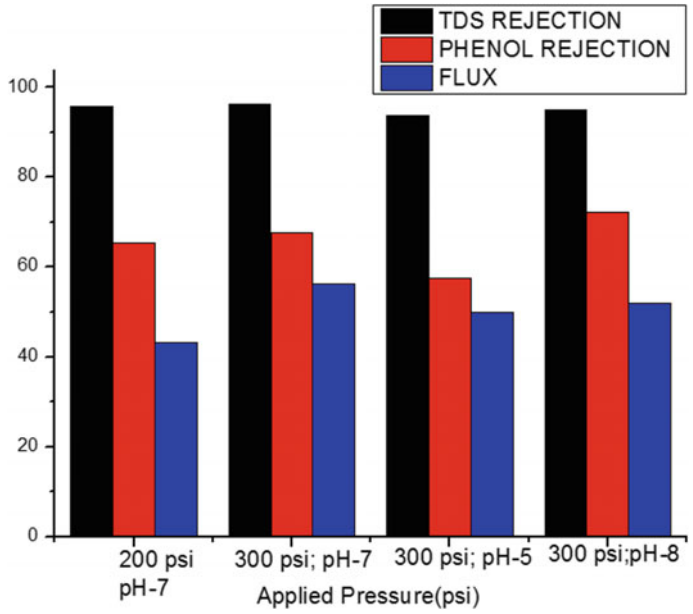

Fig. 3 Rejection of phenol and total dissolved solids at different applied pressure

the permeate flux. On enhancing pressure and deflating organic concentration, the permeate flux increases. However, temperature had no significant influence, but pH has a profound influence on the phenol removal.

3.4 Characterization of TFC RO Membrane

As reported by Jewrajka et al. (2013), TFC RO membrane was synthesized by interfacial polymerization as described in the experimental section. The membrane consists of a typical network-like structure of polyamide which is well reported in the literature with ridges and valleys associated with aromatic C=C stretching of PSf support.

4 Conclusion

Synthetically prepared coke oven wastewater was treated by microbial and TFC RO membrane which was compared to the work reported from ozone–activated carbon treatment. The objective was to remove phenol effectively under the hindering effect of cyanide and ammonia. With the help of coke oven isolated bacterial strain *Alcaligenes faecalis* JF339228, it was found that up to 80.88% of phenol was removed

vivekvardhan2@gmail.com

which proved its potency as phenol degrader. On the other hand, with the help of TFC RO membrane at 300 psi and pH 8, phenol can be removed up to 75.25%. The rejection of total dissolved solids was found to be 96.14%. The combination of microbial and TFC RO membrane process will be a novel strategy and greater phenolic removal can be achieved by the combination of these two treatment processes. It may be concluded that only RO process is not as efficient and a combination of the above processes is necessary to accomplish desired abatement.

Studies on Lead Removal from Simulated Wastewater in Packed Bed Bioreactor Using Attached Growth Technique

Moumita Bose, Siddhartha Datta and Pinaki Bhattacharya

Abstract The present study deals with removal of lead from simulated wastewater using a continuous packed bed bioreactor packed with lead-resistant *Acinetobacter sp 158* immobilized on coconut coir chips. *Acinetobacter sp 158* was isolated from battery industry effluent mud, and biocatalysts were made by using attached growth technique. In order to investigate reactor performance, a set of programmed experiments was performed. The potential of bioconversion of lead through immobilized cell was studied by changing initial substrate concentration along with flow rate with an intention to predict removal of lead through judicious modeling and simulation exercise.

Keywords Bioremediation of lead · Immobilized lead-resistant strain · Biodegradable packing matrix · Packed bed bioreactor

1 Introduction

Amongst the various heavy metals, lead is highly carcinogenic and mutagenic in nature. Random discharge of such hazardous element lead and its compounds as industrial waste from a number of industries, viz battery industry, painting industry, coal-based powder generation industry, mining industry, etc., into the environment (Murthy et al. 2012; Samanta et al. 2012; Vesper et al. 1996; Forstner and Wittmann 2012; Adriano 2001). It is needless to mention that mixing of this heavy metal ions into soil and water beyond its threshold hazardous limit is a potential threat to the entire ecosystem. In order to mitigate lead pollution, chemical industries have been forced to follow lead-containing waste discharge limit set up by Environmental Protective Agencies.

vivekvardhan2@gmail.com

The main constrain arises for abating lead contamination is globally applied chemical-based conventional waste treatments reduce the level of lead up to a definite extent which is beyond that the stipulated one. In order to bring down the amount of lead in industrial waste, industry is highly reluctant to adopt again such expensive chemical treatment techniques which make the end product costly. Bioremediation is the only possible route to bring down the amount of lead of industrial effluent near about the threshold value set by Environment Protecting Authorities in developing countries. In order to achieve the permissible limit, conventional waste treatment techniques should be tied up with biological remediation pathways. Although experimental investigation on small-scale batch mode study of lead bioremediation was reported earlier (Chakraborty et al. 2013; Rhee et al. 2014; Li et al. 2016; Kalita and Joshi 2017), a proper programmed and systematic continuous mode operation is needed from bioprocess point of view for successful application of the technology on an industrial scale.

2 Materials and Methods

2.1 Chemicals

Tryptone–Glucose–Yeast Extract Broth (HIMEDIA, India), Lead nitrate [$Pb(NO_3)_2$] (SRL, India), 99.9% of Ethanol (MERCK, India), and distilled water were used for this investigation.

2.2 Preparation of Growth Media

0.1 kg/m^3 lead-incorporated tryptone–glucose–yeast extract broth was used as growth media.

2.3 Preparation Simulated Wastewater

In the present experiment, a stock solution of lead nitrate solution containing kg/m^3 of lead was prepared by adding metered quantity of lead nitrate in double distilled water. In order to make simulated wastewater of definite concentration, stock solution was diluted according to the need.

vivekvardhan2@gmail.com

Fig. 1 Raw coconut chips

2.4 Preparation of Packing Matrix

In the present investigation, outer shell of coconut was collected from local market and cut into small chips (shown in Fig. 1). Coconut chips were washed properly and sundried.

2.5 Microorganism

Previously, isolated lead-resistant bacterium *Acinetobacter sp 158* (Bose et al. 2017) was used in the present investigation.

vivekvardhan2@gmail.com

2.6 Immobilization of the Whole Cell on the Matrix and Its Maintenance

In order to immobilize the whole cell on coconut chips following attached growth technique, 200 ml of culture media and 22.739 gm of coconut chips were introduced in each 500 ml conical flask. These two flasks were autoclaved at 0.2 MPa at 121 °C for 15 min. In order to prepare selective media containing lead metered quantity of UV sterilized lead solution was added into each flask. After that, 20 ml broth culture of lead-resistant *Acinetobacter sp158* was inoculated into each flask in a laminar flow chamber. The open ends of both the flasks were plugged with sterile cotton and placed on rotary shakers by maintaining shaking speed 80 rpm at 37 °C for 48 h. When attached growth was visually appeared, the biocatalyst was loaded into sterile glass column. In order to keep microorganism alive on matrix during shut-down period, the packing portion was submerged in fresh sterile lead supplemented TGY broth.

2.7 Packed Bed Bioreactor Design

A packed bed bioreactor made up of BOROSIL glass column of 615 mm length and 38.8 mm inside diameter was used to treat lead-containing simulated wastewater. In order to support the packing materials, a retaining screen with perforation of 1 mm diameter was inserted at the bottom of the column. In order to collect sample solution from axial direction, the reactor was equipped with three outlet nozzles present 70 mm, 150 mm, and 330 mm, respectively, from the bottom of the column. Simulated wastewater was sent into the packed bed section from the bottom of the column with the help of a peristaltic pump in a predetermined flow rate. In order to maintain aerobic condition, sterile air was sparged into column through air filter after each run. Inlet flow rate of simulated wastewater was measured by rotameter. In order to see overall pressure drop, a U-tube manometer was connected with the packed column. The schematic diagram of bioreactor is shown in Fig. 2. In order to understand the performance of bioreactor, three different operating parameters, viz inlet concentrations of lead (0.05–0.2 kg/m^3), superficial velocities (1.43312–4.29936 m/h), and bed heights (0.07–0.33 m) were considered. After treatment, amount of lead present in simulated wastewater collected from outlet probes was measured using atomic absorption spectrophotometer (Perkin Elmer, Germany).

vivekvardhan2@gmail.com

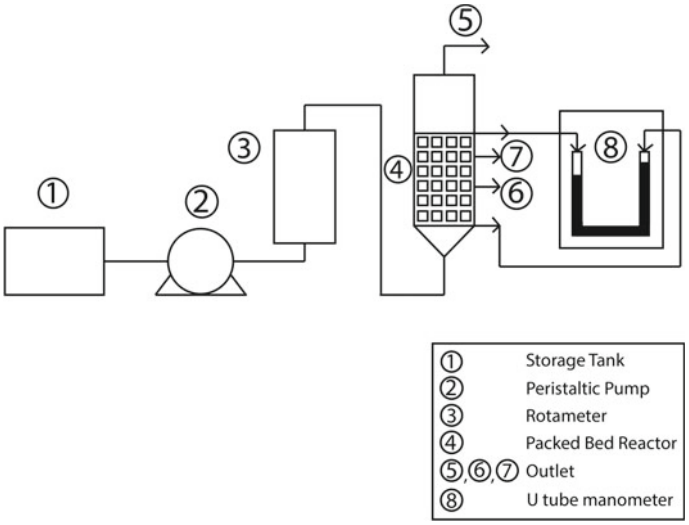

Fig. 2 Schematic diagram of bioreactor setup

3 Results and Discussions

3.1 Analysis of Performance of Data

In order to explain performance of packed bed bioreactor, a family of curves (Fig. 3a–c) has been constructed using experimental data to determine the lead removal capability of the continuous bioreactor. Figure 3a shows a plot of variation of substrate concentration (S) in axial direction (B) using initial substrate concentration as parameter. It is apparent from those Fig. 3a–c that for each substrate concentration, higher the superficial flow rate, lower is the removal of lead. This is an expected phenomenon, higher superficial velocity gives lower residence time resulting in lower removal of lead, and consequently, lower flow rate gives long residence time to convert higher amount of lead. Another set of plot was drawn (Fig. 4a–c) to understand the relation between substrate concentrations and bed height with superficial velocity as parameter. It is revealed that conversion is gradually increased with the increase of initial substrate concentration for a fixed flow rate due to more availability of electron donor in the vicinity of immobilized cells. In the present set of experiment, the maximum removal of lead was achieved to the tune of 32.4% under the operating condition of 0.2 kg/m^3 initial lead concentration and 1.43312 m/h of superficial substrate flow rate.

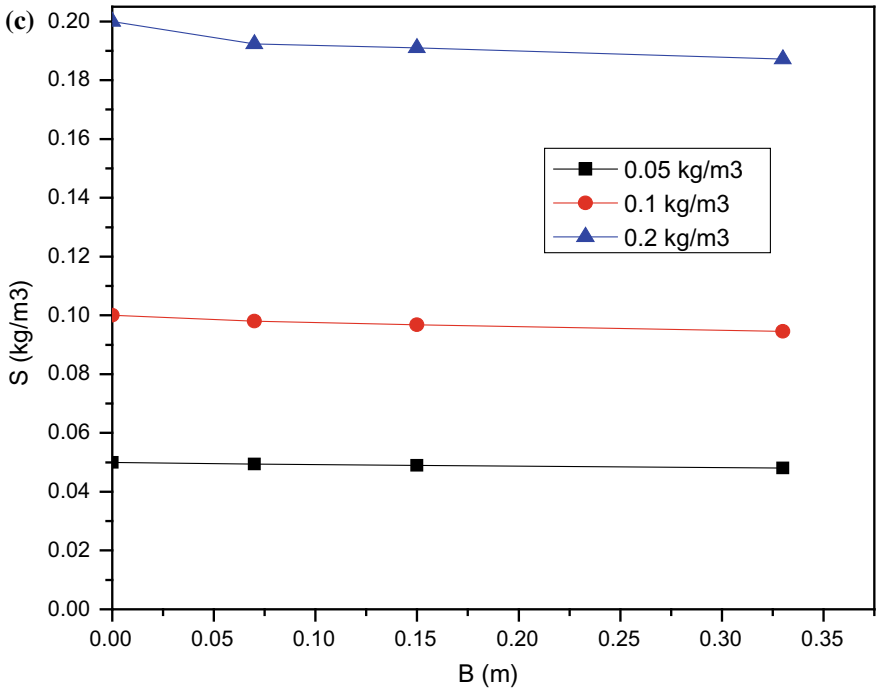

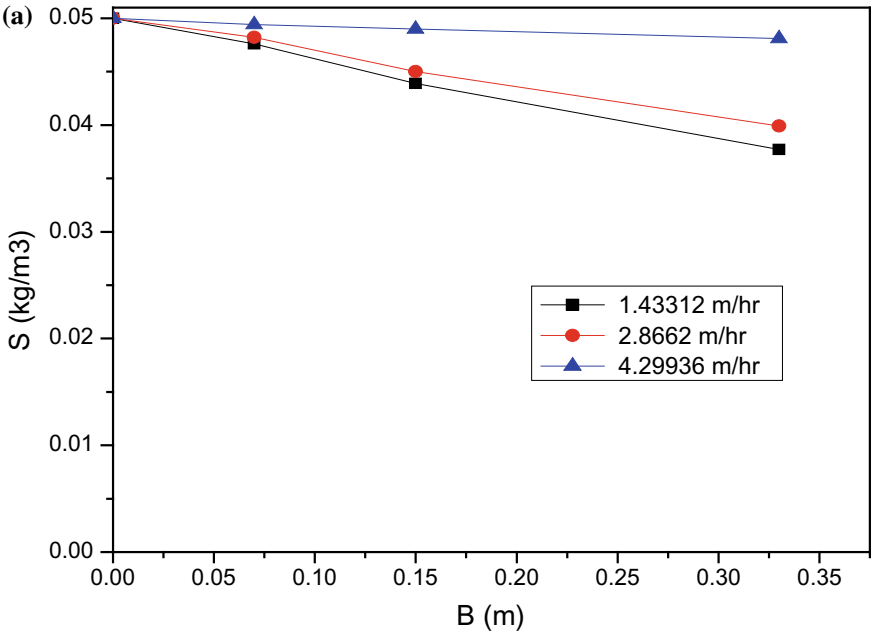

Fig. 3 (continued)

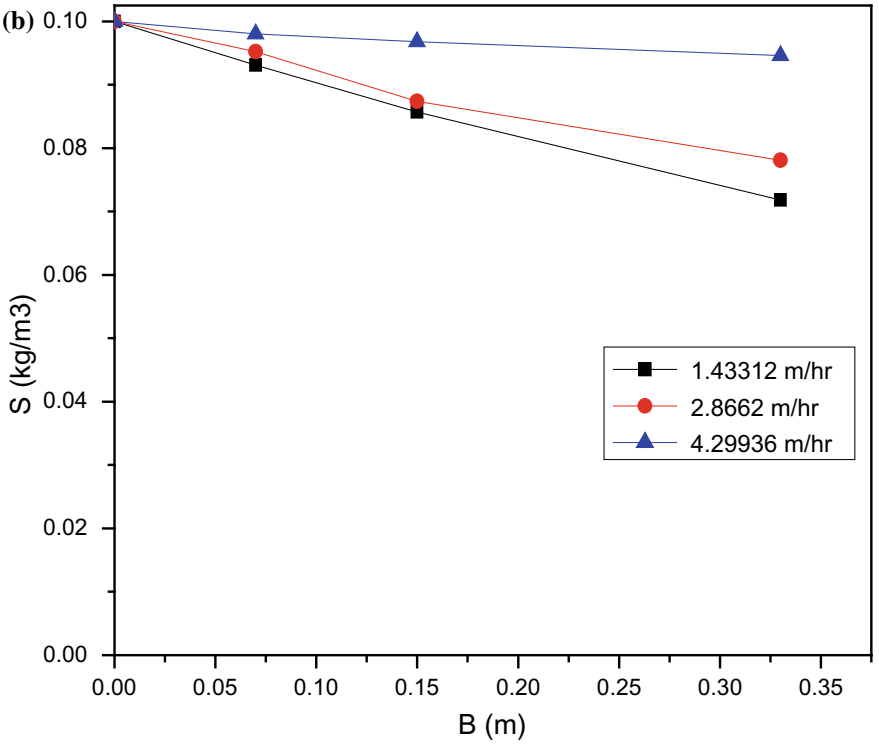

4 Conclusions

The present investigation reveals successful application of *Acinetobacter sp 158* immobilized form on coconut chips as biocatalyst in a packed bed bioreactor to treat lead-containing wastewater in continuous mode. Easily available coconut chip can be applied as packing matrix to make the process economically viable. The promising experimental results are an indication of carrying out an extensive research using broad spectrum of operating variables.

Sustainable Growth and Survival of *Litopenaeus Vannamei* Through Wastewater Recycling

K. Kavitha and P. V. Krishna

Abstract Nowadays, aquaculture activities play a major role in increasing the organic waste and toxic compound in the aquatic water bodies. Along with the development of aquaculture, there is an ever-increasing aquaculture waste both on productivity inside the aquaculture system and on the ambient aquatic ecosystem. Therefore, it is apparent that appropriate wastewater recycling processes are needed for sustainable aquaculture development. Hence, the best environmentally acceptable "biofloc technology" (BFT) has been developed. The present study aims the application of BFT to recycle the wastewater nutrients. Pacific white shrimp, Litopenaeus vannamei, was selected to be culture. Three cement tanks C_1, C_2, and C_3 with a stocking density of 120 PL/m^2 were assigned for the study. C_1 is taken as control and C_2, C_3 as test. In BFT, excess of nutrients in aquaculture systems is converted into microbial biomass, which can be consumed by the cultured animals as a food source and the remaining are used for agriculture purpose. This technology has also the capacity to control harmful pathogens in aquaculture. The microorganisms of biofloc successfully converted the toxic ammonia and nitrite into nutritious diet and maintained the water quality in the safety levels for the shrimp. This study has been made to summarize the features and management aspects of the environmental friendly BFT to achieve sustainable aquaculture.

Keywords Biofloc technology · Sustainable aquaculture · Recycling · Wastewater · International society of waste management · Air and water

1 Introduction

Globally, India occupies the second position after China, with sharing 10.0% of world's aquaculture production (FAO 2016). The vast resources in terms of water bodies and species of fish and shellfish in different regions of the country provide a wide array of culture systems and practices. The shrimp, *Litopenaeus vannamei,* is the major contributor in the aquaculture production. However, intensification of

vivekvardhan2@gmail.com

the aquaculture activities generates an immense amount of excess organic pollutants that are likely to cause acute toxic effects and long-run environmental risks (Piedrahita 2003). It is reported that effluents released from the aqua farms contain more pollutants than the other industries. A lot of chaos from the public and the environmentalists is due to the discharge of untreated aqua wastages into natural water bodies. Discharge of this untreated water is contaminating the natural water bodies causing outbreak of diseases, imbalancing the biodiversity and ecosystem. To overcome all these challenges and to conserve the ecological sustainability, biofloc technology (BFT) has been developed. Because of economical, environmental, and marketing advantages over the conventional system, BFT has been implemented successfully in shrimp farming. Compared to conventional aquaculture techniques, BFT provides more economical alternative and sustainable technique in terms of minimal water exchange and reduced feed input making it a low-cost sustainable technology for sustainable development (Avnimelech and Kochba 2009; De Schryver et al. 2008). BFT involves the manipulation of C/N ratio to convert toxic nitrogenous wastes into the useful microbial protein and helps in improving water quality under a minimal/zero water exchange system (Ahmad et al. 2017). Moreover, BFT offers a sustainable aquaculture tool by simultaneously addressing its environmental, social, and economical issues. In this context, BFT can also be used in the specific case of maintaining appropriate water quality, and thus, it can reduce the pollution of the pond water. With these positive effects, the present study was undertaken to evaluate the growth and survival of *L. Vannamei* in BFT.

2 Materials and Methods

2.1 Tank and Floc Preparation

Specific-pathogen-free (SPF) seed, *L. vannamei* (PL 9), obtained from a local hatchery. The PL was carried in oxygenated double-layered polythene bags to the laboratory in specific fish transportation tanks. Before releasing the PL, all the tanks were cleaned and disinfected using bleaching powder and dried for 2 days. The biofloc was prepared as per the protocol described by Avnimelech (2012). In brief, on the first day ammonium chloride was added to initiate nitrogen source in the system. On third and fifth day carbon sources were added and on day seven double the quantity of carbon source was added. Due to the addition of carbon and nitrogen source, the color of the water changed to light brown indicating the formation of floc. After tank preparation on the day nine, the PL was brought to farm side and were treated with potassium permanganate, and tank water was added slowly into the seed bags to adjust the salinity and pH; subsequently, the PL was released slowly into the tanks C_1, C_2, C_3 (each with 54.6 m^2) at a stocking density of 120/m^2. Among three tanks (C_1, C_2, C_3), C_1 was taken as control, i.e., without application of biofloc, and C_2, C_3 were taken as test which consist of biofloc. All the tanks were supplied with aeration

vivekvardhan2@gmail.com

for sufficient supply of oxygen which is necessary for the formation of biofloc and also for shrimp.

2.2 Analysis of Water Quality Parameters

Water samples for the analysis were carried throughout the study period. Surface water temperature was recorded between 6:00 and 9:00 during the morning hours and between 5:00 and 6:00 during the evening hours with the help of Mercury thermometer. Samples were collected in separate reagent bottles and analyzed by standard methods of (APHA 2005). pH of the water was measured by using the laboratory model ELICO pH meter. Transparency of the water column was assessed with the help of Secchi disk. In case of dissolved oxygen, the collected water samples were fixed with modified/Winkler's titration method (APHA 2005). The cones Imhoff were used to measure the quantity of biofloc which have marked graduations on the outside that can be used to measure the volume of solids that settle from 1 L of system water.

2.3 Microbiological Analysis of Water

Microbiological analysis of water was done regularly thrice a week. To observe the Vibrio count, spread plate technique was used. One ml of cultured water was serial diluted and 10^8, 10^9 ml of serially diluted culture water was spreaded on Thiosulfate citrate bile salts sucrose (TCBS) agar and incubated overnight at 37 °C to find out the presence of *Vibrio* spp.

2.4 Feed Management

L. vannamei fed with commercial diet, Blanca feed pellets (CP Aquaculture, India private limited) was used for four times daily at 6 am, 10 am, 2 pm, 6 pm. The feed quantity was estimated depending on the floc volume. No water exchange was done during the culture period except addition of water to refill the water levels after siphoning out the wastes. Sludge was removed regularly in order to control Nitrite and TSS in the system.

vivekvardhan2@gmail.com

3 Results and Discussions

Water quality parameters, i.e., salinity, temperature, pH, dissolved oxygen, and transparency ranges, are presented in Table 1. Dissolved oxygen (DO) concentration and temperature were similar between treatments throughout the trial. The oxygen dissolved in the system is an important factor not only for the respiration of aquatic organisms but also to maintain favorable chemical and hygienic environment. Muthu (1980) stated that the DO should not be lower than 3.5 ml/l in shrimp culture pond. But in the biofloc system, the aeration should be more than 5.0 mg/l (Avnimelech 2012). In the present investigation, the dissolved oxygen content was ranged from 6.0 to 7.0 mg/l in the system. Continuous aeration was done during the culture period, and therefore, the oxygen level exceeds the limit. The temperature is an ecological factor which influences the hydrological parameters, which in turn influences the metabolism, growth, and other biochemical processes. The optimum range for warm water species is 24–30 °C (Ramanathan et al. 2005). In the present study, the water temperature range varied from 27 to 29 °C. Shrimps are poikilothermic that can modify their body temperature to the environment in normal conditions. The continuous aeration will circulate the equal temperature in the biofloc system. pH is one of the important environmental parameters which decides physiological process of shrimps. The optimum range of pH is from 6.8 to 8.7 and should be maintained for maximum growth and production (Ramanathan et al. 2005). The best condition is from 7.8 to 8.5. If pH changes significantly, it makes shrimp shocked, weakened, and stops eating. If high or low pH extends for a long time, it will make shrimp grow slowly and susceptible to diseases. In the present study, the pH concentration was ranged from 8.0 to 8.5 which is the best condition for shrimp growth. Salinity is the most important factor influencing many functional responses of the organism such as metabolism, growth, migration, osmotic behavior, reproduction. Sudden fluctuation in salinity will affect the osmoregulatory functions of growing organism and lead to mortality. In the present study, the salinity was maintained at 6 to 7 ppt. During the culture period, the salinity was maintained at 6 ppt, but sometimes, it reached 7 ppt. The transparency of water was 15 cm.

The values of ammonia, nitrite, and nitrate were presented in Fig. 1. The results revealed that the ammonia was 0.05 mg/l in the system initially due to the addition of ammonium chloride. After that, it increased to 0.08 mg/l and then gradually decreased. The heterotrophic bacteria present in the biofloc can absorb ammonia 40

Table 1 Water quality parameters

S. no.	Parameters	Range
1	Salinity (ppt)	6–7
2	Temperature (°C)	27–29
3	pH	8.0–8.5
4	DO (mg/)	6.0–7.0
5	Transparency (cm)	15–16

vivekvardhan2@gmail.com

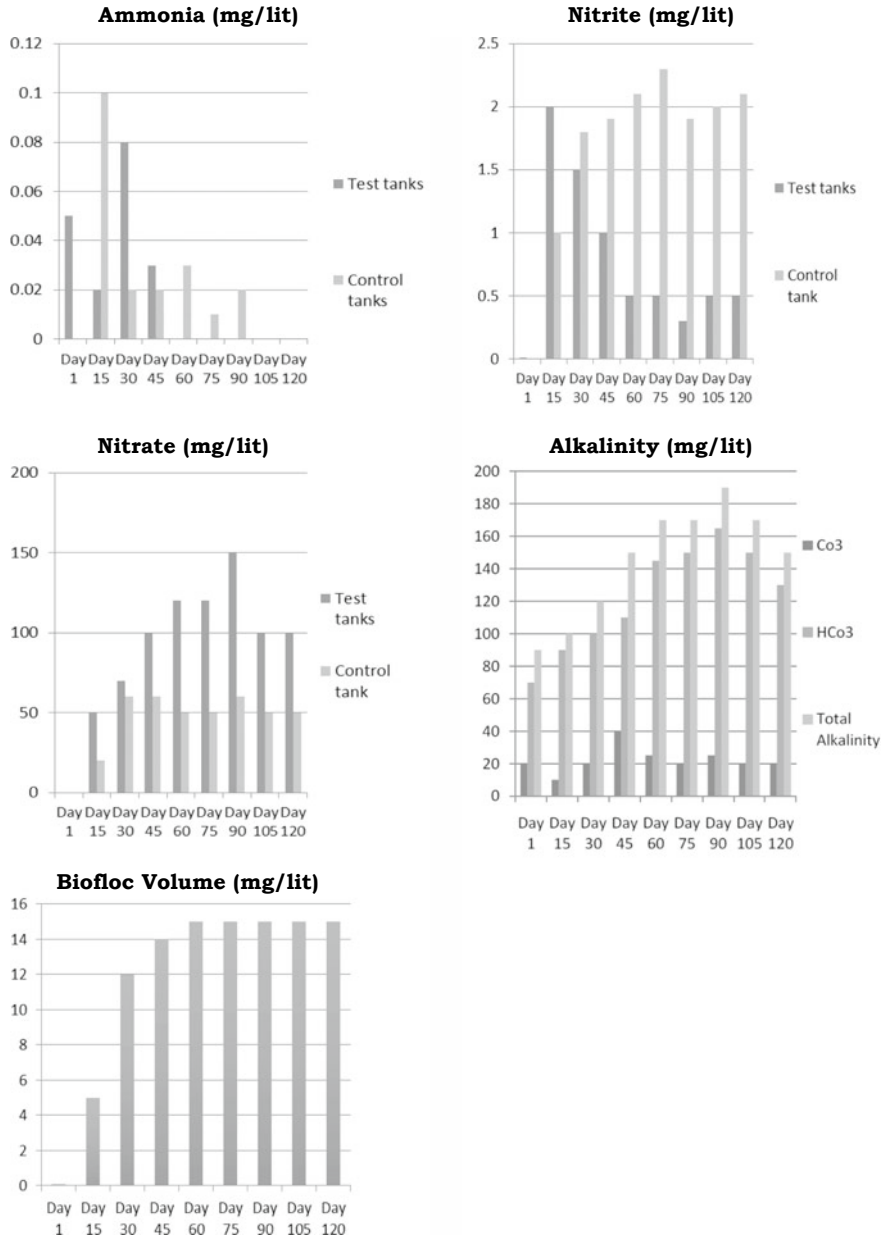

Fig. 1 Water quality parameters

vivekvardhan2@gmail.com

times faster than nitrifying bacteria. Thus, biofloc has the capability of balancing ammonia concentration in the culture system (Ebeling et al. 2006). In addition, De Schryver and Verstraete (2009) stated that biofloc grown in the bioreactor can convert 98% ammonia into nitrate at a concentration of 110 mg L^{-1} day^{-1}. The ability of heterotrophic bacteria to absorb the ammonia is influenced by the ratio of carbon and nitrogen (C/N ratio) in water where the ammonia will be absorbed quickly when C/N was higher (Schneider et al. 2006). The nitrite level was 0.01 mg/l, and then it increased to 2.0 mg/l after 15 days of culture. By increasing the carbon source, removing sludge, and decreasing the feed quantity controlled the nitrite level to 0.5 mg/l. The low value of nitrite in the biofloc system is probably due to the conversion of ammonia to nitrite by heterotrophic bacteria which in turn utilized by micro-algae for growth (Avnimelech 1999; Ebeling et al. 2006). This is an indication that the nitrification process occurred in the culture medium (Stickney 2005). Nitrate, which is the final product from the nitrification of ammonia, is the least harmful nitrogenous compound for shrimp (Van Wyk and Scarpa 1999). In the present study, nitrate ranged between 100 and 150 mg/l. Lower nitrite and higher nitrate concentrations were recorded, due to the formation of biofloc. The total hardness of the water was 1800–1850 mg/l. When alkalinities are maintained from 40 to 160 mg L^{-1} in the BFT system, no significant effect on the TSS, ammonium, nitrites, and nitrates has been determined (Piérri 2012). pH increases when the alkalinity increases above 160 mg L^{-1}, as well as the tendency of increase of heterotrophic and ammonium oxidant bacteria increases with a decrease in nitrites oxidant bacteria (Piérri 2012). Thrice during the culture period alkalinity was reduced to 100 mg/l, in order to increase it sodium bicarbonate was added to maintain the C:N ratio at 15:1. Calcium and magnesium were maintained at a rate of 1:2.5. No H_2S was observed during the entire culture period. In the initial days, the color of the water was light brown and gradually changed to brown color and then to green color. In the day one, the floc volume was 0.1 ml/l, and it increased to 15 ml/l. The quantity and quality of floc were monitored regularly.

The floc volume was presented in Fig. 2. The microscopic observation of floc shows rotifers, copepods, algae, bacteria, etc. But sometimes protozoans like zoothamnium and vorticella were also observed in the floc. Few yellow colonies of Vibrio spp were seen in microbiological analysis; however, there is no disease outbreak throughout the culture period. In aquaculture, the principal source of waste is ultimately the manufactured feeds that are necessary to increase production beyond natural levels (Iwama 1991). According to Avnimelech (2012), reducing the feed quantity and increasing the floc volume reduces the aquaculture waste and also the feed cost. Hence, the adoption of this technology increases the efficiency of feed utilization, because organic and inorganic metabolites, as well as unused or partially used food, are recycled by microorganisms into microalgae and bacterial biomass, which tend to coalesce into flocculated material (bioflocs).

In the present study, biofloc tanks achieved a survival rate of 77% and the growth rate was 27 g with a total production of 135 kgs. Large amounts of manure are required to meet the nitrogen requirements of agricultural crops. For regional agricultural field crops, aquaculture manure is also used as principal nitrogen source for better

vivekvardhan2@gmail.com

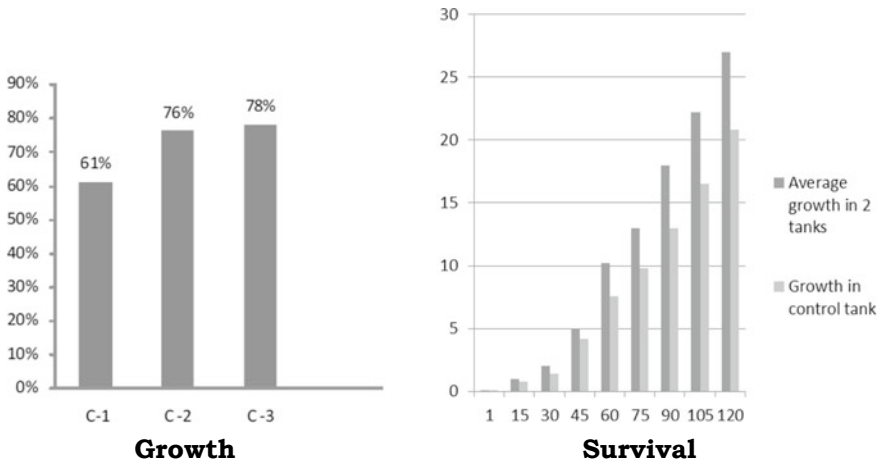

Fig. 2 Growth and survival

effects. On-site, smaller-scale agricultural ventures or non-commercial gardening seem more appropriately scaled for using aquaculture wastes (Yeo et al. 2004). The post-harvested water was used to grow vegetables present near the pond or else the same water can be reused to culture the next crop.

4 Conclusion

Biofloc technology is an environmental and sustainable technology used in aquaculture to maintain water quality through converting nitrogenous waste into bacterial proteinaceous biomass after the addition of carbohydrate sources and also can be subsequently consumed by the cultivated aquatic organisms. In the present study, the biofloc system can maintain the good water quality parameters and recycles the wastewater in shrimp culture. Hence, the BFT is an eco-friendly approach reducing pollution; as there is zero or minimal water exchange to eradicate the environmental pollution and economic problems associated with aquaculture.

Reuse of Washing Machine Effluent Using Constructed Wetland: The Circular Economy of Sanitation

Shruti Sharma, B. Lekshmi, Rahul S. Sutar, Yogen J. Parikh, Dilip R. Ranade and Shyam R. Asolekar

Abstract Currently, due to the practice of traditional linear economic model, water resources are under extreme pressure. The lack of technically efficient and economically feasible solutions for water and wastewater treatment and poor management of water assets are responsible for the lack of access to safe water in both rural and peri-urban communities. The present study attempts to achieve the fundamental principles of circular economy which consists of regeneration and restoration by treating the laundry wastewater using constructed wetland and its reuse for various other purposes. The composition of detergents used in a domestic washing machine constitutes of wide range of chemicals. Consequently, the produced laundry wastewater contains varieties of compounds including surfactants, softeners, alkalis, bleach, hydro-tropes, xenobiotic organics, sodium, phosphorus, nitrogen and micro fabrics from clothing. Based on the calculation of water balance on a domestic washing machine, the water consumption has been approximated to be 5000 MLD, while consumption of detergents was estimated to be 3800 TPD (equivalent to 3000 TPD of COD) approximately. Evidently, the treatment of laundry wastewater is the need of the hour. At IIT Bombay, the constructed wetland technology having the horizontal subsurface system entitled 'CW4Reuse' has been developed for treatment and management of effluents. In the present study, 'CW4Reuse' has been utilized for treatment of laundry wastewater from a family consisting of five members (approximately 75 L/d). The wetland bed has a plan area of 1 m^2 and a depth of 0.5 m. *Canna Indica* (family: *Cannaceae*) has been used as the vegetation system for effluent treatment. The qualitative and quantitative analysis of the laundry wastewater showed a significant removal of BOD, COD, TSS, VOC_S heavy metals, nitrogen, phosphorus and pathogens (proxy: MPN). The treated laundry effluent can be reused for gardening, vehicles cleaning and flushing.

1 Introduction

Water is a limited natural resource and is essential for the survival of all elements of earth's ecosystem. It plays a crucial role in supporting the day-to-day demands of urban, industrial and agricultural sector and thus holds a special position in a nation's economic growth. This wonder liquid also serves as the basic building block of sustainable development and contributes to the socio-economic growth, healthy environment and survival of living beings. However, in the present situation, due to the ever-growing population, industrialization and other economic actions, the demand as well as usage of freshwater supply has increased many folds. Consequently, it has laid the natural water resources under extreme pressure. For instance, it was found that the consumption of freshwater due to domestic activities contributes up to 70–80% of the total volume of wastewater, and out of domestic usage of freshwater as mentioned above, laundry wastewater constitutes up to 33% (Asano 2002; Harrison 2007; Mohamed et al. 2014a, b).

In the twenty-first century, the issues associated with the water shortage and freshwater supply are of increasing concern worldwide (Fragkou and McEvoy 2016; Hoekstra 2016; dos Santos et al. 2018). Furthermore, the higher carbon and energy footprints as well as high operation and maintenance cost associated with centralized wastewater treatment plants pose a significant challenge towards wastewater reclamation and reuse (Martínez-Huitle et al. 2015). In order to deal with the current situation of water shortage, there is an urgent need of sustainable and strategic planning where the wastewater would be considered as the valuable economic good rather than a waste product. The goals of sustainability can only be achieved by implementing the aforementioned concept of waste to wealth rather than following the traditional linear economic model.

In such scenario, the development of decentralized wastewater treatment systems would be one of the best possible solutions which could be implemented at a small scale with a closed loop of wastewater recycling and reuse facilities (Piratla and Goverdhanam 2015; Capodaglio 2017; Wael et al. 2017). It is a pressing need of today to develop efficient water and wastewater treatment systems that are capable of recycling and reuse of treated effluents (Mekala et al. 2007; Garcia and Pargament 2015). Additionally, the treatment system should be environment friendly, easy to use and should involve low operation and maintenance cost.

In the context of freshwater consumption in domestic activities, washing machines occupy the foremost position. It was estimated that approximately six litres of water are consumed per kg of laundry (dos Santos et al. 2018). It is worthy to note that in the past few decades, the concept of wastewater reclamation and reuse has gained significant attention within the scientific communities, and efforts are being made to recycle and reuse the large volume of effluents coming from various industries such as pharmaceuticals, dairy, leather, agricultural sector and textile industries (Szpyrkowicz et al. 2005; Özcan et al. 2008; Babu et al. 2009; Hajjaji et al. 2013; Rodrigo et al. 2014; Ganiyu et al. 2015; Elabbas et al. 2016; Benazzi et al. 2016; Solano et al. 2013). But, the treatment, recycle and reuse systems dedicated to the laundry effluents are

vivekvardhan2@gmail.com

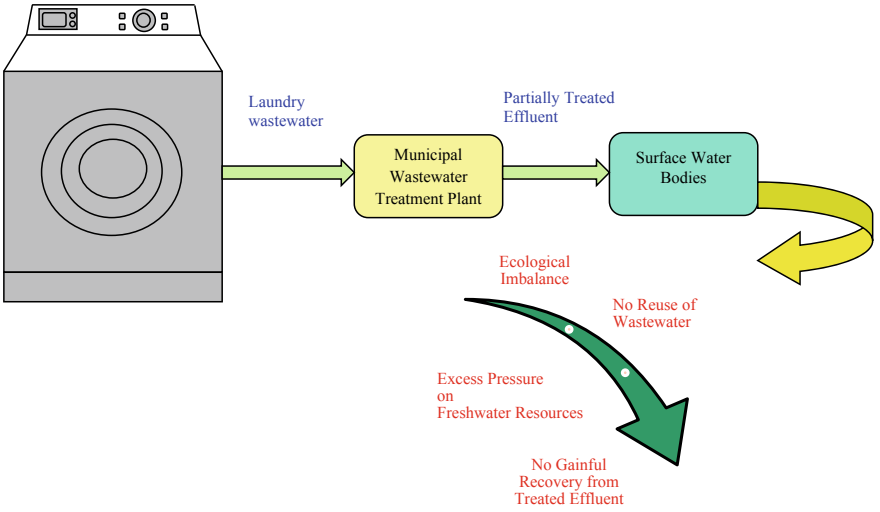

Fig. 1 Current Indian scenario of laundry wastewater

still in the nascent stage, and most often, they are discharged into municipal sewer lines without any prior treatment (Sheth et al. 2017; Durán et al. 2018). In this modern era, nearly every household and industry uses washing machines for cleaning and washing of textiles and in this process generates a huge volume of wastewater which often gets discharged into sewer pipelines despite of having diverse composition which needs special attention before treatment and disposal (Braga and Varesche 2014) Fig. 1 shows the current Indian scenario of laundry wastewater treatment.

Various treatment techniques have been used for treatment of laundry wastewater consisting of physico-chemical methods, oxidation techniques, biological (both aerobic and anaerobic) and integrated methods (Jardak et al. 2016). However, most often such treatment systems are accompanied with high operation and maintenance cost, higher carbon footprint, skilled labours and are energy intensive in nature. Thus, it is imperative to look for sustainable laundry wastewater treatment technologies that would involve low-cost infrastructure and would be easy to operate and maintain without compromising with the water quality. The decentralized wastewater treatment technologies consisting of on-site treatment facilities or sequential treatment systems could be a viable approach for dealing with the heavily loaded washing machine effluents. The natural eco-centric treatment technologies such as constructed wetlands (CWS) would be one of promising solutions for treating the laundry wastewater and the further reuse of treated effluents for high-end purposes.

2 Characterization of Laundry Wastewater and Its Environmental Implications

The laundry wastewater consists of miscellaneous composition and primarily includes surfactants, organic dyes, nitrogen, phosphorus, alkalis, bleach, fillers, suspended solids, micro-fibres, pathogens, micro-plastics and xenobiotic compounds which pose a serious threat to the environment as well as to the living organisms present in the receiving water bodies (Howard et al. 2005; Goel and Kaur 2012; Hidalgo-Ruz et al. 2012; Tripathi et al. 2013; Zavala et al. 2014; dos Santos et al. 2018; Durán et al. 2018). However, the main ingredients of laundry wastewater consist of surfactants, bleach, additives and softeners (Jakobi and Lohr 1987; Abu-Zreig et al. 2003). The quality of laundry effluents depends upon the type of laundered material and the cleaning agents used during washing (Bering et al. 2018). The use of powder detergents often results into significantly higher pH and an elevated concentration of salts like carbonates, bicarbonates, sulphates and chlorides in comparison with liquid detergents (Goel and Kaur 2012). The chemical composition of powder detergent particularly the fillers and builders used during the preparation process might be responsible for such higher pH and concentration of various salts as mentioned above. In a study conducted by Patterson (2004), it was reported that due to the higher solubility of sodium salts and cost-effectiveness, a variety of sodium salts are used in laundry detergents. Some of them include sodium sulphate, sodium tripolyphosphate and sodium carbonate. However, the powder detergents were found to contain exceptionally high content of sodium and phosphorus salts. Primarily, the usage of sodium sulphate as the fillers in laundry powders significantly contributes to the high salinity and electrical conductivity (EC) of laundry wastewater as compared to liquid detergents. The water quality analysis as reported by the author revealed that the usage of powder detergent for laundry purpose resulted into the higher total dissolved solids (TDS), pH, EC, chlorides and sulphates in the laundry effluent. The discharge of such untreated or partially treated laundry effluent negatively affects the soil structural properties as well as the plant growth.

The occurrence of linear alkylbenzene sulphonate (LAS), one of the most widely used anionic surfactants, in water bodies was found to be toxic for aquatic organisms (Spirita Sharmili et al. 2015). The acute toxicity test conducted on the Danio rerio, commonly called as the zebra fish reported that the presence of LAS in the receiving streams causes adverse impacts on the gills and hence arises the respiratory problems in such freshwater organisms. Similar findings have also been reported by Sobrino-Figueroa (2013). In their study, the author revealed the genotoxic characteristics of commercial laundry detergents and anionic surfactants. The environmental impacts occurring due to the discharge of partially treated or treated laundry wastewater have been shown in Fig. 2.

Vasanthi et al. (2013) documented modifications in the biochemical constituents of the fish species *Cirrhinus Mrigala* in the presence of commonly used household detergent known as Tide. Kidney was reported as the most affected organ during the toxicity study. The occurrence of detergents in the natural water bodies adversely

vivekvardhan2@gmail.com

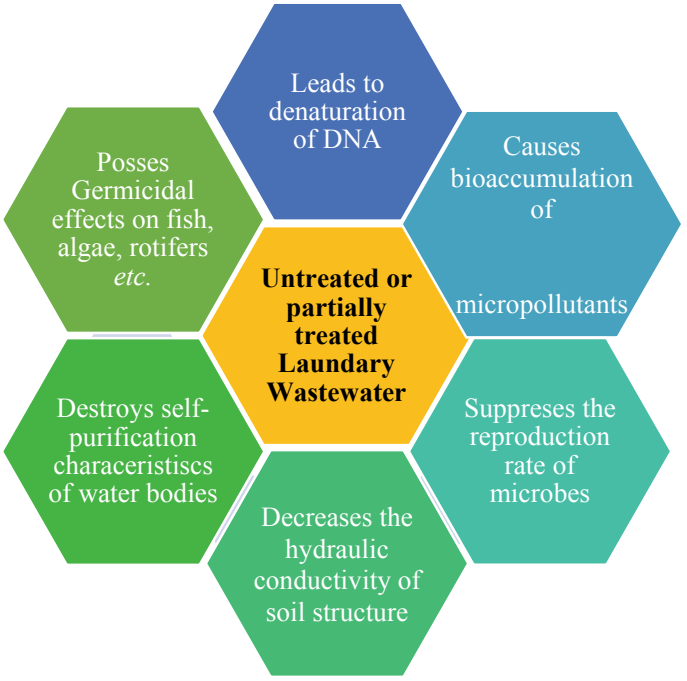

Fig. 2 Environmental implications of untreated, treated or partially treated washing machine effluent

impacts a wide range of aquatic organisms at different trophic hierarchy ranging from micro-algae to macrophytes (Sobrino-Figueroa 2018). The toxicity of the compounds is attributed to the presence of surfactants, enzymes, bleaching agents and silicates.

The toxicity of wheel detergent for mussel (*Lamellidens marginalis*) was determined using the concept of lethal dose 50 (LC 50) and was found that asphyxiation is the common phenomenon of death caused due to the gills impairment (Shingadia and Sakthivel 2003). In connection with the above-reported literature, the acute and chronic toxicity study performed by Saxena et al. (2005) for four different detergents demonstrated that the ill-effects of untreated laundry wastewater for aquatic organisms are not only limited to the gills damage, but it also has the potential to alter the hormonal secretion, reduction in the red blood cells count and surface behaviour.

It has been reported that the anionic surfactants found in laundry wastewater have the potential to bind with peptides and DNA and thus may induce changes in the folding pattern of poly-peptides chain of aquatic organisms present in the downstream, thereby affecting their metabolic functions (Ivanković and Hrenović 2010). With perspectives of human toxicity, it was found that the amphoteric character of anionic surfactants eases their accumulation in living tissues (Cserháti et al. 2002). Similar results have also been reported by Tolls et al. (1994). The fabric softeners used in detergents contain quaternary ammonium complexes as one of the major

vivekvardhan2@gmail.com

components, and it is noteworthy that these compounds are potential germicides as well as toxic even at a concentration of mg/L for different aquatic lives such as fish, mussels, rotifers and algae (Lawrence 1970; Waters 1982; Di Nica et al. 2017). The study conducted by Effendi et al. (2017) revealed the suppressing effect of detergents on the bacterial growth in the marine environment. The occurrence of linear alkylbenzene sulphonate in water bodies destroys the organoleptic characteristics and hinders the self-purification process of receiving streams (Cserháti et al. 2002).

In many developing countries, there is a common practice of discharge of laundry wastewater into the soil system which leads to various adverse effects on soil structure and its various physico-chemical characteristics. The highly saline nature of laundry wastewater owing to the substantial use of detergents decreases the hydraulic conductivity of the soil system when discharged untreated (Gross et al. 2008). It has also been found that the composition and permeability of soil also get negatively affected when irrigated with washing machines effluent containing high levels of sodium ions (Mohamed et al. 2018). The high concentration of alkaline laundry detergent increases the soil pH, thus affecting the biological functions of soil micro-organisms (Sivongxay 2005; Travis et al. 2010). Furthermore, it has also been demonstrated that the alkaline laundry wastewater causes dispersion of oil particles and ultimately increases its cation exchange capacity (Anwar 2011).

In addition to above, the occurrence of micro-plastics as well as fibres in the aquatic ecosystem shed during the washing and cleaning process has become one of the worldwide issues nowadays (Cole et al. 2011; Kang et al. 2018a, b). It was approximated that greater than 1900 fibres get discharged off from a single cloth in a washing cycle, thus representing the potential of laundry effluents to be the major source of micro-plastics pollution (Andrady 2011). The ill-effects of micro-plastics on marine flora and fauna are well documented in the various studies and currently are of a serious concern around the globe (Browne et al. 2008, 2011).

3 Constructed Wetlands: The Natural Eco-Centric Treatment Technology

The wetland system that has been designed and constructed aiming at the treatment of water and wastewater by imitating the natural processes within the controlled environment is referred as the constructed wetland (CW) (Vymazal 2011a, b). There are various advantages of CW which include low costs, easy operation and maintenance, low energy consumption, robust, highly efficient for a wide range of contaminants, sustainable, green technology and high ecological value (Carvalho et al. 2017). The few advantages of constructed wetlands have been shown in Fig. 3. Due to these unique characteristics of this eco-centric technology, appreciable progress has been observed in the application of CWs in last few years (Vymazal 2014; Wu et al. 2014; Fu et al. 2016).

vivekvardhan2@gmail.com

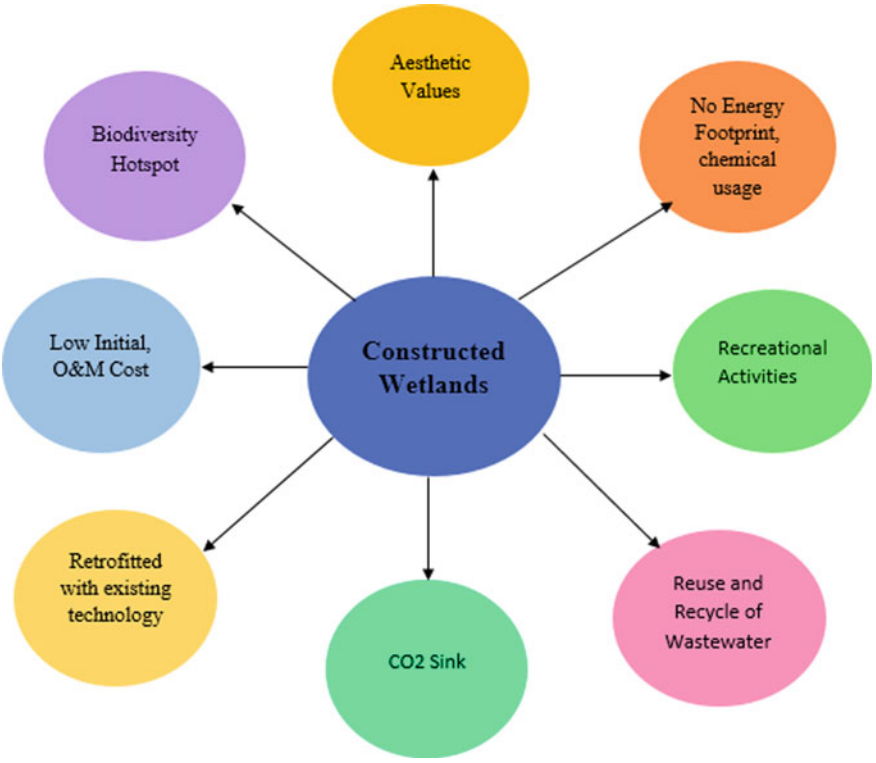

Fig. 3 Advantages of constructed wetlands owing to their application for water and wastewater treatment

The recent advancements in these engineered system have made CWs a promising alternative to the conventional treatment systems for providing access to clean water and sanitation to small communities, households, schools, colleges, etc. (Garcia et al. 2010). Furthermore, it can also be implemented as a decentralized treatment systems in the regions that are deprived of centralized public sewage treatment systems and are economically developing (Brix 1999; Vymazal 2009). Constructed wetlands are suitable for small growing communities (<200,000) and for medium size population (200,000–500,000). Globally, it has been found that constructed wetland can be successfully used for providing efficient treatment to wide varieties of wastewater ranging from urban wastewater to landfill leachates and from municipal to industrial wastewater (Doherty et al. 2015).

Constructed wetlands can be classified on various basis; however, the prime criteria for categorization are hydrology (surface flow and subsurface flow), the type of vegetation growth (emerged, submerged and floating) and flow direction (vertical and horizontal) (Vymazal 2011a, b). Constructed wetlands with surface flow are also commonly known as free surface CWs. It consists of open water surface having floating, submerged or emerged vegetation (Kadlec 2009). The various processes

vivekvardhan2@gmail.com

consisting of both physico-chemical and biological were found to be responsible for treatment of wastewater in surface flow CWs (Merz 2000).

In these systems, generally, the organic removal was carried out by microbial degradation, while suspended solids get removed due to physical processes (Kadlec et al. 2017). The satisfactory removal of nutrients particularly phosphorus can also be achieved by using surface flow CWs but at lower removal rates (Vymazal et al. 1998). Mostly, such surface flow CWs are used for providing tertiary treatment to storm water runoff and municipal sewage (Vymazal 2011a, b).

The horizontal subsurface flow constructed wetlands (HFCW) consist of an inlet where the wastewater is introduced into the system and is allowed to flow quietly approximately on a horizontal path through the porous medium under the wetland beds planted with the emergent vegetation to the outlet of the system (Vymazal 2009). During the course of wastewater movement under the beds, it comes in contact with the complex matrix of an anoxic, anaerobic and aerobic zone (Vymazal 2011a, b). The roots and rhizomes provide oxygen to the substrate material and constitute the aerobic zone (Brix 1987). In this case, the system structure is wrapped with liners in order to avoid any leakage (Vymazal and Kropfelová 2008a, b). The HF CW is very effective in elimination of organic, suspended solids, heavy metals and microbial contamination (Vymazal 2009).

Generally, the pollutant degradation is carried out under both aerobic and anaerobic conditions. However, the anaerobic processes play a prominent role in decomposition and removal of contaminants (Brix 1990; Vymazal and Kropfelová 2008a, b). The fundamental advantage of HWCWs is that they are capable of treating the diluted influents derived from combined sewage (Vymazal 2011a, b). The flow within the porous media is sustained by the gravity, and hence, no electrical power is required to maintain the desired flow.

Another important component of a wetland system is substrate which is also known as support matrix (Yang et al. 2018). The substrates are well known for their crucial role in enhancing the treating efficiency of the wetland system. Some of them include providing surfaces for bio-film development, support for the growth of macrophytes, adsorbent for contaminants elimination, etc. (Wu et al. 2015). Apart from conventional pollutants, they are also acknowledged for the exclusion of emerging pollutants like pharmaceuticals, xenobiotics and toxic metals (Dordio and Carvalho 2013; Hu et al. 2015). The traditional substrates, like different types of soil, gravel, were used as the supportive system for the vegetation growth with low or negligible functions on pollutant removal (Wen-Ling et al. 2011). Furthermore, the low removal efficiency and frequent clogging of the traditional substrate have led to the development of new matrix material like construction wastes, clay aggregates and waste tire fragments (Scholz and Xu 2002; Calheiros et al. 2008; Mateus et al. 2012; Chyan et al. 2013; Shi et al. 2017). The vegetation system is one of the unique characteristics of constructed wetlands, and it distinguishes this eco-centric technology from other traditional treatment systems like soil filters, oxidation ponds and aeration channels (Vymazal 2011a, b). These are the essential component of wetland systems owing to their numerous properties in relation to treatment processes and efficiency (Brix

vivekvardhan2@gmail.com

1997). Some of the most commonly used plant species are *Phragmites Australis, Phalaris Arundinacea, Canna Indica* and *Typha Latifolia* (Vymazal 2011a, b).

4 The Potential Role of Constructed Wetlands for Treatment of Laundry Wastewater

The ability of CWs for the treatment of wide range of wastewater wetlands with diverse composition is well evident in past studies. Apart from municipal wastewater (Coleman et al. 2001; Brix and Arias 2005), it could also be used for treating and recycling of wastewater coming from various industries like petrochemical (Yang and Hu 2005), textile (Bulc and Ojstršek 2008), tannery (Calheiros et al. 2007), mining (Gerth et al. 2006), dairy (Mantovi et al. 2003), laundry (Davison et al. 2006), distillery (Billore et al. 2001), etc. In addition to above mentioned, wetland systems are also found to be capable of treating of extensive range of pharmaceuticals (Matamoros et al. 2007; Li et al. 2014), endocrine disruptors (Chapman 2003; Wirasnita et al. 2018), nutrients (Kang et al. 2018a, b; Ndulini et al. 2018), pathogens (Gersberg et al. 1989; Karim et al. 2004) and organic micropollutants (Matamoros et al. 2008; Carranza-Diaz et al. 2014).

In spite of the proven potential, the role of CWs for treatment, recycling and reuse of laundry effluents is still unexplored. As per author's knowledge, the fate, behaviour and transformation of laundry pollutants using dedicated constructed wetlands have not been studied till yet. However, there are few studies available where the discrete removal and decomposition of few surfactants (both anionic and cationic) and xenobiotic compounds have been reported (Huang et al. 2004; Šíma and Holcová 2011; Dordio and Carvalho 2013; Vymazal 2014; Thomas et al. 2017; Pérez-López et al. 2018).

The major research gap found in the literature is the lack of appropriate technology for treatment, processing and reuse of laundry effluents. Currently, the most common practice is to discharge the laundry effluents to municipal sewer lines without any prior treatment which ultimately leads to serious environmental issues Thus, there is need of development of sustainable treatment technology for treatment of laundry wastewater aiming at gainful reuse of treated effluents

5 Innovative Approach for Treatment of Washing Machine Effluents Using Constructed Wetlands—A Way Towards Circular Economy

In light of the above-mentioned facts, an attempt has been made to investigate the treatability of laboratory-scale constructed wetland for treatment of washing machine

vivekvardhan2@gmail.com

effluents coming from an urban household. The salient advantages of the wetland system include low cost, easy operation and maintenance and no energy requirement.

In the present study, horizontal subsurface flow-based constructed wetland system entitled 'CW4Reuse' at IIT Bombay has been employed for the treatment and management of washing machine effluent. The laundry effluent is generated from a family consisting of five members which are approximately estimated to be 75 L/d. The plan area of the wetland bed was 1 m^2, whereas the depth of the bed was restricted to 0.5 m. *Canna Indica* (family: *Cannaceae*) has been used as vegetation system for effluent treatment. The physical and chemical analysis carried out in laboratory-scale reactors showed significant removal of BOD, COD, TSS, VOCS heavy metals, nitrogen, phosphorus and pathogens (proxy: MPN). The obtained water quality was found to be consistent with USEPA standards. The treated laundry effluent can be reused for gardening, vehicles cleaning, floor washing and flushing. The current work is in the progress.

6 Conclusions

The laboratory-scale constructed wetland presents a promising solution for treatment of laundry effluents. Furthermore, the effluent water quality parameters are found to be within the permissible limits as demonstrated by the regulatory standards The treated effluents can be further reused for various household activities like vehicles cleaning, gardening, toilet flushing, floor washing, etc. The current study would be helpful in dealing with the issues of water scarcity in urban and peri-urban regions and would also result into the minimization of freshwater consumption.

7 Future Scope of Work

The facets associated with the tertiary treatment of the treated effluents will be investigated in the coming future for recycle and reuse of laundry effluents for high-end applications.

Acknowledgements The authors of this research paper acknowledge RGSTC and IIT Bombay for providing the partial funding to support the ongoing research work.

Removal of Methylene Blue Dye by Using Lemon Leaf Powder as an Adsorbent

B. Sarath Babu and G. Yamini

Abstract Wastewater from textile industries is a major cause of water pollution in most developing countries. In order to address the issues of water pollution and high cost for treatment processes, the use of an inexpensive and environmentally benign adsorbent has been studied. Dyes accumulate in wastewater could affect aquatic life, human health, and overall ecosystem adversely. In this project, the lemon leaves powder adsorbent is used to remove methylene blue dye. The adsorbent has been investigated in a batch type and design expert software experiments (Box-Behnken method) to evaluate the process parameters are agitation time, adsorbent size, adsorbent dosage, initial concentration, temperature and at a pH of 5.0. The results of experiments show that the maximum percentage removal of methylene blue by using lemon leaves powder is 90.7% found to be in optimum conditions are concentration of dye is 150 mg/L, temperature of the solution is 313 K, adsorbent dosage is 11 g/L. Maximum adsorption capacity (q_{max}) of lemon leaf powder is found to be 19.19 mg/g.

Keywords Lemon leaves · Methylene blue dyes · Concentration of dye solution · Sorbent dosage

1 Introduction

Dyes are the most harmful pollutants from different processing industries—textile, paper, food, plastic, and cosmetic industries. The removal of these dyes from effluents is a major task and it creates environmental problem. Very low concentration of dyes is effected the light penetration in water bodies and photosynthesis. At the same time, some of the dyes act as carcinogenic and mutagenic in nature (Saha 2010). The conventional methods are used for removing dyes and heavy metals from aqueous solution are coagulation, flocculation, membrane separation, and adsorption, etc. (Hymavathi and Prabhakar 2018). These conventional techniques used for dyes removal are expensive, have average efficiency, and are running in sequential steps (Hasan 2008). Earlier, the adsorbent used in adsorption process is activated carbon,

vivekvardhan2@gmail.com

which is expensive. Different studies have been made on the possibility of adsorbents using mineral sorbents, activated carbon, peat, chitin, rice husk, soy meal hull, and agrowastes (Deepak et al. 2017).

Adsorption is the adhesion of molecules (ions and atoms) to the surface of a solid or liquid or accumulation of ions on the surface of adsorbent. The material that is being adsorbed or concentrated is called adsorbate and the solid which adsorbs adsorbate is called adsorbent. It is also called surface phenomenon. The adsorption operations can be batch mode and/or continuous mode. Depending on the nature of the forces between adsorbate and adsorbent, the adsorption is of two types—physisorption and chemisorptions.

In physisorption, the binding is by weak Vander Waal's forces. Hence, it is called Vander Waal's adsorption. This force is due to the fluctuating dipole moments on the interaction between adsorbate and adsorbent. In chemisorption, the forces of attraction between adsorbate and adsorbent are as strong as chemical bond.

1.1 Methylene Blue

It has been described as "the first fully synthetic drug used in medicine". It was first prepared in 1876 by German chemist Heinrich Caro. The drugs and dyes are worked in the same way of treatment purpose. This use is no longer recommended because side effects such as vomiting, headache, shortness of breath, high blood pressure, red blood cell breakdown, etc. Methylene Blue is used in redox indicator, water testing, biological staining and aquaculture.

In the current study, removal of methylene blue by lemon leaf powder is investigated through batch experimentation at different levels of initial solution pH, dye concentration, and different sizes of adsorbent.

2 Materials and Methods

2.1 Methylene Blue Preparation

An accurately weighed quantity of dye dissolved in distilled water to prepare a stock solution (1000 ppm). Solution used in the experiment for the desired concentration obtained by further dilution. Dye concentration is determined by using absorbance values measured before and after the treatment at 507 nm with UV visible double beam spectrophotometer.

vivekvardhan2@gmail.com

2.2 Lemon Leaf Powder (Adsorbent)

The lemon leaves can be used to treat nerve disorders like insomnia, nervousness, and palpitation. Lemon leaf will serve as a good and better alternative to Valium and other synthetic sedatives *which by the way have side effects. To get maximum result from lemon leaf, take the preparation* daily for at least one month. The lemon leaf is also used for de-worming. The lemon leaves can be blanched and used to infuse teas, wrap seafood or meat and roasted, steamed or grilled.

2.3 Batch Adsorption Process

Adsorption experiments are carried out in a 500 mL of conical flask containing known amount of adsorbent with dye solution. The flask is then shaken using mechanical rotating shaker at 120 rpm. After that the solution is filtered and the residual dye concentration is measured at λ max using UV Visible spectrophotometer.

Batch adsorption studies are performed to study the effects of adsorbent size, contact time, pH, concentration, temperature, and adsorbent dosage. The effects of concentration, temperature, and adsorbent dosage are studied by using design method. The adsorbent (lemon leaf powder) is weighted by using weight balance. The adsorbate (methylene blue) solutions are prepared and maintained pH by using pH meter. After the weighting of adsorbent and preparation of adsorbate solution in conical flask, put that conical flask in incubator shaker for agitation purpose and to maintain parameters such as time, temperature, and rpm. After the collection, the sample is filtered using filter paper. The resulted solution is analyzed by using UV visible double beam spectrophotometer.

The percentage removal and the amount of dye adsorbed are calculated as follows (Hymavathi and Prabhakar 2017):

$$\text{Percentage removal of dye} = ((C_o - C_f)/C_o) \times 100$$

where, C_o is initial concentration (mg/L) and C_f is final dye concentration (mg/L)
Amount of dye adsorbed $= (C_o - C_f)\ V/W$, $V =$ Volume of dye solution (mL),

$$W = \text{Amount of adsorbent(g)}$$

3 Design of Experiments

Factorial experimental design was used to optimize the preparation conditions and dye removal efficiency. RSM designs allow us to estimate interaction and even

vivekvardhan2@gmail.com

Table 1 Levels of different process variables for removal of methylene blue onto lemon leaf powder

Factors	Level of Box-Behnken		
	Low (−1)	Middle (0)	High (+1)
Initial concentration (mg/L) (*A*)	50	100	150
Temperature (K) (*B*)	293	303	313
Adsorbent dosage (g/L) (*C*)	2	11	20

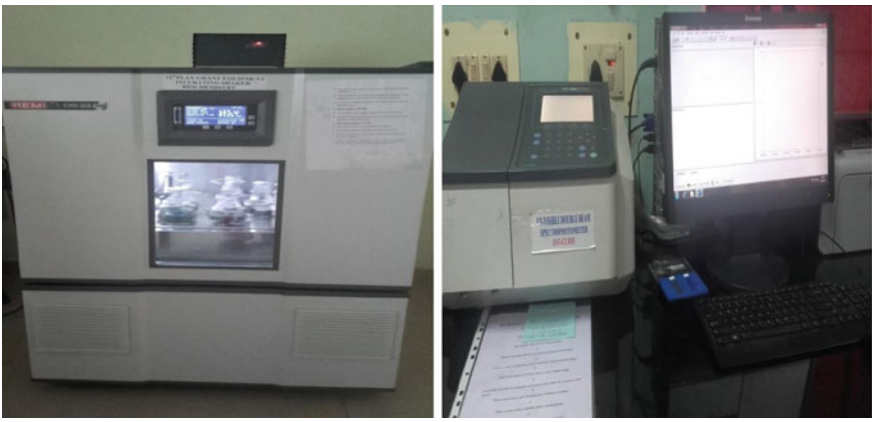
quadratic effects and hence give us the idea of the (local) shape of the response surface under investigation.

The parameters (time, adsorbent size, agitation, and pH) are done by single-step process to get optimum values. These values are attached to each run of design experiment.

Box-Behnken design is used to optimize the number of experiments with maximum efficiency for an RSM problem involving three factors—initial concentration (*A*), temperature (*B*), and adsorbent dosage (*C*) and three levels (high, middle, and low) as given in Table 1. The levels were fixed based on the preliminary experiment trials and also the available literature. The experimental parts are as shown in Figs. 1 and 2.

Fig. 1 Experimental parts weighing balance and pH meter

vivekvardhan2@gmail.com



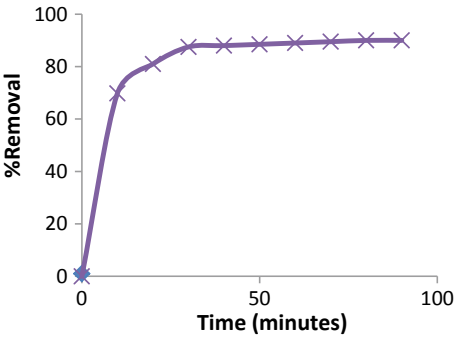


Fig. 2 Incubator shaker and UV visible double beam spectrophotometer

4 Results and Discussion

4.1 Effect of Agitation Time

The solution pH is adjusted with 0.1 N NaOH and 0.1 N H_2SO_4 in each flask containing 50 mL solution with 50 mg/L of Methylene blue dye. A required amount of 74 μm particle size of lemon leaves powder is added to the contents of the flasks and the flasks are agitated at constant speed and at room temperature, on an orbital shaker. Flasks are withdrawn periodically; the content filtered and final concentration of dye is estimated by using Eq. 1. The effect of agitation time is shown in Fig. 3.

Fig. 3 Effect of agitation time

vivekvardhan2@gmail.com

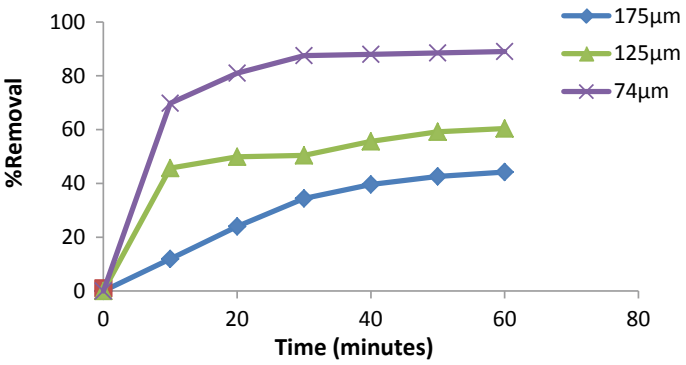

Fig. 4 Effect of adsorbent size

4.2 Effect of Adsorbent Sizes

A 50 mL of the stock solution of 50 ppm taken and with various sizes of adsorbents (175,125 and 74 µm) of adsorbent is taken into 250 mL conical flask, maintaining pH of 5.0, at room temperature and kept for agitation at 120 rpm using an orbital shaker. At the end, the equilibrium time of 80 min samples is withdrawn and filtered using whatman filter paper and tested for its optical density using UV spectrophotometer. The effect of adsorbent sizes is shown in Fig. 4.

4.3 Effect of PH

In order to find the effect of pH, the experiments conducted at various pH values from 2 to 11 in acidic and alkaline conditions, respectively. The pH value is adjusted using 0.1 N NaOH and 0.1 N H_2SO_4. For this work, we have taken 50 mL of 50 ppm of methyl blue dye and 1 g of adsorbent, at room temperature and the sample withdrawn from the shaker at the time of 80 min. The collected sample is tested for its optical densities using the UV visible spectrophotometer. The effect of pH on percentage removal of MB by LLP is shown in Fig. 5.

The experimental and model-predicted responses are given the model (Box-Behnken model) in Table 1. Levels of three process variables for methylene blue removal using lemon leaves are shown in Table 2. The process variables—initial dye concentration, adsorbent dosage, and temperature are studied experimentally, and the complete set of data is fitted to a quadratic model in Eq. 1. Figure 6 % Removal—Predicted versus actual model normal plots for residuals.

$$R1 = 85.80 + 4.43 * A + 1.17 * B - 2.13 * C + 0.29 * AB - 1.70 * AC - 0.36 * BC - 0.25 * A^2 - 0.89 * B^2 - 0.3 * C^2 \quad (1)$$

The R^2 adjusted is 0.996 and R^2 predicted is 0.977; the difference of regression coefficient is <0.2 is well the acceptable norm and the signal. Optimum levels of the three variables studied in the experiment and the model have been presented in Table 3.

There is a good correspondence between the experimental and model-predicted values of the optimum operating conditions.

A comparison of percentage removal of methylene blue—actual versus model-predicted and normal plots for residuals is shown Fig. 6. The residuals, the difference

vivekvardhan2@gmail.com

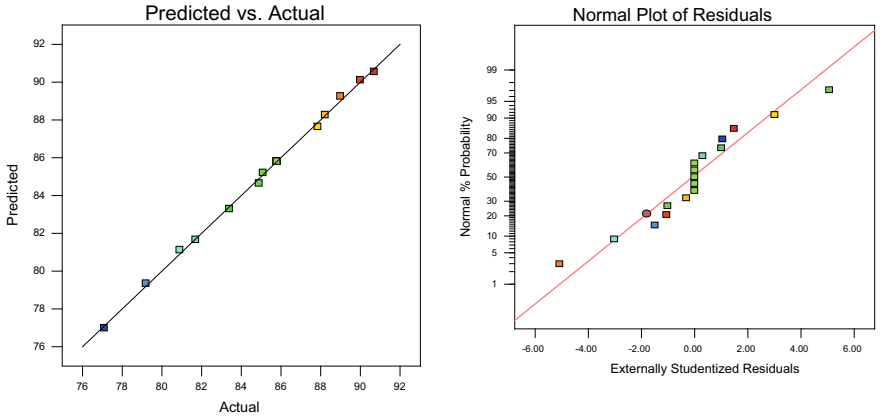

Fig. 6 % Removal—predicted versus actual model normal plots for residuals

Table 3 Optimum levels—methylene blue on to lemon leaves powder

Name of the variable	% Removal of methylene blue	
	Experimental	Optimum values
Dye conc. (Co) mg/L	150	149.63
Sorbent dosage (w), g/L	11	9.6
Temperature (T), K	313	307.5
% Removal	90.7	90.55

between the experimental and observed responses and the predicted responses are examined using the normal probability plots of the residuals. If the model is adequate, the points on the normal probability plots of the residuals should form a straight line.

5 Conclusion

Effectiveness of *Lemon leaves to remove Methylene blue* dyes is thoroughly investigated in the present work and the outcome is promising. Operating parameters, such as concentration of dye solution, initial solution pH, sorbent dosage, and temperature are optimized are shown below.

Optimized conditions	Time (min)	pH	% Removal	q_{max} (mg/g)
Concentration of dye = 150 mg/L	80	5	90.7	19.19
Temperature = 313 K				
Adsorbent dosage = 11 g/L				

vivekvardhan2@gmail.com

Lemon leaves are a good, low-cost, and easily available sorbent for the treatment of methylene blue.

Development of a Low-Cost Column Type Filter Based on Agricultural Waste for Removal of Fluoride from Water

C. M. Vivek Vardhan and M. Srimurali

Abstract Population explosion and subsequent increase in demand for food have resulted in adoption of modern methods of agriculture, thereby generating huge quantities of agricultural wastes. India being an agricultural nation generates large amount of Rice Husk warranting proper utilization before disposal. Concomitantly, fluorosis caused due to consumption of excessive fluoride is posing a serious threat to mankind. Therefore, in this study, an attempt has been made to develop a low-cost column type filter based on Rice Husk for removal of fluoride from water. Lanthanum was used to enhance the fluoride removal capabilities of Rice Husk Ash. Continuous-flow column studies were conducted and investigated for its potential in removing fluoride from water. It was observed that 37.8 L of water of initial fluoride concentration 10 mg/L could be brought down to permissible limits in 1890 min and can be safely consumed. The developed low-cost filter utilizes an agricultural waste and protects people from fluorosis especially of rural and isolated communities.

Keywords Adsorption · Defluoridation · Water · Low-cost · Lanthanum

1 Introduction

Agricultural wastes are generated in huge quantities in agriculture-based nations such as India. It is estimated that the annual generation of Rice Husk in India is about 24 million tons (Pandey et al. 2012). Though a minor portion of it finds application in production of silica, cement and refractory bricks, majority of it is dumped and remains non-utilized. Therefore, an effective way of utilizing the same is required. On the other hand, contamination of groundwater with fluoride and the resulting fluorosis is a major threat faced by mankind. Fluoride has dual impacts on living organisms. In lower concentrations, fluoride is very beneficial as it assists in formation of bones

vivekvardhan2@gmail.com

and prevents dental decay, whereas, in higher concentrations, it causes serious health issues such as skeletal fluorosis, dental fluorosis, mental derangements, dwarfishness, etc. Therefore, it is imperative that fluoride has to be removed from water before consumption. The World Health Organization (WHO) has stipulated a maximum permissible limit of 1.5 mg/L of fluoride in drinking water. Various technologies are available for defluoridation of water and are partially successful to various extents. But, as fluorosis is not yet completely eradicated, the focus has recently shifted to use of rare earth materials as adsorbents for defluoridation with a fairly reasonable degree of success (Vivek Vardhan and Srimurali 2015, 2016, 2018). However, research is still deficient on achieving a dual advantage of simultaneously utilizing waste and removing fluoride from water. Therefore, in this study, an attempt was made to employ Rice Husk Ash impregnated with Lanthanum for removal of fluoride from water in continuous-flow mode and thereby develop a filter using endemically available wastes. Thus, the main objectives of this work are to impregnate Lanthanum on to Rice Husk Ash and to test it for fluoride removal at varying rates of flow rates, initial fluoride concentrations and bed depths.

2 Materials and Methods

2.1 Chemicals

All reagents used in the present investigation were procured from E. Merck Ltd, India and were of analytical reagent grade. Sodium fluoride of 221 mg was dissolved in distilled water and made up to 1 L in a volumetric flask to prepare a stock fluoride solution of 100 mg/L. Stock solution was diluted appropriately to obtain fluoride solutions of required working concentrations.

2.2 Adsorbent

Rice Husk Ash (RHA) was procured from a local rice mill and was sieved to a mean size of 475 μm.

2.3 Adsorbent Preparation

Lanthanum carbonate of varying weights was mixed with 0.05L of distilled water, and 0.1 N HCl was added to it dropwise until Lanthanum Carbonate got dissolved completely. To this solution, 0.1 N NaOH was added under constant stirring until precipitates were visually observed. RHA of mean size 475 μm and 20 ± 0.2 g weight

vivekvardhan2@gmail.com

was added to this mixture. This mixture was mixed for 6 h in a magnetic stirrer. Subsequently, it was decanted, dried and heated at 300 °C for 4 h in a muffle furnace. It was thoroughly washed with distilled water and dried. The obtained material is Lanthanum-Impregnated Rice Husk Ash (LIRHA).

2.4 Continuous-Flow Experiments

Fixed bed down-flow column studies were performed using a Pyrex glass column of inner diameter 2.54 cm and depth 1 m. Cotton was placed at the base to support aggregates. The column was filled with aggregate of mean size 600 μm to a depth of 30 ± 1 cm at the base. On its top, LIRHA of varying depths of 20 cm, 30 cm and 40 cm was filled. Aggregate of mean size 600 μm and of varying depths of 30 ± 1 cm, 40 ± 1 cm and 50 ± 1 cm was filled on the adsorbent to ensure an equally distributed flow of tap water spiked fluoride solution onto the sorbent bed. The set-up of the column is depicted in Fig. 1. Aqueous fluoride solutions of various concentrations of 5 ± 0.1 mg/L, 10 ± 0.1 mg/L and 15 ± 0.1 mg/L were passed

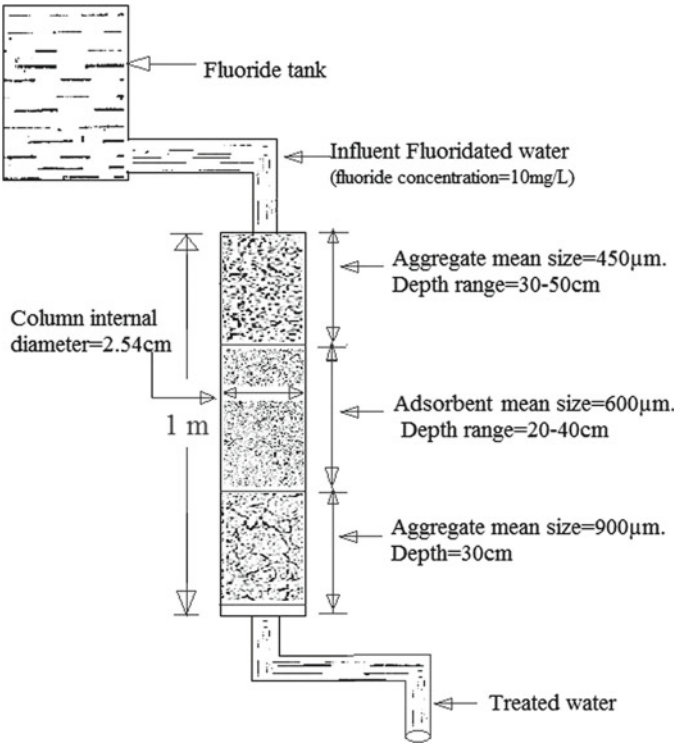

Fig. 1 Column set-up block diagram

vivekvardhan2@gmail.com

through it. Flow rates of the solution were varied at 10 ± 0.2 ml/min, 15 ± 0.2 ml/min and 20 ± 0.2 ml/min. At regular intervals of time, effluent samples were collected and analysed for residual fluoride concentration, until the effluent concentration of fluoride equalled the influent concentration.

2.5 Analysis of Continuous Sorption Experiments

Analysis of breakthrough curves gives an insight into the performance of fixed-bed column. The time taken for breakthrough and time taken for complete exhaustion of column gives characteristic information for determining the performance and dynamics of adsorption of a column (Chen et al. 2013). Breakthrough of the column is considered to have occurred when the effluent concentration (C_t) has reached about 0.1% of influent concentration (C_o), and exhaustion of column is considered to have occurred when effluent concentration has reached about 95% of influent concentration (Kundu and Gupta 2007). However, from fluoride removal point of view, 15% fluoride removal (i.e. up to effluent concentration of 1.5 mgF^-/L) is considered for analysis. A breakthrough curve is obtained by plotting values of (C_t/C_o) versus (t) (Han et al. 2009). Effective effluent volume (V_{eff}) can be calculated from Eq. (1) (Ramavandi et al. 2014).

$$V_{\text{eff}} = Q \cdot t_{\text{total}} \tag{1}$$

where Q is volumetric flow rate (ml/min), and t_{total} is flow time (min). The value of total mass of fluoride adsorbed (q_{total}) (mg) can be obtained from the area under the breakthrough curve, found by integrating the adsorbed concentration (C_{ad}, mg/L), within the functioning time limits (Ramavandi et al. 2014) (Eq. 2).

$$q_{\text{total}} = \frac{Q}{1000} \int_{t=0}^{t=\text{total}} C_{\text{ad}} \mathrm{d}t \tag{2}$$

where $C_{\text{ad}} = C_o - C_t$.

The maximum fluoride adsorption capacity (q_{eq}) can be calculated as follows, as given in Eq. (3)

$$q_{\text{eq}} = \frac{q_{\text{total}}}{m} \tag{3}$$

where m is dry weight of adsorbent used in column (g).

Fluoride was analysed using SPADNS method (APHA 2005), using a spectrophotometer, Evolution 201.

vivekvardhan2@gmail.com

3 Results and Discussion

3.1 Continuous-Flow Column Studies

To evaluate the practical applicability of LIRHA for defluoridation, in continuous-flow mode, fluoride-rich water was passed through columns consisting of varying depths, at different flow rates and different influent fluoride concentrations.

3.1.1 Effect of Bed Depth

LIRHA bed depths were varied, and the corresponding variations in related parameters such as time for exhaustion of column and effective volume of water treated were evaluated and presented in Table 1. Increase in bed depth resulted in increase in the effective volume of water treated and took more time for the column to get exhausted. Breakthrough curves were drawn between t versus (C_t/C_o) for various bed depths, and the plots are presented in Fig. 2. It is clear from this figure that with

Table 1 Values of column parameters obtained at different bed depths, flow rates and initial fluoride concentrations for defluoridation using LIRHA

Q (ml/min)	(C_o) (mg/L)	Z (cm)	t_{total} (=Total flow time in min)	V_{eff} (ml)	q_{total} (mg)	q_o (mg/g)
15	10	20	2790	41,850	273.1	4.149
15	10	30	5130	76,950	468	4.739
15	10	40	6930	103,950	770.3	5.85
10	10	30	12,780	127,800	783	7.928
20	10	30	1890	37,800	270.1	2.735
15	5	30	11,700	175,500	484.3	4.904
15	15	30	2790	41,850	343.1	3.475

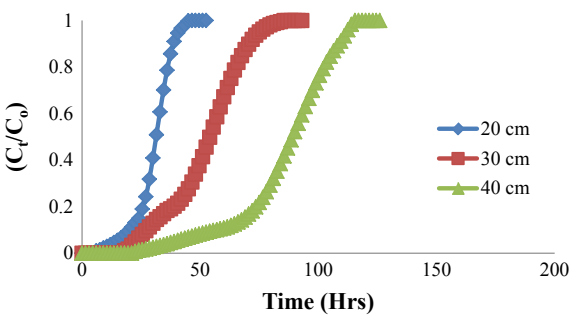

Fig. 2 Breakthrough curves for the effect of bed depth on defluoridation of water using LIRHA

vivekvardhan2@gmail.com

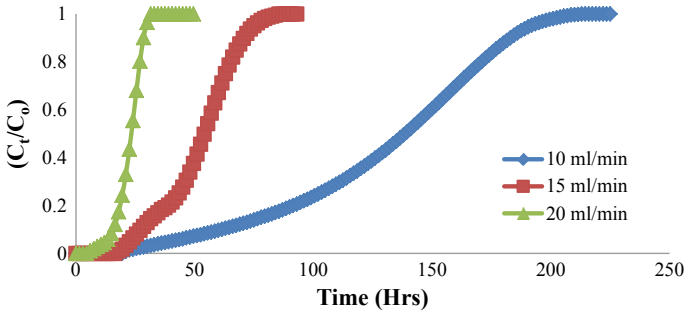

Fig. 3 Breakthrough curves for the effect of flow rate on defluoridation of water using LIRHA

increasing bed depth, the slope of column gradually decreases, marking a broadening of the mass transfer zone, resulting in increased fluoride sorption.

3.1.2 Effect of Flow Rate

Rate of flow of influent fluoride solution into the column was varied, and the corresponding variation of dependent parameters is presented in Table 1. It can be observed from this table that with increase in flow rate, the column gets exhausted rapidly because it gets saturated rapidly. Figure 3 shows the breakthrough curve drawn between t versus (C_t/C_o) for varying flow rates. From this figure, it can be seen that, with increasing flow rate, the breakthrough curves become steeper, and the uptake of fluoride too decreases. This could be due to adsorption taking place, only through film diffusion, because of lesser residence time (Ye et al. 2018).

3.1.3 Effect of Initial Fluoride Concentration

Concentration of fluoride in the influent aqueous solution was varied, and its impact on defluoridation in continuous mode was studied. The influence of variation of initial fluoride concentration on the effective volume treated, and uptake of fluoride and sorption capacities are presented in Table 1. From the table, it can be observed that, with increase in influent fluoride concentration, the adsorption capacity of column too increased gradually. Higher fluoride concentration effectively overcomes mass transfer resistance and therefore transfers fluoride effectively on to the surface of LIRHA. Breakthrough curves were plotted between t versus (C_t/C_o) for different influent fluoride concentrations and are presented in Fig. 4. From this figure, it can be seen that with increase in initial fluoride concentration, the gradient of the breakthrough curve increases, resulting in decreased mass transfer zone. This indicates that intraparticle diffusion controls the adsorption process (Manna et al. 2018).

vivekvardhan2@gmail.com

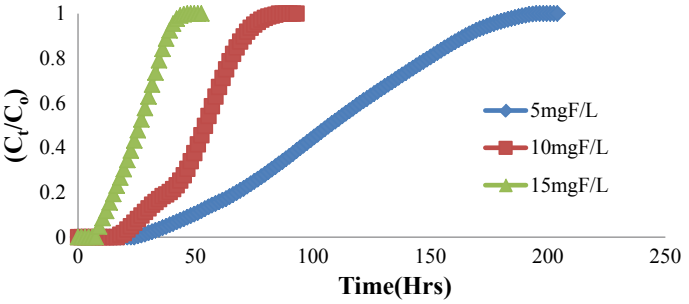

Fig. 4 Breakthrough curves for the effect of initial fluoride concentration on defluoridation of water using LIRHA

4 Concluding Remarks

The aim of this work is to simultaneously utilize the agricultural waste Rice Husk Ash and to remove fluoride from water.

Continuous-flow column studies demonstrated that LIRHA is capable of removing fluoride from water to less than the permissible limits.

Thus, the agricultural waste, Rice Husk can be effectively utilized for removal of fluoride from water, especially in rural and isolated communities.

Oxidative Photocatalytic Degradation of Methylene Blue in Wastewater

Ajit Kumar Tallapaka, Jyothi Thati and Sailu Chintha

Abstract Aqueous methylene blue (MB) dye solution was subjected to photocatalytic degradation by ultraviolet (UV) irradiation with titanium dioxide (TiO_2) catalyst. Batch experimental studies were conducted with 250 ml of different methylene blue concentrations of 20, 30, and 40 mg/l, with catalyst loadings of 25, 50, and 100 mg, at different pH of 3, 7, and 9 to find the degradation of dye. A maximum degradation of 86% methylene blue dye was achieved for concentration 20 mg/l using 100 mg TiO_2 catalyst irradiated for 190 min in presence of UV light of wavelength 254 nm.

Keywords Photocatalysis · Titanium dioxide · Advanced oxidation process · Methylene blue · International society of waste management · Air and water

1 Introduction

In this modern society, any kind of wastewater stream from industrial processes or households contains organic chemicals because of its vast usage, disposal of the same without proper treatment results in exposure to humans and environment (Belgiorno et al. 2007). In textile manufacturing and dyeing industries usage of water and dyes are very high among the quantity 50% of the dyes are send out to wastewater which causes the environment pollution (Lin et al. 2012). Dyes have global usage in textiles, leather, plastics, paper, food and cosmetic industry to color their products, which could be characterized by strong odor, high chemical oxygen demand (COD) and broad range of pH (Mohabansi et al. 2011). So, the treatment of wastewater generated in textile industry has got great attention because of its considerable impact on creating environment pollution. Textile processing unit effluent is usually released to municipal sewage treatment plants or directly into waterways (Cooper 1993). The conventional techniques currently used can only transplant the non-bio-degradable mass into sludge, which causes other types of pollution which need to be treated further (Stock et al. 2000). In these circumstances, traditional dye wastewater treatment processes have become very demanding for existing plants. As a consequence

vivekvardhan2@gmail.com

of these problems, advanced oxidation process (AOP) contemplated as an implied technology for dyes' wastewater treatment. The concept of AOP was proposed in the 1980s since then different advanced oxidation technologies have been studied and applied for treatment of industrial wastewater and also for municipal wastewater (Deng and Zhao 2015). Among the available technologies, heterogeneous photocatalysis using an irradiated dissipation of titanium dioxide (TiO_2) is considered as an alternate process for removing organic compounds from wastewater (Chladova et al. 2011).

Oxidative photocatalysis is one of the AOP and an alternative method for collapsing the organic pollutants in air and water. In this process, it includes light, photocatalyst, and an oxidizing agent to achieve the desired chemical reaction (Hassaan and El Nemr 2017). Titanium dioxide is found to be more productive for photocatalytic degradation of organic pollutants due to faster electron transfer to molecular oxygen. TiO_2 is a selective photocatalyst for the environmental engineering application; due to its capacity to provide total mineralization, nontoxic, low-cost, reusable, photostable, alkali, resistance to acid and organic solvents (Ameta et al. 2013; Gültekin and Ince 2007). For TiO_2 preparation, there are many procedures available, often used methods are sol-gel method, hydrothermal processing and gas-phase reaction.

In sol-gel method, high purity materials are used and, when it is transformed into liquid state by mixing with a solvent, it has lot of benefits such as uniformity of products, low cost and easy control of chemical stoichiometry and microstructure (Mohabansi et al. 2011).

Various classes and types of dyes are used in textile industry; among them, Methylene Blue, which is a cationic dye was selected for degradation studies in this work. Because, methylene blue is considered as a toxic dye and it can bring up very harmful influences on the living things due to inhalation. Problems include breathing complications, vomiting, diarrhea, and nausea (Lin et al. 2012). The structural formula of methylene blue is given in Fig. 1 (Mohabansi et al. 2011) (Table 1).

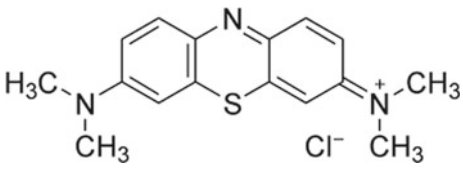

Fig. 1 Methylene blue structure

Table 1 Methylene blue properties (Mohabansi et al. 2011; Deng and Zhao 2015)

Properties of Methylene Blue	
Chemical formula	$C_{16}H_{1s}N_3SC1$
Chemical name	3.7-bis(Dimethylamino)-phenothiazin-5-ium chloride
Molecular weight	319.85
Melting point	100–110 °C
Density	1.1 g/cm^3

vivekvardhan2@gmail.com

This current research work mainly aims on the effective removal of MB dye from wastewater using oxidation photocatalysis using titanium dioxide as catalyst.

2 Experimental Work

2.1 Materials

Methylene blue (MB) analytical grade purchased from Fisher scientific, titanium dioxide (TiO_2), and distilled water.

2.2 Method

Experiments were conducted in a borosilicate glass batch reactor of capacity 250 ml placed in a special UV cabinet equipped with UV light emitting 254 nm wavelength. The extent of degradation of MB was analyzed by UV spectrophotometer (Schimadzu model UV-1800). For obtaining calibration data, the MB dye solution concentrations were calibrated initially at 664 nm wavelength corresponding to the maximum absorbance noticed. In the present work, TiO_2 was considered as a photocatalyst for the deterioration of methylene blue dye in wastewater (Lin et al. 2012). Parameters studied were weight of catalyst, concentration of dye, and pH irradiated for 190 min.

- Weight of (TiO_2) nanocatalyst (25, 50, 100 mg).
- Methylene blue concentration of (20, 30, 40 mg/l).
- pH range of (3.0, 7.0, 9.0).

The residual amount of MB was determined by the use of a UV spectrophotometer (Shimadzu, model UV-1800). According to the characteristic absorbance peaks recorded with spectrophotometer, MB concentration was determined at 664 nm by the UV detector (Figs. 2 and 3).

$$\% \text{ degradation} = \frac{C_{MB0} - C_{MB}}{C_{MB0}} \times 100$$

2.3 Preparation of Catalyst

Titanium dioxide (TiO_2) nanocatalyst was produced by the ultrasonic-assisted sol-gel method using titanium (IV) iso-propoxide (98%) as precursor. Briefly, titanium

vivekvardhan2@gmail.com

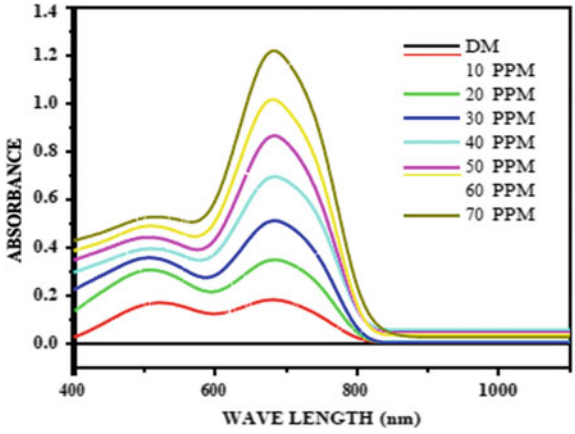

Fig. 2 Maximum absorbance of MB dye solution for different concentrations at 664 nm

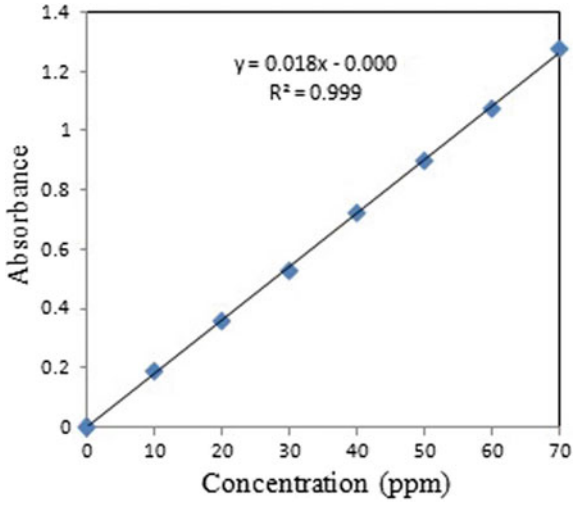

Fig. 3 Calibration curve for MB dye at 664 nm

iso-propoxide (TI) is dissolved in 2-Propanol to yield TI solution. A second solution is then prepared by mixing 2-Propanol with water, and this solution was slowly adding up to the TI solution to form the TiO_2 gel. The gel was changed into a yellow block crystal after drying at 105 °C for 5 h in oven. The resulting powder was then subjected to calcination at a temperature of 500 °C for 6 h (Karami 2010).

2.4 Characterization Studies: X-Ray Diffraction (XRD)

The XRD pattern of nanocatalyst (TiO_2) in Fig. 4 shows the presence of three main peaks at $2\theta = 25.3°$ (101), 26.1°, and 37.0°, which is an attributive indication of an

vivekvardhan2@gmail.com

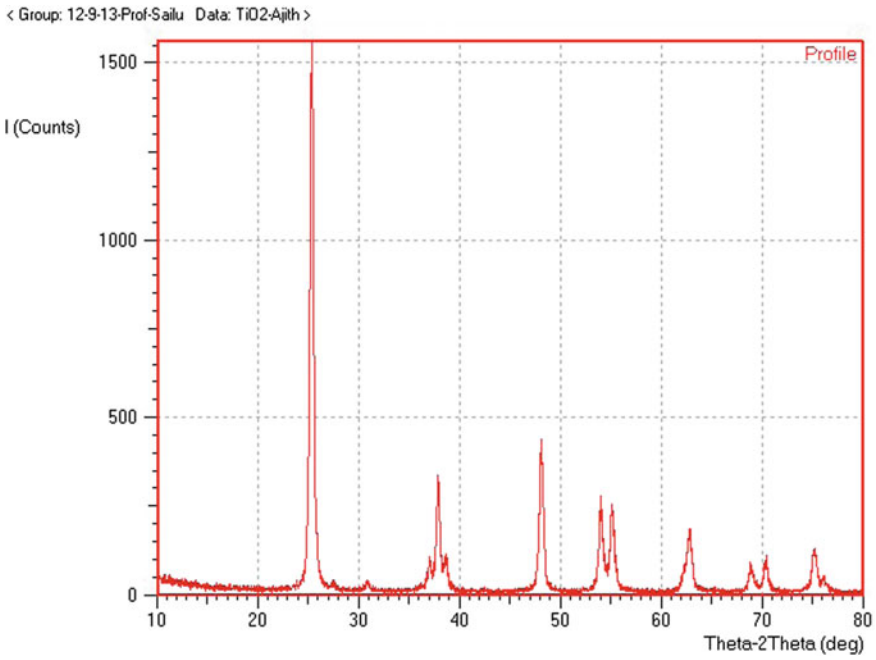

Fig. 4 XRD photograph of (TiO_2) catalyst

anatase TiO_2. Contrarily, minor diffraction peaks noticeable at $2\theta = 27.5°$ (110) and 31.5°, which correlates to rutile TiO_2. The outcome is in correspondence with its mineral configuration bearing anatase to rutile ratio of 83:17 (Karami 2010).

2.5 Analysis by Scanning Electron Microscope (SEM)

Scanning electron microscope is used for the characterization of the morphology of surface and particle size. SEM analysis results the particle size as 156–382 nm (Fig. 5).

Particle size, zeta potential were analyzed by nano particle analyzer (Horiba model SZ-100 series); From the analysis the catalyst (TiO_2) mean particle size (388.8 nm) and Zeta potential (−39.6 mV) were noted (Fig. 6).

vivekvardhan2@gmail.com

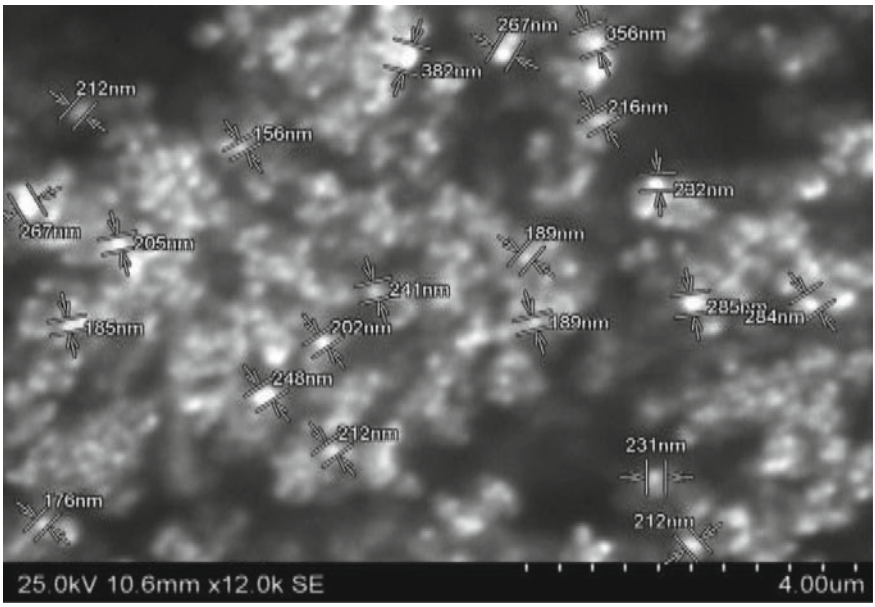

Fig. 5 SEM micrograph of (TiO_2) nanocatalyst

3 Results and Discussion

3.1 Effect of MB Dye Concentrations and TiO_2 Catalyst Loading

The influence of catalyst is shown in Figs. 7 and 8 and it is clear that for nano sized catalyst (TiO_2) prepared has substantially removed MB dye with in considerable time of 190 min. A considerable % of removal was observed with 100 mg catalyst for 20 mg/l of MB solution and to the extent of 86%. Using TiO_2 as photocatalyst, 20 ppm methylene blue in water was irradiated for 10 h and achieved 57.06–84.14% of degradation (Ameta et al. 2013). This is because of the photocatalytic activity of TiO_2 catalyst apparently depends on numerous factors, such as the pore size and number, surface area, the amount of hydroxyl content in TiO_2 catalyst, and so on (Yu et al. 2000).

3.2 Effect of PH

An important parameter in the photocatalytic reaction is the pH of solution. The effect of pH on the degradation of MB was investigated over a pH range of (3.0, 7.0,

vivekvardhan2@gmail.com

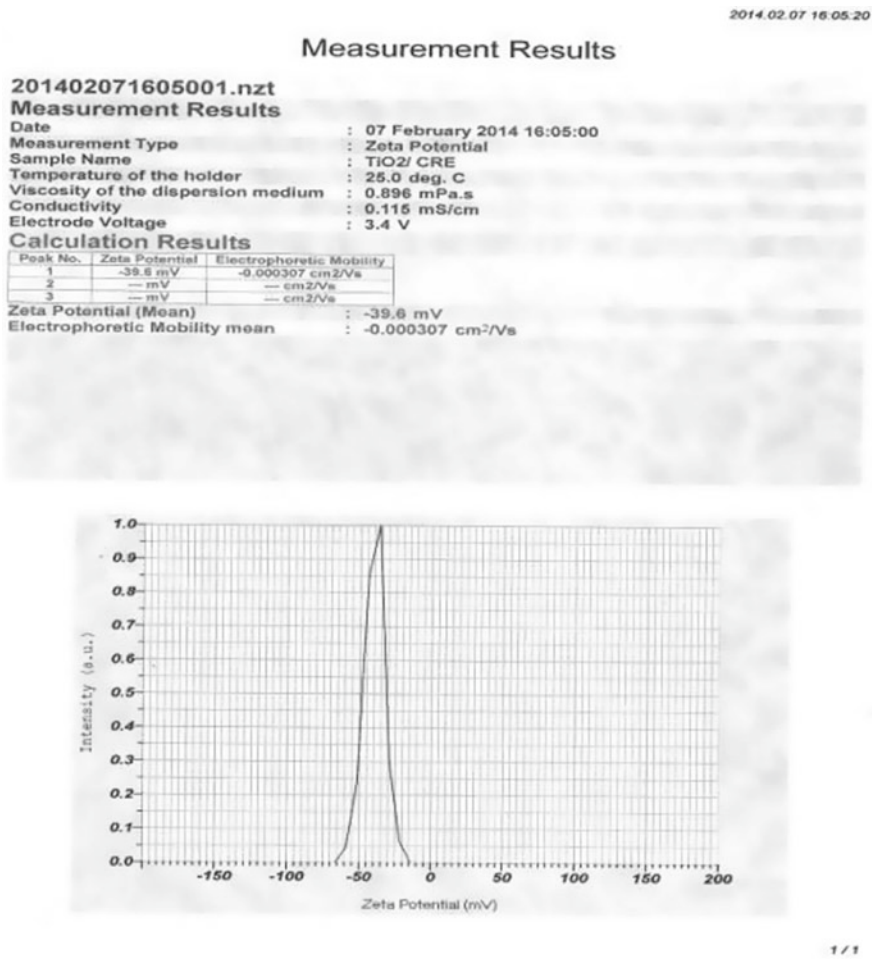

Fig. 6 TiO_2 catalyst nanoparticles analysis

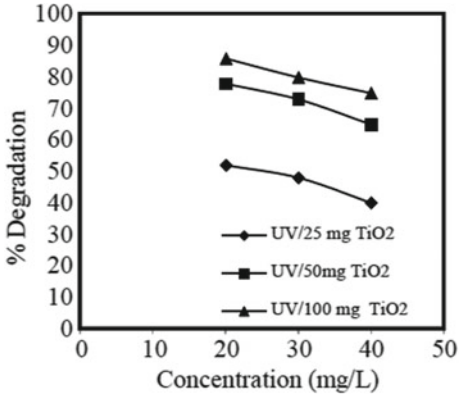

Fig. 8 Methylene blue degradation with concentration at different catalyst loadings

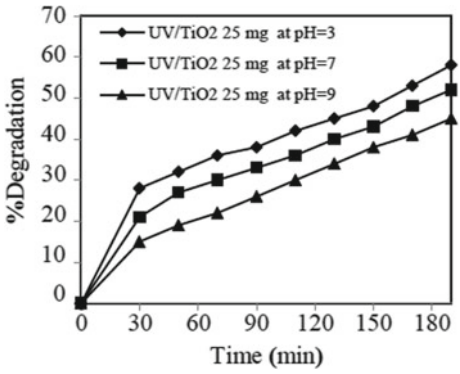

Fig. 9 Methylene blue degradation with time at different pH levels

9.0) using 25 mg/250 ml of TiO_2 in 190 min irradiation. With increasing pH, the degradation of methylene blue has decreased (Fig. 9). Based on nature of the organic pollutants, an increase of the pH will have a positive or negative effect on their degradation rate and consequently the mineralization rate of the solution. The pH is a complicated parameter since it is correlated to the ionization state of the surface and has a significant influence on the removal of organic pollutants (Mohabansi et al. 2011; Aziz et al. 2019).

4 Conclusion

The deterioration of methylene blue dye solution was studied by oxidative photocatalysis. The degradation was strongly influenced by the factors such as TiO_2 catalyst loading, initial dye concentration, and pH of the solution. The maximum degradation (86%) of dye solution (20 mg/L of initial dye concentration) was achieved using

vivekvardhan2@gmail.com

100 mg of TiO_2 in 190 min of irradiation under UV light. The deterioration of methylene blue dye is efficient in acidic solution, and it was more at pH of 3. This method is promising to use for the removal of methylene blue dye present in wastewater.

Bioremediation of Textile Azo Dyes by Marine Streptomyces

Bhoodevi Chakravarthi, Vani Mathakala and Uma Maheswari Devi Palempalli

Abstract The present study was carried out to explore the efficiency of marine *Streptomyces sviceus* in the bioremediation of reactive textile azo dyes by considering Congo red-21 as model dye. *Streptomyces sviceus* shows optimum decolourization of Congo red-21 in nutrient glucose broth at 96-h duration under static conditions. Toxicity of the degraded metabolites of Congo red-21 was assessed through phytotoxicity, genotoxicity, acute toxicity and cytotoxicity assays. The *Allium cepa* roots treated with Congo red-21 dye exhibited chromosomal aberrations like polyploidy interphase nucleus and vagrant chromosomes. In contrast, no significant changes were noticed with degraded sample of Congo red-21. These results demonstrate the non-toxic nature of the degraded sample of Congo red-21 on the growth of higher plants and further confirm the bioremediation potential of marine *Streptomyces sviceus*.

Keywords Bioremediation · Mitotic index · Acute toxicity · Streptomyces · MTT assay

1 Introduction

Textile industries predominantly employ chemical dyes compared to natural dyes because of their wide spectrum of colours and cost economy in production due to synthesis. Among the different textile dyes, azo dyes represent 70% and are widely used for dyeing different types of textile fabric material (Chen Cheunbarn et al. 2008). Azo dyes are integral part of textile industry, and they damage ecosystem through textile effluents during dyeing process. The release of azo dyes into the natural environment results into the conversion of azo group to toxic aromatic amines which are highly carcinogenic and mutagenic to humans (Jadhav et al. 2007; Lade et al. 2015). Further, the release of textile dye effluent into water stream changes the pH scale and increases the BOD, COD and total organic carbon of the water bodies (Mathur and Pradeep 2007; Lade et al. 2012).

The conventional wastewater treatment processes are unable to remove the reactive dyes due to their stability, colourfastness and resistance towards degradation.

vivekvardhan2@gmail.com

The recalcitrance of the reactive azo dyes is mainly due to the presence of ($-N=N$) which are of synthetic origin (Bafana et al. 2008). Due to their synthetic origin and complex fused aromatic structures, the reactive azo dyes are highly difficult to degrade by utilizing conventional effluent, treatment procedures such as pH neutralization, coagulation followed by biological treatment (Anajeneyulu et al. 2005).

For the last ten years, bioremediation is being adopted as an effective alternative method for degradation, mineralization and detoxification of azo dyes. Bioremediation is considered as an eco-friendly and cost competitive alternative to physicochemical degradation of textile effluents (Raja et al. 2016). The effectiveness of biodegradation depends on the adaptability and bioremediation potential of selected organisms (Gupta et al. 2011). Several microorganism including bacteria, fungi, algae and actinomycetes have been utilized for the degradation and mineralization of azo dyes.

Currently, there has been an intensive research on the application of marine actinomycetes in the degradation and mineralization of azo dyes. Actinomycetes are gram-positive filamentous bacteria widely distributed in terrestrial and marine ecosystem. Actinomycetes have a profound role in the marine system due to their adaptation to the low concentration of carbon substances for their growth and their ability to degrade xenobiotic compounds. The quantitative data on the decolorization and mineralization of reactive azo dyes by actinomycetes and its enzymes is limited. Thus, the development of novel decolorization method by exploiting the marine microbial community is need of the hour for effective removal of azo dyes from textile effluents. Keeping in view the significance of marine actinomycetes, the present study is designed to assess the bioremediation potential of marine ***Streptomyces sviceus*** by using congo red-21 as a sample dye.

2 Materials and Methods

2.1 Materials

The reactive azo dye Congo red-21 was collected from the retail vendors at Madanapalli and Puttur towns of Chittoor district, A.P., India. ***Streptomyces sviceus*** was isolated from marine sediment samples collected from the Bay of Bengal coastline of Nellore district of A.P. state. All other chemicals and solvents used were of analytical grade procured from SD fine and Sigma chemicals.

vivekvardhan2@gmail.com

3 Methodolgy

3.1 Decolourization of Congo Red-21 Under Static/Shaking Conditions

Streptomyces sviceus was cultivated for 48 h in 250 ml conical flask containing 100 ml of nutrient glucose broth, and the medium was supplemented with 400 mg/l of Congo red-21. The dye degradation activity of *Streptomyces sviceus* was determined under static and shaking conditions (150 rpm) at 28 ± 2 °C in orbital shaking incubator. An aliquot (3 ml) of the culture medium was withdrawn at regular time intervals and subjected to centrifugation at 10,000 rpm. The supernatant was collected and used for measuring the percentage of decolorization (Parvez. R et al. 2015).

3.2 Assessing the Toxicity of Dye and Degraded Metabolites

The bioremediation potential of *Streptomyces sviceus* KN_3 was assessed through genotoxicity, acute toxicity and cytotoxicity assay of Congo red dye and its degraded metabolites. Toxicity of the Congo red-21 dye and its degraded metabolites was analysed using *Allium cepa* as in vivo model.

3.3 Cytogenetic Analysis

The cytotoxicity of control and degraded Congo red-21 dye was assessed through the cytological changes in the cells of Allium cepa roots. The seeds were soaked in distilled water for 2 h and further placed on wet filter paper at 23–25 °C for germination under dark conditions. After germination, the Allium cepa seedlings were divided into three groups. Control group treated with distilled water, Group-II with untreated Congo red-21 dye and Group-III with treated Congo red-21 dye. After 72 h of treatment, root tips were carefully cut and fixed in a freshly prepared Carnoy fixative (3:1 v/v absolute alcohol and glacial acetic acid) and stored in 70% ethyl alcohol at 40 °C for 24 h.

Root tips of Allium cepa were thoroughly washed and hydrolyzed in HCl at 60 °C for 4–6 min. The tips were washed and stained with Fulgent reagent for 2 h (Navya et al. 2013). The deeply stained terminals of root tips were squashed in a drop of 45% acetic acid on a glass slide. After covering with cover slip and sealing, the slides were examined for measuring mitotic indices and frequency of mitotic abnormalities.

$$\text{Mitotic index(MI)} = \frac{(\text{Number of dividing cells in all phases of mitosis}) \times 100}{\text{Total number of counted cells}}$$

vivekvardhan2@gmail.com

$$\text{Abnormalities of Mitosis (\%)} = \frac{(\text{Total number of abnormal cells}) \times 100}{\text{Total number of dividing cells}}$$

3.4 Phytotoxicity

Toxicity of Congo red-21 and its degradation metabolites on germination of plants was assessed by using green gram and fenugreek seeds. The seeds were treated daily with 5 ml of parent Congo red-21 dye (400 mg/L) and its degraded metabolites. The length of root, shoot and the percentage of seed germination were recorded after 10 days.

3.5 Acute Toxicity Test

To study the effect of Congo red dye and its degradation metabolites, on fish mortality and their behaviour, acute toxicity test was conducted using zebrafish as in vivo model. The Congo re-21 dye degraded by the *Streptomyces sviceus* strain KN_3 was subjected to centrifugation at 10,000 rpm for 30 min. The supernatant was collected, filtered through membrane filters. About 100 ml of clear filtrate was taken in a beaker, and then, 24-h-old neonates of zebrafish were added. The experiment was carried out at room temperature for 48 h under dark conditions, and the number of immobile organisms was counted after exposing to light for 30 s.

3.6 Cytotoxic Activity Assay

The cytotoxic activity of the degraded metabolites was assessed by MTT assay (Lavanya et al. 2014) The effect of degraded dye sample on the cell viability was assessed through mitochondrial dehydrogenase activity (3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide) (Claiborne et al. 1979). Raw 264.7 cells (**Murine macrophages**) were seeded (2×10^4 cells/well) and incubated for 24 h at 37 °C in 5% CO_2 atmosphere for the adherence of the cells to the flat bottom of the 96-well plates. The cells were treated with different concentrations of Congo red-21 control and degraded sample (25, 50, 75 and 100 μg/ml) for 24 h. At the end of the incubation, media was removed and washed with 0.01 M PBS (pH 7.4) followed by the addition of 25 μl of MTT solution (5 mg/ml in PBS) to each well and incubated for 3 h at 37 °C. After incubation 0.1 ml of extraction buffer (20% SDS in 50% dimethylformamide) was added and incubated for 30 min to extract the purple-blue MTT Formosan crystals. The absorbance was measured at 540 nm using micro-plate reader (Biotek-255907), and the percentage of cell survival was calculated.

vivekvardhan2@gmail.com

4 Results

The effect of static and shaking conditions on rate of decolorization of reactive azo dyes was analysed at different time intervals (0–96 h). The maximum decolorization of Congo red-21 was noticed at all-time points under static conditions. *Streptomyces sviceus* showed 70% of decolorization under shaking condition, and the rate of decolourization was accelerated to 90% under static (Fig. 1).

4.1 Effect of Congo Red-21 and Its Degraded Metabolites on Root Elongation

The effect of Congo red-21 control dye and its degraded sample was tested on the root elongation of Allium cepa. The root growth was totally blocked in the presence of control dye, and on the other hand, the effect of dye properties on the root growth was reduced to 50% after degradation by *Streptomyces sviceus* (Fig. 2). The average length of Allium cepa root accounts to 4.36 cm after 72 h of growth in the presence of water. In contrast, the dye control restricted the root growth to a level of 0.85 cm, whereas in the presence of degraded sample, the root growth was 2.86 cm which was found to be nearly 60% of root length with water (Table 1).

4.2 Cytogenetic Analysis of Congo Red-21 Dye and Its Degraded Products

Allium cepa is considered as a remarkable genetic model to assess the genotoxic effects of Congo red-21 and its degraded metabolites. The inhibitory effect of Congo red-21 dye on elongation of root length was due to the aberration in mitosis of growing cells. From the microscopic observation of the section cuttings, it was observed that the number of undivided cells was high in Congo red dye treated root tips. The

vivekvardhan2@gmail.com

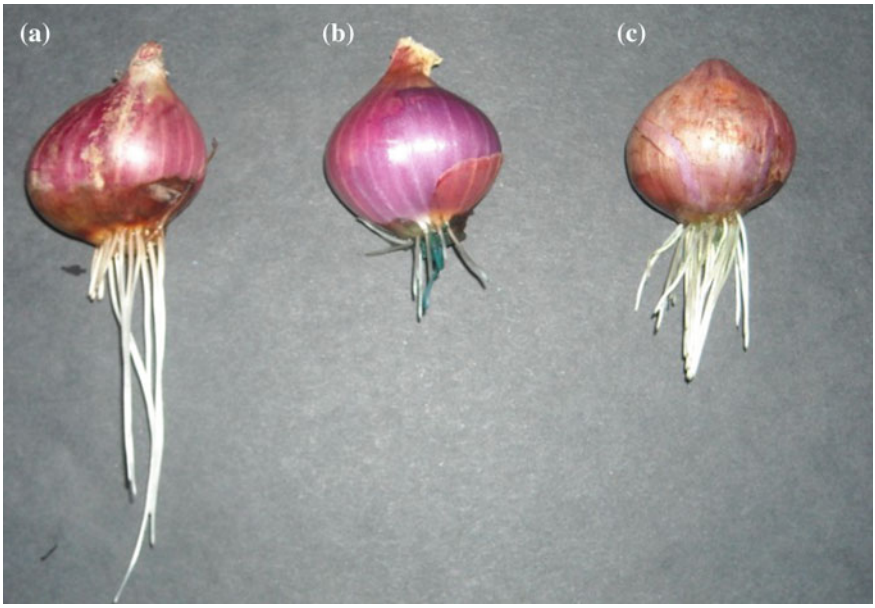

Fig. 2 Influence of Congo red-21 dye and its metabolites on root elongation of *Allium cepa.* **a** Water control, **b** Congo red-21 dye control, **c** Congo red-21 dye degraded sample

Table 1 Elongation of Allium cepa roots

Particulars		Root length ± SD (cm)
Water control		4.36 ± 0.26
CR-01 dye control		0.85 ± 0.32
CR-01 degraded sample	(400 mg/l)	2.86 ± 0.30

number of dividing cells and mitotic index (MI) was found to be high in the roots treated with degraded dye sample which indicates the nontoxic nature of degraded dye was represented in Table 2.

In order to detect the genotoxicity of Congo red-21 and its metabolites, the four phases of cell division were considered to measure the chromosomal aberration. The Allium cepa roots treated with Congo red-21 dye exhibited polyploidy interphase nucleus, C-metaphase, spindle disturbance at anaphase, disoriented chromosome, sticky chromosome and vagrant chromosomes (Fig. 3). In contrast, no significant changes were noticed with degraded sample of Congo red-21. The results demonstrate the nontoxic nature of the degraded sample on the growth of higher plants and further confirm the bioremediation potential of *Streptomyces sviceus* (Fig. 4).

vivekvardhan2@gmail.com

Table 2 Mitotic index of Allium cepa root tip cells exposed to Congo red-21 dye and its degraded metabolites

Treatment	Number of cells analysed	Number of dividing cells	% of Mitotic index
Water	172	82	47.67
Congo red-21 control dye (400 mg/l)	91	9	9.89
Congo red-21 degraded with *Streptomyces sviceus*	158	45	28.48

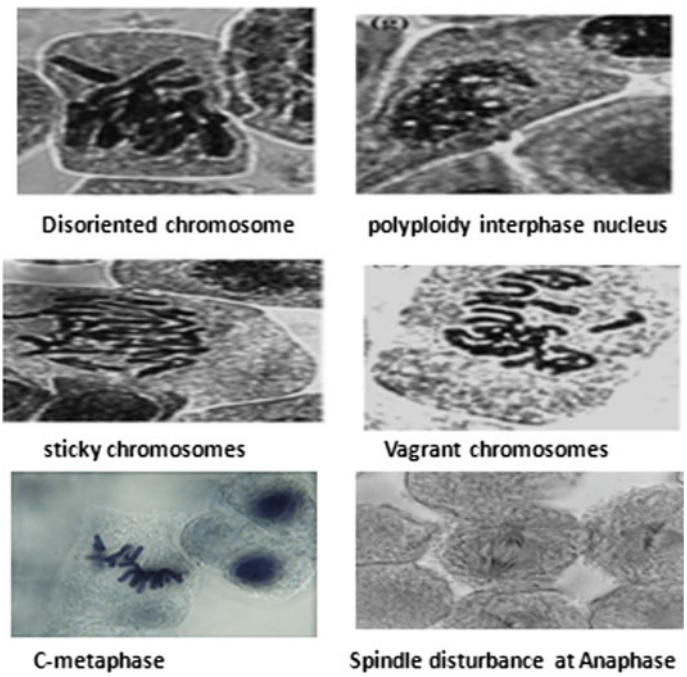

Fig. 3 Photomicrographs of meristematic cells of *Allium cepa* roots treated with the Congo red-21 dye

4.3 Phytotoxicity of Congo Red-21 Dye and Its Degraded Products

The germination percentage of green gram seeds was studied to assess the phytotoxicity of degraded metabolites of Congo red-21. The seedlings of green gram showed 2.1-fold (80%) higher germination rates with degraded Congo red-21 sample in comparison with control dye (38%) (Table 3). The length of plumule and radi-

vivekvardhan2@gmail.com

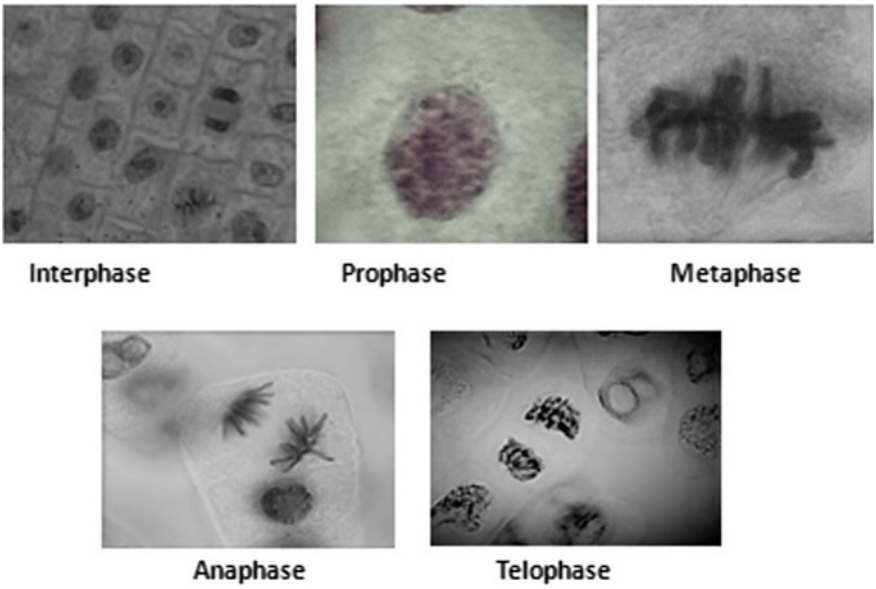

Fig. 4 Photomicrophs of meristematic cells of Allium cepa roots treated with Congo red-21 degraded with *Streptomyces sviceus*

cle was observed to be significantly affected by Congo red-21 parent dye than their metabolites, indicating less toxic nature of degradation metabolites as compared with parent dyes (Fig. 5).

4.4 Acute Toxicity Test

The acute toxicity assay was carried out in water containing Congo red-21 (400 mg/L) and different concentrations (100, 250 and 400 mg/l) of degraded Congo red-21 sample. The results of the toxicity assay are tabulated as per cent death of zebrafish. The percentage mortality was found to be high at all concentrations. In contrast, the degraded sample with 400 mg/l dye concentration showed mortality from 3 to 11% at different time intervals (Table 4). These results suggest that release of untreated Congo red-21 dye is a critical concern to the environment and human health, whereas dye treatment with *Streptomyces sviceus* could be used for detoxification and mineralization of azo dyes (Fig. 6).

vivekvardhan2@gmail.com

Table 3 Influence of Congo red-21 dye and its degraded metabolites on germination of green gram seeds

Samples	Percentage of germination										Average shoot length (cm)	Average root length (cm)

vivekvardhan2@gmail.com

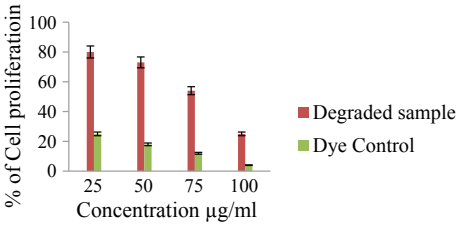

Fig. 7 Cytotoxicity of Congo red-21 and its decolorized sample against RAW 264.7 cells (values are expressed as the mean ± SEM of three independent experiments statistical significance 1% level ($p \leq 0.01$))

4.5 Cytotoxicity of Degraded Products

MTT assay was carried out to analyse the toxic nature of Congo red-21 dye and degraded metabolites on the cell proliferation of RAW 264.7 macrophages. The assay was performed with different concentrations (25–100 µg/l) of degraded product.

The proliferation of RAW 264.7 macrophage cell lines was inhibited due to the toxic nature of Congo red-21 control dye. In contrary to the parent dye, 30–80% of cell proliferation was noticed with varying concentration of degraded samples shown in (Fig. 7). The visibility of cell proliferation even at higher concentration of degraded products confirms mild interference and nontoxic nature of the degraded product and further, the bioremediation potential of *Streptomyces sviceus* strain KN_3 (Fig. 8).

5 Discussion

The discharge of azo dyes, through textile effluents, into the water stream and soil may escalate the pollution. The environmental and health hazards of textile dye effluents have been a subject to research scrutiny for a long time. The present research originated based on the need to gaze into bioremediation potential of *Streptomyces sviceus isolated from marine sediment samples.*

The cytotoxicity, mutagenicity of the azo dyes were analysed though root shape, elongation, mitotic index and chromosomal aberrations (Misra and Fridovich 1972). The decrease in root growth to an extent of 45% represents the toxic of the xenobiotic compounds on the plants (Wierzbicka M. 1999). Our results demonstrate the cytotoxic nature of Congo red-21 dye and nontoxic properties of its degraded metabolites. Mitotic index (MI) is the hallmark for estimating the frequency of cellular division and inhibition of mitotic activities which are the indices to mark the cytotoxicity of the synthetic as well as natural compounds (Amin et al. 2002). Reduced MI is due to the inhibition of DNA synthesis, and decrease in mitotic index is considered as an important indicator to pollution in affected environments, particularly at the sites

vivekvardhan2@gmail.com

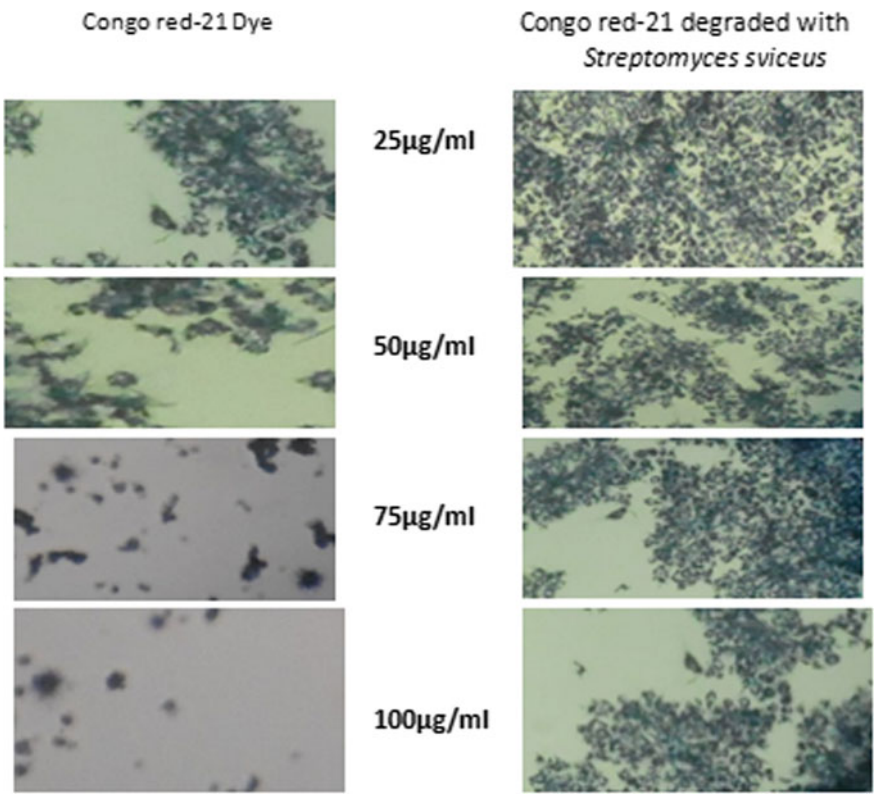

Fig. 8 Proliferation of RAW 264.7 cells in the presence of Congo red-21 dye and its degraded products

contaminated with azo dyes (Marcano et al. 2004). In the experimental study, mitotic index of degraded Congo red-21 sample was lower than that of water control, and in contrast, the mitotic index was improved significantly in *Allium cepa* meristematic cells treated with degraded dye sample. Decrease in mitotic index was reported with orange red dye and CI disperses blue 291 (Tsuboy et al. 2007). The reduced MI is attributed to the onset of prophase, blocking one or more mitotic phases (Pillai et al. 2011). Chromosomal aberrations were assessed to detect the genotoxic activity of Congo red-21 dye and its degraded metabolites. The meristematic cells treated with Congo red-21 dye represented the most common aberration like polyploidy interphase nucleus, C-metaphase, sticky metaphase with chromosomal adherence, spindle disturbance at anaphase and vagrant chromosome. The chromosome adherence may be an indicator for genotoxic effect of azo dye which may result in irreversible cell damage and necrosis. The disturbance at spindle prevents the migration of the chromosome towards the pole and chromosomes become attached to results to each other through bridges and results in the condensation and chromosome, stickiness (Pillai

vivekvardhan2@gmail.com

et al. 2011). Chromosome adherence or stickiness indicates the toxic effects of xenobiotic compounds which are irreversible and leading to death (Kalyani et al. 2008). This report is in correlation with our results, where reduction in mitotic index was noticed with Congo red-21 dye. These results clearly suggest the cytotoxic effect of Congo red-21 dye and the nontoxic nature of degraded metabolites.

The bioremediation potential of *Streptomyces sviceus* was assessed through phytotoxicity assay. The phytotoxicity of the dye was detected by measuring the potential of Congo red-21 dye and its metabolites on the germination of green gram seeds. The results show that the degraded metabolites were not toxic to germination of green gram seedlings and good growth of plants was observed when compared to control.

Evaluating the toxicity of azo dyes before and after degradation of bacteria is necessary as the dye and their metabolities are phytotoxic and toxic to aquatic and human health (Phugare et al. 2011). Acute toxicity tests by using Daphnia magna or zebrafish as in vivo model are well-known screening method for analysing the lethal toxicity of xenobiotics and their metabolites to animal and human health. The relative toxicity of Congo red-21 and its degradation product after treatment with *Streptomyces sviceus* strain KN_3 were studied by acute toxicity with zebrafish.

The cytotoxic effect of Congo red-21 dye and its degraded metabolites on RAW 264.7 macrophages was studied by MTT assay. Befana and chakrabarti 2008 reported the cytotoxicity of DR 28 dyes at different levels of biodegradation by biodegradation by *Bacillus velezensis*.

The mouse fibroblast cell line was used as in vitro model for assessing the cytotoxicity of red 141 and reactive red 2 dye degraded by *Bacillus lentus* (Kumar and Bhat 2012). Our results explained the nontoxic nature of degraded sample by promoting cell proliferation of RAW 264.7 cells.

6 Conclusion

From the present study, it can be concluded that *Streptomyces sviceus* is highly potential in the detoxification of the reactive azo dyes, particularly Congo red-21 dye. Thus, the present research study provides ample evidence for bioremediation of azo dyes by marine Actinobacteria.

Use of Sewage to Restore Man-Made Waterbodies—Nutrient and Energy Flow Regulation Approaches to Enabling Sustainability

Seema Sukhani and Hoysall Chanakya

Abstract Sewage ingress into lakes and man-made waterbodies have for long been considered a "Tragedy of the Commons", and numerous attempts have been made to avoid them. Agriculture development and urbanization send nutrient and C laden run-off/sewage into these waterbodies causing eutrophication. This study shows that with minor interventions involving anaerobic digestion for C/N removal and managing trophic levels to lower bacterial biomass at the inlet points can reduce the daily nutrient and energy budgets into these waterbodies while providing much needed water to compensate for daily evaporation (2.5–4 m/year) and maintaining water levels in them. From an understanding of regulating trophic levels, this minimal nutrient and energy input to the waterbody can be managed to raise fish and birds or only harvested fish so as to primarily keep the water quality at a desirable level while also sustaining the waterbody round the year without need for freshwater inputs for long periods, thus converting the "tragedy of the commons" to a "blessing of the commons".

Keywords Man-made waterbodies · Restoration · Lakes · Anaerobic digestion · Protozoa · Ecosystem · Trophic levels · International society of waste management · Air and water

1 Introduction

Sewage ingress or its increasing use to fill up man-made waterbodies alters the balance of the aquatic or near freshwater ecosystems such as lakes and tanks causing them to function less efficiently. It contains significant quantities of nutrients which are otherwise limiting in natural waterbodies and mechanisms to handle these needs to be sought. Such nutrient ingress results in higher primary productivity in terms of excess growth of algae, plants and cyanobacteria and this phenomenon is known as eutrophication. Disposal of sewage has been a major issue in urban and peri-urban areas and its entry into waterbodies is becoming inevitable. Nutrient inputs into such

vivekvardhan2@gmail.com

waterbodies have always been considered a liability, while in reality it can now be converted into a blessing. With installation of self-managing sewage treatment systems within a lake, most of these nutrients can be converted into useable resources in terms of energy, fodder and human food including food for other animals (biogas, algal biomass, fish and water birds). However, there is a gap in understanding the balance between nutrient/C loads in effluent of treatment system and their effect on aquatic ecology and self-purification capacity of waterbodies. In this paper, we attempt to show how to convert this "Hardins-Tragedy of the Commons" to a "Blessing of the Commons".

It is now well understood that aquatic ecosystems such as lakes and tanks operate as semi-closed input-output ecosystems (Hannon 1973). The focus while understanding management of lakes had been directed to eutrophication (primary producers), predators (zooplanktons) and improving water quality. Effects of primary producers both in bottom-up (nutrient input to fish/birds) and top-down cascade (fishes-phytoplankton/bacteria) types of aquatic systems have been used in management of tanks. Not until recently, new water quality indicators and control methods had been investigated, and one of emerging approach now uses fish biomass and its harvesting as an important indicator for nutrient harvest and control systems for water quality management (Sosa-López et al. 2005). Such indicators and knowledge about different trophic cascades can be a decisive factor for site-specific management plans for solving water quality problems and re-establishing biotic community (Hansson et al. 1998). However, very little research effort is invested in understanding changes among food web properties across environmental conditions of such man-made aquatic ecosystems. Inspiration can be taken from marine biology where focus has not only been on establishing direct control on producers but integration of other trophic levels and developing a holistic picture. Thus, the completion of a food chain provides an equally effective control mechanism for reducing eutrophication or nutrient ingress in such aquatic systems. Another important factor which has not been receiving proper attention is the impact of secondary treated water on food webs. Most of the organisms' energy is stored in organic carbon bonds within the plant and animal biomass and ~45–55% of dry weight of living entities in freshwater accounts for carbon (Vitousek et al. 1997). This C can very well said to be currency of energy transfer (Dodds 2002). Thus, here we will attempt to understand carbon balance and metabolism at different trophic levels of lake which have an integrated two-stage input sewage treatment unit upstream and trophic levels as shown in Fig. 1.

The main objective is to understand change in flow of carbon and organisms from grazing or production food chain to mineral food chain when selective biological intervention is made and how subsequent trophic levels will be affected.

2 Discussion

2.1 Raw sewage cannot be let directly into the lakes. In Fig. 1, two scenarios have been shown which highlight the effect of quality of influent on lake ecology.

vivekvardhan2@gmail.com

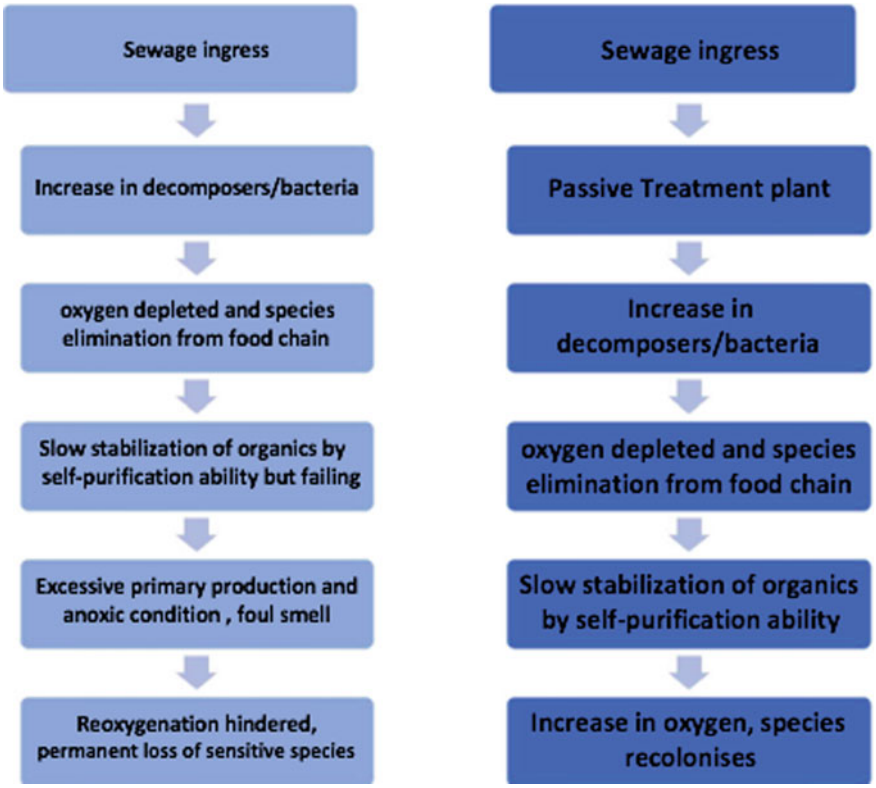

Fig. 1 Effect of quality of influent on lake ecology

1. Near saturation or more load will cause DO to drop significantly. The self-purification process is slow (as the only basis of material exchange is through diffusion and organisms), thus a considerable area from point of discharge will seem polluted. Often the only organisms to flourish will be sewage bacteria, fungus, certain worms and fly larvae. Some species of animals (catfish) and plants (floating hydrophytes, e.g. water hyacinth) may also survive, but it will eradicate endemic species in that area especially fishes. Facultative anaerobic bacteria also thrive in such environment giving off foul smell. Phytoplankton, which can survive in severe organic pollution, will start metabolizing intermediates/exudates (acetate) of anaerobes, hindering reoxygenation. Without any aid and continuous discharge, lake area will remain anoxic and obviously polluted.
2. Treatment plant near the discharge point will bring the influent quality near sub-saturation level. Any leftover organic pollutant apparent after this point will disappear within a short distance in the lake through natural process. Mild pollution can be actually beneficial to waterbody, as it will increase the nutrient and energy supply to micro-organisms and enhance primary productivity. It will not only make the water reusable, but also give returns in terms of energy-rich algal

vivekvardhan2@gmail.com

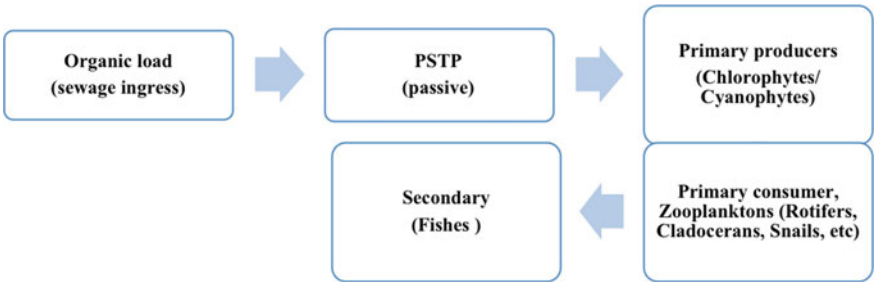

Fig. 2 Schematic of treatment plant and trophic levels in lake

biomass or animal fodder and top most trophic level, i.e. fishes which can be used for human/animal consumption.

2.2 We are using trophic cascade concept to understand aquatic ecology modification due to changes in water source and using simple 3-level cascade in lakes after treatment. This cascade from phytoplankton to fish attempts to simplify the true representation of real-world complexity of food web for the current discussion without diminishing the importance to look at this as a complex interlinked system. Thus, these generalizations will be a foundation in understanding complex interactions of other minor groups and their interactors with the ones mentioned above (Fig. 2).

2.1 Passive Treatment Sewage Plant

Proposed unit is two stages with first stage to be anaerobic and second stage to be phytoflagellate/protozoan driven. In the anaerobic reactor, the phenomenon causing mixing is sludge upwelling as shown in Fig. 3. The details of design and laboratory scale systems that provide the necessary mass/energy balance are published elsewhere.

This reaction system is followed by action of phytoflagellates and protozoans, which play a dual role being grazers on planktons and heterotrophic bacteria, while also stabilizing inorganic carbon through photosynthesis. These communities may itself regulate plankton biomass and turbidity by grazing. Being flagellated, they have the capability of vertical and horizontal movements, which in turn makes them ideal bio-convectors. However, they also pose a problem of an inability to generalize the process with regards to compartmentalizing nutrients and energy to each trophic level. Nevertheless, they are important actors in treatment of sewage and their functional role in a full-scale system is another study objective which will be in focus for future studies.

As mentioned in an earlier publication, the peak wastewater input required to maintain a 10 ha waterbody would be 1 MLD that compensates for the evaporation from the waterbody surface. Schematic of reduction in carbon and other nutrients

vivekvardhan2@gmail.com

Fig. 3 Sludge upwelling in anaerobic reactor increases mixing with fresh input water, increases active bacterial number over a hundred-fold and reduces holding time to 8–16 h

is shown in Fig. 4. The reduction in nutrients has been extrapolated from various lab and field studies (plant under construction). The dominant phytoflagellates are mostly Euglenoids.

Total residence of water in treatment unit is 3 days, in which approximately 75% carbon, 50% nitrogen and 25% phosphorus is reduced. Partially treated water from this point enters the lake, where total residence is 263 d. Most likely because of light availability and soluble nutrients, Chlorophyceae will follow. Nitrogen and phosphorus content is about 10–17 and 1–1.5% of algal DW (Wang et al. 2010). Thus, considering 50% nutrient transfer, per day primary production is expected to be ~30–150 kg/d, which is well under the grazing limit by primary consumer.

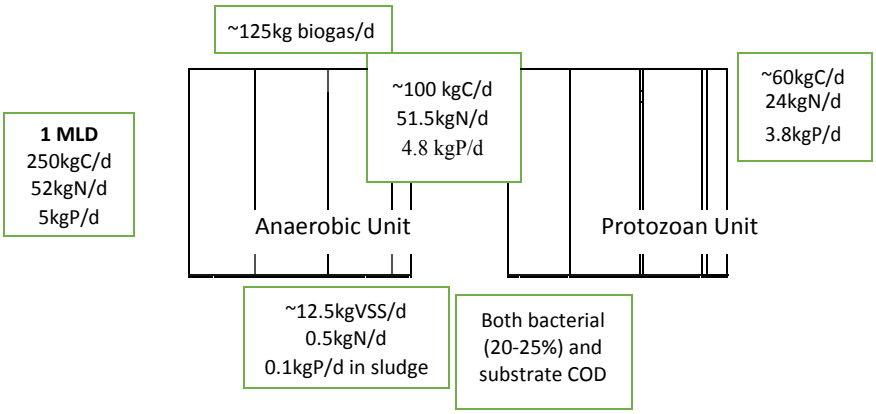

Fig. 4 Overall schematic of PSTP and trophic levels

vivekvardhan2@gmail.com

2.4 Rotifers, cladocerans, snails and crustaceans are major groups of primary consumer, but cladocera are key players in lakes/waterbodies and dominate the zooplankton community both in species, biomass and abundance (Walseng et al. 2006). With their large body sizes, edibility for planktivorous fishes and faster clearance rates, Daphnia spp. (cladocerans) are major actors in trophic cascade (McQueen et al. 1986). Large Daphnia have been reported to filter efficiently algae with cell diameters between 1 and 30 μm and are a major grazer. For this reason, in this paper, Daphnia are used as representative of all grazers and primary consumers. They have a capability to consume ~0.18 mg algae/day per cell (calculated from Mcmahon and Rigler 1965), and their natural abundance is in range of 106–7 cells/ml. Considering a high value of 50% carbon transfer, biomass of grazer is expected to be 30–70 kg/d. This in turn translates to fish productivity of ~15–30 kg/day. Thus, total revenue which can be generated from a 1 MLD plant is 125 kg biogas (60% methane), 100 kg algae dry weight and ~20 kg fish. As for bacteria, viruses and saprophytes, current knowledge about their diversity is still limited, and hence, they have not been addressed here, although clearly they are key components of food web. Fish production can either be controlled by appropriate harvesting techniques for human use or the waterbody may be allowed for bird preserve with an appropriate stocking density of different feeding types. This latter approach not only avoids human consumption but can increase avian biodiversity in the location. This waterbody when used for education or recreation can provide higher daily revenue than fish harvest and can be made a lot more economically sustainable and has been discussed previously.

3 Conclusion

Understanding of phytoflagellates in slightly intervened environment and their trophic role and interaction with other communities is still an open area of research. This, when combined with an anaerobic reactor to remove organic C and some N, can be effectively used to restore and sustainably maintain waterbodies even in areas where sewage/nutrient ingress into aquatic systems threaten waterbody health and sustainability. Man-made lakes and tanks receiving sewage (treated or raw) possess a status far from freshwater status and can be sustained with this approach wherein, in future some foundational works need to be done. Real-time understanding of all trophic levels under various nutrient conditions and changes with respect to abiotic factors has yet to be gained. There is thus a need to modify our current understanding and approach to use of water quality indicators and traditional trophic levels established for freshwater for these man-made waterbodies.

Two-Stage Passive High-Throughput Sustainable Sewage Treatment Process: Laboratory Study and Future Scope

Seema Sukhani and Hoysall Chanakya

Abstract Large volumes of sewage need to be handled in the emerging SDG 6 scenario, and low energy/maintenance options are required for distributed and unattended situations. In this direction, a novel two-stage system was developed consisting of a primary anaerobic digestion followed by protozoan/phytoflagellate bacteria/residual OM (organic material) removal stage. Anaerobic purification by sludge upwelling found naturally in idle lagoons was firstly emulated and hastened by encouraging deeper sludge beds that upwell, disperse sludge and maintain high MLVSS without need for mechanical sludge recirculation. In the second stage, a Euglena-driven system that removes mixotrophically, bacteria and residual solids provide reasonably acceptable treated water quality at a HRT < 2d. In this paper, we discuss the preliminary findings. Overall reduction of 70–80% COD, 55% TKN, 25% P and >90% turbidity was achieved. While optimization and in-depth understanding of functionality are being investigated, this system appears to be a good alternative to conventional treatment technologies where space constraints are less and distributed treatment with low interventions is required.

Keywords Wastewater treatment · Passive natural process · Protozoa and phytoflagellates · Anaerobic treatment

1 Introduction

As the world seeks to address sustainable development goals (SDG6) such as sanitation and clean water, providing a household level or decentralized village/town level sewage treatment systems become very important. Sustainability criteria demand the use of less expensive systems as well as low energy options. Towards this, passive decentralized systems are essential where treated water has qualities acceptable at least for surface irrigation or local reuse. The problem is exacerbated when the barely treated sewage flows into nearby natural and man-made water bodies such as lakes and tanks which are generally deprived of natural run-off that was prevalent in the

vivekvardhan2@gmail.com

past. To these locations, these withering waterbodies have been the most sustainable sources of water and have been the lifeline in arid/semi-arid regions of India. Traditionally in India, these man-made water bodies were fed with only rainwater (run-off) and were interconnected as a cascade. Water collected was used for both irrigation and domestic purposes throughout the year. However, due to the changing land-use pattern, diversion of valley systems and climate triggered weather patterns, loss of interconnectivity, catchment area changes and point discharges of sewage and human wastes, these water bodies have lost their capability for self-purification and water is far from reusable quality.

As indicated above, any new sewage generated from providing total sanitation will need to be treated and reused to meet sustainability goals. National programs in India emphasize this. Thus, while restoring water bodies at locations with a significant change in land-use patterns, including urbanization, we need to treat such decentralized wastewater in a passive and low energy approach. We seek to evolve new ways to treat these two types of wastewater. Firstly, evolve a treatment system that can work starting from a household (HH) level in rural, peri-urban and urban locations (daily discharge 250–400 l) to 1MLD levels for preventing water bodies from eutrophication, function as pre-treatment methods before the wastewater is returned to lakes and man-made water bodies. Firstly, the possibility of using this passive two-stage process is discussed for maintaining a water body for which run-off alone has become insufficient to hold enough water on a yearly basis. To solve this problem, we attempt to top-up the evaporative losses by using treated/partially treated sewage as water source with a passive treatment system constructed within the lake body. A new passive treatment technology is required which can overcome difficulties encountered while installing traditional STPs. Activated sludge process and SBR are most commonly applied treatment technologies in India but their high economic demand (~ Rs. 34–73/kL CPCB 2007) depending on level of treatment achieved, sludge production and disposal problems, technical expertise and no direct economic return make them inviable to adopt. Thus, conventional processes are not ideal for this purpose. Yet, natural water bodies remove pollutants through a combination of physical, chemical and biological processes (Skurlatov 1988; Koronelli 1996). Our main objective is to focus on biological energy and material transfer between different trophic levels and their role in treatments. The general trend is anthropogenic wastewater or agricultural run-off extended anoxic/anaerobic zone-phytoflagellates/ciliates/protists—algae—rotifers/cladocerans/snails/crustaceans—fishes—birds. In earlier publication, we proposed a passive treatment plant which would work on the principle of natural purification of water bodies while treating incoming sewage in 2–3 days to irrigation water quality by facilitating and optimizing each stage of natural purification.

In this proposed novel process, functional roles will be discussed for the first two stages using from experimental data (1L). First unit or stage is an anaerobic system, being most efficient carbon removal systems with approximately 70–80% of removed soluble/particulate carbon being converted to the gas phase. The by-product gas (~0.11–0.3 m^3/kg BOD) is an energy source when if collected can make the treatment economically sustainable. Sludge production is also less (2–10% of BOD removed) due to the lower growth and energy transfer in anabolic activities of

vivekvardhan2@gmail.com

anaerobic bacteria. Following this in the second stage, phytoflagellates, ciliates and protists which engulf suspended bacterial mass to finally reduce residual BOD and turbidity to levels <20NTU. Phytoflagellates are most abundant eukaryotic plankton in freshwater. Mixotrophic phytoflagellates (e.g. Euglenoids, Dinoflagellates) are known to provide both functions of protozoa and algae and are crucial actors in maintaining balance in biological system. Apart from being photosynthetic and using inorganic carbon to give off oxygen, they eliminate excess bacteria (Bird and Kalf 1987), cyanobacteria (Cole and Wynne 1974) and other algae, promote flocculation (e.g. Ochromonas, Aaronson 1973a, b) and help to decrease turbidity of effluent as well as BOD and suspended matter (Gerardi 1995; Curds 1968). These organisms have also been reported to release exoenzymes for extracellular digestion especially for flocculated and colloidal particles (Sanders and Porter 1988). Clearance rates (through both by ingestion and aid of enzymes) have been noted to range from $10^{3–4}$ bacteria/ml h. During some of laboratory experiments, approximately 7–77 bacteria have been found ingested per flagellate per hour depending on species (Sanders and porter 1988).

These studies suggest that mixotrophy (utilization of particulate food and dissolved organic matter), as well as photosynthetic fixation of organic matter in phytoflagellates, is a balanced process that can be regulated by environmental conditions possibly light or availability of soluble nutrients (nitrogen and phosphorus or vitamins) or both. Many observational and laboratory studies have reported of phagotrophy in phytoflagellates but so far no attempt has been made to use multiple consumption mode of these unique organisms in wastewater treatment. In this study, we have employed only two stages namely anaerobic digestion followed by the protozoan reactor to demonstrate a novel technique for in-line treatment of sewage to restore water bodies or to be applied as passive decentralized small-scale sewage treatment plants.

2 Materials and Methodology

Synthetic wastewater was used to study the treatment capability of anaerobic unit (4L) and protozoa (1L). The composition of media was kept constant throughout the experiment apart from during shock load (near 70d). Composition of media was 0.4 g/L—rice powder, 0.25 g/L—milk powder, 0.05 g/L—urea and 0.025 g/L—KH_2PO_4 with estimated COD of 640 mg/L, emulating typical sewage. The operating mode was fed-batch (fed twice in a day).

Filterable and total COD measurements were made for effluent from anaerobic reactor. MLVSS was estimated periodically. In order to understand the functional role of protozoa (1L), reactors were set up and operated in a similar mode as that of anaerobic system. The input for these reactors was effluent from anaerobic reactor described above. As light is an important factor, illumination with white LED was arranged (2 k lux) and nutrient reductions were monitored in both light and dark conditions. All the testing methods were from APHA. For stage 1, SVI, MLVSS

vivekvardhan2@gmail.com

through gravimetry, turbidity and COD are reported, whereas for second unit TKN with titrimetry, total phosphorus through persulfate digestion, nitrate, nitrite through cadmium reduction and turbidity along with COD were measured for stage two.

3 Results and Discussion

Stage 1: Anaerobic digestion has been applied for the treatment of various industrial and household wastewaters. The reactor set-up was operated in up-flow mode. The wastewater was introduced at the bottom of the tank, where sludge bed was maintained. The operation was at 27% (v/v) sludge volume with SVI of 27 ml/g VSS. The MLSS at time of operation was 6.4–8.2 g/L. Figure 1 shows total COD reduction for 75 days. While conducting this experiment, the reactor was already in steady-state condition. To establish functionality and kinetics of total reduction, total load was always kept below 1 kg COD/m^3 d. (~0.6 kg COD/m^3 d), which emulates sewage wastewater. To understand disturbances such as overload, from 70th day, load is increased to ~1.4 kg COD/m^3 d. This sudden load caused sludge to come out and a sudden dip in total COD reduction. Although within 5d, reactor had started to stabilize again. This will be monitored further for behaviour under different types of shocks.

Average COD reduction achieved so far has been 55% with 0.79/d of decay rate constant. Nitrogen and phosphorus removal in the reactor is >10%; thus, data is not shown here. The average turbidity of effluent from this stage was 110–180 NTU.

Stage 2: Traditionally, application of anaerobic technology is only as a pre-treatment due to negligible removal of nutrients such as nitrogen and phosphorus and the presence of these cause high algal growth when disposed of directly and restrict its reusability to only agricultural lands. Phytoflagellates and protozoa due to

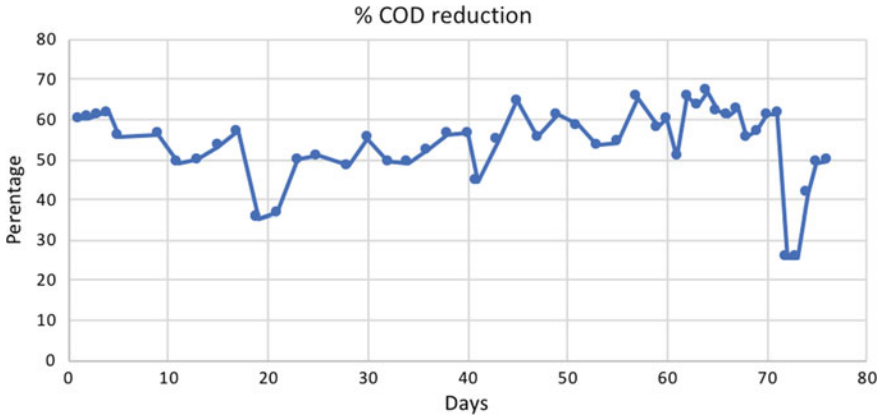

Fig. 1 COD reduction of 75 days in stage 1 anaerobic sludge bed reactor

vivekvardhan2@gmail.com

capability of exhibiting multiple growth modes (Unpublished data, CST 2018) can remove a significant level of these nutrients.

The effluent from the first reactor was used as input of protozoan/phytoflagellate reactor. Figures 2, 3 and 4 show per cent and average removal of nutrients, COD and turbidity. To understand different modes and partition, the reduction levels between heterotrophic/phagotrophic and autotrophic/phagotrophic, experiments were conducted in light and dark. To the best of our knowledge, this has been not attempted before. The light requirement of phytoflagellates is significantly low, and it was necessary to maintain light limitation so as to maintain stable condition for them. Thus, 2000 lx (~30 $\mu M/m^2$ sec) of white LED illumination was provided. Although other intensity of lights was studied, this seemed to give the best results (Unpublished data, CST 2018).

In dark, due to the lack of photosynthesis, only two modes of nutrition can be functional. Either residual carbon source in particulate or soluble form is taken up or

	Parameter	% reduction
Light	COD	30
	TN	50
	TP	31
	Turbidity	70
Dark	COD	20
	TN	13
	TP	17
	Turbidity (%)	52

Fig. 2 Removal capabilities of phytoflagellates in light and dark in stage 2 reactor

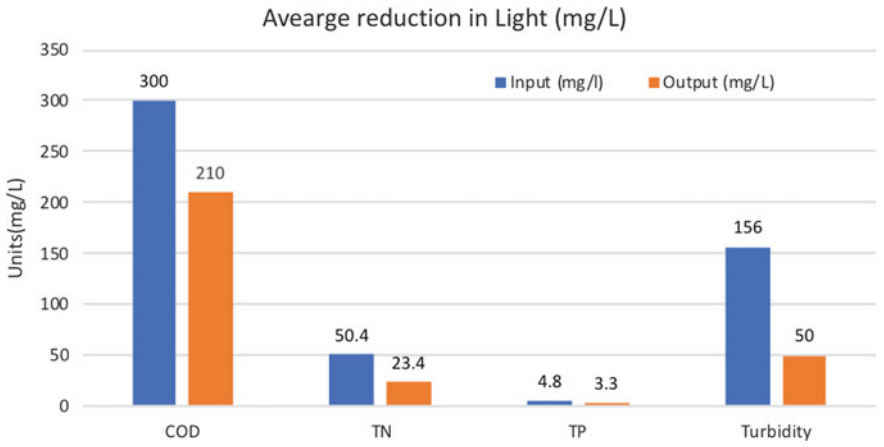

Fig. 3 Average overall performance and nutrient reduction under illumination

vivekvardhan2@gmail.com

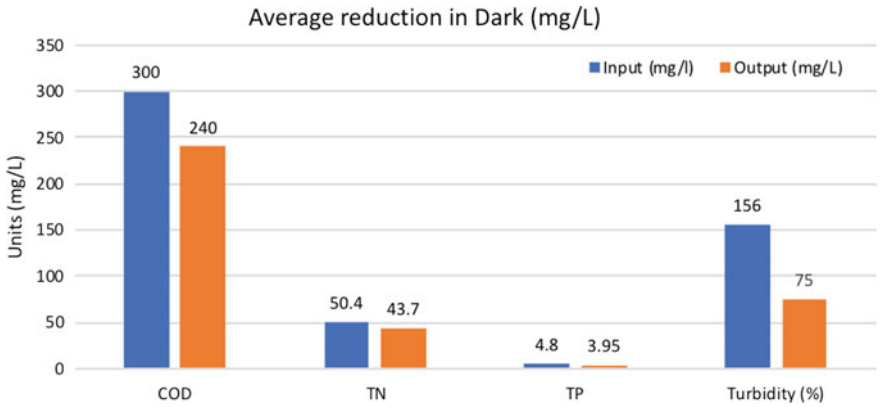

Fig. 4 Average overall reduction in dark

bacteria are being engulfed. In both cases, turbidity and COD from water are removed as shown in Fig. 3. However, the most interesting part is removal of additional COD and turbidity under light, which is counterintuitive as during illumination, inorganic carbon can also be fixed and total COD is expected to increase. This needs further research.

Apart from being an effective disinfectant, there is significant nitrogen and phosphorus removal as well (50 and 30%, respectively). This will ultimately reduce nutrient and C load on the discharge side. Adverse environmental factors such as low light, high bacterial turbidity and particulate forms of nutrients (nitrogen/phosphorus or vitamins) are some of the factors which might act as a switch between protozoa/phytoflagellates and chlorophyceae algae. Phagotrophy and mixotrophy as a source of nutrients have been reported for several algae species of Chrysophytes, Dinophyta and Cryophytes (Provasoli 1958; Aaronson 1980). This ability can be used in post-treatment of anaerobic effluent (Fig. 4).

4 Combined Nutrient Balance in Both the Units

When both units are operated sequentially, the expected reduction 70% COD, 55% total nitrogen, 25% phosphorus and most importantly ~80% turbidity reduction. Using this, technology enables it to be energetically independent with no aeration requirements. Even illumination requirements, which are very high in any algae tertiary treatment, are reduced and post-water is less turbid, bacteria-free and soluble nutrient-rich which can be directly used in flushing, gardening or agricultural fields and in the case of water body restoration (Fig. 5).

vivekvardhan2@gmail.com

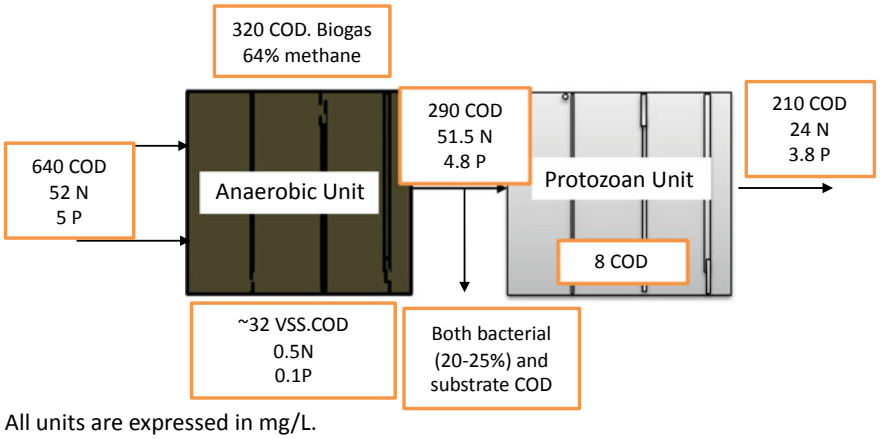

Fig. 5 Flow of nutrients from both reactors and their functionality combined. Although some COD is present in the overall effluent, water is clear (<20NTU) and hardly any biologically useful C

5 Conclusion and Remarks

Difficulty in the operation of anaerobic reactors is to maintain stable conditions and mediating effects of overloads, the presence of inhibitors, changing abiotic factors (temperature). Early detecting indicators of any disturbance are necessary, so that reactors can be operated normally before its efficiency is reduced or methanogenic activity and biomass are washed off. A 27% v/v sludge in the first reactor is expected to overcome these issues. For the second unit, much less is known about the pathways in which organisms are able to function in light. Long-term studies on sludge stability and different photoperiods also need to conduct for this process to be established as stable. Apart from that, what are the other species which have the capability of performing dual roles and how these systems can be optimized is the future scope of this novel treatment process.

Design and Characterization of Cold Plasma Ozonator for Wastewater Treatment

Harsha Rao, Lakshminarayana Rao, Haritha Haridas, D. K. Manju, S. Swetha and Hoysall Chanakya

Abstract As water scarcity becomes more severe, the need for more sustainable and holistic approaches to deal with the limited freshwater becomes more important. Developing decentralized technological solutions for grey water recovery from households and small communities is a potential way forward to reduce freshwater consumption. Towards this, in this study we report the design and characterization of a small-scale ozonator. The ozonator developed is used to degrade laundry grey water coming from consumer homes, SDBS and methyl orange. Ozonation of grey water from the washing machine resulted in 68.7% chemical oxygen demand (COD) reduction in 1 h of treatment at 1.2 g/h of ozonation. Ozonation of anionic surfactants (SDBS) and methyl orange resulted in 66.4% and 91.9% reduction in their concentration, respectively, over a period of 120 min of treatment. The kinetics studies show that the ozonation of grey water and SDBS follows first-order kinetics.

Keywords Grey water · DBD ozone generator · SDBS · Methyl orange · International society of waste management · Air and water

1 Introduction

Water scarcity is a universal problem. The UN Sustainable Development Goal 6 "Ensure access to water and sanitation for all" recognizes the right of citizens to access safe water and sanitation. Water scarcity, poor water quality and inadequate sanitation have a measurable negative impact on energy, public health and food security. By 2050, it is predicted that one in four people are likely to live in a country affected by chronic or reoccurring shortages of water. Indian domestic water consumption, especial in urban localities, is increasing and is expected to triple from the current demand by 2050. Domestic wastewater treatment and reuse are an attractive option to water conservation and management.

vivekvardhan2@gmail.com

Grey water is any type of domestic wastewater that comes from kitchen sinks, washing machines, baths and hand basins free from urine and faecal matter (Jefferson et al. 2000). Grey water can be easily treated right at its source of origin and can be recycled for secondary usages such as gardening, floor and car washing purposes. There have been several technologies for the treatment of grey water including simpler natural treatment systems such as vertical wetlands to more advanced and complex treatment options such as membrane bioreactors (MBR) (Merz et al. 2007). Choice of grey water treatment technologies depends on its robustness to handle variations in organic, inorganic and pathogen concentration in grey water influent and consistently produce an effluent of an appropriate and safe quality to meet the required water quality standards for reuse. Advanced oxidation techniques such as ozonation owing its inherent strength to effectively treat a wide range of grey water (Den and Zhao 2015).

Ozone is a three-oxygen containing molecule having an atomicity of three. Ozone is a powerful disinfecting and oxidizing agent. The oxidation potential of ozone is 2.07 V which is 152% more than the next powerful oxidizing agent chlorine which has an oxidation potential of 1.36 V. Ozonation is a water treatment technique which is based on diffusing ozone into a water column. Ozonation is an advanced oxidation process, which involves in situ production of very reactive hydroxyl radical species, which are known to attack a wide range of organic compounds and microorganisms. When ozone is bubbled into water, it reacts with inorganic and organic compounds either directly or indirectly by the formation of hydroxyl radicals and oxidizes electron-rich molecules (Ried et al. 2009). Ozonation finds application for both disinfection and degradation of pollutants, inorganic and organic included (Ried et al. 2009). Ozonation is widely used in drinking water treatment systems because of its ability to disinfect without adding any other chemicals and/or leaving behind any residual chemicals like chlorine. Ozone can be produced by pumping in enough energy to break the firm O_2 bond to form O. Ozone production by electric discharge (DBD) is the most effective, economical and dependable means of controlled ozone production. It involves discharging high voltage, milliamp currents, across a gap through which filtered dry air or pure oxygen is flowing. The reaction is initiated when free, energetic electrons in the plasma zone ionize the oxygen molecules to form ozone.

Historically, ozonation has been used as the sole disinfection step in drinking water systems. Drinking water ozonation systems are large-scale systems which are capable of producing 100's of kg of ozone per hour. Using ozonation in decentralized household grey water treatment systems requires small-scale, reliable, low-cost compact ozone generators which are easy to operate and have minimum maintenance.

In this work, we report on the design and operation of a small-scale ozone generator which can be used for treatment of grey water coming from a typical 4-member household. The ozone throughput has been characterized for ozone production capacity, and its application in treatment of grey water from washing machines, degradation of SDBS and methyl orange has been studied.

vivekvardhan2@gmail.com

1.1 Design of Dielectric Barrier Discharge (DBD) Plasma Ozone Generator

Dielectric barrier discharge (DBD) is a promising method of producing non-thermal plasma, which is widely used in a variety of industrial applications including ozone generation. Advantages of the DBD are its simplicity of its operation, capability to work at near room temperature and pressure and ability to work with very simple off-the-shelf commercial power supplies. In this work, a cylindrical electrode design ozone generator has been designed as shown in Fig. 1. In this design, an aluminium hollow cylinder, having 6 cm ID, 12 cm length and 3 mm wall thickness acted as one of the electrodes. An aluminium wire of diameter 3 mm and length 2.5 m wound as a coil formed the second electrode. A glass tube of diameter 6.5 cm ID, 14 cm length and 2 mm wall thickness placed in between these two electrodes formed the dielectric. A leak-tight acrylic casing, 10 cm OD and 15 cm length, with one air inlet port and one ozone outlet port, held the electrode assembly together. Compressed air was passed through the ozone generator. Many reactive species are produced during the plasma discharge in the air. In the gas phase, depending on the operating power level, nitrogen and oxygen molecules are dissociated by the energetic electrons in the discharge mostly leading to the formation of radicals (O and OH), ozone (O_3), nitrogen oxides (NO, NO_2), and excited N_2 through several reaction pathways (Sivachandiran and Khacef 2016).

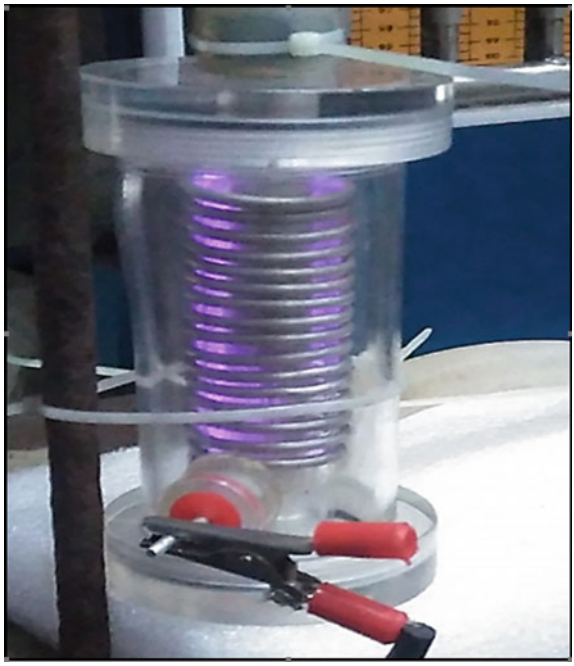

Fig. 1 Co-axial DBD plasma ozone generator

vivekvardhan2@gmail.com

When compressed air is passed through the plasma zone, various reactions are initiated. When free, energetic electrons interact with the compressed air, they dissociate oxygen molecules as shown in Eq. 1:

$$e^{-1} + O_2 \rightarrow 2O + e^{-1} \tag{1}$$

Following this, ozone is formed by a three-body collision reaction:

$$O + O_2M \rightarrow O_3 + M \tag{2}$$

M is a collision partner. It can be O_2, O_3, O or N_2.

1.2 Wastewater Treatment Using Ozonation

Ozone is known to completely oxidize organics to CO_2 and water either through direct reaction or through the formation of hydroxyl radicals. Oxidation reactions initiated by ozone in water are generally complex in nature, only part of the ozone reacts directly with dissolved solutes. Another part may decompose before reaction. Such decompositions are catalyzed by hydroxide ions and other solutes. Highly reactive secondary oxidants, such as $OH^{\cdot}$ radicals, are thereby formed (Wang 2012).

The reactions of ozone with water include

$$O_3^- \rightarrow O^- + O_2 \tag{3}$$

$$O^- + H_2O \rightarrow OH^{\cdot} + OH^- \tag{4}$$

Ozone oxidizes electron-rich molecules attached to carbon–carbon double bonds such as aromatics and splits the long-chain compounds making them biodegradable.

In this study, anionic surfactants such as sodium dodecylbenzene sulphonate (SDBS) are chosen for the ozone degradation studies because of its widespread use in numerous detergents and other household cleaning products. It belongs to the group of surfactants called linear alkyl benzene sulphonates (LAS). The average SDBS concentration in domestic wastewater ranges between 1 and 10 mg/L (Zhang et al. 1993). Conventional oxidants such as hydrogen peroxide and potassium permanganate have little effect on the removal of LAS, and when chlorine is used, low yields of chloroform; a known carcinogenic compound is formed. Ozonation of SDBS in aqueous solution consists of a free radical mechanism, in addition to direct reactions of molecular ozone. A general mechanism of the ozonation of SDBS can be summed up as shown in Equations 5 and 6.

Direct reaction:

$$\mathrm{NaDBS} + z\,O_3 \rightarrow \text{intermediates} \rightarrow \text{final products}\left(CO_2,\ SO_4^{2-}, H_2O\right) \tag{5}$$

vivekvardhan2@gmail.com

Free radical reaction:

$$\text{NaDBS} + \text{OH}^{\cdot} \rightarrow \text{intermediates} \rightarrow \text{final products}\left(\text{CO}_2,\ \text{SO}_4^{2-}, \text{H}_2\text{O}\right) \quad (6)$$

The decolourization of methyl orange by ozonation was also studied in this work. Azo dyes are widely used in textile and paper industries. Disposal of dye-rich wastewater from these industries is an environmental concern since the associated colour is quite noticeable and may have carcinogenic effects. When ozonation of an azo dye is conducted, the possible pathways are homolytic fission of the excited dye into radicals, electron transfer of the excited dye to form a radical dye cation, decomposition by superoxide radical anion and decomposition by singlet oxygen, resulting in a reduction in colour (Wang 2012).

2 Materials and Methods

2.1 Materials

A commercially available high voltage AC power supply system (Power: 80 W, Output: 10 kV 30 mA) was used as a power supply for DBD plasma generator. All chemicals (SDBS and methyl orange) were of reagent grade, and they were used as received. Stock solutions were prepared in distilled water.

2.2 Experimental Methods

The experimental set-up consists of a long cylindrical PVC pipe which acted as an ozone contact reactor, a co-axial DBD plasma ozone generator which produced ozone from compressed air, grey water circulating pump and spray nozzle system which increased the contact time between ozone and grey water and an air compressor, as illustrated in Fig. 2. Three types of studies, namely (1) laundry grey water treatment using ozonation, (2) SDBS destruction using ozonation and (3) methyl orange degradation studies, were all conducted in batch mode. The ozone throughput from the designed plasma ozonator was characterized using the wet KI method. The ozone throughput at different airflow rates was measured.

In a typical laundry grey water treatment batch experiments, 4 L of grey water to be treated is filled in the pipe. A mixed water sample obtained by mixing the discharge water from a household laundry washing machine's rinse cycle and wash cycle water in 1:1 ratio was used in this study. Compressed air at a known flow rate from the compressor is fed to the plasma generator, and the outlet from plasma generator is bubbled through the grey water. Ceramic aerators capable of producing fine bubbles were used as submerged aerators. System was provided with a recirculation

vivekvardhan2@gmail.com

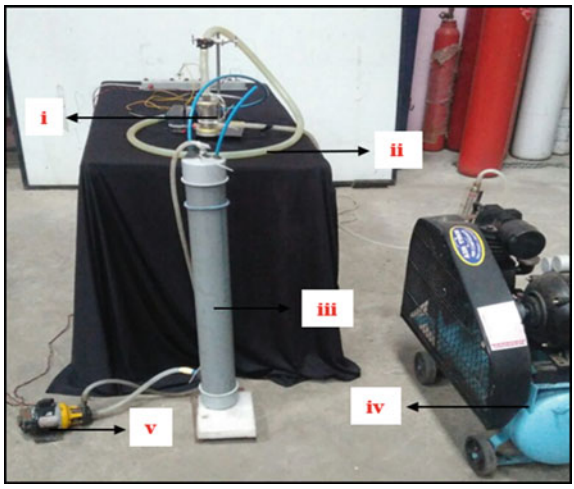

Fig. 2 Experimental set-up for ozonation of grey water. (i) DBD plasma generator, (ii) ozone inlet, (iii) batch reactor, (iv) air compressor, (v) water circulating pump

pump fitted with a nozzle spray to maximize contact time between ozone and grey water. Water samples were collected at regular frequency over the entire duration of ozonation which was up to 60 min. Parameters such as COD, TOC and pH of the grey water were measured using standard procedures. Attempts were also made to determine the kinetics of the COD reduction due to ozonation.

In a typical SDBS destruction batch experiments, 1L of water having an initial concentration of 7 ppm of SDBS was taken in a batch reactor and the ozone was bubbled through. Water samples at regular intervals were taken and analysed for SDBS concentration and pH as a function of ozonation time. The concentration of SDBS was determined using methylene blue active substances (MBAS) method. Attempts were also made to determine the kinetics of the SDBS reduction due to ozonation.

To study the methyl orange degradation, 1 L of water having an initial concentration of 500 ppm of methyl orange was taken in a batch reactor and the ozone was bubbled through the water. Water samples at regular intervals were taken and analysed for methyl orange concentration and pH as a function of ozonation time. The concentration of methyl orange was determined using UV spectrophotometer.

3 Results and Discussion

3.1 Ozone Throughput Studies

Figure 3 shows the ozone throughput as a function of inlet airflow. As can be seen from Fig. 3, increasing airflow rate increased ozone throughput. For 20 lpm of airflow rate, 1210 $\pm$ 10 mg/h of ozone throughput was obtained, and at 100 lpm of airflow

vivekvardhan2@gmail.com

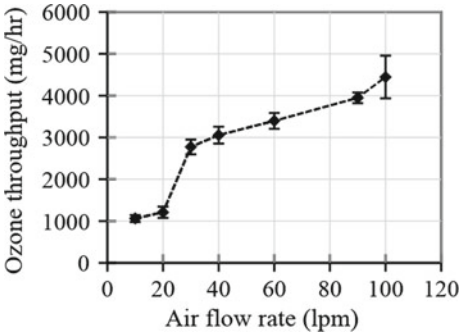

Fig. 3 Ozone throughput (mg/h) as a function of airflow rate (lpm) for co-axial DBD plasma reactor

rate, the ozone throughput measured was 4500 ± 500 mg/h of ozone. We believe that increase in airflow rate leads to higher plasma volume in the reactor leading to higher ozone throughput.

3.2 Treatment of Grey Water Using Ozonation

The feed grey water, which was a mixed sample collected from a household laundry machine, had an initial COD in the range between 500 and 900 mg/L. A 4 L sample was treated using ozonation at 20 LPM of airflow rate. Under these conditions, we noticed that ozonation resulted in 68.7% reduction in COD reduction in the first one hour of treatment at 1.2 g/h of ozone flow rate. During experiments, we noticed that though the grey water coming from the laundry machines created foam during initial 10–15 min, it quickly stopped showing the chemical degradation of surfactants present in the grey water. Figure 4 shows the visual appearance of grey water as a function of ozonation time. As shown in Fig. 4, with ozonation, the turbidity of the water reduced and at the end of 60 min of ozonation, the water looked clear. As illustrated by Fig. 5, in 60 min of treatment the COD reached the effluent discharge limit of 250 ppm in all the treated samples regardless of initial value of COD. The pH remained alkaline, between 8 and 9, during the treatment of laundry grey water.

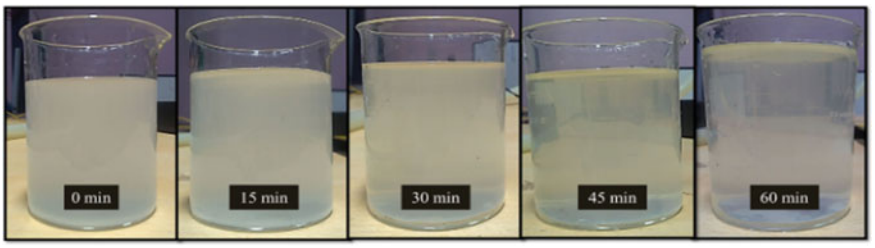

Fig. 4 Reduction in turbidity of laundry grey water over the period of ozonation

vivekvardhan2@gmail.com

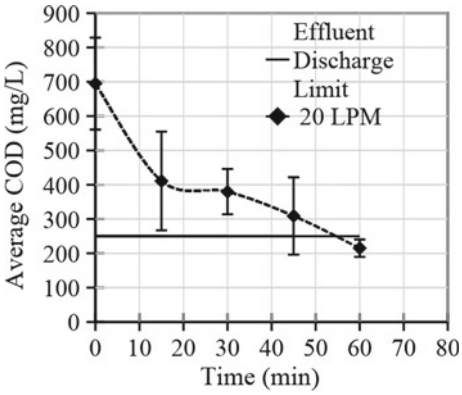

Fig. 5 Reduction in chemical oxygen demand (COD) as a function of time (min) for 4 L of ozonated washing machine discharge at 20 lpm airflow rate

The laundry grey water which typically is rich in SDBS surfactants gets reduced through the hydroxyl mechanism of oxidation as discussed in Sect. 1.2. Due to its electrophilic nature (electron preferring), the $OH^{\cdot}$ can non-selectively oxidize almost all electron rich organic molecules including SDBS.

Total organic Carbon (TOC) was also measured using a Shimadzu TOC-5000A unit by combustion catalytic oxidation method and detection using an infrared gas analyzer. The TOC for ozonated laundry water reduced from 69.1 to 28.2 ppm in 60 min of treatment.

The first step in modelling the process for the study of the kinetics of wastewater ozonation is the determination of the rate constant of the ozone reactions. The kinetic studies of wastewater ozonation are shown in Fig. 6. As can be seen in Fig. 6, we can see that the reduction of COD follows first-order kinetics with respect to ozone and solute concentration at 8.8 pH. Table 1 shows the rate constants of the destruction of various compounds with ozone.

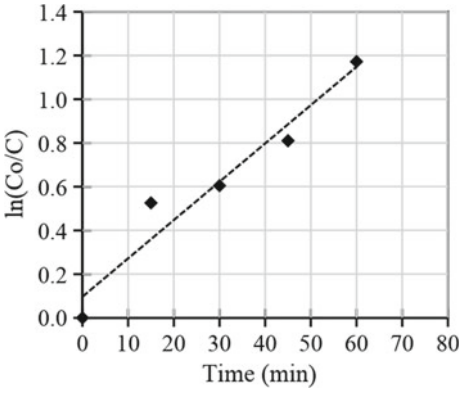

Fig. 6 In (Co/C) versus time (min) for 4 L of ozonated washing machine discharge at 20 lpm airflow rate

vivekvardhan2@gmail.com

Table 1 Reaction rate constants of ozone

Component	pH	k_{O3} (s^{-1})
COD	8.8	0.0197
SDBS	8.5	0.0213

3.3 Removal of SDBS Using Ozonation

SDBS concentration gradually reduced to 66.4% of the initial amount over a period of 120 min as shown in Fig. 7. We believe that this observed reduction is mainly due to its reaction with $OH^{\cdot}$ radical. The solution remains alkaline over the period of ozonation. Alkaline conditions favour the ozonation rate of the SDBS compound, since hydroxyl radical reactions are the main route of its degradation. It follows first-order rate kinetics as shown in Fig. 8 and Table 1.

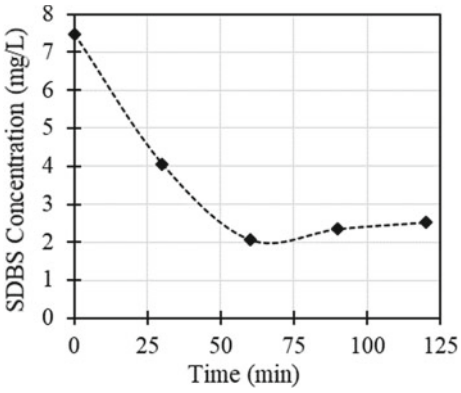

Fig. 7 SDBS degradation by ozonation as a function of time (min) at 20 lpm airflow rate

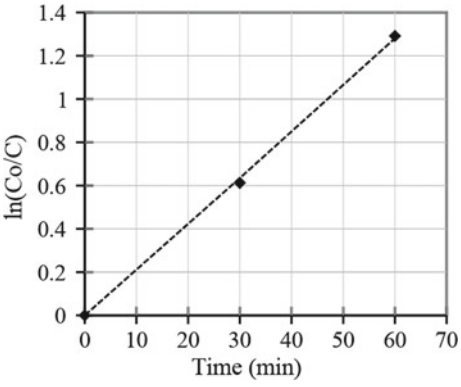

Fig. 8 In (Co/C) versus time (min) for SDBS ozonation at 20 lpm of airflow rate

vivekvardhan2@gmail.com

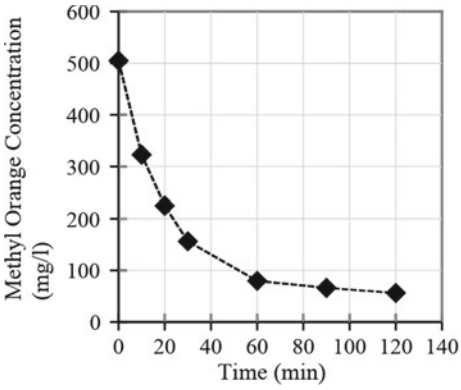

Fig. 9 Methyl orange degradation by ozonation as a function of time (min) at 40 lpm airflow rate

3.4 Methyl Orange Degradation by Ozonation

The decolouring of 1 L methyl orange solution was studied using DBD plasma generator at 40 lpm (3.05 g/h of Ozone) of airflow rate as illustrated in Fig. 9. The dye concentration of 500 ppm with the initial pH of 6.7 was fixed. Experimental results confirm that 91.9% reduction in methyl orange colour concentration was observed over a period of 120 min of ozonation.

4 Conclusions

This study has demonstrated that a small-scale reliable ozone generation system can be developed and can be used to treat domestic grey water. The following can be concluded:

- Ozonation of grey water from washing machine resulted in 68.7% and 59.2% reduction of COD and TOC, respectively, in 1 h of ozonation, regardless of the initial COD value of the sample.
- Turbidity of samples decreased to a significant extent over the course of ozonation. Foaming also reduced after treatment which indicates ozonation causes surfactant degradation in grey water.
- Ozonation of anionic surfactants and methyl orange resulted in 66.4% and 91.9% reduction in concentration, respectively, over a period of 120 min of ozonation. The solution remained alkaline over the period of ozonation.
- Ozonation is highly recommended due to its degradation effectiveness, rate of degradation, relatively simple experimental design and scalability.

Natural Adsorbents for Removal of Different Iodine Species from Aqueous Environment: A Review

Jakkapon Phanthuwongpakdee, Sandhya Babel and Tatsuo Kaneko

Abstract Radioactive iodine in the nuclear waste can cause adverse effects on the human and other living organisms. I-129 and I-131 are released into the aqueous environment via the nuclear accident, weapon testing, scientific procedures as well as hospitals. The radioactivity of these substances is fatal to human and other living creatures. This study reviews different types of natural adsorbents that can be utilized for the application of radioactive iodine remediation in the water. To solve the problem, scientifically, the conventional anion-exchange resin is typically employed for the anionic species of iodine, but it is deemed unsustainable due to dependency over petroleum-based chemical. As a result, there is a need for the search of more sustainable adsorbents, which include activated carbon, soil and clay materials, mineral and even polysaccharide. The activated carbon, when impregnated with silver, can adsorb up to 126.9 mg/g of I^-. In its fiber form, the adsorbent has the equilibrium capacity of 305 mg/g. Clay can be modified to contain quaternary amine functional group and has I^- coefficient sorption, K_D, value of 297–9610 mL/g. For the mineral, many kinds had been tested for iodine removal. Non-modified hydrotalcites can reach I^- adsorption equilibrium of 192.5 mg/g in 1 day, while the magnetite–imidazole-coated silica adsorbed 130 mg/g within 40 min. The cyclodextrin–chitosan complex has one of the highest I_2 adsorption capacities of 1200 mg/g. The information shows that natural adsorbents can be considered as a green alternative to the conventional anion-exchange resin, and more studies to optimize these materials are needed in the future.

1 Introduction

Radioactive iodine contained in the nuclear waste can create adverse effects on human and other living organisms. Of all the iodine isotopes, I-129 and I-131 should be the most concerned in term of environmental impact and human health. With its 8 days of decay half-life, Iodine-131 (I-131) is described as the most hazardous radionuclide released into the environment (Morita et al. 2010). Similarly, I-129 can also create such adverse health effect to human. It has a lower activity per ton of fuel, but possess a potential to create a long-term risk and is a major problem related to waste disposal (Denham et al. 2009). I-129 exists in a sufficient quantity, and it has a much longer half-life time at 1.6×10^7 years. During the time of the large-scale accident, I-131 might be a more problematic species due to its higher radioactive energy while the accumulation of I-129 in the groundwater and soil has been observed around the nuclear waste disposal sites such as Savannah River and Hanford Site (Denham et al. 2009).

It is known that radioactive element is created by cosmic radiation and the natural disintegration series of other elements (Kohman and Edwards 1966). On the other hand, it is also produced by anthropogenic activities such as weapons testing, science experiment, medical procedures, and the fission process in nuclear power plants. Table 1 shows the major sources and incidents that have caused the released of radioactive iodine. Creating energy from the fission process in nuclear power plants seems to be one of the promising ways of securing electrical power in the future. However, since the first nuclear power plant was constructed, the safety concern relating to its waste products, which are being released into the environment, has been the issue to be dealt with (Ramana 2009). Chernobyl disaster occurred in 1986 with the explosion of reactors in Chernobyl Nuclear Power Plant located in Pripyat, Ukraine. Following the Earthquake near Japan in March 2011, the tsunami destroyed parts of Fukushima Nuclear Power Plants, releasing the substance from the reactors into the environment. Savannah River Site, Hanford Site, Nevada Testing Site, and nuclear reprocessing plants are adding amounts of radioactive iodine into the water resources as well.

When comparing the natural products to those of the quantity released by human actions, it can be seen that human contributed to a much higher amount of radioactive iodine (Kohman and Edwards 1966; Hu et al. 2010). According to Toxicological Profile for Iodine, radioactive iodine can destroy thyroid gland and increase the risk for hypothyroidism, thyroid nodules, and cancer (Agency for Toxic Substances and Disease Registry 2004). Human's thyroid gland, naturally, adsorb iodine for the purpose of hormonal, growth, and metabolic regulation. It can contain up to 30–40 times of iodine concentration than that of in the bloodstream (Braverman and Cooper 2005). Moreover, the pathway of iodine includes the adsorption from the gastrointestinal tract and lungs which the substance eventually ends up in the bloodstream (Agency for Toxic Substances and Disease Registry 2004). Iodine can also be found in other parts of human body including gastric mucosa, salivary glands, mammary glands, choroid plexus, ovaries, placenta, breast tissues, breast milk, and

vivekvardhan2@gmail.com

skin (Jhiang et al. 1994; National Academy of Science 1999). The exposure pathway of radioactive iodine to human includes the ingestion of cow milk, fruits, vegetable, fish, water, and inhalation (National Academy of Science 1999; Peterson et al. 2007).

A large amount of iodine in the ocean can also create negative feedback to the earth's ozone layer. The iodine in the sea and marine aerosol are important aspects of the earth's temperature and sun radiation regulation (O'Dowd et al. 2002). Above the ocean, 25% of ozone chemical had been lost due to the emission of iodine and 70% increase in ozone depletion due to iodine is estimated from that of in pre-industrial era (Prados-Roman et al. 2015). High accumulation of long-lived I-129 in the ocean can contribute to such adverse effects.

With all the impacts mentioned, the scientific field has been challenged with the search for a suitable technology to remove and immobilize the pollutant, especially in the water environment. The technologies used for radioactive iodine removal in the water are summarized in Table 2. The techniques include membrane separation, electrolysis, chemical precipitation, phytoremediation, and adsorption. The membrane separation and electrolysis are mostly limited to the drinking water application. While these techniques could remove more than 90% of the radioactive iodine in various concentrations, the pre-treatment by adsorption is still needed to prevent the process failure (Hamasaki et al. 2014; Chae and Kin 2014). The drawback of chemical precipitation is that the addition of chemical such as polyaluminum chloride (PAC) and silver-containing agent is not suitable for the open environment (Kosaka et al. 2012; Eden et al. 1952). As a result, treatment plant is usually required, and transportation of contaminated water is thus required. Species of brown algae were proven to accumulate iodine, but the process takes time and further studies are required to control the rate of accumulation (Küpper et al. 1998; Nitschke and Stengel 2014). For the adsorption, the synthesized polystyrene-based adsorbent is commonly used. However, its dependence on petroleum-based chemical is deemed unsustainable.

In this report, the adsorption of radioactive iodine, iodide, and iodate is being considered. It reviews different kinds of natural adsorbents with and without modification that can be employed for adsorption of different iodine species. It also presents the optimum conditions for each adsorbent. The comparison of the adsorption capacities between each group and with ion-exchange resin is also reported. Thus, this review helps in identifying the potential natural adsorbents for the removal of iodine from water environment.

2 Principle of Adsorption

Adsorption is the process of the association or/and adherence of fluid phase on the surface of the solid phase. This can happen in two ways-— through physical and/or chemical interactions. The physical adsorption usually deals with London dispersion forces (as one of Van der Waals forces). London dispersion force is an intermolecular attraction between uneven electrons and protons, creating temporary dipole. The

Table 2 Typical techniques used for the removal of radioactive iodine in the water

Types of technology	General principle of removal	Maximum iodine removal (%)	Initial concentration	Reference
Membrane separation	1. Pressure-driven—use of pressure to force the water through the membrane where the particulate is separated from the water, depending on the membrane porous size 2. Ion-exchange—use of membrane with a cationic functional group to trap the anionic iodine species	>95	365 kBq/L	Hamasaki et al. (2014), Sancho et al. (2006), Van Der Bruggen et al. (2003)
Coagulation–flocculation–sedimentation	Precipitation of iodine species with polyaluminum chloride (PAC) and silver nitrate in acidified environment	>95	150 μg/L	Kosaka et al. (2012), Eden et al. (1952), Kitada et al. (2015)
Electrolysis	Separating the anionic species of radioactive iodine by applying direct electrical current (DC)	99	4000 μg/L	Hamasaki et al. (2014)
Phytoremediation	Bioaccumulation and/or surface adsorption by species of algae and water plants	>60	1000 kq/L	Morita et al. (2010), Fukuda et al. (2014), Hosseini (2010)
Polystyrene-based anion-exchange resin	Anion-exchange and adsorption between anionic species of iodine and Cl^- or OH^- on the resin beads	>70 (2979.6 mL/g K_D and 5.9 μg/g maximum adsorption)	7.88 μg/L	Parker et al. (2014)

vivekvardhan2@gmail.com

interaction energy depends on the surface contact area of the molecules, polarizability (based on molecule size) and the number of pi-bonding present. The chemical adsorption deals with ionic and covalent bonding between the target molecules and the functional group of the adsorbent. The physical adsorption is usually weaker than the chemical adsorption.

The binding process of adsorption is related to Eq. (1).

$$\Delta G = \Delta H - T\Delta S \tag{1}$$

where, ΔG is the change of Gibbs free energy expressed in kJ/mol and T is temperature. ΔG is associated with the adsorption process as shown in Eq. (2).

$$\Delta G = -RT \ln K \tag{2}$$

where, K is the thermodynamic constant related to the binding of the sorbate to the adsorbent. R is the gas constant. ΔG is related to the spontaneity of the adsorption process where the higher in negative value of ΔG reflects more energetically favorable adsorption (Plazinski 2012). Substituting Eq. (1) into Eq. (2) would yield Eq. (3).

$$\ln K = -\frac{\Delta H}{RT} + \frac{\Delta S}{R} \tag{3}$$

For an experiment with changing in temperature is observed, ΔH and ΔS can be obtained from the slope and the intercept of the plot ln$K$ against 1/T.

If we are determining the equilibrium relationship between solid and aqueous solution, we can first equilibrate the known adsorptive solution and the sorbent at a fixed temperature and pressure. The equilibrium relationship, described by isotherms, will be obtained when the adsorptive solution and the adsorbent are allowed to make contact for a period of time. The amount of adsorption or amount of mass of solute adsorbed per unit mass of adsorbent, q (expressed in mol/g or mg/g) can be calculated with the mass balance equation (Eq. 4).

$$q = \frac{(C_\mathrm{i} - C_\mathrm{e})V}{m} \tag{4}$$

where, C_i and C_e are the initial and final adsorptive concentration, respectively. V is the volume while m is the mass of the adsorbent. To determine the most suitable adsorption model, it is important to understand that the adsorption isotherms exhibit many different shapes for a different combination of sorbates and sorbents. By plotting q against C_e, if a linear graph is obtained, the relationship between q/C_e can be expressed as a ratio of solid solution distribution coefficient K_D (Eq. 5).

$$K_D = \frac{q}{C_\mathrm{e}} \tag{5}$$

vivekvardhan2@gmail.com

Linear adsorption usually occurs at low solute concentration and low amount of sorbate (Delle Site 2001). If the plot of q against C_e yields a nonlinear graph, it indicates that after a period of time, the sites of sorbent become saturated and the degree of adsorption does not change anymore. Two kinds of models can be used for this particular case. The first model derived from the equation of the change in final concentration over time which expressed as Eq. (6).

$$\frac{\partial C_e}{\partial t} = -k_1 m \Delta C_e (q_{max} - q) + k_2 q m \tag{6}$$

where q_{max} is the adsorption capacity or adsorbed solutes concentration corresponding to the total number of surface sites. k_1 and k_2 are the rate constant for adsorption and desorption. The rate of adsorption is assumed to be proportional to C_e and to the difference in q_{max} and q. The equation can be reduced to express the relationship between q and C_e Eq. (7).

$$q = \frac{q_{max} K_L C_e}{1 + K_L C_e} \tag{7}$$

where, K_L is the Langmuir constant or coefficient related to the enthalpy of adsorption. To get a linear relation between q and C_e, the Eq. (8) is used.

$$\frac{1}{q} = \frac{1}{q_{max}} + \frac{1}{K_L C_e q_{max}} \tag{8}$$

where, q_{max} can be calculated from the inverse of the intercept. Therefore, K_L can be calculated with the inverse of slope multiply by q_{max} obtained.

In Langmuir model, the relation between q and q_{max} can be described as when the solute concentration is increasing at low surface coverage with the available adsorption sites reaching saturation and q is increasing linearly to approach q_{max}. The model has q_{max} representing monolayer coverage and assumes that adsorption energy is independent of degree of surface coverage (Delle Site 2001). It also assumes the energy to be equal for all sites, where only localized ones are involved in the adsorption process without interaction between adjoining sorbed molecules (Delle Site 2001).

The second model takes into account the degree of surface coverage and sorption energy for the sites. It is called Freundlich model where the relationship of q and C_e is expressed as Eq. (9).

$$q = K_F C_e^n \tag{9}$$

where, K_F is used as the Freundlich coefficient and n is the exponent relates to adsorption intensity and free energy. To get the linear plot for Freundlich isotherms, log transformation is used (Eq. 10).

vivekvardhan2@gmail.com

$$\mathrm{Log}q = n\mathrm{Log}C_e + \mathrm{Log}K_F \tag{10}$$

Using the linear plot of Freundlich model, n and K_F can be obtained from the slope and intercept, respectively. If n is 0, a constant adsorption-free energy at all sorbate concentration is observed. On the other hand, a value of n more than 1 means the increase in the presence of sorbate enhances the free energies for further adsorption, but when n is less than 1, weaker free energies with increasing sorbate is observed.

It is worthy to note that the linear, Langmuir or Freundlich isotherms equation cannot solely explain the sigmoidal isotherm relation. Instead, sigmoidal behavior signifies the combination of two different adsorption mechanisms, one after another. It occurred due to alternation in the functional groups during the adsorption, numerous components of a heterogeneous sorbates or diversity in free energies related to the adsorption process.

3 Natural Adsorbents for Iodine

3.1 Activated Carbon

Iodine adsorption by activated carbon has been reported for several decades. The activated carbon is derived from the carbonaceous materials such as coconut, nutshell, wood, and lignin. Sometimes, it is made of coal and can be described as activated coal (for this report, the activated coal maybe refers as an activated carbon). The gaseous iodine adsorption capacity is typically used to characterize the commercial activated carbon in the form of "iodine number," which refers to how much amount of iodine (mg^2) is being adsorbed by a gram of activated carbon. The activated carbon is, therefore, regarded as a potential adsorbent for the radioactive iodine in the water. Activated carbon has been utilized and studied extensively for both air and water pollution adsorption because of its large surface area. Many studies have shown a successful iodine adsorption of radioactive venting from the nuclear power plant exhaust pipe and that of polluting the air environment (Adams and Browning 1960; Zhou et al. 2014). However, in this report, the only removal of iodine in the water is considered and summarized in detail.

The activated carbon adsorbs sorbates by London dispersion force. It consists of micro-, meso- and macropores structures, where the major adsorption of iodine occurs mostly at the micropores (Yang et al. 1993). As a result, it is critical how these pores are arranged depending on the form of the activated carbon (Barkauskas and Dervinyte 2004). The comparison of activated carbon in different forms is exhibited in Table 3. One study compared the ability of granular and fiber activated carbon to remove I_2 and I^- (prepared by HI), in the acetic acid (Yang et al. 1993). Under acidic environment, the activated carbon fiber could absorb 305 mg/g I_2 and 350 mg/g I^-, higher than the adsorption capacity of 195 mg/g I_2 and 205 mg/g I^- in the granular form of activated carbon (Yang et al. 1993). The outcome coincided with the BET

Table 3 Comparison of iodine adsorption with different types of activated carbon

Type of activated carbon	[a]Maximum iodine adsorption (mg/g)	Removal (%)	Equilibrium time	Experimental condition					Reference
				Iodine species	Initial iodine concentration (mg/L)	Adsorbent dosage (g/L)	Medium	pH	
Carbon fiber	305	–	2 h	I_2	800	–	Acetic acid	–	Yang et al. (1993)
Granular	195	–	24 h	I_2	800	–	Acetic acid	–	Yang et al. (1993)
Granular	0.635	87.50	–	I^-	1.015	1	DI water	8	Hoskins and Karafil (2002)
Granular	1.68×10^{-3}	18.50	–	I^-, IO_3^-, I_2	9.19×10^{-3}	1	Groundwater	8.2	Parker et al. (2014)
Granular	–	60	–	I^-	40×10^{-3} to 50×10^{-3}	–	Tap water	7	Sato et al. (2011)
1.05 wt% silver-impregnated carbon	~126.9	–	–	I^-	~1 to 200	1	DI water	5	Hoskins and Karafil (2002)
Silver-activated carbon aerogel	0.638	–	7 day	I^-	0.15	~0.2 (2000 g/L/min)	DI water	7	Sánchez-Polo et al. (2006)
Copper-modified activated carbon	1.91	95.7	2 h	I^-	2	1	DI water	1	Zhang et al. (2017)

[a]The value is obtained from the experimental data and not from the mathematical model

vivekvardhan2@gmail.com

surface area for activated carbon fiber which is two times higher than that of the granular form. In fiber form, micropores were exposed to the surface of the sorbate, creating a fast iodine binding and diffusion rate (Yang et al. 1993). On the other hand, in granular form of activated carbon, there was a sequence binding and diffusion of iodine from the mesopores at the surface to micropores within the bulk of the sorbate (Yang et al. 1993).

Besides the physical form of activated carbon, its activation processes involved are important aspects in the adsorption mechanism. In the production phase, biomaterials would go through pyrolysis or oxidation for its physical activation to produce an activated carbon. In the pyrolysis process of activated coal where the temperature was increased to about 400 °C, iodine adsorption sites in coal were enhanced with increasing oxygen cross-link, and this results in higher adsorption capacity (Rodriguez and Marsh 1987). On the other hand, the oxidation process decreased the size of micropores and reduced the adsorption capacity in the activated carbon (Rodriguez and Marsh 1987).

In the laboratory experiment, the activated carbon could remove up to 87.50% of 2 mg/L iodide in the solution (Hoskins and Karafil 2002). However, studies have shown that the removal of iodine in other types of water medium may yield lower iodine removal. Compared to the results of the batch experiment using distilled water, the one with 50 μg/L I^- and IO_3^- in tap water showed 60% and almost 0% removal, respectively (Sato et al. 2011). On the other hand, the result of adsorption in groundwater was the lowest with about 20% maximum adsorption at 9.77 μg/L initial total iodine (Parker et al. 2014). The presence of other chemical species in groundwater environment may cause a competition on available sorption site, resulting in less removal percentage (Parker et al. 2014).

The activated carbon possesses several O_2-containing functional groups such as carbonyl, phenol, lactone, and carboxyl group (Barkauskas and Dervinyte 2004; Nwosu et al. 2009). It is still not certain which group, in particular, is responsible for the sorption of iodine. However, there was an attempt to find the relation between the number of these functional groups in the nutshell, quantified by the method of NaOH titratable surface and iodine sorption capacity (Nwosu et al. 2009). The sorption of iodine was found to be dependent moderately on the quantity of functional groups with a linear statistical correlation of 0.6115 (Nwosu et al. 2009). Isolating each functional group for the model would provide an answer to which O_2-containing functional group is responsible for this sorption process.

Many times, the porous carbon can be modified to contain the inorganic material such as silver and aluminum for different sorption specification. Silver-impregnated carbon is often used for iodine sorption, and it is proved to be able to adsorb more iodine. The sorption capacity value of 1.05% silver-impregnated activated carbon was nearly two times higher than that of virgin activated carbon (Hoskins and Karafil 2002). However, with only 0.05% of silver impregnation, there was no significant change in the value compared to that of virgin activated carbon (Hoskins and Karafil 2002). The silver-activated carbon aerogel was also brought to study in the dynamic adsorption test, where the results exhibited about 0.251–0.638 mg/g sorption capacity, depending on pH and porous characteristics of the aerogel (Sánchez-Polo et al.

vivekvardhan2@gmail.com

2006). The nano-composite of Cu_2O/Cu-activated carbon was synthesized with the ability to remove 95.7% of 2 mg/L I^- and has about 1.91 mg/g adsorption capacity.

The sorption of iodine to activated carbon is affected by pH. At higher pH, activated carbon absorbed iodine less effectively as elevated amount of OH^- competes for the positive adsorption sites (Hoskins and Karafil 2002). The pH effect was demonstrated in the batch experiments of unmodified and copper-impregnated activated carbon. The results showed that all kinds of the activated carbon experience a lower I^- adsorption capacity as pH increases from 3 to 11, although the copper-impregnated activated carbon was shown to be more stable across the pH range (Sánchez-Polo et al. 2006).

The unmodified activated carbon may not be the best selection for the aqueous iodine adsorption because its efficiency decreases drastically when it is used in the natural environment. However, the modification can help to improve its performance. The carbon fiber and silver-impregnated activated carbon are among the best adsorbents in this category. In addition, the activation of biomaterials has brought about the potential in finding alternative and innovative way of making activated carbon. Several waste products such as coffee residue (Boonamnuayvitaya et al. 2004; Boonamnuayvitaya et al. 2005), soybean oil cake (Tay et al. 2009), and even cigarette butts (Sun et al. 2017) became possible raw materials for the activated carbon, and these ideas could be applied for iodine removal in the future.

3.2 Soil and Clay

Iodine is often found as a content of natural soil and clay. Many times the soil itself is contaminated by radioactive iodine (Mimides and Kathariou 2005; Miyake et al. 2012). However, based on the contamination occurrences, it can be a potential natural-derived and low-cost sorbent for the pollution removal in water.

Organic and inorganic matters in soil are both responsible for the sorption of iodine. The iodine content in soil was found to be highly correlated to the amount of oxylate-soluble Al in the near-neutral pH condition and to the amount of oxylate-soluble Fe in the more acidic environment (Whitehead 1978). Generally, I^- and IO_3^- are ionically attracted to the positive charge provided by the free hydroxides of Fe and Al (Whitehead 1984). Table 4 shows iodine adsorption capacity and K_D value of different types of soil and clay. In a batch experiment, the maximum I^- adsorption of 6.59×10^{-3} mg/g occurred in the soil with 4.81% Fe oxide and 5.66% Al oxide, while the maximum IO_3^- adsorbed in the soil with 0.64% Fe oxide and 0.60% Al oxide was 3.41×10^{-3} mg/g (Dai et al. 2009). The experiment was set up with 100 g/L soil dosage at 25 °C for 40 h (Dai et al. 2009).

Nevertheless, in the natural organic constituents of soil, where the positive charge is still scarce, the iodine can still covalently bond and form complexes with functional groups presented in the soil such as phenol, thiol, and amine (Sakuma and Marzukee 1995; Whitehead 1974; Kaplan et al. 2014). The soil samples with higher content of organic matter, organic carbon, calcium carbonate, nitrogen, phosphorus, potassium,

vivekvardhan2@gmail.com

and sulfur were found to adsorb iodine (Fukui et al. 1996; Nath et al. 2010). A batch experiment revealed the ability of the collected sandy loam soils to adsorb 1.3×10^{-4} to 1.60×10^{-4} mg/g of I^- adsorption at its capacity (Nath et al. 2010).

Nearly all the sorbate can be desorbed and recovered from the soil (Nath et al. 2010). However, this means that iodine sorption in the soil can be unstable under the condition where pH and temperature fluctuate. The adsorption of iodine may increase and reach its maximum at about 70 °C (Fukui et al. 1996; Hosseini et al. 2013). However, after that point, the adsorption was observed to decrease with the temperature. Higher pH condition decreased the sorption of iodine species in soil due to the OH^- presence, which competes for the adsorption sites (Fukui et al. 1996). The sorption of iodine is affected by the presence of other anions only when the pH value is below neutral (Fukui et al. 1996).

The increasing uptake of I^- and IO_3^- is dependent and independent on the time of contact, respectively (Fukui et al. 1996). Smaller soil grain size promotes a better iodine adsorption due to the increase in surface area (Fukui et al. 1996). However, unlike the activated carbon, IO_3^- is selected for soil instead of iodide. The adsorption of iodate is found to be higher than that of iodide in different temperature and pH condition (Dai et al. 2009; Fukui et al. 1996).

Besides natural soil, clay is another potential adsorbent that has been studied for the removal of iodine. Naturally, clay mineral is limited in its iodine adsorption ability but due to its high retention of cationic species. The non-modified clay, argillite and kaolinite, had K_D value of 0.21 mL/g and 47.09 mL/g, respectively. However, by modifying the materials, iodine removal efficiency could be improved significantly (Kaufhold et al. 2007). By placing inorganic interlayer cations into natural clay, organoclay was produced with available adsorption sites for the iodine (Riebe et al. 2005). For instance, smectite, vermiculite, and bentonite treated with hexadecylpyridinium chloride ($C_{21}H_{38}N^+$ Cl^-) yielded K_D values of 297, 372 and 2800 mL/g, respectively (Riebe et al. 2001, 2005). More efficiency of 3600 mL/g was observed with the K_D value of 3600 mL/g after treating bentonite with hexadecyltrimethylammonium bromide ($C_{19}H_{42}N^+$ Br^-). The commercial clay, ClayFloc™ 750, has the highest K_D value of 9610 mL/g (Li et al. 2014). The adsorbent was designed to contain cage-like structure aluminosilicate minerals, sulfur, iron, nitrogen-containing substitutions as well as quaternary amine functional group (Kaplan et al. 2015).

Although most of the study regarding the iodine adsorption of soil and clay presented the efficiency in the form of coefficient, K_D, overall, the collected soil was found to have very low maximum iodine adsorption capacity. Nevertheless, like the activated carbon, modification of clay was found to have higher efficiency than that of the unmodified adsorbent. In this category, the commercial product, ClayFloc™ 750, exhibited the highest K_D value of 9610 mL/g. HDPy-bentonite and HDSMB-bentonite had over 2000 mL/g K_D value. The unmodified entisol and argillite were presented with the lowest value of K_D.

vivekvardhan2@gmail.com

3.3 Mineral

Since it could be found in soil and clay, the inorganic matter or minerals adsorb iodine ions in various ways. IO_3^- and I^- are adsorbed to the mineral with the mechanism of specific adsorption (replacement of hydroxyl group) and electrostatic force, respectively (Evans and Hammad 1995). Minerals containing metal ions adsorb iodine and form insoluble metal iodides, while anionic exchange process is also possible for those that contain other anions beside the ions of iodine (Sazarashi et al. 1994). Several researchers have studied the iodine sorption ability of different kinds of inorganic matters. Table 5 shows the summary of iodide sorption capacity on minerals and rocks from various studies.

Zeolite is a group of hydrated aluminosilicate mineral. The examples of natural zeolite include clinoptilolite, mordenite, and chabazite. The commercial zeolite was capable of removing a high amount of positive radioactive ions of strontium, barium, and cesium (Sato et al. 2011; Lonin et al. 2015). However, it could absorb a minimal amount of iodine. With the initial iodine concentration of 40–50 μg/L, the commercial zeolite removed up to about 20% of I^- and less than 10% of IO_3^- (Sato et al. 2011). In a dynamic adsorption test, with a 4-day contact time, 0.1 g natural zeolite yielded the maximum K_D value for 1.65×10^5, which seems to be a huge number of the coefficient (Lonin et al. 2015). However, in the same research, the K_D values of zeolite for Nd(III) and Sm(III) were observed to be more than three times that of iodine at 7.48×10^5 and 5.47×10^6, respectively (Lonin et al. 2015).

A modified form of zeolite might be more promising for the removal of iodine in water. Silver ion-exchange zeolite has been observed to remove iodine at the capacity of approximately 1.5 mol/g or 190.356 g/g in the air stream (Choi et al. 2001). Modifying zeolite to include hydroxyapatite and hydroxyfluorapatite increased the stability of iodine captured by the sorbent from the air stream (Watanabe et al. 2009). Although methodologies in the mentioned literature are for the removal of radioactive in the gas phase, the same techniques and sorbent can be adapted for the removal contaminant from the aqueous phase, in the future.

Cinnabar exhibited high K_D value as well as removal percentage (Sazarashi et al. 1994). The hydrotalcite also had a relatively high iodine adsorption capacity of 192.5 mg/g (Paredes et al. 2006). When the adsorbent was doped with silver, to produce a silver-hydrotalcite, the iodine uptake capacity increased to 495.5 mg/g (Bo et al. 2016). On the other hand, at optimum conditions, allophane, attapulgite, and chalcopyrite exhibited low K_D value and removal percentage (Sazarashi et al. 1994). For bismuth oxide, with 20 mg/L initial concentration, the adsorbent took 10 h to remove 70 and 80% of I^- and IO_3^-, respectively (Liu et al. 2016). The adsorbent may remove more IO_3^- than I^-, but the K_D values suggested that the adsorbent favor the removal of the latter (Liu et al. 2016).

The bismuth oxide was very stable in water at pH 7 as only 2.3% of iodine leaching was reported after a 12-h leaching experiment (Liu et al. 2016). However, as the pH increased, the sorption capacity decreased (Liu et al. 2016). With the anion competition experiment, the bismuth oxide has shown a strong I^- selectivity in the

presence of other anions, but CO_3^{2-} or Cl^- could pose a strong competition for the sorption sites (Liu et al. 2016). Lastly, the researchers studied the removal of iodine in the synthetic seawater, using Fukushima Nuclear Power Plant as a reference. The bismuth oxide could remove 60–100% of the iodine in the seawater, depending on the initial concentration of iodine added (Liu et al. 2016).

The metallic mineral could be modified for iodine adsorption. The silica was coated with magnetite and imidazole. The sorbent was brought for the iodine removal, and the result was satisfactory with 98% iodine removal and about 130 mg/g maximum final sorption capacity (Madrakian et al. 2012). Up to 90% of iodine was recovered from the sorbent (Madrakian et al. 2012). ZIF 8 or (Zn(2-methyl-imidazolate)$_2$) a type of metal–organic framework (MOF) which contained zinc was studied for its ability to remove iodine vapor (Hughes et al. 2013). A gram of ZIF 8 adsorbed up to 0.66 g of iodine (Hughes et al. 2013). The research on this sorbent should be continued in the future with the sorption experiment in the water.

A natural material called gossypol was modified to have zeolite-like morphology. The material is called gossypol P3 polymorph and is described as a phenolic aldehyde pigment, extracted from cotton plants and seeds. It was investigated for its ability to remove iodine in the aqueous solution. The results confirmed for an iodine inclusion, which the molecules enter the extended cavities of the channels within the zeolite-like structure of the gossypol P3 polymorph (Talipov et al. 2007). The sorbent should be subjected to a batch experiment in the future.

Several kinds of minerals have shown promising results. The silver-hydrotalcite had almost 500 mg/g iodide removal capacity and has been able to remove I^- in the seawater, so it becomes one of the best adsorbents in this category. The results of bismuth oxide also exhibited high K_D for both I^- and IO_3^-, and it is one of a few adsorbents that have been reported for the successful removal of IO_3^-. Consequently, the mineral is considered as one of the most essential adsorbents that contribute to the radioactive iodine removal and should be studied further for better results.

3.4 Polysaccharide

Starch and iodine have been known to react to form unique complex formation. The reaction has often been used in the analytical chemistry field for over a century (Szente et al. 1999). It was claimed that iodine form a complex with both amylose and amylopectin in the presence of water (Saibene and Seetharaman 2006). As a result, iodine can be used to determine amylose and amylopectin content in various kinds of starches such as those in corns and potatoes (Rendleman 2003). Knowing that such complex formation exists, there were some attempts to use natural and synthetic polysaccharide in iodine sorption (Table 6).

Chitin is a natural polysaccharide which was found in 1884. It is the most abundant natural polysaccharide, second to cellulose, found in the exoskeleton of arthropods like shrimps and crabs. Chitin and its ability to bind iodine have been studied for drug delivery (Takahashi 1987). Chitin was reacted with iodine, and the results showed that

vivekvardhan2@gmail.com

Table 6 Iodine adsorption by polysaccharides

Polysaccharide	[a]Maximum capacity (mg/g)	Equilibrium time	Experimental condition					Reference
			Iodine species	Initial iodine concentration (mg/L)	Adsorbent dosage (g/L)	Temperature	pH	
Chitin	116.67	24 h	I_2	~3.8×10^4	100	–	–	Takahashi (1987)
Chitosan	100	24 h	I_2	~5×10^4	2	25	–	Chen and Wang (2001)
Cyclodextrin–chitosan complex	1200	24 h	I_2	~5×10^4	2	25	–	Chen and Wang (2001)
Calcium alginate–silver chloride	152.032	–	I^-	5.5–10	5	25–55	4–10	Zhang et al. (2011)
TiO_2-Fe_2O_3-PVA alginate beads	~20	3 h	I^-	200	50	25	8	Majidnia and Idris (2015)

[a]The value is obtained from the experimental data and not from the mathematical model

vivekvardhan2@gmail.com

1 and 3 g of chitin were bound to 0.149 and 0.35 g of iodine, respectively (Takahashi 1987). A report presented the synthesis of chitin aerogel with silver impregnation, which the porous adsorbent was capable of adsorbing I_2 from the vapor (Gao et al. 2017).

Chitosan is another kind of polysaccharide, which was made from chitin by the process of alkaline deacetylation. It is considered to be one of a few natural cationic polymers. It is soluble in aqueous solution and can be modified into many forms such as gel, films, and fiber. In a batch experiment using 0.1 g chitosan beads in 50-mL ethanol solution of various iodine concentrations, the maximum sorption capacity was found to be about 0.2 g iodine per a gram of chitosan (Chen and Wang 2001). A K_D value of 88 mL/g was presented in another study (Li et al. 2014).

Cyclodextrin is a sugar molecule that linked to form a ring. It is produced from starch, and like chitin and chitosan, it has been studied extensively for food and drug delivery system (Chen and Wang 2001). A study exhibited a process of cyclodextrin entrapping the gaseous radioactive iodine in a nuclear waste management (Szente et al. 1999). Although the study was done for the air contamination, it shows that cyclodextrin could adsorb iodine in the presence of water vapor. A complex of cyclodextrin–chitosan was found to have a maximum iodine removal capacity of 1200 mg/g (Chen and Wang 2001).

The alginate is another adsorbent that has been researched for the iodine adsorption. It has been proposed that mucilaginous layers, the cells that cover the surface of brown algae, play an important part of iodine sorption ability (Loderio et al. 2005). Within these mucilaginous layers, alginic acid is contained, which is the main ingredient of sodium alginate. Sodium alginate is a compound that is used for pharmaceutical and commercial chelator product to pull I-131 and Sr-90 from bodies of the consumers (Loderio et al. 2005; Sutton et al. 1971). However, the alginate is an anionic polysaccharide. As a result, some studies impregnated it with various kinds of metals, for iodine sorption in the batch experiments. The iodine adsorption on calcium alginate–silver chloride composite yielded the adsorption capacity within the range of 132.742–152.032 mg/g across a set of initial iodine concentration and temperature (Zhang et al. 2011).

The alginate could also be taken to react with Polyvinyl alcohol (PVA), titania (TiO_2), and maghemite (γ-Fe_2O_3) to create a unique sorbent (Majidnia and Idris 2015). The TiO_2-Fe_2O_3-PVA alginate beads were shown to adsorb iodine in an aqueous solution with about 20 mg/g maximum uptake (Majidnia and Idris 2015). pH 8 provided the optimum condition for the sorption mechanism as the highest iodine percentage removal of about 98%, in 200 mg/L iodide initial concentration, was obtained (Majidnia and Idris 2015). Additionally, it was shown that TiO_2-Fe_2O_3-PVA alginate beads can be reused for more than seven times with only 10% reduction of sorption efficiency is observed at the seventh usage (Majidnia and Idris 2015).

Compared to those of the other categories, the research on polysaccharide was found to be limited. Still, the cyclodextrin–chitosan complex exhibited one of the most iodine uptake capacities across all the adsorbent categories. The complex was only studied for the binding of I_2, but, like the calcium alginate–silver chloride, it can possibly be modified for the removal of the anionic species in the natural

vivekvardhan2@gmail.com

environment. Since polysaccharide is widely available, further research should focus on identifying the potential adsorbents.

4 Comparative Study of Natural Adsorbents to the Conventional Anion-Exchange Resin

The ion-exchange resin is the adsorbent often used in conventional water softening and treatment. It is also a useful material for several other practices including medical procedure, food production, and agriculture. Ion-exchange resins usually contain a cross-linked polymer matrix with ion-active sites throughout the structure. It has an ability to adsorb ions with a minimal effect on the chemical formation of the solutes and the form of targeted ion (DOWEX 2000). Ions can be recovered from the sorbent in the process called regeneration, which returns the resin to its initial state.

The anion-exchange resin is usually produced from polystyrene. It is engineered to have quaternary amine on the surface. Attached to the N^+ is Cl^- or OH^- that can be exchanged with the target anionic contaminant. Several commercial anion-exchange resins were used to remove I-129 from the underground water environment. The commercial resin has a total iodine maximum loading capacity of 8.27 μg/g (Parker et al. 2014). I^- is observed to be a more desirable species for the sorbent with the maximum capacity of 5.90 μg/g (Parker et al. 2014). On the other hand, only about less percentage removal of IO_3^- was reported without the value of maximum capacity (Parker et al. 2014). A recent study on the iodide adsorption by silica-based poly(4-vinyl pyridine) resin yielded the contaminant removal capacity of 148.23 mg/g (Ye et al. 2019).

It would be inaccurate to directly compare the adsorption capacity and equilibrium time of different adsorbent to the anion-exchange resin. This is because the experiments were performed in different condition with different iodine quantification techniques. However, the summary of the sorption mechanism, maximum capacity or $K_{D,}$ and prices of natural adsorbents and anion-exchange resin are shown in Table 7. The sorption mechanism is different for all the natural adsorbent. The price for activated carbon is cheap but the adsorbent itself relies on the modification to improve its iodine adsorption capacity. The commercial bentonite, ClayFloc™ 750, may also have one of the highest K_D values, but it requires the process of synthesis with organic compound containing quaternary amine. The amylose and amylopectin in polysaccharide are also responsible for the binding of I_2 but like the activated carbon, in order to improve the adsorption capacity of anionic iodine species, the adsorbent still depends extensively on the modification with the organic and inorganic with cationic functional groups. The cyclodextrin–chitosan complex seems to have the highest maximum capacity. Nevertheless, only I_2 was used in the experiment, and the adsorbent is expensive compared to the others.

vivekvardhan2@gmail.com

Table 7 Comparison between the natural adsorbent and conventional anion-exchange resin

Types of natural adsorbent	Adsorption mechanism	Maximum I^- adsorption capacity or K_D from a specific adsorbent	Price/g for specific adsorbent
polystyrene-based Anion-exchange resin	Ion-exchange Cl^- or OH^- with the anionic species of I^-	5.90 μg/g in the underground water environment	~0.84 USD for Dowex-1 chloride form[a]
Activated carbon	1. London dispersion forces 2. Forming bonds with functional group carbonyl, phenol, lactone and carboxyl group 3. Ionic bonding, if modified with metal	305 mg/g from carbon fiber 126.9 mg/g from silver-impregnated carbon	<0.01 USD for untreated, granular, 6 × 12 mesh[b]
Soil and clay	1. Covalently bonded and form complexes with functional groups such as phenol, thiol, and amine 2. Ionically and electrostatically attracted to the positive charge provided by the free hydroxides of Fe and Al	9610 mL/g from the commercial bentonite containing quaternary amine	–
Mineral	1. Specific adsorption (replacement of hydroxyl group) 2. Electrostatic force to cationic components 3. Ion-exchange at the quaternary ammonium, if modified with quaternized agents	192.5 mg/g from hydrotalcites 495.5 mg/g from silver-hydrotalcites 70–80 mg/g from bismuth 130 mg/g silica coated with magnetite and imidazole	<0.01 USD for 4A zeolite[c] ~0.11 USD for hydrotalcite[a] ~0.07 USD for bentonite[a] ~4.58 USD for bismuth (III) oxide[a]
Polysaccharide	1. Form complex with the polysaccharide functional groups; amylose and amylopectin 2. Physical precipitation, ionic bonding, and electrostatic force, if modified with metal	1200 mg/g from cyclodextrin–chitosan complex 152.032 mg/g from calcium alginate–silver chloride	~3.11 USD for β-Cyclodextrin[a]

5 Conclusions and Future Work

From the literature compiled in this report, the problem of radioactive iodine in the water is not a new phenomenon. The research on iodine adsorption has been studied extensively to remove the contaminant from the water so that human and other living thing are not at risk. The natural adsorbents are abundant and can be easily obtained. Some of the natural adsorbents seem to outperform the conventional anion-exchange. With 1200 mg/g iodine adsorption capacity, cyclodextrin–chitosan complex seems to be one of the promising adsorbents, but it is still only efficient for removing I_2 and quite expensive compared to the other adsorbents. On the other hand, the adsorbent like activated carbon, clay, mineral, and alginate rely on the modification to yield a high adsorption efficiency. 495.5 mg/g I^- removal was reported for the silver-hydrotalcites. The carbon fiber and calcium alginate–silver chloride adsorb up to 305 mg/g and 152.032 mg/g of I^-, respectively. The bentonite, which was synthesized to contain quaternary amine, has a very high K_D value of 9610 mL/g.

Most of the adsorbent seem to exhibit the selectivity toward I^-. Only the collected clay and bismuth oxide were reported to adsorb more IO_3^- than I^-. The activated carbon was found to adsorb I^- and I_2, while the chitin, chitosan, and cyclodextrin, unless modified with cationic-containing agent, have only been reported for I_2 inclusion. Moving forward, the batch experiment of the potential adsorbent should be performed with both IO_3^- than I^- as these are prominent species that exist in the water.

In addition, it is recommended that the kinetic and batch experiment are conducted on the potential materials like gossypol, chitin aerogel, and ZIF 8. These adsorbents were successfully tested for the adsorption of gaseous iodine, so they might be able to adsorb the iodine as well in the water. In term of modification, there are still more room for impregnation and synthesis so that the natural materials contain the desired functional group. Besides, the research on using plant materials as iodine adsorbent is still limited. The experiments should be conducted on plant parts that contain the cationic components so that we may uncover new kinds of natural adsorbent.

Lastly, if these materials are found to be highly selective for the iodine contaminants, we can benefit from them not only in term of environmental safety, but also economical values and industrial applications. Continuing the research on this topic is crucial in leading us to the more sustainable future and creating us a better well-being of both human and other living creatures.

An Insight into Characterization, Mechanism and Kinetics of Congo Red Sorption Using Biowaste FRLP

Mohan Rao Tamtam and Basava Rao Vudata Venkata

Abstract Commercial utilization of solid waste is superior to other waste management methods in environment point of view. Dry leaves have potential utility as an adsorbent. The abundantly available biomass *Ficus religiosa* leaf powder (FRLP) was used as an adsorbent for the removal of pollutants like congo red (CR) from aqueous solution. The nature and mechanism for the removal of CR were determined from characterization and kinetic studies. The results reveal the hydrogen bond between various functional groups of adsorbent and the dye. The rate of transport is of pseudo-second-order type.

Keywords *Ficus religiosa* · Congo red · Kinetics · XRD · SEM · FTIR

1 Introduction

Global solid waste generation is around 1.3 billion tonnes per year, with a footprint of 1.2 kg per person per day. By 2025, it is expected to reach 2.2 billion tonnes, with the current phase of population growth, industrialization and urbanization. East Asia and the Pacific region generate approximately 270 million tonnes annually with a per capita of 0.44 kg per person per day. Projected statistics reveals that China and India face serious problems of waste management compared to any other country (http://www.worldbank.org/en/topic/urbandevelopment/brief/solid-waste-management). India is one of the top ten countries producing solid waste with more than 10^5 metric tonnes per day. It is anticipated that population of India would be about 1823 million by 2051 and about 300 million tons per annum of MSW will be generated (http://www.cpcbenvis.nic.in/newsletter/solidwastejun1997/jun1997.htm).

vivekvardhan2@gmail.com

Around 60% of solid waste from lower and middle income country like India is organic. And leaf litter is one of the major contributors of organic waste. Dry leaf piles are considered unsightly and shelter for disease-causing agents (http://www.earthamag.org/stories/2018/4/9/dont-burn-those-dry-leaves-put-them-to-good-use-instead). Open air burning is a general practice to alleviate this problem, but it contributes to air pollution, and hence, global warming. Commercial utilization is a superior method over other solid waste management strategies. Recent literature review proves the capability of dry leaves as a potential adsorbent in chemical industrial sector and water treatment plants (Mohan Rao and Basava Rao 2016).

In this present study, *Ficus religiosa* leaves are powdered and used as an adsorbent to recover synthetic dye, Congo red dye from water effluents. This paper focuses on the characterization of adsorbent, the binding mechanism and the kinetics.

2 Materials and Methods

2.1 Preparation of Anionic Dye Solutions

Congo red (CI = 22,120) was supplied by Merck (Mumbai, India). Initially, a solution of 1000 mg/L was prepared and then diluted as per the requirement.

2.2 Preparation of the Adsorbent

Ficus religiosa leaves were collected directly from the trees in the local area, rinsed with water to remove the debris and dried in an oven at 80 °C to a constant weight. The dried leaves were made to powder of required size and finally packed in desiccators.

2.3 Biosorption Experiments

Original dye solution of concentration 1000 mg L^{-1} was prepared. And it was diluted to various concentrations up to 25 mg L^{-1}. Pre-calculated amount of adsorbent (0.01–1 g) was measured accurately with an analytical balance (sX200) and added to 50 mL of feed solution; pH of the solution was measured with a digital pH meter (ELICO-L1 612) and varied (2–10) by using 0.1 N HCl and 0.1 N NaOH solutions. The adsorbent solution was agitated with Remi make Temperature Controlled Orbital Shaker (REMI—CIS 24 BL). At the end, the samples were collected and centrifuged to remove the suspended solid particles using REMI C 24 centrifuge. The clear liquid

vivekvardhan2@gmail.com

was collected and analyzed using UV–VIS Spectrophotometer (SYSTRONICS-117) at a wavelength of 498 nm under different conditions.

2.4 Characterization

A scanning electron microscope SEM model EVO 18, Carl Zeiss, was used for the microstructure analysis of the sample surface. EDS (Oxford Instrument) was attached to it for elemental analysis of the sample. The X-ray diffraction of the sample was obtained with SHIMADZU make XRD 7000. Fourier transmission electroscope was used to identify the functional groups on biomass. The sample was examined using SHIMADZU, FTIR 8400S.

3 Results and Discussion

3.1 Characterization

The SEM image at 10,000× magnification is shown in Fig. 1. It shows irregular surface with some small particles.

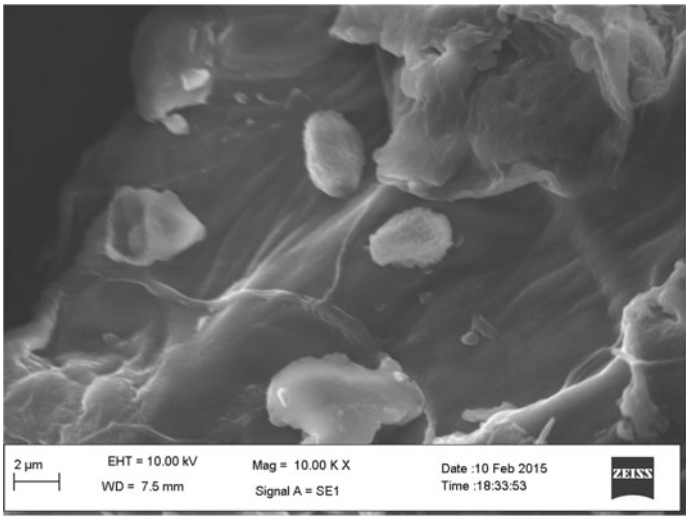

Fig. 1 SEM micrograph of FRLP

vivekvardhan2@gmail.com

X-ray diffraction spectra of FRLP are shown in Fig. 2. The overall XRD spectrum is indicative of an amorphous nature of the adsorbent. Amorphous materials have greater specific surface area and more active sites which render them good adsorbents.

EDS analysis was carried out to identify the minerals present in FRLP. EDS spectrum has been shown in Fig. 3. It shows the presence of minerals like Ca, K, Cu, Na and Mg with C and O as major compositions.

The FTIR spectral data of FRLP are shown in Fig. 4. It shows the presence of several functional groups that can interact with pollutants like CR in the adsorption process. A broad peak in the range of 3300–3450 cm^{-1} is the characteristic

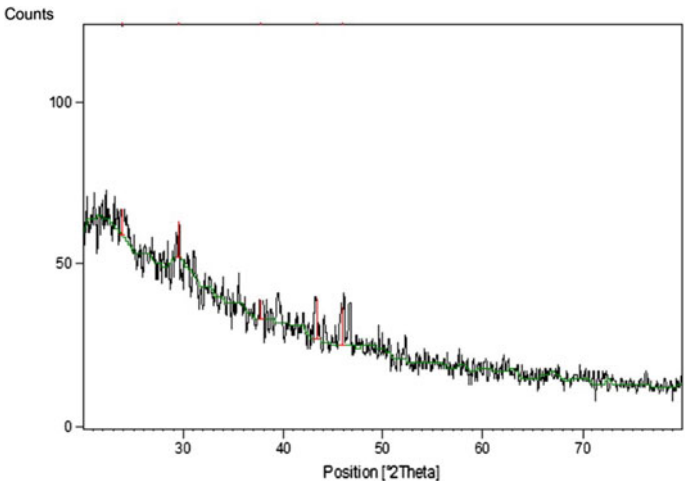

Fig. 2 X-ray diffraction spectra of FRLP

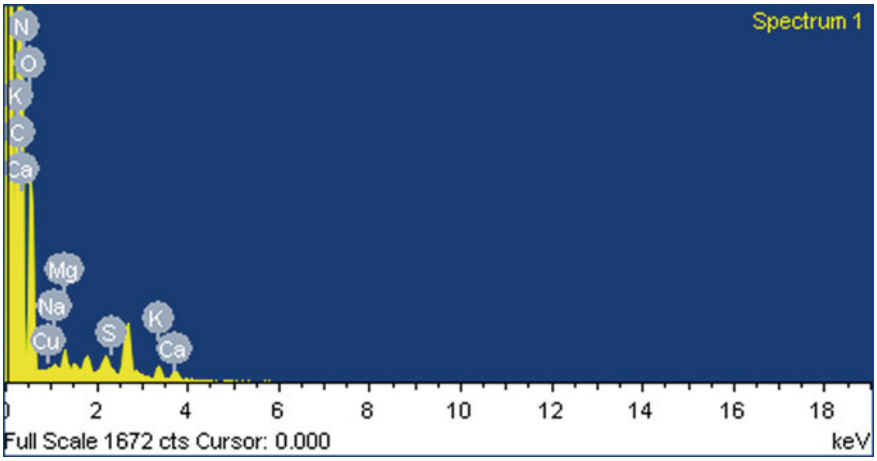

Fig. 3 EDS spectra of FRLP

vivekvardhan2@gmail.com

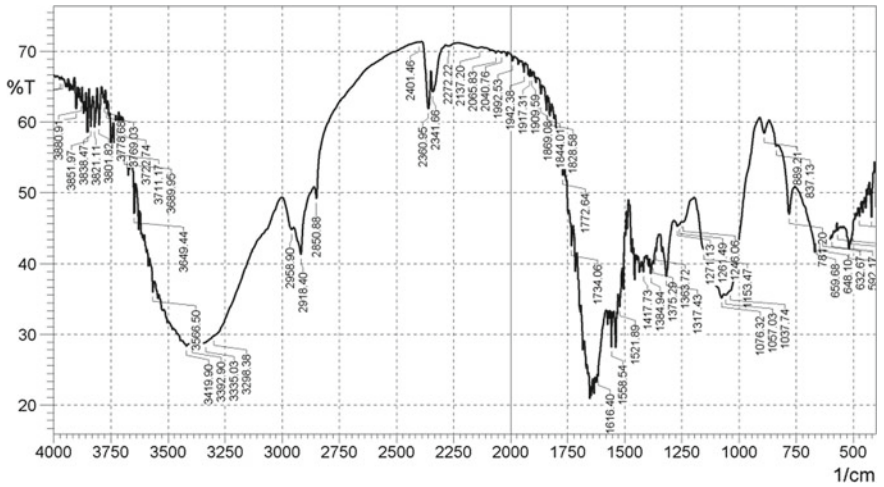

Fig. 4 FTIR spectra of FRLP

of O–H/N–H stretching frequencies and may be attributed to the presence of alcohols, phenols, amines and carboxylic acids in FRLP. The absorbance at 2918 and 2850 cm^{-1} is due to aliphatic C–H stretching in alkanes. While the absorption at 2360 cm^{-1} appears due to C≡C stretching, medium peaks at 2341, 1616 cm^{-1} could be attributed to C–H stretch in cellulose and starch. The weak but sharp peaks at 1558 and 1417 cm^{-1} could be ascribed to C–H deformation in lignin. Similarly, relatively less intense sharp peaks at 1384, 1375 cm^{-1} are characteristics of C–H bending vibrations of alkanes while C–hetero atom stretching frequencies for C–O and C–N bonds at 1076, 1057 cm^{-1} clearly indicates the presence of carboxylic acids/alcohols/amines. The presence of alkyl halides is confirmed by typical C–Cl stretching frequencies at 837 and 781 cm^{-1}, and the absorption for glycosidic linkage in hemi-cellulose appears at 889 cm^{-1}.

Interpretation of analytical data obtained from our studies revealed that FRLP contains various organic components which include alcohols, long-chain hydrocarbons, aliphatic alcohols along with fibers, tannin, different types of proteins and carbohydrates. Besides, it is rich in minerals like calcium, phosphorus, iron, copper, magnesium and sodium. These observations were further supported by the studies conducted by Chitra Gupta (2012).

3.2 Adsorption Kinetics Study

Kinetic studies help to estimate the time of operation and give an idea about the mechanism of the process. In this study, pseudo-first-order and pseudo-second-order kinetic models were applied to determine the suitable rate expression. The linear

vivekvardhan2@gmail.com

form of pseudo-first-order rate expression of Lagergren based on solid capacity is generally expressed as follows (Purkait et al. 2007):

$$\ln(q_e - q_t) = \ln q_e - K_1 t \tag{5}$$

where q_e and q_t are uptake at equilibrium and at time t, respectively, and K_1 is the rate constant (min^{-1}). A straight line for the plot of log ($q_e - q_t$) versus t would suggest the applicability of the model. The values of K_1 and q_e can be calculated from the slope and intercept of this line.

The linear expression of pseudo-second-order kinetic model of Ho and McKay (1999) (Acemioğlu 2004) is given below:

$$\frac{t}{q_t} = \frac{1}{K_2 q_{2e}^2} + \frac{t}{q_{2e}} \tag{6}$$

where K_2 is the rate constant in unit g min^{-1}. A linear relationship to the plot of t/q_t versus t implies applicability of the pseudo-second-order kinetics.

Various experiments were conducted with different initial concentrations (25, 50, 150 mg/L). Samples were withdrawn at different time intervals, and the data were tested for the kinetic models. Kinetic parameters were calculated from the linear plots of pseudo-first- and second-order models (Fig. 5) and the results of which have been given in Table 1. Adequacy of the model was tested in terms of R^2 values and by comparing uptakes that were actual and estimated by the models. The R^2 values for pseudo-first- and second-order models at 25, 50 and 150 mg/L were 0.73, 0.88 and 0.70 and 1, 1 and 0.998, respectively. Estimated equilibrium uptake values of the pseudo-second-order model are very close to that of actual. However, such is not the case of pseudo-first-order. Hence, the adsorption mechanism is closer to a pseudo-second-order process. It is similar to the observations cited for adsorption of Congo red on activated carbon, calcium-rich fly ash and $CaCl_2$ modified bentonite (Purkait et al. 2007; Liping Guo and Wang 2009; Jing et al. 2011).

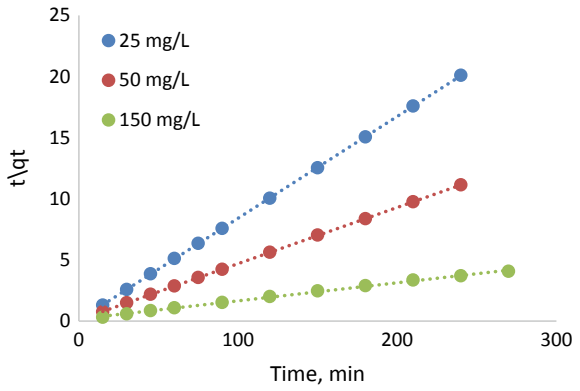

Fig. 5 Pseudo-second-order kinetics for biosorption of CR using FRLP

vivekvardhan2@gmail.com

Table 1 Kinetic parameter constants for biosorption of CR using FRLP

		Pseudo-first-order reaction			Pseudo-second-order reaction		
C_o (mg/L)	$q_{e,\,exp}$ (mg/g)	K_1 (min^{-1})	q_e (mg/g)	R^2	K_2 (g min^{-1})	q_e (mg/g)	R^2
25	11.94	0.043	2.63	0.73	1748.90	12.05	1
50	21.56	0.026	4.70	0.88	4633.23	21.74	1
150	70.68	0.029	138.24	0.70	26,573.13	71.43	0.998

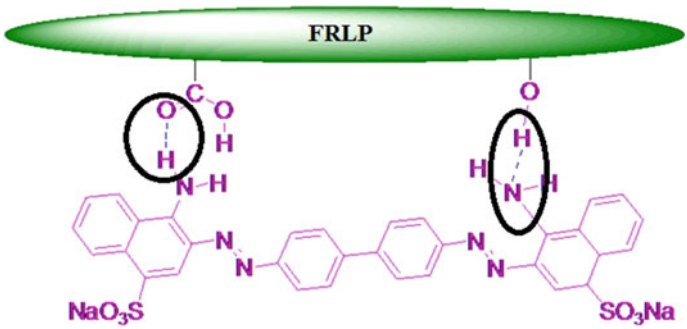

Fig. 6 Proposed mechanistic model for CR adsorption on FRLP

3.3 Mechanistic Studies

Based on the above studies, a type of physical interaction or physisorption model caused by weak hydrogen bond forces of various functional groups present on the surface of FRLP with those of aromatic amine functionalities of Congo red is expected. As could be observed from the proposed mechanistic model depicted in Fig. 6, the basic carbonyl part from the carboxylic acid is H-bonded to the electron-deficient hydrogen atom of the aromatic amine while the simple hydroxyl groups are presumably hydrogen bonded to electron-rich nitrogen atom of the amine. These non-covalent interactions are in agreement with the model proposed earlier (Mao et al. 2008; Kumar et al. 2010) and appear to provide the requisite stabilization for adsorption.

4 Conclusions

FRLP is an amorphous material with greater specific surface area. It contains various organic components like alcohols, hydrocarbons, along with fibers and tannin which are rich in functional groups. Based on the studies, hydrogen bond is expected between carbonyl group of carboxylic acid and the electron-deficient hydrogen atom

vivekvardhan2@gmail.com

of the aromatic amine. In addition, simple hydroxyl groups are presumably hydrogen bonded to electron-rich nitrogen atom of the amine. In kinetic studies, pseudo-second-order model best described the sorption kinetics compared to other models.

Novel Utility of Bacteria of Fish Gut Wastes Collected from Local Markets for Detoxification of Textile Dyes and Recycling of Water for Cultivation

Cherasala Reddi Roja, Vempalli Sumathi, Duvvuri Sai Vinathi, Taticherla Hemalatha, D. C. Reddy and Varada Kalarani

Abstract Preliminary survey shows that an average of 500 kgs of fish waste is being produced per day from each local fish market. Several such markets are in function in whole of Chittoor district alone. These wastes are known to be either underutilized to produce low market value products or dumped in open water systems. Fish waste management has been one of the major problems of concern since it will have the greatest impact on the environment. Fish gut is rich in bacteria; some of which are beneficial or probiotic. Complete utilization of fishery waste for recovering high-end products would be a fruitful strategy to overcome the issue as well to increase the economic gain. Worldwide dyestuff and pigments worth s $10.6 billion (2008) are being produced. India is the second largest exporter of dyestuffs and intermediates among developing countries, after China. The textile industry accounts for the largest consumption of dyestuffs, at nearly 80%. Dye containing waters are known for reducing efficiency of seed germination, plant growth and elongation of shoot and roots (Nirmalarani and Janardhanan in Madras Agric J 75:41, 1988), carcinogenic and mutagenic (Venturini and Tamaro in Mutation Res 68: 307–312, 1979; Mathur et al. in Appl Ecol Environ 4(1):111–118, 2005), causing skin and eye irritation, reducing aquatic life affecting liver, gill, kidney, intestine and gonads as well as liver damage in humans (Badr et al. in Mol Biol Evol 17:499–510, 2008). In spite of the above, the industrial effluents with greater than admissible levels of dyes are noticed to be released into open water systems. Microorganisms are known to reduce the dyes by secreting enzymes such as laccase, azoreductase, peroxidase and hydrogenase. Reduced forms of dyes are further mineralized into simpler compounds and are utilized as their energy source. Hence in the present study, *Bacillus subtilis* and *Terribacillus saccharophillus,* isolated from the gut of *Labeo rohita* (*Gendi*), the most local delicacy collected from the market, were examined for their ability to decolourize the textile dye, malachite green (MG). UV-Vis studies showed that both *B. subtilis* and *T. saccharophillus* have an ability to degrade methyl red, the azo dye.

vivekvardhan2@gmail.com

Further, Fourier transform infrared spectroscopy (FTIR) studies of *B. subtilis*- and *T. saccharophillus*-treated dye solutions after 0, 24 and 48 h showed remarkable change and reduction in the number of functional groups with progress in treatment time, clearly illustrating the impact of both these bacteria in degrading the dye molecules. Phytotoxicity studies further clearly demonstrated that addition of *B. subtilis* and *T. saccharophillus* to the growth medium used for seed germination significantly degrades the dye integrity resulting in reduced toxicity and significant rise in the rate of germination. This study demonstrated the beneficial use of bacteria of fish gut waste as good biological agents for water treatments, specifically for degradation of textile dye effluents making it suitable to recycle for irrigation purposes.

1 Introduction

Ever since the beginning of humankind, colour has become an important property of expression. Colourants are being used for painting and dyeing of their surroundings, clothes and even skins. Till the middle of the nineteenth century, all colourants were derived from natural sources. With the invention of aniline purple and Tyrian purple with excellent dyeing properties by Perkin in 1896 followed by benzene structure by Kekule strongly stimulated the production of various synthetic dyes leading to replacement of natural dyestuffs with synthetic ones from the beginning of the twentieth century, they were replaced by synthetic dyestuffs (Welham 2000). Worldwide demand for natural dyes is about 10,000 tones. Production of dyestuff and pigments in India is close to 80,000 tons and stands as second largest exporter of dyestuffs and intermediates among developing countries, after China. Textile industry accounts for the largest consumption of dyestuffs, at nearly 80% and the major source of ecotoxic hazard ranging 10–200 mg l^{-1}. The principal route by which dyes enter in the environment is via wastewater. As dyes are designed to be chemically and photolytically stable, they are highly persistent in natural environments.

The International Agency for Research on Cancer (IARC) has classified various dyes like benzidine being associated with cancer (Venturini and Tamaro 1979; Anonym 1982; Mathur et al. 2005). Further, benzidine is known to be carcinogenic to the variety of mammalian species, including humans and reported to induce hepatocellular carcinomas and neoplastic liver nodules in rats after 13 weeks of exposure (Robens et al. 1980). Apart from being phytotoxic (Parshetti et al. 2006), textile dyestuff and wastewaters are detected to be causative for significant reduction in erythrocyte count in the freshwater fish *Gambusia affinis* (Sharma et al. 2009).

Among the commonly used dyes, malachite green (MG) is a multi-organ toxin causing decreased food intake, growth and fertility rates along with damaging liver, spleen, kidney and heart in aquatic species (Werth and Boiteaux 1967; Culp et al. 1999) and irritation to the gastrointestinal tract in humans and permanent injury in eyes (Kumar et al. 2006). Methyl Red (MR) is a commonly used monoazo dye in paper printing and textile dyeing and in the preparation of commercial products (Lachheb et al. 2002). MR is well known to cause eye, skin, respiratory tract and

vivekvardhan2@gmail.com

mucous membrane irritation (Mahmoud et al. 2010) and also liver damage upon repeated exposure (Badr et al. 2008). Crystal violet (CV), a triphenylmethane dye, is extensively used in human and veterinary medicine as a biological stain and as a textile dye. It is also used in the preparation of paints and printing. CV is reported to persist in the environment for a long period posing toxic threat to the environment. Therefore, there is an urgent need to develop such eco-friendly and cost-effective biological treatment methods, which can effectively remove the dye from industrial wastewaters for the safety of environment, as well as human and animal health.

1.1 Dye Removal Methods

Textile dyestuff and wastewater are recalcitrant to the degradation. Several physical techniques based on adsorption, osmosis, ultrafiltration, microfiltration and chemical techniques such as coagulation or flocculation combined with flotation and filtration, precipitation/flocculation, electroflotation, electrokinetic coagulation, conventional oxidation irradiation or electrochemical processes were employed to remove colour from the dye containing wastewaters. Several factors, including dye type, wastewater composition, dose or costs of required chemicals, operation costs, environmental fate and handling costs of generated waste products imposed the technical and economic feasibility of each method employed. In general, each technique has its own limitations (Cooper 1993; Maier et al. 2004).

Alternatively, biological treatments are opted to completely degrade dyes (Verma and Madamwar 2003; Moosvi et al. 2005; Pandey et al. 2007; Khalid et al. 2008), ever since microorganisms were found to reduce the dyes by secreting enzymes. Biodegradation methods such as (a) decolourisation using fungi such as *Phanerochaete chrysosporium*, *Trametes* sp. and *Aspergillus* sp, (b) adsorption using live or dead microbial biomass, (c) anaerobic methods to decolourise azo dye using bacteria such as *Bacteroides* sp., *Eubacterium* sp. and *Clostridium* sp. and (d) aerobic oxidatively decolourisation methods. But due to xenobiotic nature, azo dyes are not totally degraded (Laing 1991; Panswald et al. 2001). Moreover, azoreductase and laccase are the two extracellular enzymes that are primarily involved in the bioremediation of textile dyes for which all the microorganisms may not serve as a source.

Fish is highly proteinaceous and easily digestible and a good delicacy. Several fish markets are in operation in each city of Andhra Pradesh. Recent survey revealed that an average minimum 500 kgs of fish waste is generated from each of the fish markets that contain fish scales, fins, gut and other parts of the viscera which is partially used or discarded becoming the main source of pollution and environmental contamination.

Hence in the present study, *Bacillus subtilis* and *Terribacillus saccharophillus* isolated in our laboratory from the gut wastes of freshwater fish, *Labeo rohita*, were examined for their ability to decolourize malachite green. Degraded products were also characterized through, UV-Vis spectroscopy and FTIR and phytotoxic studies.

Malachite Green

3 Methodology

1. Assessment of Dye Decolourization
   B. subtilis and *T. saccharophillus* were inoculated separately in 250 ml of nutrient broth and incubated at 37 °C for 24 h. After incubation, 25 ml (100 mg/l) of MG was taken, and 5 ml of each bacterial suspension of 10^7 CFU/ml was added separately. The flasks were kept in orbital shaker and incubated at 37 °C. Samples were drawn at 0-, 24- and 48-h intervals centrifuged at 10,000 rpm for 10 min, and the level of decolourization was assessed by measuring absorbance of the supernatant at wavelength maxima (lambda m) of the dye using UV-Vis spectrophotometer.
2. Extraction and Analysis of Dye Degradation Products—UV-Vis spectral analysis
   After complete decolourization of the dye suspended solutions, culture broth was centrifuged at 7000 rpm for 15 min. Equal volume of n-butanol was added to extract metabolites from the supernatant. The extracts were evaporated after removal of aqueous content with anhydrous Na_2SO_4 in a rotary evaporator, dried at 40 °C and used for further analysis.
   The supernatant samples (2 ml; 250 μg/ml) obtained before and after treatment with *B. subtilis* and *T. saccharophillus* were subjected to spectral analysis between

vivekvardhan2@gmail.com

250 and 700 nm. The UV-Vis spectral analysis was carried out using Hitachi UV-Vis spectrophotometer (UV 2900).
Percentage decolourization was calculated from the following formula and tabulated.

$$\%\,\text{Decolorization} = \frac{\text{Initial OD} - \text{Final OD}}{\text{Initial OD}} \times 100$$

3. Fourier Transform Infrared Spectroscopy (FTIR) analysis
Fourier transform infrared spectroscopy (Bruker ALPHA—T) **of** samples MG (0 h), 24 and 48 h decolorization products was carried out. The FTIR analysis was done in the mid-IR region of 400–4000 cm^{-1} with 16 scan speed. The samples were mixed with spectroscopically pure KBr in the ratio of 5:95, the pellets were fixed in sample holder, and the analysis was carried out. The transformation of the interferogram into FTIR is carried out mathematically using the software OPUS.
4. Phytotoxicity Studies (Durve et al. 2012)
Effect of MG on the pattern of seed germination of *Vigna radiate* (Moong) was evaluated. The seeds were germinated in sterile Petri dishes, layered with sterile circular filter paper (diameter 10 cm). Ten seeds were irrigated at room temperature (28 ± 2 °C) for three days with 2 ml of water (control); MG and one of the two bacterial suspensions. Every day 2 ml of respective sample solution was applied to the surface of the filter paper. Each treatment was replicated for three times. Observations were made on daily basis, and rate of germination (%) and root length (cm) were measured.

3.1 Statistical Analysis

Significant differences in the parameters such as shoot and root length were assessed through students' t-test ($p > 0.05$ level).

4 Results and Discussion

1. Dye decolourization

Gradual change in MG colour from bright green to light green up to 48 h after the inoculation of B. *subtilis* and *T. saccharophillus* isolated from the fish gut wastes was observed (Fig. 1).

44/34% decolourization of MG, by *B. subtilis* and *T. saccharophillus* suspended media, respectively, following 24 h of incubation, indicated the ability of these two selected bacteria to rapidly decolourize azo dyes (Fig. 2). Continued exposure up to

vivekvardhan2@gmail.com

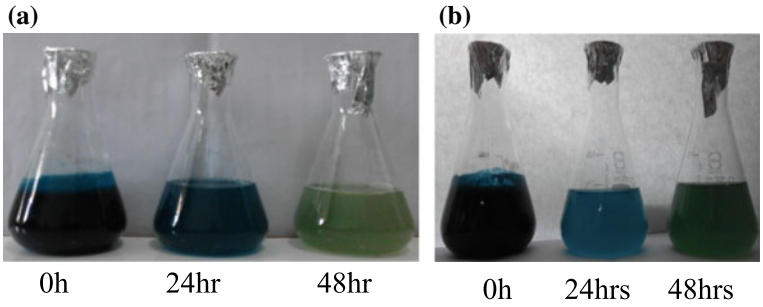

Fig. 1 Malachite green (MG) dye decolourization at 0, 24 and 48 h by **a** *B. subtilis* and **b** *T. saccharophillus*

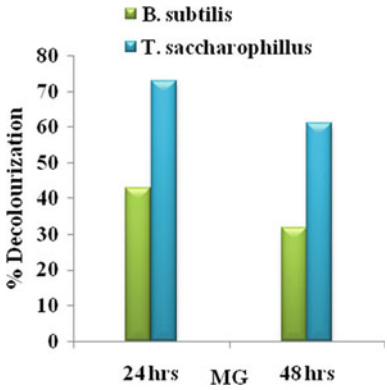

Fig. 2 Percentage decolourization of MG with *B. subtilis* and *T. saccharophillus* after 24 and 48 h compared to 0 h

48 h was found to further increase the above-mentioned levels to 73/63%, respectively. In each case compared to *T. saccharophillus* (Fig. 2), *B. subtilis* showed the higher decolourization ability.

Rodriguez et al. as early as in 1999, reported that several industrial dyes were decolourized biocatalytically by extracellular enzymes secreted by microbes. The decolourization effect of different bacterial species may vary. It was reported earlier that the adsorption of chromatophores on the cell surface of the microorganisms results in the decolourization of the dye. The possible mechanism is biosorption which is dependent on functional groups in the dye molecule (Fu and Viraraghavan 2002). Effective decolourization of azo dyes by *Pseudomonas luteola* was reported by Chang and Lin (2000), while Olukanni et al. (2006) reported decolourization by the strain of *Micrococcus.* While Yatome et al. (1991) reported *B. subtilis* to degrade crystal violet, Mabrouk and Yusef (2008) observed its capability in degrading fast red dyes. Malachite green was enzymatically reduced to leucomalachite green and also

vivekvardhan2@gmail.com

converted to N-demethylated and N-oxidized metabolites (Cha et al. 2001). Similarly, Pandey and Upadhyay (2010) demonstrated the ability of *Pseudomonas fluorescens* to degrade orange dyes, first by broking it down to 3, 7-diamino-4 hydroxynaphthalene-2 sulphonic acid sodium salt, which is nontoxic in nature. *Psuedomonas aeruginosa* was observed to cause 78, 76 and 24% decolourization of MR, MG and CV after 24-h incubation by Durve et al. (2012). Recently, Abubacker and Mehala (2014) reported 65, 55 and 50% of decolourization of MG incubated for 96 h with *P. fluorescens*.

2. UV-Visible Spectral Analysis of Dye Degradation

Results of UV-Vis spectroscopic analysis are presented in Fig. 3a, b. Single prominent peak at 615 nm is obtained in UV-Vis spectrum of MG. During absorption or adsorption, it was observed that the intensity of the peak of spectrum decreases with course of time followed by its disappearance with concomitant appearance of some new peaks which were correlated to metabolites produced during degradation. Recording of UV-Vis spectra (200–900 nm) of ethyl acetate extract of MG (250 mg/L) treated with *B. subtilis* showed new peaks at 230 and 330 nm in the present study indicating the degradation of MG resulting in the production of new metabolites in 24 and 48 h (Fig. 3a, b). Further, the appearance of new peaks at 215 and 300 nm in case of treatment with *T. Saccharophillus is* also evincing similar effect. This absorbance was probably a result of impact of similar type of metabolites or/and fragments obtained after degradation of dye molecules by the respective bacteria. These results clearly

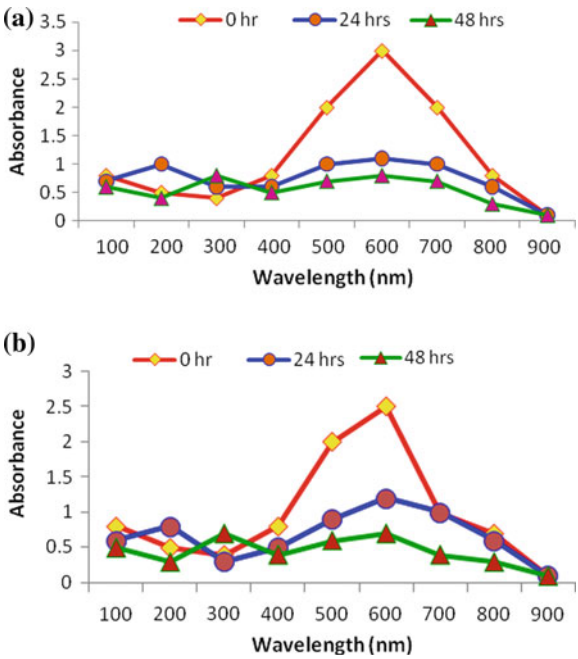

Fig. 3 **a** UV-visible spectra of MG at 0 h (control) and after MG degradation by *B. subtilis* (0, 24; 48 h), *T. saccharophillus* (0, 24 h; 48 h)

vivekvardhan2@gmail.com

indicate the colour-removing ability of *B. subtilis* and *T. saccharophillus* and hence their potential as biodegrading agents.

In the UV spectra, the decrease in absorbance of the peaks at 220 nm corresponds to benzene ring as demonstrated by Yang and Reilly (1987), and the formation of new peak at 260 nm suggested the reductive destruction of azo-conjugated structure as explained by Feng et al. (2000). The appearance of two new peaks after degradation of MG by *Pseudomonas sps* was shown by Du et al. (2011).

3. Fourier Transform Infrared Spectroscopy (FTIR) analysis

MG (control) and its degraded metabolites are confirmed by FTIR analysis. Remarkable variations were observed in the region 3500–500 cm^{-1} of the FTIR spectroscopy of MG (control), 0-, 24- and 48-h-degraded metabolites of MG by *B. subtilis* and *T. saccharophillus* (Figs. 4a and 5c). FTIR spectra of control MG (control), 0, 24 and 48 h of MG showed the specific peaks in region 2000–500 cm^{-1} representing mono- and para-benzene rings (Tables 1 and 2).

Spectral analysis (FTIR) of MG (0 h) and degraded products (24/48 h) showed functional groups such as alkyl halides, alkenes, carboxylic acids, nitro compounds similar to MG (control). Functional groups such as alcohols and phenols were observed in MG (control), and MG (0 h) was found to be absent after treatment. Extra functional groups such as alpha- and beta-unsaturated aldehydes and ketones were observed in 24-h-treated samples. The variations in the FTIR spectra of MG and those following 24 and 48 h of treatment with *B. subtilis* and *T. saccharophilus* were considered as an indication of biodegradation.

4. Phytotoxicity Studies

Seed germination and plant growth bioassay are the most common techniques used to evaluate the phytotoxicity (Kapanen and Itavara 2001).Water bodies used for irrigation purposes contain untreated effluents from dyeing industry. This practice is of great environmental concern as it is associated with biotic and ecosystem health. Soil fertility is directly and indirectly dependent on irrigation water. Biodegradation of effluent leads to generation of various degradation products. Therefore, it is virtually important to study the toxicity impact of these degradation products on plants (Kalyani et al. 2008).

Phytotoxicity studies using malachite green and its degraded products on *Vigna radiata* are shown in Table 3. The relative sensitivity of *Vigna radiata* towards the MG dyes and its degradation products was studied. 100% germination was observed in the seeds irrigated with tap water (control) (Fig. 6a). Germination of *Vigna radiata* was observed to decrease to 93% with water containing MG dye (Fig. 6b). But germination of *Vigna radiata* seeds soaked in water containing MG treated with *B. subtilis* or with *T. saccharophillus* was 100% (Fig. 6c, d).

The root length in water (control)-treated seeds was 1.5, 4.03 and 9.1 cm on Day 1, 2 and 3, respectively (Table 3), while the same was 0.63, 1.03 and 1.8 cm, respectively, for MG-treated seeds. But following treatment with *B. subtilis* in spite of MG treatment, the seeds showed the root lengths of 1.03, 2.35 and 3.4 cm, respectively. But similar groups treated with *T. saccharophillus* showed root length of 0.85, 2.13

vivekvardhan2@gmail.com

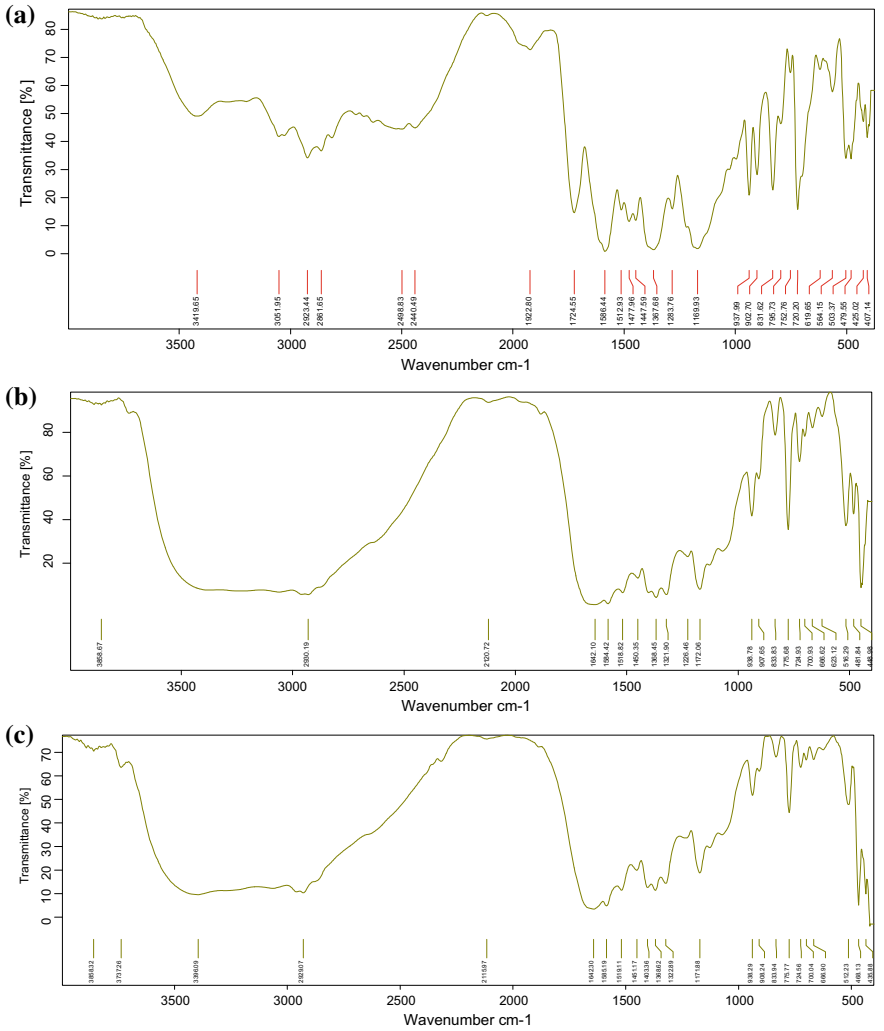

Fig. 4 **a** FTIR spectra of MG (control), **b** FTIR spectra of MG were obtained 0 h by *B. subtilis*, *and* **c** FTIR spectra of MG were obtained 0 h by *T. saccharophillus*

and 2.83 cm respectively (Table 3). Higher root length was observed in seeds grown with treated water compared to the rest of the groups. The results of phytotoxicity studies revealed that the biodegraded products of MG were not toxic to seeds, and hence, the germination process was not affected.

Ren et al. (1996) demonstrated the toxicity of polycyclic aromatic hydrocarbons (PAHs), anthracene (ANT), benzo[a]pyrene (BAP) and fluoranthene to the duckweed, *Lemna gibba L.* and *Brassica napus L.* seeds. These authors used the germination efficiency, root and shoot growth, and chlorophyll content, as a measurement

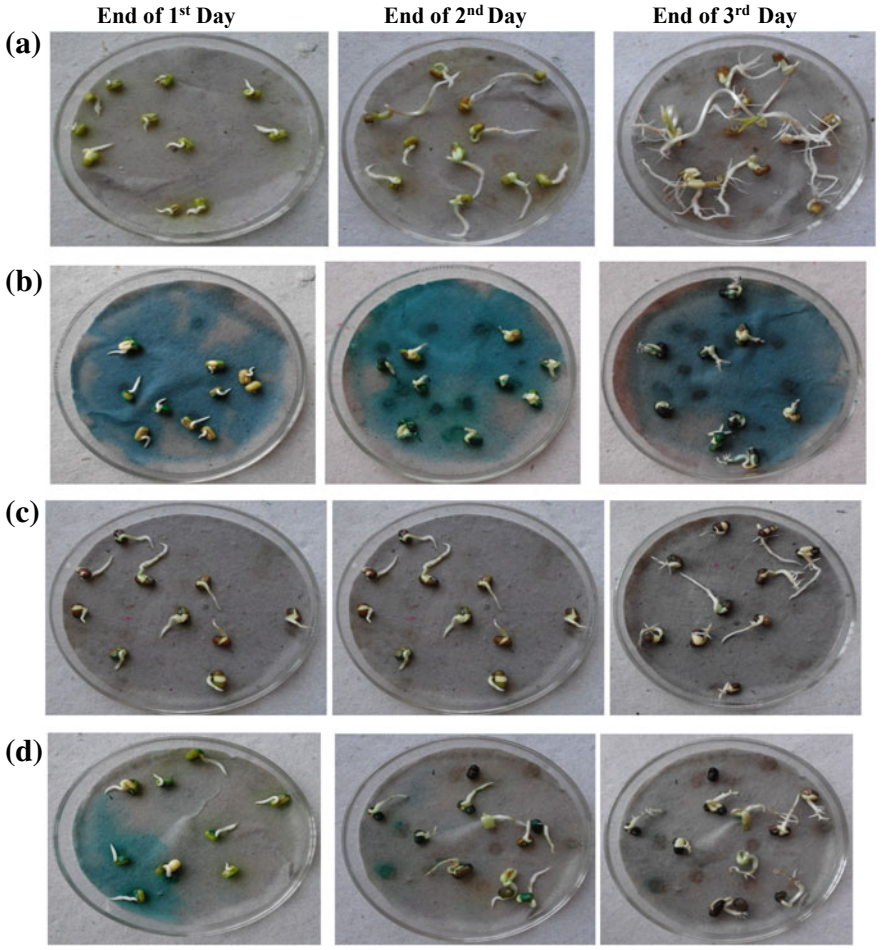

Fig. 6 *Vigna radiata* (Moong) seed germination for 3 days with **a** normal water, **b** water containing malachite green, **c** water containing malachite green treated with *B. subtilis* and **d** water containing malachite green treated with *T. saccharophilus*

for toxicity. Moawad et al. (2003) showed that the textile dyes were toxic to the seed germination process of four plants such as clover, Triticum spp wheat, tomato and lettuce. Though MG is toxic to microbes and plants, its degradation by microorganisms results in significant reduction in its toxicity (Parshetti et al. 2006; Ayed et al. 2009; Chaturvedi et al. 2013). Parshetti et al. (2006) also reported that biodegradation product of MG formed by action of *Kocuria rosea* was nontoxic. Du et al. (2011) also reported that degraded product formed by biodegradation of MG by *Pseudomonas aeruginosa* is nontoxic.

vivekvardhan2@gmail.com

5 Summary and Conclusions

In the present study, *B. subtilis* and *T. saccharophillus* isolated from the gut wastes of freshwater fish; *L. rohita* were found to degrade azo dye.

UV-Vis studies showed that *B. subtilis* and *T. saccharophillus* have a significant ability to degrade azo dye such as malachite green.

Fourier transform infrared spectroscopy (FTIR) studies demonstrated that remarkable change and reduction in the number of functional groups occur with progress in treatment time clearly illustrating the impact of both the bacteria on the degradation of malachite green.

Phytotoxicity studies further clearly showed that addition of *B. subtilis* and *T. saccharophillus* to the growth medium of seeds can successfully increase the rate of germination through degrading integrity of the dye.

Thus, this study clearly demonstrated that the fish gut bacterial isolates such as *B. subtilis* and *T. saccharophillus* can serve as good tools to treat wastewaters, especially the textile dye effluents. Further, these wastes which otherwise are thrown into water bodies or dumped in open lands leading to additional pollution can well be avoided and explored for their reutilization using probiotic microbes.

Utilization of Rice Husk Ash for Defluoridation of Water

C. M. Vivek Vardhan and M. Srimurali

Abstract Effective utilization and safe disposal of solid wastes is one of the major challenges placed before the modern-day scientist, in the wake of exploding population. Rice husk is a major agricultural waste being generated by an agricultural nation such as India, and therefore warrants proper utilization before disposal. On the other hand, fluorosis is a burning problem caused due to consumption of groundwater consisting of excessive fluoride, prevalent in several parts of the world. Therefore, in this study, Rice Husk Ash was impregnated with Lanthanum and investigated for defluoridation of water by adsorption. Batch adsorption experiments were conducted for fluoride removal using Lanthanum-Impregnated Rice Husk Ash (LIRHA) and tested for various parameters such as pH, time of agitation, influence of ions, and optimum dosage of sorbent. It was observed that LIRHA removed fluoride to less than the permissible limit in the naturally encountered pH of water. The optimum time and dosage of LIRHA were found to be 240 min and 6 g/L, respectively. The anions phosphates and chlorides were found to be detrimental for fluoride sorption probably due to competitive of those ions with fluoride on the active sorption sites on LIRHA. Thus, this study revealed that the agricultural waste, Rice husk can be effectively utilized for removal of fluoride from water and subsequently disposed off safely.

1 Introduction

India being an agricultural nation generates huge quantities of Rice husk as agricultural waste. About 24 million tons of Rice husk is being generated by the nation annually (Pandey et al. 2012). A minor portion of this waste is used as cattle feed and in manufacture of cement and refractory bricks. The remaining major portion is dumped, which results in its decomposition and subsequent emission of methane gas. Therefore, an effective way for utilizing rice husk has to be found and subsequently disposed safely. Concomitant to this challenge, contamination of groundwater with fluoride and the resulting fluorosis is a major threat faced by mankind. Fluoride has dual impacts on living organisms. In lower concentrations, fluoride is very beneficial as it assists in formation of bones and prevents dental decay, whereas in higher concentrations, it causes serious health issues such as skeletal fluorosis, dental fluorosis, mental derangements, dwarfishness, etc. Therefore, it is imperative that fluoride has to be removed from water before consumption. The World Health Organization (WHO) has stipulated a maximum permissible limit of 1.5 mg/L of fluoride in drinking water. Various technologies are available for defluoridation of water and are partially successful to various extents. But, as fluorosis is not yet completely eradicated, the focus has recently shifted to use of rare earth materials as adsorbents for defluoridation with a fairly reasonable degree of success (Vardhan and Srimurali 2018; Vivek Vardhan and Srimurali 2015, 2016). However, research is still deficient on achieving a dual advantage of simultaneously utilizing waste and removing fluoride from water. Therefore, in this study, an attempt was made to employ Rice Husk Ash impregnated with Lanthanum for removal of fluoride from water. The main objectives of this study are to: (1) Impregnate Lanthanum onto Rice Husk Ash, (2) Find the optimum time of agitation and the dosage of sorbent required, (3) Investigate the influence of pH on fluoride removal, and (4) Study the impact of anions on defluoridation.

2 Materials and Methods

2.1 Chemicals

All reagents used in the present investigation were procured from E. Merck Ltd., India and were of analytical reagent grade. Sodium fluoride of 221 mg was dissolved in distilled water and made up to 1 L in a volumetric flask to prepare a stock fluoride solution of 100 mg/L. Stock solution was diluted appropriately to obtain fluoride solutions of required working concentrations.

vivekvardhan2@gmail.com

2.2 Adsorbent

Rice Husk Ash (RHA) was procured from a local rice mill and was sieved to a mean size of 475 μm.

2.3 Adsorbent Preparation

Lanthanum carbonate of varying weights was mixed with 0.05 L of distilled water and 0.1 N HCl was added to it drop wise until Lanthanum carbonate got dissolved completely. To this solution, 0.1 N NaOH was added under constant stirring until precipitates were visually observed. RHA of mean size 475 μm and 20 ± 0.2 g weight was added to this mixture. This mixture was mixed for 6 h in a magnetic stirrer. Subsequently, it was decanted, dried, and heated at 300 °C for 4 h in a muffle furnace. It was thoroughly washed with distilled water and dried. The obtained material is Lanthanum-Impregnated Rice Husk Ash (LIRHA).

2.4 Batch Adsorption Experiments

Teflon flasks of 250 mL capacity and a working volume of 100 mL were used throughout the experiments. Laboratory spiked fluoride solutions of 10 ± 0.2 mg/L were prepared and adsorbent of required dosage was added to each flask. These flasks were agitated in a rotary shaker of make Kaizen imperial. The optimum rate of agitation for highest removal of fluoride was determined by varying the speed of agitations at 40, 80, 120, 160, and 200 rpm, at 25 ± 1 °C. Highest fluoride removal was observed at 160 rpm and so all experiments were conducted at this speed of agitation. After agitating for stipulated time periods, the contents were withdrawn, filtered in a Whatman filter paper of size 42, and analyzed for fluoride removal using SPADNS method (APHA 2005). Fluoride was analyzed using a spectrophotometer, Evolution 201, of Thermo Scientifics. pH adjustments were carried out using 0.1 N NaOH and 0.1 N H_2SO_4. Individual ions of Cl^-, SO_4^{2-}, PO_4^{3-}, HCO^{3-}, and NO^{3-} were added in concentration of 250 ± 5 mg/L in addition to fluoride ions to evaluate its impact. Concentration of Lanthanum was measured using an atomic adsorption spectrophotometer AAS, GBS 932 plus.

vivekvardhan2@gmail.com

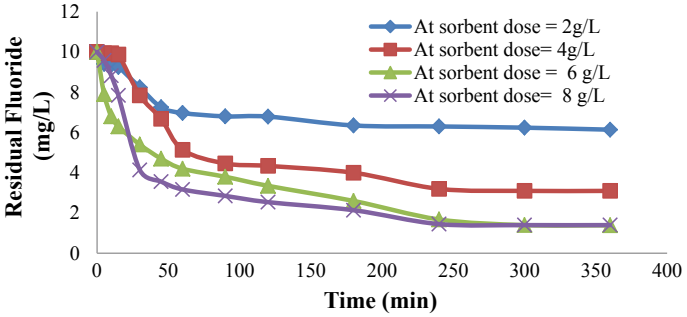

Fig. 1 Influence of time of agitation and dose of LIRHA on defluoridation

3 Results and Discussion

3.1 Time and Dose Studies of RHA and LIRHA

Experiments were carried out to arrive at the optimum time and dose required for adsorption to take place using LIRHA and the results are presented in Fig. 1. It can be observed that the time and dose of sorbent required for defluoridation using LIRHA are 240 min and 6 g/L, respectively, which left a residual fluoride of 1.39 mg/L.

3.2 Influence of pH

Role of pH on defluoridation using LIRHA was examined and the results are presented in Fig. 2. It can be observed that LIRHA performed better in removing fluoride from water in a pH range of 7–9. Formation of HF ions at lower pH values and OH

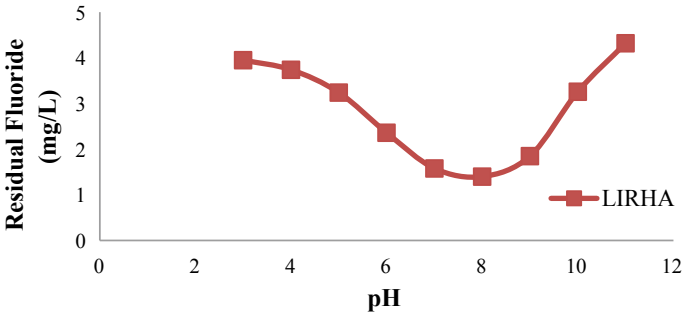

Fig. 2 Influence of pH of solution on fluoride removal by LIRHA

vivekvardhan2@gmail.com

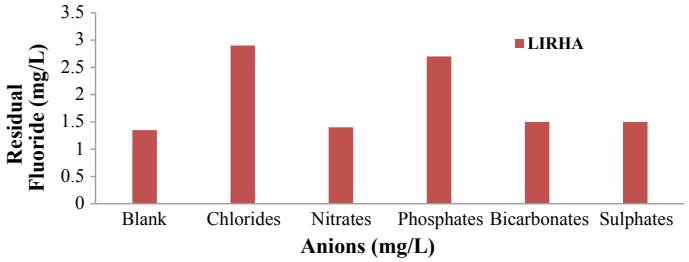

Fig. 3 Influence of anions on sorption of fluoride by LIRHA

ions at higher pH values could be the reason for lesser defluoridation below and above the optimum pH ranges observed.

3.3 Influence of Anions

Efficiency of fluoride removal by LIRHA was tested in the presence of the anions Cl^{-}, SO_4^{2-}, PO_4^{3-}, HCO^{3-}, and NO^{3-}, each individually and the results are presented in Fig. 3. It can be observed that chlorides and phosphates impeded sorption of fluoride by LIRHA, whereas the ions nitrates, bicarbonates, and sulfates exhibited a lesser influence. Similar trend of competition of phosphates with fluorides for active sorption sites was reported by Bia et al. (2012) on ion modified montmirillonite. Chlorides were also reported to be highly competitive against fluoride for sorption on expanded clay aggregate, according to Sepehr et al. (2014).

4 Concluding Remarks

The aim of this work is to simultaneously utilize the agricultural waste Rice Husk Ash and to remove fluoride from water.

Agitated non-flow batch studies demonstrated that LIRHA is capable of removing fluoride from water to less than the permissible limits.

Normally encountered pH range was found to be favorable for fluoride removal by LIRHA.

It was observed that the time and dose of LIRHA required for defluoridation were 240 min and 6 g/L, respectively.

Presence of anions such as phosphates and chlorides exerted a detrimental effect on removal of fluoride from water using LIRHA, possibly due to competition of ions.

These investigations revealed that the agricultural waste Rice Husk can be utilized toward removal of fluoride from water and should be disposed off safely.

Comparison of the Suitability of Activated Carbon Derived from *Mangifera indica* by Four Physicochemical Methods for the Removal of Methylene Blue Dye

Moumita Biswas, Anirban Ghosh and Saswata Bose

Abstract Activated carbon (AC) from mango (*Mangifera indica*) peels was developed through four environmentally benign methodologies. Activated carbons were prepared by both thermal and chemical activation and termed mango peel activated carbon (P-MPAC). One involving a single physical activation was termed P-MPAC. Two methods, involving the two-step activation process where chemical activation (using H_2SO_4) was followed by physical activation. One of the two variants activated at 300 °C was termed as C-300-MPAC and the other activated at 700 °C was termed C-700-MPAC. One has an additional physical activation before the two-step activation process was named PCP-MPAC (physical 300 °C—chemical–physical 700 °C three activation steps). Thermal activation was done at two temperatures 300 and 700 °C to explore the effect of high- and low-temperature thermal activation in generating pores on the surface of the AC. The four variants (namely P-MPAC, C-300-MPAC, C-700-MPAC, and PCP-MPAC) were explored to determine the ideal method of AC preparation. Their ability as an adsorbent for the removal of a basic dye methylene blue was examined. The pH and adsorbate concentration was optimized to get ideal conditions for the removal of the two respective dyes from their respective aqueous solutions. ACs activated at 700 °C performed significantly better at removing dyes from their aqueous solution. Three-step activation showed an enhanced effect in removing the impurity.

vivekvardhan2@gmail.com

outstanding 40% of the total produce worldwide which stands at an estimated amount of 46 million metric tons as of 2016. India thus produces a high amount of organic waste rich in functional group in the form of mango peels and seeds which have little use as a delicacy but can be tapped into as a very good source of producing resource from waste (FAOSTAT 2005).

The edible part (the pulp), which makes up to 33–85% of the fresh fruit depending on the various breeds of the fruit finds use both in households and commercially. Household use is mostly seasonal in nature, i.e. during the fresh fruit comes into the market, but commercial uses run throughout the year. Household uses mainly include consuming the fruit raw due to its one of a kind flavour and also making pickles from the dried fruit. The major commercial products made from the fruit are milkshakes, drinks, and juices. Brand names such as Maaza and Slice which specializes in mango-related beverages are hardly unknown to any in India. Processed products such as nectars, concentrates, jam, jelly powders, fruit bars, and dried mango products also require a huge amount of the fruit produce (Wu et al. 1993).

Processing of the fruit entails that 7–24% of the entire weight of the fruit which constitutes the mango peels turns into waste. Mango peels mostly end up turning into a stockpile of waste that remains unused that serves no end. Although possessing chemical characteristics, which indicate a rich source of bioactive compounds such and enzymes such as protease, peroxidase, polyphenol oxidase, and carotenoids use of these essential organic structures have not yet been found. There is also an abundant content of vitamins C and E, dietary fibres, enzymes, and carbohydrate content of 20.80–28.20% in dry weight samples of mango peel (Ajila et al. 2007). Despite these beneficial traits not only has there been any suitable application of them but also these rich organic produce end up being incinerated or being left to putrefy. Land usage is hampered and the over hygiene of the environment in which such commercial usage of mango is being carried out is jeopardized. Presence of functional groups such as carboxylic (pectin) and hydroxyl groups (cellulose) is reported in the polymers contained in abundance in the mango peel matrix. The presence of these functional groups increases the chance of mango peels being favoured as suitable material for the production of AC (Pehlivan et al. 2008; Shukla and Pai 2005; Xuan et al. 2006).

In the current condition of the planet, where all the resources including the land, water bodies, and air are getting polluted beyond imagining, saving the environment is the need of the hour. Many water purifying technologies are available to mankind for use such as electro-coagulation, membrane filtration, electrochemical destruction, ion exchange, irradiation, advanced oxidation, ozonation, precipitation but none prove to be as cheap and effective as the method of adsorption (López-Grimau and Gutiérrez 2006). Carbonaceous materials such as AC prove to be some of the most effective adsorbents having relatively lower production costs too. An application of the as-obtained industrial by-product(waste)-mango peels would be saving a lot of resources. Currently, activated carbon is mostly derived from charcoal, wood derivatives bones, and nutshells. The option and scope of producing ACs from organic sources are wide and endless. Attempts are being made worldwide to produce AC from organic wastes to reduce the load on the environment (Lakshmi et al. 2009; Lillo-Rodenas et al. 2003). An application like producing AC would

vivekvardhan2@gmail.com

serve the dual purpose of not only help reducing the load on the land used by commercial users of mango pulp but also contribute to the cleaning up of water by being used as an adsorbent to remove the pollutants to produce safe water for drinking and recreational processes.

The main aim of work is to design a suitable adsorbents derived from mango peels, to test their effectiveness in the removal of dyes, and to explore treatment methods during production which give rise to desired traits in an AC towards removal of dyes. Many organic sources have been tried as sources for the production of AC but mango peels irrespective of its chemical properties are not a much explored precursor for AC production. Methylene blue dyes were removed using the ACs prepared by the four respective routes of mango peel activated carbon (MPAC) production.

2 Materials and Methods

2.1 Preparation of AC

Local markets of Kolkata were selected as the source of the MPs. The as-obtained MPs contained juice of mangoes and were not purified. Thus, a two-step washing procedure was adopted. This consisted of thorough and repeated washing by tap water after which washing by double distilled water ensued. This step was followed by two drying steps; first of all, the sun drying for one day followed by oven drying at 100 °C for 24 h. Drying was stopped at the stage when the mango peels obtained a nice crunchy texture ideal for hand grinding. This is followed by thorough grinding of the mango peels which resulted in fine particles of powdery material named as mango peel grinded powder (MPGP).

2.1.1 Thermal Activation

MPCP the powder was taken in several silica crucibles in measured amounts and carbonized ensued at 700 °C for 2 h in a muffle furnace. The product obtained from the muffle furnace after thermal activation was sieved through a 250 μm mesh to obtain the AC. The AC so produced was called as temperature activated-mango peel activated carbon (P-MPAC).

2.1.2 Chemical Activation

First Process

MPCP was taken in glass petri dish and mixed thoroughly till with concentrated H_2SO_4 in 1:1 weight ratio till uniformity was obtained. This mixture was kept

vivekvardhan2@gmail.com

overnight (24 h) under stirring at room temperature. The product thus obtained was then washed with double distilled water repeatedly till neutral pH was reached. The powder after neutralization was then transferred into silica crucibles and carbonized at 700 °C for 2 h in a muffle furnace. The product obtained from the muffle furnace after thermal activation was sieved through a 250 μm mesh to obtain the AC. C-700-MPAC was the name given to the as-produced AC.

Second Process

MPCP was taken in petri dish and mixed thoroughly with concentrated H_2SO_4 in 1:1 weight ratio till uniformity was obtained. This mixture was kept overnight (24 h) under stirring at room temperature. The product thus obtained was then washed with double distilled water repeatedly till neutral pH was reached. The powder after neutralization was then transferred into silica crucibles and carbonized at 300 °C for 3 h (as we maintain temperature well below 700 °C, we have raised the time of carbonization to 3 h) in a muffle furnace. The product obtained from the muffle furnace after thermal activation was sieved through a 250 μm mesh to obtain the AC. C-300-MPAC was the name given to the as-produced AC.

Third Process

MPCP was taken in a silica crucible and carbonized at 300 °C for 2 h. The obtained product was crushed thoroughly and mixed with equal proportion of concentrated H_2SO_4 in 1:1 weight ratio. This mixture was kept overnight (24 h) under stirring at room temperature. The product thus obtained was then washed with double distilled water repeatedly till neutral pH was reached. The powder after neutralization was then transferred into silica crucibles and carbonized at 700 °C for 1 h in a muffle furnace. The product obtained from the muffle furnace after thermal activation was sieved through a 250 μm mesh to obtain the AC. PCP-MPAC was the name given to the as-produced AC.

2.2 Preparation of Adsorbate

The 10 μM solution of methylene blue dye solution was prepared to be used as the adsorbate in the adsorption studies. 1.6 mg of methylene blue of analytical grade was added to 500 ml of double distilled water to prepare the 10 μM solution of methylene blue.

vivekvardhan2@gmail.com

2.3 Reagents and Analytical Measurements

The reagents used were of analytical grade, they were supplied from EMPARTA. The adsorbate used was methylene blue was supplied by SRL (Shanghai Richem International). H_2SO_4 used was of 98% purity. Mango peels were obtained from local markets in Kolkata. Double distilled water was used in all solutions.

3 Effect of pH

One of the most fundamental parameters that effect how efficiently an adsorption process will perform is the pH of the solution. The charges present on the surface of the adsorbent and the electrical interactions between the adsorbent and adsorbate is greatly affected by the pH of the solution. Speciation and degree of ionization are also affected by the pH of a solution. The effect of pH of solution on adsorption of dyes (concentration = 10 μM) using MPAC (m = 1 g/l) was evaluated at different pH varying from 1 to 11 at 303 K for six hour and the results are plotted in Fig. 1. It could easily be understood from the figure that low pH of 3 is the most favourable pH for carrying out the further adsorption studies as the highest percentage of removal was obtained at it.

Point of zero charge (PZC) is defined as the pH for which the adsorbent surface bears no charge. Any increase of pH from the PZC will render the surface negatively charge and any decrease from the PZC will make the surface positively charged. Thus, PZC is the optimum for the purpose of adsorption studies. It is clear from the figure MPAC must have a PZC of 3 for methylene blue dye and act neutral at this pH.

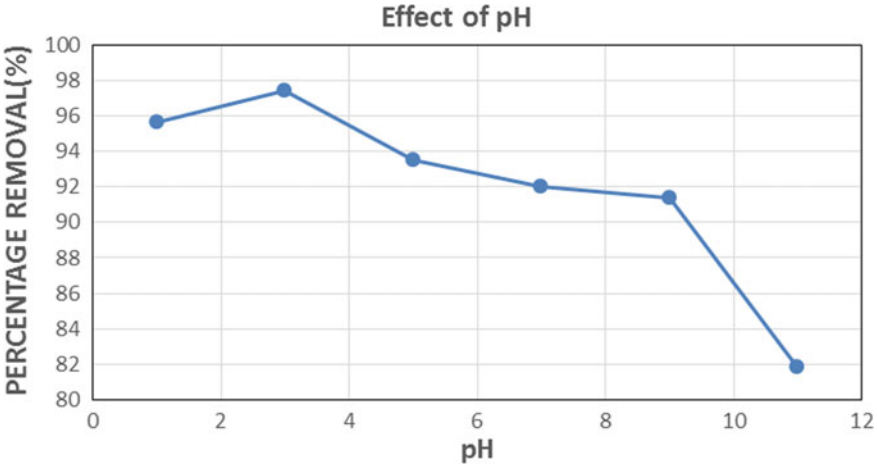

Fig. 1 Effect of initial pH as a function of percentage removal for methylene blue dye

vivekvardhan2@gmail.com

3.1 Batch Kinetic Study

Experimental study was conducted in batch mode for exploring the ability of the MPACs for the adsorption of methylene blue dye from its aqueous solution. The experiments were performed in Erlenmeyer flasks containing 50 nl of dye solution. 50 mg of the prepared adsorbents were added to the prepared 10 micromolar solution of methylene blue dye. Stirring was conducted at 500 RPM. Initial pH of the solution was changed using 0.1 N NaOH/0.1 N HCl. Filtrate analysis was carried out using UV-VIS spectrophotometer at $\lambda_{max} = 554$ nm for methylene blue. The dye adsorbed per unit weight of MPACs and percentage removal of Rhodamine B was calculated using following equations (Fig. 2):

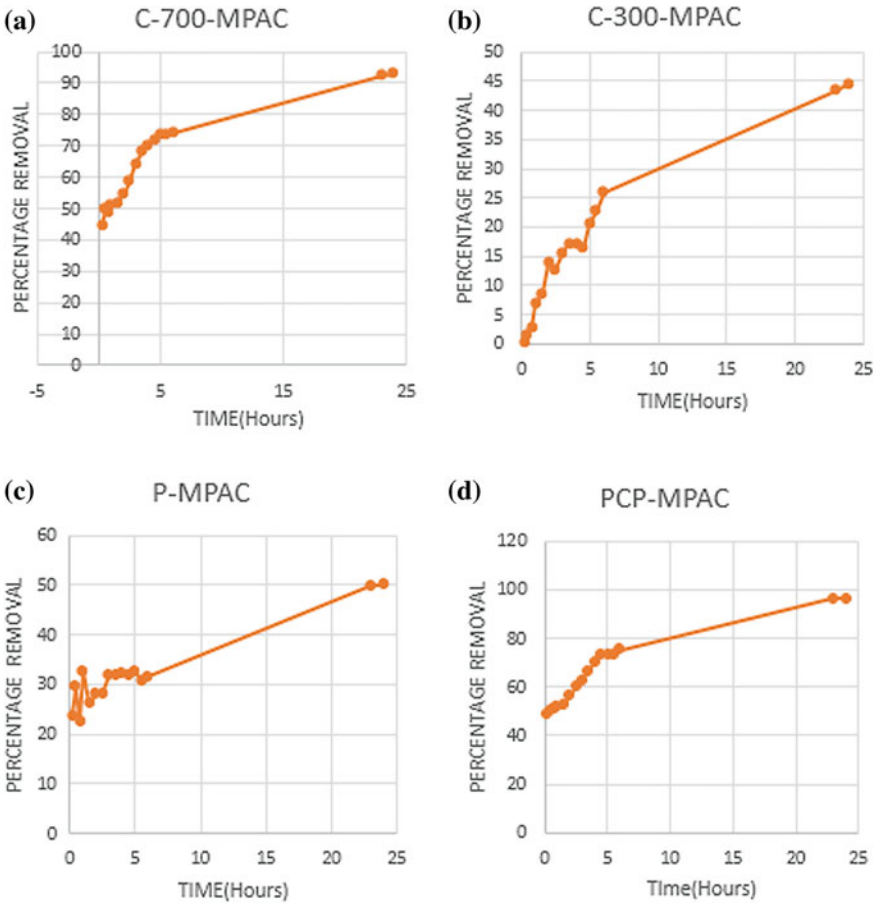

Fig. 2 % removal versus time plot for **a** C-700-MPAC; **b** C-300-MPAC; **c** P-MPAC; **d** PCP-MPAC

vivekvardhan2@gmail.com

$$\text{Adsoption Capacity}\,(q_e) = \frac{(C_0 - C_e)V}{m}$$

$$\%\,\text{Removal} = \frac{(C_0 - C_e) * 100}{C_0}$$

where

C_e Residual or equilibrium concentration of dye solution (mg/l)
C_o Initial concentration of dye solution (mg/l)
m Amount of MPAC (g)
q_e Amount of dye adsorbed on BPAC/adsorption capacity (mg/g)
V Volume of dye solution (l).

4 Adsorption Kinetics Results

The results of the kinetic study along with the predicted model (shown in bold text in Table 1) are listed in Figs. 3 and 4.

5 Discussion

The inference that can be drawn from the batch study is that PCP-MPAC (3.221 mg/g) and C-700-MPAC (3.0931 mg/g) having the mentioned adsorption capacities are much more superior as adsorbents than C-300-MPAC and P-MPAC having adsorption capacities 1.4291 mg/g and 1.6815 mg/g, respectively.

The enhanced ability of C-700-MPAC as adsorbent compared to the P-MPAC despite having a similar thermal treatment might be attributed to the fact that chemical activation was performed on the C-700-MPAC which can lead to the generation of oxygenated groups on the surface of the ACs. The oxygenated groups may play a crucial role in the adsorption process through chemisorption. The dual effect of high-temperature physical activation and chemisorption could lead to an enhancement of the adsorption capacity of C-700-MPAC.

P-MPAC although received a similar treatment as C-700-MPAC thermally the lack of the chemical treatment could be held responsible for the low adsorption capacity. Chemical treatment by a strongly oxidizing chemical such as concentrated sulphuric acid can generate additional oxidizing functional groups which aid in the adsorption of the dye from its aqueous solution. It can also be seen in the case of C-300-MPAC that although it received both chemical and physical treatment it is the temperature of activation which made a huge difference in adsorption capacities. It may be inferred that the low temperature of 300 °C is not sufficient to complete the thermal cracking of the precursor mango peels.

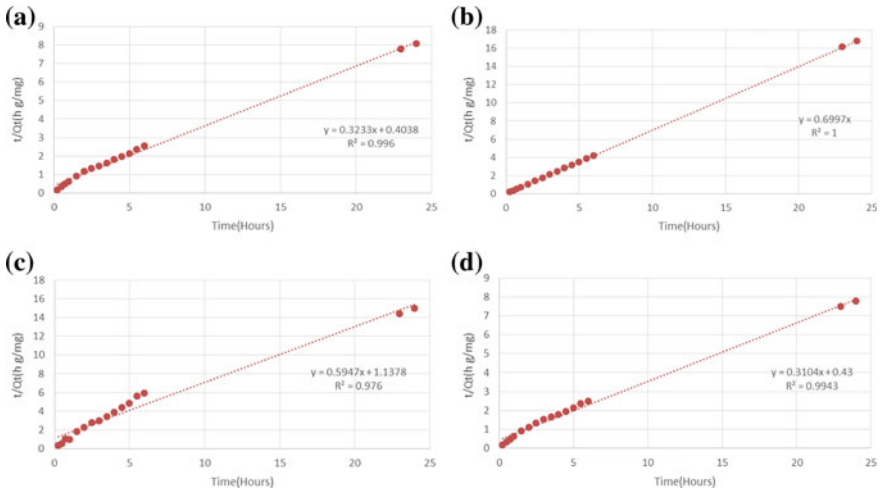

Fig. 4 Second-order kinetic data for **a** C-700-MPAC; **b** C-300-MPAC; **c** P-MPAC; **d** PCP-MPAC

PCP-MPAC shows the most superior removal and this could be attributed to quite a few factors. Mild carbonization plays an important role in proper chemical activation. Thus, sulphuric acid has a more enhanced effect of chemical activation since partly generated pores are already available. This also reduces the energy consumption in producing the activated carbon. Although it may seem that there are three steps in producing the activated carbon but certainly the amount of time spent activating at the higher temperature is essentially reduced making the process energy efficient in totality.

6 Conclusions

It can be safely concluded that MPs can act as suitable precursors for producing high-quality ACs. These ACs can be used to remove one of the most abundant pollutants of the textile industry namely methylene blue dye. Using MPs as a source for AC achieves the dual purpose of not only producing a substance capable of cleaning the waters of our planet but also helps reduce solid waste in the form of MPs that are either incinerated to produce gaseous pollutants or end up as landfill. Since MPs are a waste product of different beverage industries and mango beverages are available all through the year, this ensures that not only the raw material will be cheap but also available year round for continuous production of ACs. The batch adsorption studies proved that chemical activation along with thermal activation at suitable temperatures is necessary for proper performance of the adsorbent. High-temperature activation combined with low-temperature pre-carbonization proving essential to get the desired qualities in the AC.

Passive High-Rate Wastewater Treatment Using Upwelling Anaerobic Lagoons as an Alternative to Conventional Systems

Seema Sukhani and Hoysall Chanakya

Abstract Wastewater treatment processes employed today are many decades old and often do not follow emerging criteria of sustainable development promoting resource recovery as well as smaller environmental footprint while ensuring nutrient reuse and stakeholder involvement. Based on various performances reported and field observations of various poorly operating STPs in South India, it is proposed that an intermediate concept of anaerobic upwelling sludge bed reactor (USB) is proposed to operate with no O&M interventions like a septic tank but providing potential for methane and nutrient recovery at rates and HRTs as practised today, namely HRT < 24 h, loading rates 1–2 kg BOD/m^3/d, 70–80% BOD removal, 1–3 years of attention-free operation and moderate effluent turbidity. Some field scale evidence of such function at various locations is provided, and its proposed operation is discussed.

Keywords Sewage treatment · SDG-6 · Upwelling sludge bed reactor · Resource recovery · International society of waste management, air and water

1 Introduction

Developing countries face severe shortage of wastewater treatment infrastructure comprising of sewerage and collection systems, wastewater treatment and sludge disposal facilities. Lack of financial assistance and technical expertise has been some of the biggest factors for incapability to construct and operate conventional centralized STP. Absence of a reliable power supply and high costs of backup diesel power and frequent maintenance needs have been a major concern in rural and peri-urban areas in developing countries and hindered widespread deployment of STPs. Such factors also need to be considered before any technological development efforts are taken up (Verawaty et al. 2013).

vivekvardhan2@gmail.com

Further, as various countries strive to provide compliance and capabilities for various sustainable development goals, SDG-6, especially in urbanizing locations, the absence of reliable power supply hinders the use of high-rate aerobic systems as well as power-based control systems for the STPs to be set up. Thus, there is a need to develop energy neutral or energy-independent STP systems that are also ecologically safe, socially acceptable, economically viable and self-sustaining in the immediate future while also being simple to operate (Luo et al. 2014). It is believed that when small village settlements those have rapidly grown and become urbanized, the high costs of land as well as the absence of large spaces for local treatment will drive them towards decentralized STPs, and these recently urbanized locations will be the first to face such problems of the absence of appropriate technology for such locations. In this paper, a review is attempted from the capabilities of various systems focussing on low-energy systems that are likely to be suitable to the emerging sustainability, people-led and multiple by-product-driven scenario of the future.

2 Conventional Passive and Low-Energy STPs

Constructed wetlands are one of the best-known passive systems and well established with regard to their performance. Their potential is highly dependent on microbial activity, retention times, variation in load, particulate content and climatic factors such as precipitation and evapotranspiration (El-Khateeb et al. 2009; Katsenovich et al. 2009). However, major limitations of system are poor nutrient (nitrogen and phosphorus removal), large areal footprint, propensity to clog during overloads and oxygen transfer limitations.

In urban and peri-urban areas, large footprint, which is essential for good effluent in constructed wetlands (Kivaisi 2001; Foladori et al. 2013), is difficult to acquire. Footprints can vary around 0.06kg BOD/m^2d (Zhang et al. 2009; Vymazal 2011). Nutrient recovery is also very low. In a study conducted by Vymazal in 2007, out of 40–55% of N removed (initial load 250 and 630 g Nm^{-2} $year^{-1}$) and ~40–60% of TP (initial load 45 and 75 g Pm^{-2} $year^{-1}$) removed, only 100–200 g Nm^{-2} $year^{-1}$ and 10–20 g Pm^{-2} $year^{-1}$ could be harvested through vegetation biomass. Important recoverable are being lost to environment to cause pollution on the one side and unsustainability on the other. In the emergent sustainability scenario, it is imperative that a significant fraction of the sewage nutrients are harvested and made amenable for recycling and reuse.

Aerobic systems such as activated sludge process are most commonly adopted treatment technology. As mentioned earlier, for a sustainable system, high treatment efficiency and low energy consumption are the key. In aerobic systems, energy demands are high due to operation of pumps, air blowers, mixers and separators. In general, 1–25 kWh/kg COD removed is required to operate various types of aerobic system depending on technology as compared to 0.25–13 kWh/kg COD removed for

vivekvardhan2@gmail.com

anaerobic systems (Amanatidou et al. 2016; Pitas et al. 2010; Yin 2010). In a conventional system, observed biomass production rate (Y_{obs}) usually ranges between 0.12 and 0.45 kg MLVSS kg COD removed-1 (Amanatidou et al. 2016).

Such excessive sludge will hinder sedimentation and create problems while mixing and aeration. Ultimately, a large part of sludge needs to be wasted, which again has significant economic and ecological footprint in terms of drying the sludge and disposing it in landfills. It must be noted that most of the aerobic systems of today are between 50 and 150 year old and now need alternatives in the light of emerging sustainability criteria of energy, C and environmental footprint as well as resource recovery criteria.

2.1 Anaerobic System

Anaerobic treatment systems generally have low operating costs and lower environmental footprint, and they also produce biogas, compost and many value-added products. However, for reasons of a slightly lower treatment efficiency and slower reaction rates and susceptibility to near-freezing temperatures, they have often been overlooked. Effluent from an anaerobic needs a small but definite aerobic treatment. Despite these 'stated' problems associated with anaerobic systems, they still are our best option for BOD removal. Though, as mentioned above the energy requirements are lower than all systems, potentially higher loading rates than aerobic systems, most planners are not generally in favour of the anaerobic systems for various reasons of skills and monitoring needs. The future capabilities or potential would be set by high-end processes such as UASB while seeking the O&M simplicity of a septic tank. Some of the studies conducted on UASB and septic tank in various parts of world are mentioned in Table 1.

2.2 Sludge Production

Biomass production rate (Y_{obs}) during anaerobic metabolism is usually between 0.03 and 0.15 kg MLVSS/kg COD removed. Moussavi et al. (2010) after operating septic tank for 355 days concluded that depth of total sludge produced and inert accumulated was still less than half volume of reactor. This illustrates that even in simple system like septic tank, there is no need to frequently remove sludge. It was observed by Lin and Yang (1991) that sludge with a concentration of 30–40 kg TS/m^3 exhibits the highest methanogenic-specific activity. Yet under anaerobic conditions and depending upon the organisms responsible, the Yobs of sludge can range between 0.3 and 0.5 kg MLVSS/kg COD removed. There are instances of 3–5 year uninterrupted operation of anaerobic systems without need for sludge removal. Older anaerobic sludges tend to become heavier and gradually decompose to be become a lot more

vivekvardhan2@gmail.com

vivekvardhan2@gmail.com

dense, and aerobic sludge is a lot more bulky and thus typical aerobic treatment systems require weekly and monthly management of sludge. Needless to say, aerobic sludges need a lot more careful treatment since they are quite odoriferous and bulky, thus more difficult to dewater and require monthly management of sludge.

2.3 Retention Time

The reaction rates are longer in typical septic tanks due to the absence of sludge recycling (maintaining a higher level of MLVSS), a gradual accumulation of inert solids and non-specific selection of sludge. Also, the time required to reach at a steady state is somewhat long taking 1–3 months. However, in a UASB system, these factors are overcome by maintaining a specific upflow velocity, which firstly helps retaining a high level of MLVSS that is constantly recycled, and this in turn tends to select a good settleable sludge with high microbial mass (lower EPS content). The retention period for same level of treatments is approximately three times lower achieving loading rates in the range of 3–8 kg COD/m^3/d. This is a lot higher than typical aerobic system that can handle only about 1–2 kg COD/m^3/d. From this, it is obvious that we need to engineer a system which can give us treatment efficiency and throughput of a UASB and energy independence/simplicity of a septic tank. This appears feasible if it is possible to hold on to a lot of heavy anaerobic sludge in the reactor and make it to be recirculated in a passive manner without external energy application. This invokes the concept of natural phenomenon of sludge upwelling if particles are allowed to mix with the sludge at a specific rate.

2.4 Sludge Properties and Activity

Under a typical mesophilic condition of 15–28 °C, the typical density of anaerobic sludge would be 1.05–1.10 g/m^3, and this imparts a propensity to settle rapidly. Being anaerobic, there is very little tendency to accumulate a large fraction of extracellular polysaccharides (EPS) very characteristic of aerobic sludges. When fed at a near maintenance rates, the settling sludge maintained would be primarily of viable bacteria. It is thus possible to create a process that selects predominantly well-flocculated sludge, thereby gradually enhancing its settling properties. This is typical in anaerobic sewage treatment systems giving a flocculated sludge in range of 20–30 ml/g of sludge. Although granular sludge has higher methanogenic activities with SVI 10–20 ml/g/d, they are useful for soluble COD and much less for sewage. The role granular sludge (e.g. UASB) in particulate COD removal before hydrolysis has been reported to be very limited. In terms of activity, 1.2 and 1.9 kg/kg VSS/d of methanogenic activity is appropriate to achieve a F/M ratio of 0.5 or even lower. It has been observed that in lower loading rates, diversity of micro-organisms is much more and they have capability to degrading diverse compounds. In anaerobic sludge,

vivekvardhan2@gmail.com

VSS/SS ratio observed is 0.70–0.85 and wet cakes after centrifugation have 10% solids. This sludge can be used as a fertilizer by directly applying it to field.

3 Conclusion

Most wastewater systems being adopted and run today are very old and do not meet many sustainability criteria of Carbon, nutrient, energy and environmental footprint as well as societal inclusion. Meeting SDG obligations, especially to emerging urbanization, will require newer concepts of decentralized treatment with resource recovery. From various performance criteria found in literature, it is suggested that there is a need for modifying anaerobic reactors to provide the O&M and design simplicity of septic tanks while creating performance yardsticks closer to UASB processes.

The upwelling sludge bed reactor concept has been advanced to meet immediate application goals and performance criteria. Anaerobic system with one-third volumetric sludge, F/M ratio <0.5, 1.2–1.9 kg/kg VSS/d of methanogenic activity with functional MLVSS to be ~8–9 g/L, natural mixing through sludge upwelling is proposed. Based on field observations at HRT ~24 h, approximately 70–80% COD and 90% BOD removal occurs in such system. The proposed design and upwelling phenomenon are shown in Figs. 1 and 2, respectively. This system can be applied from a scale of 1MLD to a community level. This unit is a part of a sequential system and is discussed elsewhere.

Utilization of Rice Husk Ash for Defluoridation of Water

C. M. Vivek Vardhan and M. Srimurali

Abstract Effective utilization and safe disposal of solid wastes is one of the major challenges placed before the modern-day scientist, in the wake of exploding population. Rice husk is a major agricultural waste being generated by an agricultural nation such as India, and therefore warrants proper utilization before disposal. On the other hand, fluorosis is a burning problem caused due to consumption of groundwater consisting of excessive fluoride, prevalent in several parts of the world. Therefore, in this study, Rice Husk Ash was impregnated with Lanthanum and investigated for defluoridation of water by adsorption. Batch adsorption experiments were conducted for fluoride removal using Lanthanum-Impregnated Rice Husk Ash (LIRHA) and tested for various parameters such as pH, time of agitation, influence of ions, and optimum dosage of sorbent. It was observed that LIRHA removed fluoride to less than the permissible limit in the naturally encountered pH of water. The optimum time and dosage of LIRHA were found to be 240 min and 6 g/L, respectively. The anions phosphates and chlorides were found to be detrimental for fluoride sorption probably due to competitive of those ions with fluoride on the active sorption sites on LIRHA. Thus, this study revealed that the agricultural waste, Rice husk can be effectively utilized for removal of fluoride from water and subsequently disposed off safely.

1 Introduction

India being an agricultural nation generates huge quantities of Rice husk as agricultural waste. About 24 million tons of Rice husk is being generated by the nation annually (Pandey et al. 2012). A minor portion of this waste is used as cattle feed and in manufacture of cement and refractory bricks. The remaining major portion is dumped, which results in its decomposition and subsequent emission of methane gas. Therefore, an effective way for utilizing rice husk has to be found and subsequently disposed safely. Concomitant to this challenge, contamination of groundwater with fluoride and the resulting fluorosis is a major threat faced by mankind. Fluoride has dual impacts on living organisms. In lower concentrations, fluoride is very beneficial as it assists in formation of bones and prevents dental decay, whereas in higher concentrations, it causes serious health issues such as skeletal fluorosis, dental fluorosis, mental derangements, dwarfishness, etc. Therefore, it is imperative that fluoride has to be removed from water before consumption. The World Health Organization (WHO) has stipulated a maximum permissible limit of 1.5 mg/L of fluoride in drinking water. Various technologies are available for defluoridation of water and are partially successful to various extents. But, as fluorosis is not yet completely eradicated, the focus has recently shifted to use of rare earth materials as adsorbents for defluoridation with a fairly reasonable degree of success (Vardhan and Srimurali 2018; Vivek Vardhan and Srimurali 2015, 2016). However, research is still deficient on achieving a dual advantage of simultaneously utilizing waste and removing fluoride from water. Therefore, in this study, an attempt was made to employ Rice Husk Ash impregnated with Lanthanum for removal of fluoride from water. The main objectives of this study are to: (1) Impregnate Lanthanum onto Rice Husk Ash, (2) Find the optimum time of agitation and the dosage of sorbent required, (3) Investigate the influence of pH on fluoride removal, and (4) Study the impact of anions on defluoridation.

2 Materials and Methods

2.1 Chemicals

All reagents used in the present investigation were procured from E. Merck Ltd., India and were of analytical reagent grade. Sodium fluoride of 221 mg was dissolved in distilled water and made up to 1 L in a volumetric flask to prepare a stock fluoride solution of 100 mg/L. Stock solution was diluted appropriately to obtain fluoride solutions of required working concentrations.

vivekvardhan2@gmail.com

2.2 Adsorbent

Rice Husk Ash (RHA) was procured from a local rice mill and was sieved to a mean size of 475 μm.

2.3 Adsorbent Preparation

Lanthanum carbonate of varying weights was mixed with 0.05 L of distilled water and 0.1 N HCl was added to it drop wise until Lanthanum carbonate got dissolved completely. To this solution, 0.1 N NaOH was added under constant stirring until precipitates were visually observed. RHA of mean size 475 μm and 20 ± 0.2 g weight was added to this mixture. This mixture was mixed for 6 h in a magnetic stirrer. Subsequently, it was decanted, dried, and heated at 300 °C for 4 h in a muffle furnace. It was thoroughly washed with distilled water and dried. The obtained material is Lanthanum-Impregnated Rice Husk Ash (LIRHA).

2.4 Batch Adsorption Experiments

Teflon flasks of 250 mL capacity and a working volume of 100 mL were used throughout the experiments. Laboratory spiked fluoride solutions of 10 ± 0.2 mg/L were prepared and adsorbent of required dosage was added to each flask. These flasks were agitated in a rotary shaker of make Kaizen imperial. The optimum rate of agitation for highest removal of fluoride was determined by varying the speed of agitations at 40, 80, 120, 160, and 200 rpm, at 25 ± 1 °C. Highest fluoride removal was observed at 160 rpm and so all experiments were conducted at this speed of agitation. After agitating for stipulated time periods, the contents were withdrawn, filtered in a Whatman filter paper of size 42, and analyzed for fluoride removal using SPADNS method (APHA 2005). Fluoride was analyzed using a spectrophotometer, Evolution 201, of Thermo Scientifics. pH adjustments were carried out using 0.1 N NaOH and 0.1 N H_2SO_4. Individual ions of Cl^-, SO_4^{2-}, PO_4^{3-}, HCO^{3-}, and NO^{3-} were added in concentration of 250 ± 5 mg/L in addition to fluoride ions to evaluate its impact. Concentration of Lanthanum was measured using an atomic adsorption spectrophotometer AAS, GBS 932 plus.

vivekvardhan2@gmail.com

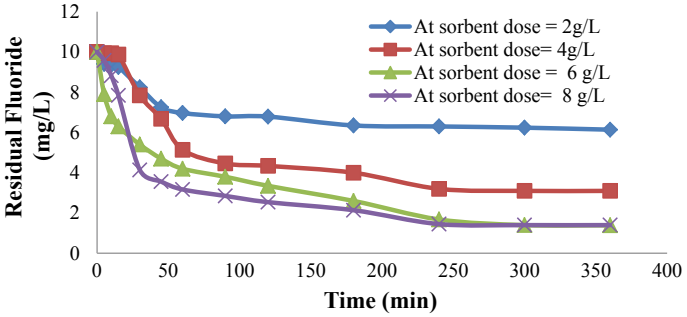

Fig. 1 Influence of time of agitation and dose of LIRHA on defluoridation

3 Results and Discussion

3.1 Time and Dose Studies of RHA and LIRHA

Experiments were carried out to arrive at the optimum time and dose required for adsorption to take place using LIRHA and the results are presented in Fig. 1. It can be observed that the time and dose of sorbent required for defluoridation using LIRHA are 240 min and 6 g/L, respectively, which left a residual fluoride of 1.39 mg/L.

3.2 Influence of pH

Role of pH on defluoridation using LIRHA was examined and the results are presented in Fig. 2. It can be observed that LIRHA performed better in removing fluoride from water in a pH range of 7–9. Formation of HF ions at lower pH values and OH

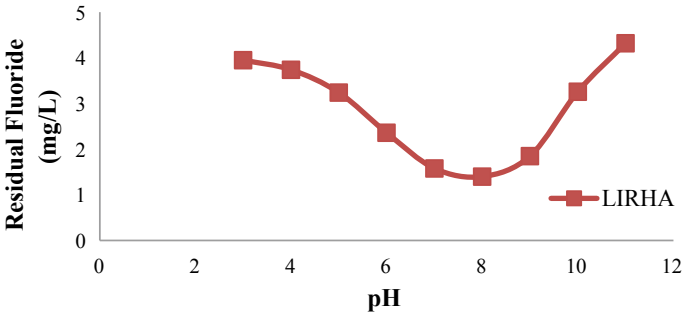

Fig. 2 Influence of pH of solution on fluoride removal by LIRHA

vivekvardhan2@gmail.com

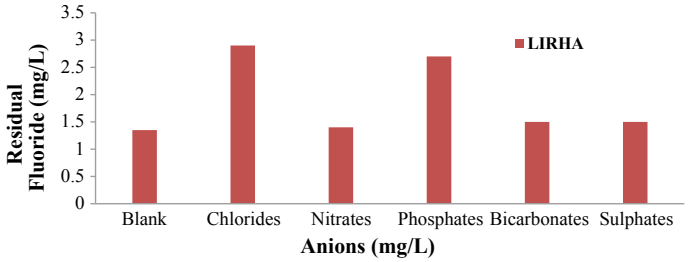

Fig. 3 Influence of anions on sorption of fluoride by LIRHA

ions at higher pH values could be the reason for lesser defluoridation below and above the optimum pH ranges observed.

3.3 Influence of Anions

Efficiency of fluoride removal by LIRHA was tested in the presence of the anions Cl^{-}, SO_4^{2-}, PO_4^{3-}, HCO^{3-}, and NO^{3-}, each individually and the results are presented in Fig. 3. It can be observed that chlorides and phosphates impeded sorption of fluoride by LIRHA, whereas the ions nitrates, bicarbonates, and sulfates exhibited a lesser influence. Similar trend of competition of phosphates with fluorides for active sorption sites was reported by Bia et al. (2012) on ion modified montmirillonite. Chlorides were also reported to be highly competitive against fluoride for sorption on expanded clay aggregate, according to Sepehr et al. (2014).

4 Concluding Remarks

The aim of this work is to simultaneously utilize the agricultural waste Rice Husk Ash and to remove fluoride from water.

Agitated non-flow batch studies demonstrated that LIRHA is capable of removing fluoride from water to less than the permissible limits.

Normally encountered pH range was found to be favorable for fluoride removal by LIRHA.

It was observed that the time and dose of LIRHA required for defluoridation were 240 min and 6 g/L, respectively.

Presence of anions such as phosphates and chlorides exerted a detrimental effect on removal of fluoride from water using LIRHA, possibly due to competition of ions.

These investigations revealed that the agricultural waste Rice Husk can be utilized toward removal of fluoride from water and should be disposed off safely.

Development of a Low-Cost Column Type Filter Based on Agricultural Waste for Removal of Fluoride from Water

C. M. Vivek Vardhan and M. Srimurali

Abstract Population explosion and subsequent increase in demand for food have resulted in adoption of modern methods of agriculture, thereby generating huge quantities of agricultural wastes. India being an agricultural nation generates large amount of Rice Husk warranting proper utilization before disposal. Concomitantly, fluorosis caused due to consumption of excessive fluoride is posing a serious threat to mankind. Therefore, in this study, an attempt has been made to develop a low-cost column type filter based on Rice Husk for removal of fluoride from water. Lanthanum was used to enhance the fluoride removal capabilities of Rice Husk Ash. Continuous-flow column studies were conducted and investigated for its potential in removing fluoride from water. It was observed that 37.8 L of water of initial fluoride concentration 10 mg/L could be brought down to permissible limits in 1890 min and can be safely consumed. The developed low-cost filter utilizes an agricultural waste and protects people from fluorosis especially of rural and isolated communities.

Keywords Adsorption · Defluoridation · Water · Low-cost · Lanthanum

1 Introduction

Agricultural wastes are generated in huge quantities in agriculture-based nations such as India. It is estimated that the annual generation of Rice Husk in India is about 24 million tons (Pandey et al. 2012). Though a minor portion of it finds application in production of silica, cement and refractory bricks, majority of it is dumped and remains non-utilized. Therefore, an effective way of utilizing the same is required. On the other hand, contamination of groundwater with fluoride and the resulting fluorosis is a major threat faced by mankind. Fluoride has dual impacts on living organisms. In lower concentrations, fluoride is very beneficial as it assists in formation of bones

and prevents dental decay, whereas, in higher concentrations, it causes serious health issues such as skeletal fluorosis, dental fluorosis, mental derangements, dwarfishness, etc. Therefore, it is imperative that fluoride has to be removed from water before consumption. The World Health Organization (WHO) has stipulated a maximum permissible limit of 1.5 mg/L of fluoride in drinking water. Various technologies are available for defluoridation of water and are partially successful to various extents. But, as fluorosis is not yet completely eradicated, the focus has recently shifted to use of rare earth materials as adsorbents for defluoridation with a fairly reasonable degree of success (Vivek Vardhan and Srimurali 2015, 2016, 2018). However, research is still deficient on achieving a dual advantage of simultaneously utilizing waste and removing fluoride from water. Therefore, in this study, an attempt was made to employ Rice Husk Ash impregnated with Lanthanum for removal of fluoride from water in continuous-flow mode and thereby develop a filter using endemically available wastes. Thus, the main objectives of this work are to impregnate Lanthanum on to Rice Husk Ash and to test it for fluoride removal at varying rates of flow rates, initial fluoride concentrations and bed depths.

2 Materials and Methods

2.1 Chemicals

All reagents used in the present investigation were procured from E. Merck Ltd, India and were of analytical reagent grade. Sodium fluoride of 221 mg was dissolved in distilled water and made up to 1 L in a volumetric flask to prepare a stock fluoride solution of 100 mg/L. Stock solution was diluted appropriately to obtain fluoride solutions of required working concentrations.

2.2 Adsorbent

Rice Husk Ash (RHA) was procured from a local rice mill and was sieved to a mean size of 475 μm.

2.3 Adsorbent Preparation

Lanthanum carbonate of varying weights was mixed with 0.05L of distilled water, and 0.1 N HCl was added to it dropwise until Lanthanum Carbonate got dissolved completely. To this solution, 0.1 N NaOH was added under constant stirring until precipitates were visually observed. RHA of mean size 475 μm and 20 ± 0.2 g weight

vivekvardhan2@gmail.com

was added to this mixture. This mixture was mixed for 6 h in a magnetic stirrer. Subsequently, it was decanted, dried and heated at 300 °C for 4 h in a muffle furnace. It was thoroughly washed with distilled water and dried. The obtained material is Lanthanum-Impregnated Rice Husk Ash (LIRHA).

2.4 Continuous-Flow Experiments

Fixed bed down-flow column studies were performed using a Pyrex glass column of inner diameter 2.54 cm and depth 1 m. Cotton was placed at the base to support aggregates. The column was filled with aggregate of mean size 600 μm to a depth of 30 ± 1 cm at the base. On its top, LIRHA of varying depths of 20 cm, 30 cm and 40 cm was filled. Aggregate of mean size 600 μm and of varying depths of 30 ± 1 cm, 40 ± 1 cm and 50 ± 1 cm was filled on the adsorbent to ensure an equally distributed flow of tap water spiked fluoride solution onto the sorbent bed. The set-up of the column is depicted in Fig. 1. Aqueous fluoride solutions of various concentrations of 5 ± 0.1 mg/L, 10 ± 0.1 mg/L and 15 ± 0.1 mg/L were passed

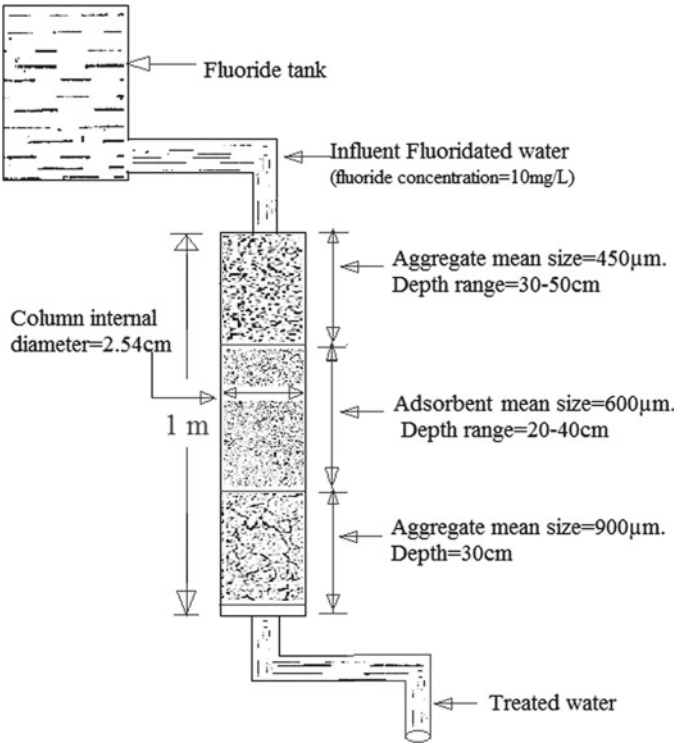

Fig. 1 Column set-up block diagram

vivekvardhan2@gmail.com

through it. Flow rates of the solution were varied at 10 ± 0.2 ml/min, 15 ± 0.2 ml/min and 20 ± 0.2 ml/min. At regular intervals of time, effluent samples were collected and analysed for residual fluoride concentration, until the effluent concentration of fluoride equalled the influent concentration.

2.5 Analysis of Continuous Sorption Experiments

Analysis of breakthrough curves gives an insight into the performance of fixed-bed column. The time taken for breakthrough and time taken for complete exhaustion of column gives characteristic information for determining the performance and dynamics of adsorption of a column (Chen et al. 2013). Breakthrough of the column is considered to have occurred when the effluent concentration (C_t) has reached about 0.1% of influent concentration (C_o), and exhaustion of column is considered to have occurred when effluent concentration has reached about 95% of influent concentration (Kundu and Gupta 2007). However, from fluoride removal point of view, 15% fluoride removal (i.e. up to effluent concentration of 1.5 mgF^-/L) is considered for analysis. A breakthrough curve is obtained by plotting values of (C_t/C_o) versus (t) (Han et al. 2009). Effective effluent volume (V_{eff}) can be calculated from Eq. (1) (Ramavandi et al. 2014).

$$V_{\text{eff}} = Q \cdot t_{\text{total}} \tag{1}$$

where Q is volumetric flow rate (ml/min), and t_{total} is flow time (min). The value of total mass of fluoride adsorbed (q_{total}) (mg) can be obtained from the area under the breakthrough curve, found by integrating the adsorbed concentration (C_{ad}, mg/L), within the functioning time limits (Ramavandi et al. 2014) (Eq. 2).

$$q_{\text{total}} = \frac{Q}{1000} \int_{t=0}^{t=\text{total}} C_{\text{ad}} \mathrm{d}t \tag{2}$$

where $C_{\text{ad}} = C_o - C_t$.

The maximum fluoride adsorption capacity (q_{eq}) can be calculated as follows, as given in Eq. (3)

$$q_{\text{eq}} = \frac{q_{\text{total}}}{m} \tag{3}$$

where m is dry weight of adsorbent used in column (g).

Fluoride was analysed using SPADNS method (APHA 2005), using a spectrophotometer, Evolution 201.

vivekvardhan2@gmail.com

3 Results and Discussion

3.1 Continuous-Flow Column Studies

To evaluate the practical applicability of LIRHA for defluoridation, in continuous-flow mode, fluoride-rich water was passed through columns consisting of varying depths, at different flow rates and different influent fluoride concentrations.

3.1.1 Effect of Bed Depth

LIRHA bed depths were varied, and the corresponding variations in related parameters such as time for exhaustion of column and effective volume of water treated were evaluated and presented in Table 1. Increase in bed depth resulted in increase in the effective volume of water treated and took more time for the column to get exhausted. Breakthrough curves were drawn between t versus (C_t/C_o) for various bed depths, and the plots are presented in Fig. 2. It is clear from this figure that with

Table 1 Values of column parameters obtained at different bed depths, flow rates and initial fluoride concentrations for defluoridation using LIRHA

Q (ml/min)	(C_o) (mg/L)	Z (cm)	t_{total} (=Total flow time in min)	V_{eff} (ml)	q_{total} (mg)	q_o (mg/g)
15	10	20	2790	41,850	273.1	4.149
15	10	30	5130	76,950	468	4.739
15	10	40	6930	103,950	770.3	5.85
10	10	30	12,780	127,800	783	7.928
20	10	30	1890	37,800	270.1	2.735
15	5	30	11,700	175,500	484.3	4.904
15	15	30	2790	41,850	343.1	3.475

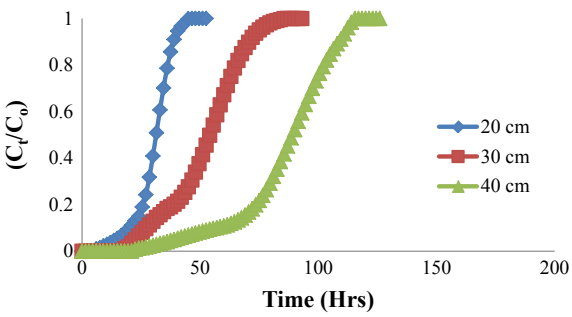

Fig. 2 Breakthrough curves for the effect of bed depth on defluoridation of water using LIRHA

vivekvardhan2@gmail.com

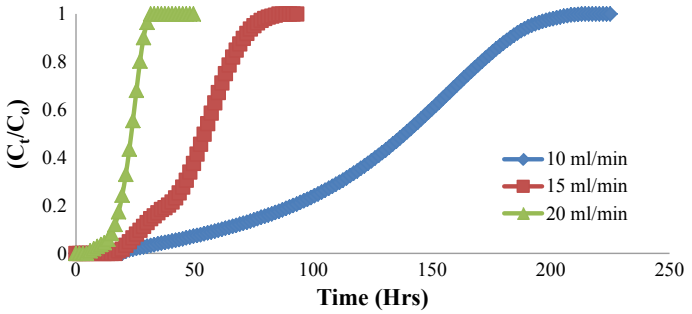

Fig. 3 Breakthrough curves for the effect of flow rate on defluoridation of water using LIRHA

increasing bed depth, the slope of column gradually decreases, marking a broadening of the mass transfer zone, resulting in increased fluoride sorption.

3.1.2 Effect of Flow Rate

Rate of flow of influent fluoride solution into the column was varied, and the corresponding variation of dependent parameters is presented in Table 1. It can be observed from this table that with increase in flow rate, the column gets exhausted rapidly because it gets saturated rapidly. Figure 3 shows the breakthrough curve drawn between t versus (C_t/C_o) for varying flow rates. From this figure, it can be seen that, with increasing flow rate, the breakthrough curves become steeper, and the uptake of fluoride too decreases. This could be due to adsorption taking place, only through film diffusion, because of lesser residence time (Ye et al. 2018).

3.1.3 Effect of Initial Fluoride Concentration

Concentration of fluoride in the influent aqueous solution was varied, and its impact on defluoridation in continuous mode was studied. The influence of variation of initial fluoride concentration on the effective volume treated, and uptake of fluoride and sorption capacities are presented in Table 1. From the table, it can be observed that, with increase in influent fluoride concentration, the adsorption capacity of column too increased gradually. Higher fluoride concentration effectively overcomes mass transfer resistance and therefore transfers fluoride effectively on to the surface of LIRHA. Breakthrough curves were plotted between t versus (C_t/C_o) for different influent fluoride concentrations and are presented in Fig. 4. From this figure, it can be seen that with increase in initial fluoride concentration, the gradient of the breakthrough curve increases, resulting in decreased mass transfer zone. This indicates that intraparticle diffusion controls the adsorption process (Manna et al. 2018).

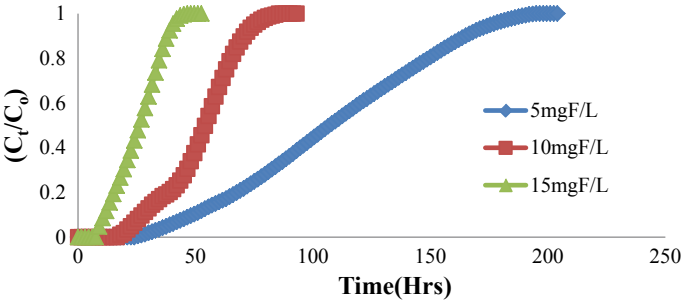

Fig. 4 Breakthrough curves for the effect of initial fluoride concentration on defluoridation of water using LIRHA

4 Concluding Remarks

The aim of this work is to simultaneously utilize the agricultural waste Rice Husk Ash and to remove fluoride from water.

Continuous-flow column studies demonstrated that LIRHA is capable of removing fluoride from water to less than the permissible limits.

Thus, the agricultural waste, Rice Husk can be effectively utilized for removal of fluoride from water, especially in rural and isolated communities.

Abstract

Lightweight concrete is a composition composed of lightweight coarse aggregates like shale, clay or slate, giving its low density characteristic. The lightweight concrete is suitable for the construction of modern buildings requiring minimal cross sections. It is increasingly used for the building of stylish foundations and has become a viable alternative to standard concrete. Lightweight concrete provides flexibility of design and significant cost savings, with lower dead load, stronger seismic structural response, longer lengths, increased fire ratings, reduced height of the story, lower size structural elements, less steel reinforcement and lower foundation costs. Due to the ceramic quality of the combine and the outstanding bonding and elastic compatibility it ensures the excellent longevity performance of structural lightweight concrete made of expanded shale, expanded clay or slate structural lightweight aggregate. The structural lightweight cellular structure of the aggregate enables inner healing through the water exertion, which is particularly useful for high-performance concrete.

Abstract

The project's aim is to evaluate response spectrum (RS) and time history (THA) of vertically irregular RC building frames using IS13920 corresponding to Equivalent static analysis and time historical analysis. Their purpose is to carry on ductility based design. The findings were contrasted with the standard structure for study and design of irregular structures. The research also concerns the evaluation of responses from strong, weak, and medium-frequency earthquakes to structures subjected to time histories. There were three types of irregularities: mass irregularity, rigidity irregularity, and irregularities in vertical geometry. Our observation shows that the shop shear force is maximal in the first floor, and decreases in all cases to a minimum in the top floor. Mass irregular structures were found to be larger than equivalent regular structures.

The irregular rigidity system has a smaller base shear and has larger interstory drifts. The absolute shifts obtained from historical study of the irregular geometry structure at the respective nodes were higher in the case of normal structures for the higher stories, but slowly as we shifted to lower stories, changes in both structures appeared to converge. Higher rigidity contributes to higher upper-story displacement. In the case of an unusual mass structure, an examination of time history provides slightly higher range for top stories than in normal structures, whereas in the case of lower stories, there are higher increase than in normal stories. When the historical study of normal and rigid irregular structure was made, it was found that the displacements in the upper stories were not very different but that the absolute displacements were greater in case of softening than in the standard structure when we moved to the lower stories. High natural frequency structures have been found to have highest response during an earthquake of low frequency. It is because the low natural frequency of high-frequency earthquake systems results in vibration that contributes to greater displacements.

If a high-rise (low natural frequency) structure is subject to high-frequency earth shifting, it contributes to minor changes. Likewise, when the high-frequency earth motion underlies a low elevation structure (high natural frequency), it results in bigger movements and when a high-elevation structure is subject to low-frequency earth motion, slight displacements happen.

Keywords: Staad Pro, Seismic Loads, Framed Structure.

1. INTRODUCTION

The structural collapse begins at points of weakness during an earthquake. This vulnerability exists because of mass discontinuity, rigidity, and structural geometry. Such discontinuous structures are referred to as abnormal. Most of our urban infrastructure is supported by dysfunctional structures. One of the main reasons for structural failures in earthquakes is vertical irregularity. For example, soft-story structures were the most remarkable collapsing structures. The effect of vertical irregularities is therefore very important in the seismic performance of structures. High variations in rigidity and mass differentiate these buildings from their normal buildings for their dynamic properties.

IS 1893 definition of Vertically Irregular structures?

Regardless of the irregularity of the building structures, their density, strength and rigidity can be

irregular in their weights. The study and construction of these buildings become more difficult when they are built in high-seismic areas.

There are two types of irregularities-

1. Plan Irregularities
2. Vertical Irregularities.

Vertical Irregularities are on the whole of five types-

i) **a) Stiffness Irregularity** - Soft Storey-A soft storey has less than 70% of the lateral rigidity above or under 80% of the total lateral rigidity over the top of the three racks.

b) Stiffness Irregularity - Extreme Soft Storey- The exceptionally soft surface is one in which lateral rigidity is not more than 60% or less than 70% of the average rigidity of the top three floors.

ii) **Mass Irregularity**- There would be considered mass anomalies when the seismic weight of any storey reaches 200% of the adjacent surface. Irregularity must not be taken into consideration in the case of roofs.

iii) **Vertical Geometric Irregularity**- A structure is considered to be Vertical geometric irregular the seismic weight of any storey exceeds 200% of the neighboring surface will be known as mass anomalies. In the case of roofs, anomalies should not be taken into account.

iv) **In-Plane Discontinuity in Vertical Elements Resisting Lateral Force**- An in-plan offset of the lateral force which resists elements larger than their length.

v) **Discontinuity in Capacity** - Weak Storey- A low floor has less than 80 percent of the lateral power in the storey above.

In accordance with IS 1893, a linear static structural analysis of a standard, restricted height structures can be employed since lateral forces are measured in this phase according to the specific structural time period based on codes. This research enhanced the effects on the higher vibrational modes and the actual distribution of forces across the range, thereby enhancing the linear dynamic analysis over the linear static analysis. Built induced earthquakes are optimized for structures, however, the forces actually operating on the structure are much greater than DBE. Thus, in higher seismic areas, a definition of ductility based architecture is favored because structural ductility decreases the distance. The primary purpose of the development of an earthquake-resistant device is for the building to be ductile enough to cope with the earthquake forces it is exposed to during an earthquake.

2. OBJECTIVES

- The structural side forces of normal and irregular buildings can be measured using the response spectrum analysis and the effects of various structures comparable.
- For research three structural irregularities, namely mass, rigidity and irregularities in vertical geometry.
- For the study of time history and comparing results the reactions of buildings subject to different types of land movements, namely low, medium and high frequency ground movement, are measured.
- Conduct an earthquake-resistant ductility-based design as per IS 13920, consistent with comparable static analysis and study of time history and comparing design variations.

3. SCOPE OF THE STUDY

- Only RC buildings are considered.
- Also vertical anomalies have been investigated.
- The structures were the subject of linear elastic analysis.
- As fixed to the base, the column was constructed.
- The contribution of the infill wall to rigidity was not taken into account. Infill wall loading was considered.
- The relation between the soil structure is overlooked.

4. RESEARCH METHODOLOGY

- A study by different scholars of current literature.
- Selection of structure forms.
- Modeling the structures selected.
- Complex analysis and evaluation of test findings on selected building models.
- Buildings are constructed according to the results of the study.

5. ANALYSIS METHODS

Seismic analyzes are a crucial method to understand buildings' response to seismic excitations more easily in earthquake engineering. In the past the structures have only been built for gravity and recent research is seismic engineering. This is part of the structural study of the earthquake and is part of the structural architecture.

Earthquake analysis approaches are special. Many of the programs included are:

I. Equivalent Static Analysis

II. Response Spectrum Analysis

III. Time History Analysis

Equivalent Static Analysis

The corresponding static analysis is primarily an elastic technique of architecture. However, it is simple to implement than the multi-model response approach, because the absolute simplification assumptions are maybe more compatible with other absolute assumptions elsewhere in the design process.

The following steps are used in the analogous static analysis procedure:

- Estimate the building's first mode response time from the spectrum design response.
- Using the basic design response range to assess the conformity with the presumed poste lastic (ductility) response level of the lateral basis shear of the entire structure.
- Distribute the base shear among the different lumped mass rates normally centered on a triangular inverted shear distribution of 90% of the base shear with 10% of the base shear being applied at the highest level to permit higher mode effects

Response Spectrum Analysis

This approach helps a building to take into account multiple modes of response. For all but extremely simple or very complex structures, this is necessary in many building codes. The structural response can be described as a combination of many different modes. To evaluate these modes for a system, computer analysis can be used. In each mode, the design spectrum corresponds to the modal frequency and the modal mass and is then combined to approximate the total structure response. The scale of forces is measured in all directions and then results are observed on the structure. The mixture methods are as follows:

- Absolute - peak values are added together
- Square root of the sum of the squares (SRSS)
- Complete quadratic combination (CQC) - a method that is an improvement on SRSS for closely spaced modes.

Time History Analysis

Techniques of time historical analysis include the step-by - step solutions in the time domain of the movement multi degree equations, which constitute the actual buildings answer. This is a structural engineer's most sophisticated method of analysis. The solution is to explicitly work with the earthquake motion chosen for a specific building as an input parameter. This research approach is generally restricted rather than to testing the suitability of hypotheses taken during the design of important structures.

The following steps in the study of time history are:

- Modal matrix estimation
- Active vector intensity estimation
- Obtaining of a standard coordinate displacement response
- Receiving the physical coordinate displacement response
- Efficient earthquake response forces measurement at each level.
- Maximum reaction estimate

Three different kinds of ground motions, namely low (Imperial), intermediate (IS code) and high frequency (India), were compare to the results. In this sense the results of an irregular structure were compared. The last thing is the nature and evaluation of irregular structures in accordance with IS 13920 relating to the related static analysis and time history analysis

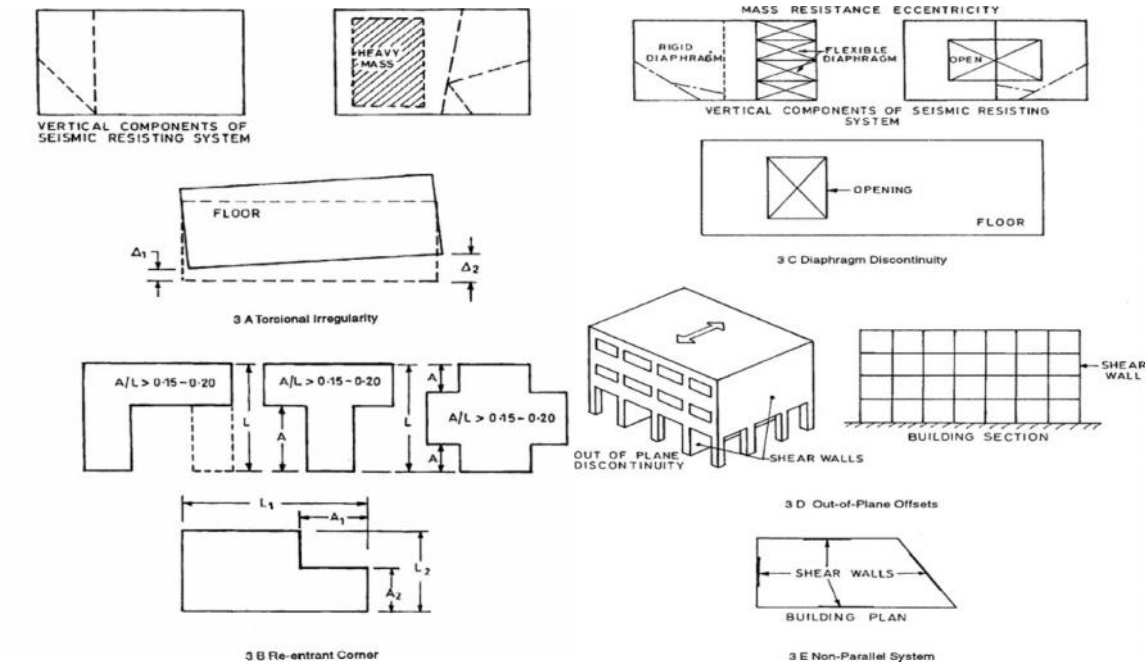

Fig. 1 Irregular Structures

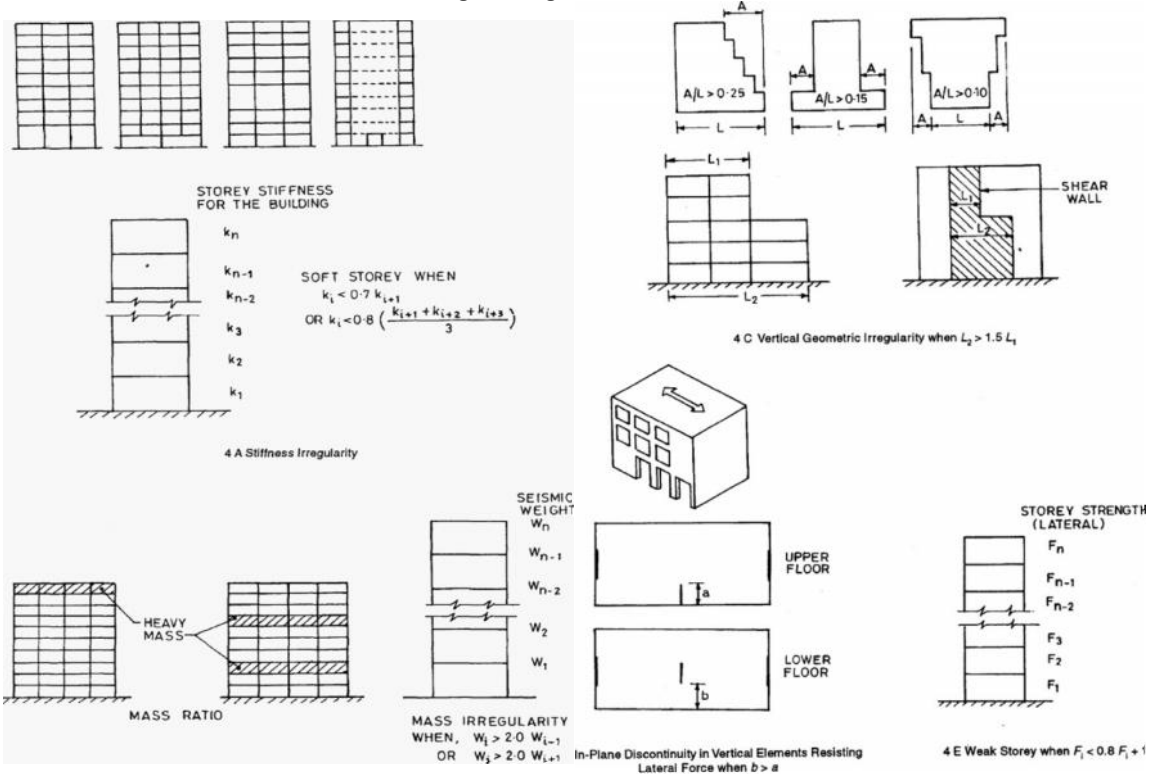

Fig. 2 Vertical Irregularity

5. METHODOLOGY

Response analysis of the structure was carried out using Staad-Pro in regular and separate irregular buildings. The shear forces for each floor were determined and each structure was drawn on a diagram.

Live Load	3kN/m^2
Density of RCC considered:	25kN/m^3
Thickness of slab	150mm
Depth of beam	400mm
Width of beam	350mm
Dimension of column	400x400mm
Density of infill	20kN/m^3
Thickness of outside wall	20mm
Thickness of inner partition wall	15mm
Height of each floor	3.5m
Earthquake Zone	IV
Importance factor	1
Type of Soil	Rocky
Type of structure	Special Moment Resisting Frame
Response reduction Factor	5

Four styles of Irregular structures, Regular building structure, irregular mass structure, ground floor structure and irregular vertically rectangular building were considered. There were 10 of the first three systems.

1. Regular structure (10 storeys):

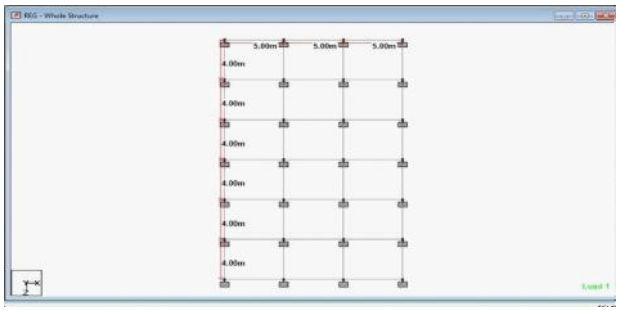

Figure 3: Standard construction plan (10 floors)

2. Mass Irregular Structure (10 storeys):

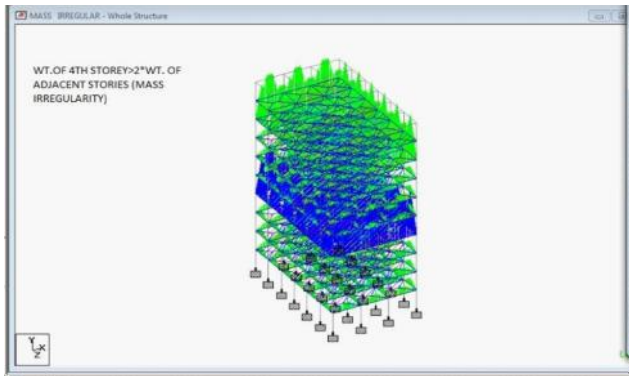

Figure 4: Mass standard building 3D view (10 floors) with 4th and 8th floor swimming pools

3. Stiffness Irregular Structure (Soft Storey):

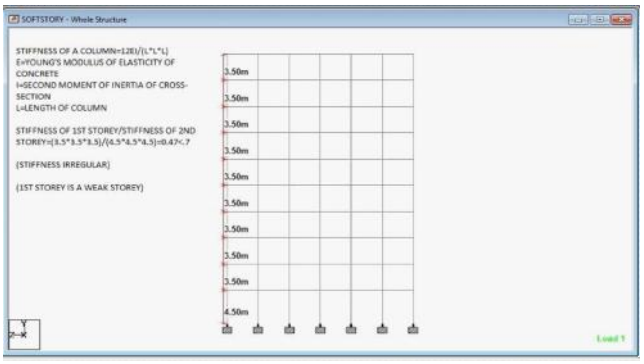

Figure 5: Irregular rigidity (10 stories) Structure

4. Vertically Geometric Irregular

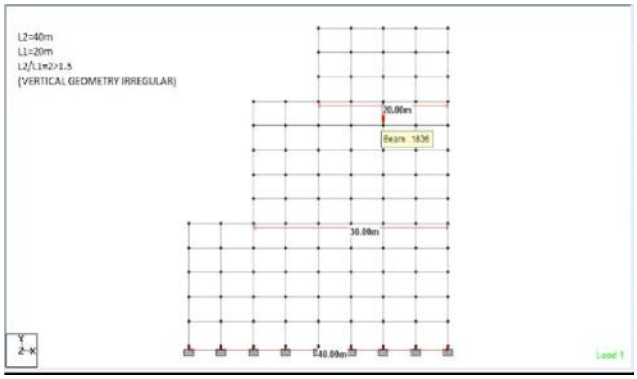

Figure 6: Vertical Geometric irregular structure (14 storeys)

CONCLUSIONS

Three different types of irregularities, namely mass irregularities and irregularities of stiffness and vertical geometry, were considered. For any type of irregularity, Response spectrum analysis (RSA) was performed and the shear strength obtained was compared with that of a normal structure. Three types of ground movement were considered with different frequency contents, i.e. low frequency (imperial), intermediate frequency (IS code), high rate (India). For each irregularity form that corresponds to the above ground movements, time history analyzes (THA) were carried out and nodal displacements were compared. The abovementioned irregular frames were finally constructed using the IS 13920, which corresponds to Static Analysis Equivalent (ESA) and the Analyzes of Time History (THA), and the results compared. We may summarize our findings as follows.

- The shelving force for the first floor was found to be maximal and decreased in all cases to a minimum in the top floor, based on RSA tests.
- The mass irregular building frames were found to have a higher base shears than equivalent normal structural frames, as per the results of the RSA.
- The abnormal stiffness of the building has less baseline shear and greater inter-store drifts, according to results of the RSM.
- The absolute displacements obtained from a study of time history of irregular geometry of construction in the respective nodes were higher than the normal building for upper stories, but slowly the lower story displacements appeared to converge in both constructions. Such a geometry, the upper stories are irregularly formed because of their lower stiffness (due to L form). Higher rigidity contributes to higher upper-story displacement.
- Time history analyzes created marginally higher displacement for the upper stories than for regular buildings in the case of mass irregular structures, while when we step down, the lower stories demonstrated higher displacement than in normal structures.
- The time history research was carried out on the normal and stiffness of irregular buildings (soft floors), but when we went down to lower stories it was found that the absolute movement in soft floors was higher than the stories of standard buildings.
- The long history research for both normal and irregular stiffness buildings (soft-story), it was discovered that displacements of upper stories did not vary significantly from one another. In the case of soft stories we moved down into lower stories but, compared to respective stories in standard buildings, absolute displacement was higher.

Tall structures have low natural frequency and have a maximum response in a low frequency earthquake.

Abstract

In the new multi-story construction in urban India, today buildings with the Hanging column have become a traditional feature. In building constructed in seismically active areas, these features are extremely undesirable. The importance of the role of the Hanging column in building analysis was clearly highlighted in this report. Alternate steps to minimize anomalies in the Hanging frames, including the stiffness balance of the first stage and above. Buildings with a Hanging column in the current scenario are a typical feature of contemporary urban India construction. In building constructed in seismically active areas, these features are highly unwanted. This research emphasizes the significance of the Hanging column in the building analysis specifically. Alternate steps to reduce the irregularity of hanging columns, including the stiffness balance of the first and last stages, are proposed. In order to investigate the response to different earthquake arouses the structure with different often contents and time-content factor, FEM codes are created for 2D multi-story frames with and without Hanging columns. Both frames with and without Hanging columns are determined by time history of floor shift, inter level drift, base shear, rotating moment. The research is conducted on a Hanging column structure. This detailed figure shows the structural layout of the building. The building considered for the analysis is a G+9 residential home by using STAAD. Pro Software. Each store's height is the same as other common data. Complete analysis where done and finally the building with Hanging column has been found to have less base shear than a building without Hanging column. The Hanging column also falls from the lower to top level of the base shear value as the Hanging column changes. Building with hanging column was also found to have more displacement than building without the Hanging column. Moving the Hanging column from the bottom to the top floors also improved displacement values. Building with hanging column was found to have more floor drift than building without a Hanging column. Shift of hanging columns from bottom to top rates was also observed to increase the storey drift values.

Keywords: FEM, G+9 Building, Hanging Column, Seismic Loading, Drifts.

1. INTRODUCTION

Today, several multi-story urban buildings in India are unavoidably accessible in the first floor. This is used primarily for parking or reception lobbies on the first level. Although the overall seismic basis shear encountered by an earthquake building depends on its natural duration, the distribution of seismic force depends on a height distribution of steepness and mass. In addition to the way the earthquake forces are brought to the ground, the action of a building in an earthquake depends critically upon its overall form, size and geometry. At different rates in a building the earthquake forces have to be carried down by the shortest path down the height to the ground; any inconsistency or discontinuity in this load transfer path contributes to a poor building efficiency.

Vertical reverse buildings (such as a hotel with few floors wider than the others) cause the earthquake forces to unexpectedly leap at discontinuity. Buildings with less columns or walls or with an unusually high amount appear to damage or collapse in the storey. Throughout the 2001 Bhuj earthquake, several buildings

in Gujarat with open ground floor to parking were collapsed or seriously damaged. Buildings with columns hanging or Hanging on beams in an intermediate floor that do not meet the base have discontinuities in the transmission route for loads

2. What is hanging column?

The Hanging column is a vertical component that sits on a beam but does not directly move the load to the foundation. There was a mistake. But on the beam rests the Hanging board. Column structure for hanging or Hanging. It ensures that the beam supporting the column acts as a foundation. This structure is known as a transmitting structure. A vertical component from base level and transferring the load to the ground is expected to be a column. The term hanging column is also a vertical feature that (due to the nature / position of the architecture) rests on a beam that is a horizontal part of the lower point (termination point). The beams move the load to other columns below it.

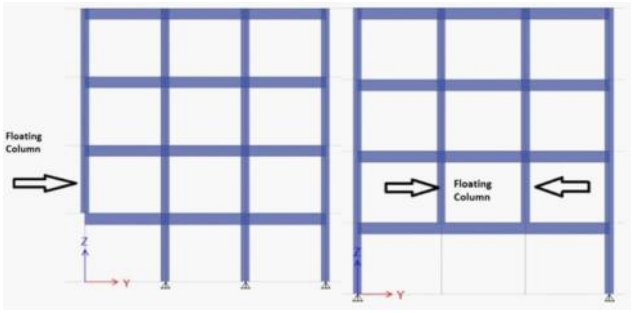

Figure 1: Hanging Column

Most projects include Hanging columns, in particular above the ground floor, where transfers are used to create more room in the ground floor. For assembly and parking purposes, such open spaces can be needed. In Earthquake zones, the transfer belt must be correctly constructed and described. The beam supports the board, a focused load.

With regard to the analysis, the column is always taken as a point load on the transfer beam and is fixed at the foundation. For the study of this type of structure, STAAD Pro, ETABS and SAP2000 may be used. Hanging columns are capable of bearing a weight load but the girder must be fairly steep with very limited deflection. Of course, looking forward, one can always find buildings more fascinating than monotonous. This should not, however, be achieved at the risk of bad conduct or building protection due to an earthquake. Architectural features that are detrimental to the buildings' earthquake response should be avoided. If not, they will be reduced to a minimum. If unusual features are used in buildings, considerably more engineering work is needed to design the building, even with simple architectural features the building may not be as good as the one. Therefore, in seismic areas, the structures already constructed with these discontinuous members are threatened. Yet such structures cannot be demolished; rather, research may be performed to strengthen the structure or to suggest some remediation. The columns on the first floor can be reinforced, the rigidity of these columns can be improved by up grading or braced to minimize lateral deformation.

3. Objective and Scope of present work

The target of the current research is

- Researching the behaviour, in earthquake encouragement, of multi-story buildings with hanging columns.
- The seismic analysis of the building with Hanging column is used for analyzes of the impact of Staad pro.
- Investigate the displacement of base shear between hanging columns in a G+9 Residential Multistoried building at different locations.

4. Research Significance

In urban areas, multi-story buildings are designed for the various purposes mentioned above by having Hanging pillars in the ground floor. Such hanging column buildings are built for gravity loads and safely subject to gravity loads, but not for earthquake loads. Therefore, in seismically prone areas these buildings are dangerous. Throughout the earthquake-resistant architecture of multi storage buildings, the project aims to raise understanding of these problems

5. Methodology

The methodology is the theoretical and systematic analysis of the methods used for the study area. This involves the systematic study of a variety of approaches and concepts connected to a information branch. Load taken into account

Dead loads

The dead load involves the weight of the walls, divisional flooring, false ceilings, false floors and the other permanent structures. A load set in its size and location is called the dead load. Dead loads may be determined by the scale and weight of various members.

For floors; unit weight of reinforces cement concrete= 25 kN/m^3 Unit weight of steel is = 78.5 kN/m^3

Imposed loads

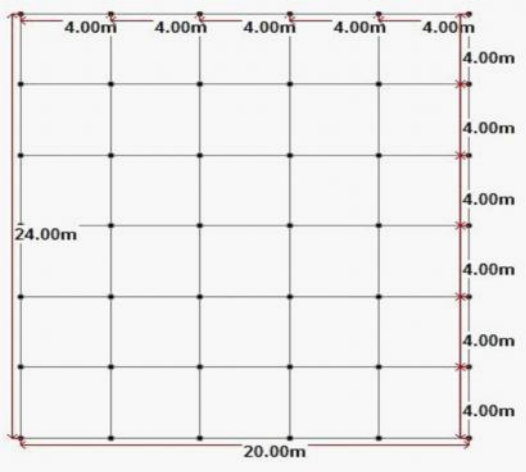

Figure 2: (G+9)-Story Steel Frame Structure

The imported load shall be generated by the intended use or occupation, in which the weight and vibrating loads and dust loads, including the weight of mobile partitions, loads dispersed and concentrated. Charges levied shall not include charges caused by the wind, the seismic activity, the snow and loads place on the structure, the differential settlements to which the structure which experience a temperature change, creeping and shrinking.

For residential buildings such as Hostels, hotels, boarding houses, lodging houses, dormitories, residential clubs: Living rooms, bed rooms and dormitories = 4.0 kN/m^3 (IS: 875, Part 2- 1987).

Wind loads

The strength of a structure due to the wind effect. As the building height increases the wind impact. At high wind speeds the wind typically blows horizontally to the ground.

6. Analysis of the Structure

The building employed in this study was designed according to the IS 800: 2007 and IS 1893 criteria (Part 1): 2002

STAAD Pro analyzes a multi-story steel structure

The architecture of the building depends on the minimum standards as laid down in the Indian Standard Codes. The basic standards for structural protection in buildings shall be protected by the concept of basic design loads to be assumed by the structure to bear for dead loads, imposed loads and other external loads. A 10 (G+9)-story steel frame is used for this analysis. The average height of the floor is 3 m and the building is 30 m. As shown in Figure 4.1, the laterals cover 24 meters by 20 meters and are divided into 4 square meter bays.

For research, the following structures are examined:

- A Rectangular Structure without a Hanging base.
- Rectangular, Hanging column structure on the ground floor
- The rectangular structure with the 3rd floor Hanging column
- The Rectangular Structure at fifth floor with Hanging column

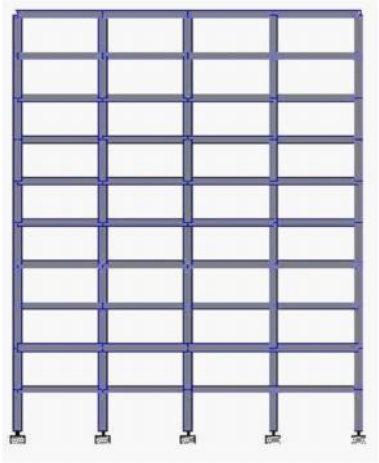

Figure 3: Rectangular Building without any Hanging column

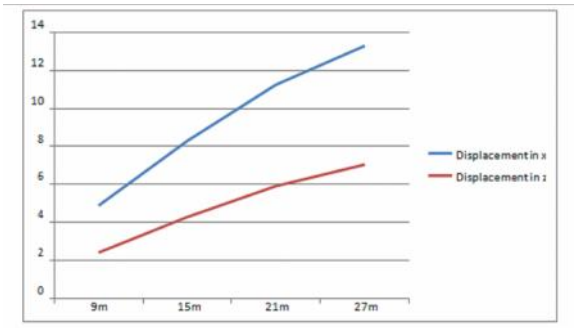

Figure 4: X-axis and Z-axis directions Displacements

It is observed from fig. 4.4 that as the height of building increases displacement is increasing from bottom to the top floor

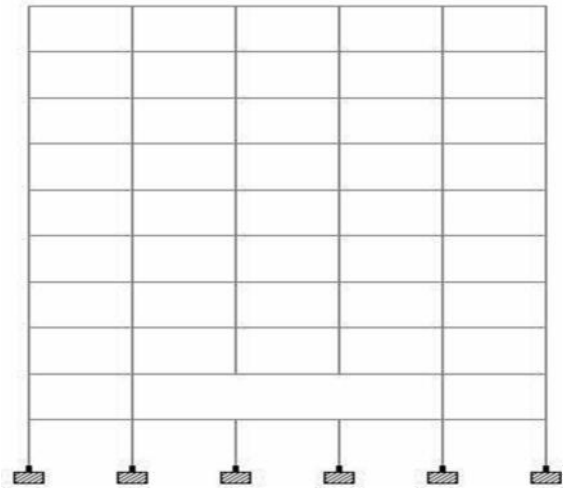

Figure 5: Square Building with hanging column at first floor

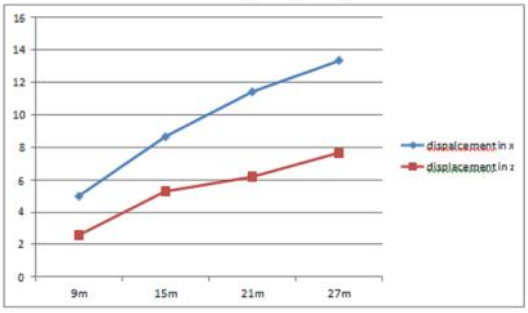

Figure 6: Displacements X-axis and Z-axis directions displacements

7. Results and Discussions

On the basis of base and shelf changes, the results of the comparative study between a building without Hanging column and a Hanging column are carried out.

Base shear:

Table 1 Base shear on different structures

S. No	Seismic Weight	Base Shear	Time Period
Structure 1	52959.43	2206.30	0.94
Structure 2	52590.00	2205.80	0.94
Structure 3	52844.92	2201.93	0.94
Structure 4	52755.85	2198.26	0.94

Displacements at different heights:

a) In x-directions (in mm):

Table 2 x displacements at different heights

S. No	9m	15m	21m
Structure 1	5.6032	9.2378	12.3277
Structure 2	6.0015	9.5231	12.3287
Structure 3	6.0004	11.3897	14.7385
Structure 4	6.1326	12.3726	16.7865

b) In z-directions (in mm):

Table 3 z displacements at different heights

S. No	9m	15m	21m
Structure 1	3.5574	5.5823	6.7277
Structure 2	3.8588	6.2626	7.2828
Structure 3	3.4724	6.8262	7.9282
Structure 4	3.6599	6.2762	9.2929

CONCLUSIONS

In comparison to the previous height classifications, a broad system classification was introduced. Various structural structures have been defined with a focus on creativity within each classification group.

The following conclusions can be drawn on the basis of the current study:

- The building with hanging column has been found to have less base shear than a building without hanging column.
- The Hanging column also falls from the lower to top level of the base shear value as the Hanging column changes.
- Building with hanging column was also found to have more displacement than building without the Hanging column. o
- Moving the Hanging column from the bottom to the top floors also improved displacement values.

- Building with hanging column was found to have more floor drift than building without a Hanging column.
- Shift of hanging columns from bottom to top rates was also observed to increase the storey drift values.

M.Visweswararao1 Professor, Department of Civil Engineering, Malla Reddy Institute of Technology, Maisammaguda

Abstract

Pedestrain crossing and the behavior of pedestrians in different conditions espically at uncontrolled crossings is a subject which needs in depth study and analysis. At uncontrolled junctions the pedestrians and their behavior , safety of pedestrian crossing is neglected and no measures are taken to systematize pedestrian crossings at these junctions.Therefore a practical study of the pedestrian road crossing data is made in this study and stastical analysis of the data is done at uncontrolled crossing junctions in mixed traffic conditions of Indian scenario. The main objective of study is to analyse the pedestrian road crossing behavior at uncontrolled junctions.

Adopting multiple regression technique the various parameters which effect the behaviour of pedestrian. Vehicular gap,driver yielding behavior,frequency of attempts to cross, age and condition of pedestrian , rolling gap are some of the parameters that decide the pedestrian crossing time and other requirements. The surveys have been conducted at all junctions between Bowenpally to Kompally on national highway

***Key words**: PedestrianRoad Crossing, Children-Adult Crossing Behaviour under Signalized Mid-Block CrossWalk.*

Design and Modelling of G+5 Commercial Building by Autodesk Revit Architecture

E. Rakesh Reddy, S. Kailashkumar

ABSTRACT---In this project we are detailed explanation how do we design and modelling of G+5 commercial building by Autodesk revit architecture, which renders complete vision of construction. With BIM new technology it is easy to model the building and we can connect to revit architecture, Revit MEP, Revit structure, Built for Building Information Modeling (BIM). In general, for building design and model can be employed by the architecture of Autodesk Revit. In addition, it can give you an exact vision via design, construction and documentation. Use the information-rich models that Autodesk Revit Architecture is useful for make more informed Building designs decisions to support0sustainable design, clash detection, construction planning, and fabrication Installation. Revit Architecture will clear picture of building excellent visualization by using V-ray software, that is made for Rendering purpose. For commercial buildings it will very helpful for visualize building before construction is made in the field.

When the Revit Architecture window is displayed, there we can see the different types of templates such as construction template, structure template, Architecture template. To accomplish this project i.e for design and modeling we use to select Architecture template.

Keywords : Families, components, mass IN-site, Levels,Grid lines.

I. INTRODUCTION

The Revit Architecture software will give the plan view, 3d model with exllent elevation, detailing diagrams, schedules for each structural elements, and with V-ray rendering software we can have realistic view with high efficiency, Building information modeling (BIM) gives the information about project design, its different views, scope, quantities, and phases when you need it. In the Revit model, every project we did will give the 2d , 3d, section views, elevations with detailing and schedules, quantities also it will provide us.

Revit Architecture collects information about each structural elements material its visualization realistic in nature and its design such as thickness height and in schedule it will give no of data such as cost type of family, no. of brick, no of doors, no. of windows etc across0all other representations of the project. In revit we can have these all 2D, 3D, nd sectional views, elevations and detailing drawing etc. in one cpmplete sheet.

A. Building Information Modeling(Bim):

•Now a days it is need of deliver of projects rapidly, more economically, and wit enhanced potential for reduced environmental impact.

•The purpose of Autodesk Revit Architecture is made for BIM. BIM is an integrated process built on coordinated, reliable information about a project from design through construction and intooperations.

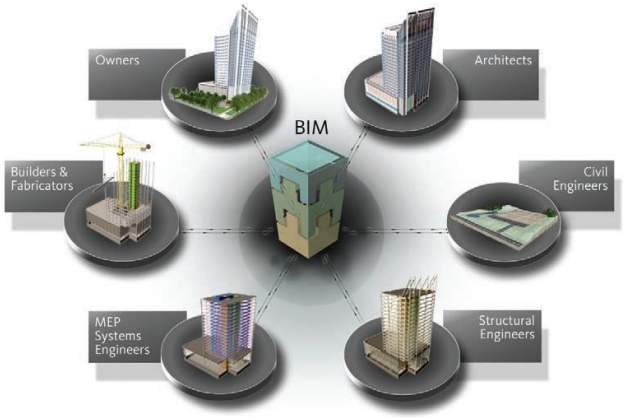

Fig. 1. BIM Process

B. Starting a Project:

1. Double Click and open Revit software
2. Initially 1st we need to select Revit architecture template from template panel
3. Then we will entering into the Revit GUI
4. We can see left side properties box and right side project browser.
5. In view menu manage units and set the units as per need
6. Now set the grids.
7. Go to application menu bar save the file with require name in specified folder.

II .PROJECT IN REVIT

A. Creating a Project:

1. Before going to design the model in revit get the plan from architect.
2. As per need set the units.
3. Using grid line draw the plan view.
4. Using draw panel draw the grid lines.
5. In draw panel we have line. circle rectangle, arc etc options.
6. Using these draw panel select the tools and complete the grid line diagram.
7. In properties box some modifying tools will be there to modify the grid lines.
8. Using copy, move, rotate, array options we can complete the grid diagram in less time.

Revised Manuscript Received on December, 30 2019.

E. Rakesh Reddy, Civil Engineering, Malla Reddy Engineering College, Hyderabad, Telangana, India.

S.Kailashkumar, Civil Engineering, Malla Reddy Institute of Technology, Hyderabad, Telangana, India

B. Name and Save The Project File:

1. After deciding project name save the file as soon as possible
2. If we save the file means we can avoid the file distraction at any moment due to power loss problem etc.
3. Click Application menu bar
4. Click on save
5. Select the required path folder, then give the name, to easy identify

B. Zoom To a View:

1. In Revit we have various zoom options to see the model very clearly.
2. Zoom in Region.
3. Zoom out (2X).
4. Zoom to fit.
5. Zoom all to fit.
6. Window zoom.
7. Zoom Sheet size.
8. We have full navigation wheel also to have clear visualization of the model.

C. Rename Levels:

1. As per the requirement we need to create the levels also for the multystoreyed building
2. For levels in go to architecture panel
3. Select level option in datum panel
4. Now draw the levels by giving floor height
5. Name the each level such grounf floor, 1sr floor etc
6. Using offset option we can give the floor height
7. In level at the two ends of the level line we have grids for adjusting level line and it will show temporary dimensions also for changing.

D. Components:

1. In component panel we have some categories in that we have doors, windows, Gates, Railings, Beds, all furnitures etc. objects, which have already created and it will available by installing Revit Architecture software itself.

2. We can import those components by selecting component option, go to browse, select the components as per need then place it in our model as per our requirement.

3. Wherever we want we can place it, and double click on that component it turns to new window in that we can modify the component modify it also, as per our need. This is best option in Revit, very userfriendly to modify the components as per our need.

Fig. 2. Component Panel

Fig. 3. Available Components

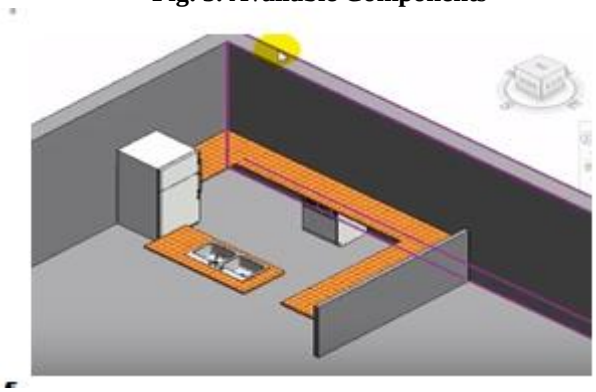

Fig. 4. Components Placed In our Model

6. Family Creation:

1. Families are nothing but components like door windows, furniture, railings, post balusters, columns, gates etc, but we need to create these as per need and we can place it in our model.
2. Creating families is very important in Revit Architecture
3. Using reference lines and reference planes, we need to draw Profile of the object as per our need
4. To make these components we have number of advanced tools.
5. Go to create panel in design panel we have tools like Extrusion, sweep, Blend revolve, Swept Blend etc
6. Using these above tools we can draw the components, and we have to save it in specifies path as family
7. To save go to application menu
8. Select save as
9. Then select family, save with required name example 'Table' could be considered one of the families within the category of Furniture.

Fig. 5. Family Creation Model

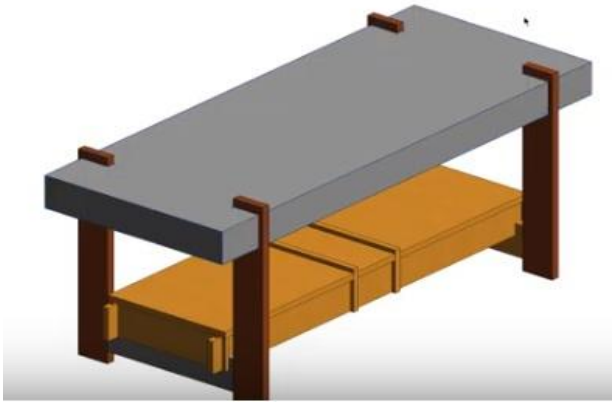

Fig. 6. Family in Realistic View Model

III. ADDING EXTERIOR WALLS

In this exercise, we will know how to create the wall and creating different types wall such as

1. Generic walls
2. Curtain wall
3. Stacked wall
4. Go to architecture panel
5. Select the wall panel
6. Then select wall Architectural
7. Then go to properties browser
8. Select the type of wall which you want
9. Then go to edit type, duplicate it and name it
10. Again go to edit option to change thickness material also
11. After that give the height for the wall
12. Then using draw panel draw the wall as per Architect plan by taking reference as the grid line diagram
13. But for the stacked wall, and curtain wall it will different:
14. For the stacked wall firstly we need to create normal walls of different thickness, height, as per need
15. Then we will combine those walls from properties browser.
16. For curtain walls there are 3 types:

1. Curtain wall: it will give directly plain type wall, there will be no curtain grids, mullions, we need add these after drawing the wall.
2. Exterior Glazing: it will available with Curtain grids only.
3. Store front: It will be available with Curtain grids and Mullions.

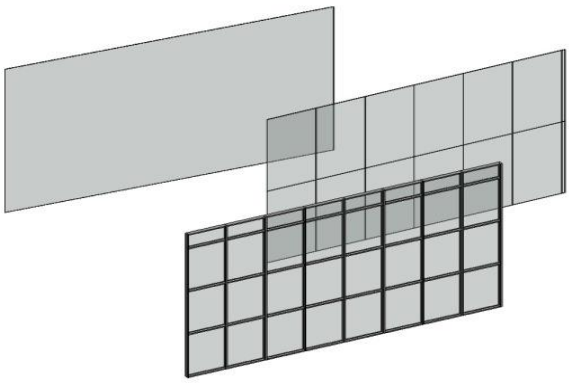

Fig. 7. Types of Curtain Wall

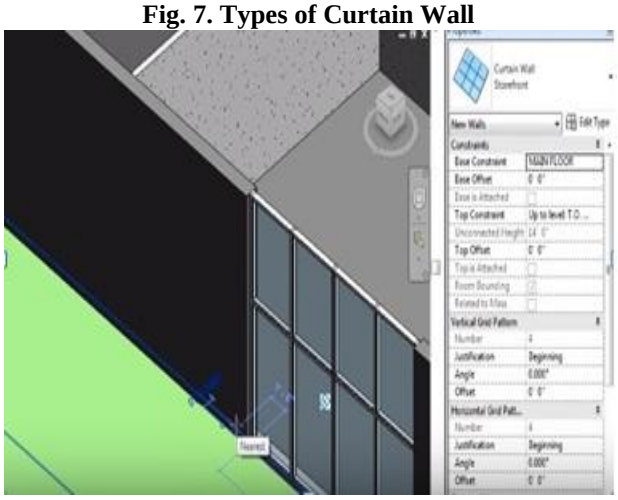

Fig. 8. Combination of Curtain Wall and Generic Wall

IV. ADDING A ROOF

In this exercise, we can know the how to create the roofs with diffent shapes and different types

1. Go to architecture tab
2. Select the roof
3. Then using draw panel draw the roof shape as per need
4. from properties we can give slope value as per need
5. By removing define slope we can have the flat slab.
6. We have roof by extrusion option to have the roof by drawing a plan like arc, line or combination of line and arc from elevation view

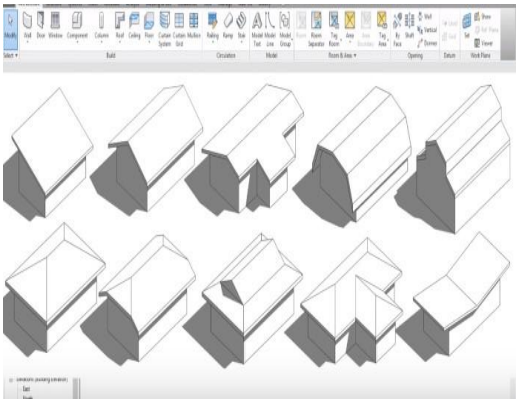

Fig. 9. Types of Roofs

1. Using offset option we can give the setbacks also
2. Using modify tools such as trim/extend, split tool we can modify the roof.
3. After creation of roof then from properties browser edit type we can change thickness and we can give the materials also.

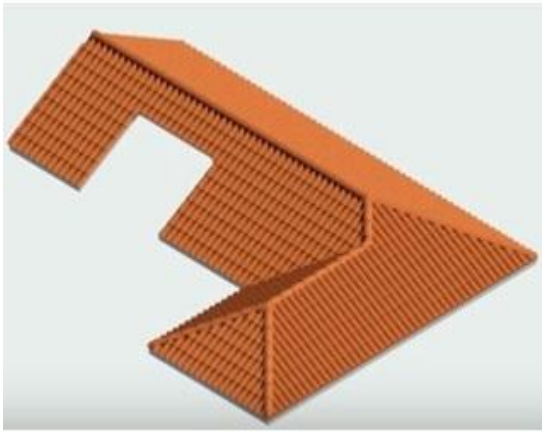

Fig. 10. Roof after Assigning Material

V. ADDING FLOORS

In this exercise, we can create floors in different shape

1. Select floor plan from project browser
2. Then architecture panel
3. Select architecture floor
4. Using draw panel draw the floor plan shape
5. Go to properties edit type, duplicate it, and name it with required name
6. We can change thickness and material also
7. We can the floors using the Pick line method, pick wall edge method
8. Drawing a closed figure in already drawn closed boundary will create hole in that particular area
9. Like that select each floor plan and draw the floors as per need
10. If the floors for all floors is same then we can copy also by using copy to clip board and paste option.

Fig. 11.Floor in Model

A. Temporary Dimensions Settings:

1. we can change the dimension by double click on dimension line
2. we can lock the dimension to avoid changing the dimension.

B. To Specify Temporary Dimension Settings:

1 .Click Manage tab

2. Additional Settings button
3. Temporary Dimensions.

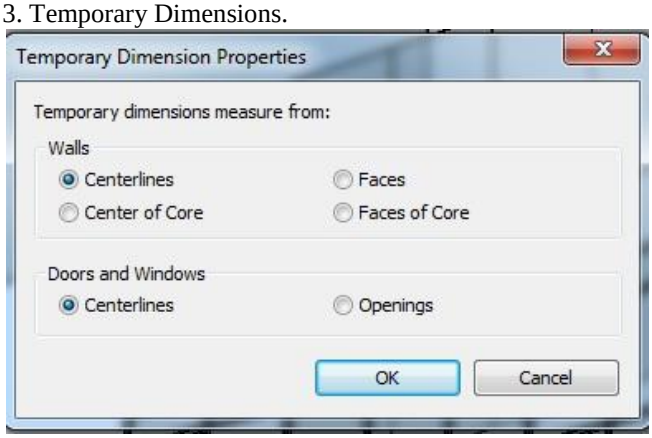

Fig. 12.Temporary Dimension Property

VI. RESULTS

Schedules & Quantities:

Procedure:

1. Click View tab
2. Create panel
3. Schedules drop-down
4. Schedule/Quantities.
5. In the New Schedule dialog, select a category from the category list as doors.
6. Select field from available fields such as family, width, height etc.
7. Click OK.
8. Select the scheduled Fields tab to add/remove field names in the schedule.
9. Using filter option we can filter the Doors by selecting the fields which we have selected previously.
10. On the Sorting/Grouping tab of the Schedule

We can sort by using different fields as we initially selected like height, thick, and family type etc.

11. Using formatting option we can set orientation and alignment for door specifications which we have selected initially.
12. Using Appearance tab we can change the grid lines, outer lines style, and also we can change the text style.

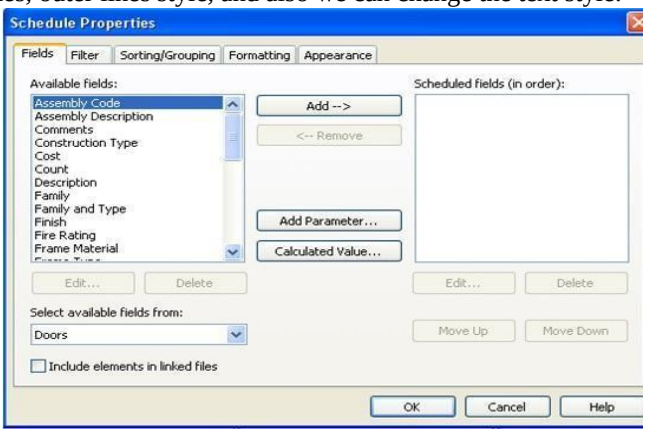

Fig. 13.Door Schedule Property Box

<Door Schedule>

VII.CONCLUSION

This project gives the realistic modeling of building and accurate families ranging from furniture to lighting fixtures, as well as import existing models from other softwares like Auto CAD etc. We can get the approximate estimations of building also using Revit Architecture. In this Project we have done planning, modeling, scheduling of Doors and we have created families also for this commercial building.

A clear design and modeling of a commercial building with the efficient0structural and architectural plans. It provides the0overall knowledge of material take off and schedule/quantities in the model of the building defined in the0project. 3 D realistic view give0the clear picture about the family and the components placed with in the building model.

Abstract. The data required for the study was collected from YMCA road in Calicut city for frame based approach. Video-graphic technique was used for the data collection by the advantage over other data collection technique. For frame based approach video frames were taken approximately with a time lag of 3 s. From extracted data calculate the speed of vehicles, porous area, areal density, density and space headway of vehicles. From porous area data, pore space distribution function was determined by using easyfit5.5 software. The difficult was arises when extracting the traffic data from video frames. So for solving that problem on screen versus on ground distance graph was prepared. Best parameter to explaining the heterogeneous traffic system obtained as areal density rather than density measurement based on R-square value. The speed, areal-density model obtained was linearly decreasing relationship.

Keywords: Frame based approach · Arial density · Density · Pore space distribution

1 Introduction

Modelling of traffic flow provides the fundamental relationships between the macroscopic traffic stream characteristics and plays an important role in the planning, design and operation of transportation facilities as it predicts the behaviour of the traffic flow. Need for the study of traffic stream characteristics and the relationships between them was recognized during the middle of the last century. The studies resulted in models describing various aspects of traffic flow. Traffic flow may be described as homogeneous or heterogeneous traffic flow. Homogeneous traffic follows strict lane discipline and the vehicles have similar static and dynamic characteristics whereas heterogeneous traffic flow does not follow any lane discipline and the vehicles have varying static and dynamic characteristics. The heterogeneous traffic flow maybe composed of both slow moving and fast moving vehicles like trucks, buses, cars, three wheelers, two wheelers, bicycles and hand drawn or animal drawn carts. In India heterogeneous traffic flow conditions exists.

In Heterogeneous traffic, vehicles do not follow the lane discipline. Such traffic will observe in developing countries like India. The traffic models developed in homogeneous traffic conditions are not applicable for heterogeneous traffic conditions. In Heterogeneous traffic, vehicles can occupy any lateral positions based on lateral space

availability and also vehicles move low speed to higher speeds. Traffic stream characteristics such as traffic volume and density is defined as a linear measurement and the characteristics are dependent only headway, are insufficient when traffic is heterogeneous. Measures such as areal density will assessed for suitability. Areal density is defined by "the sum of total area projected by vehicles on the ground per unit area of roadway (vehicles per square meter)".

Research studies on modeling of heterogeneous traffic are limited in developing countries. Previous studies mainly focused on understanding the interaction between vehicles in the case of heterogeneous traffic. A relation needs to be established between the microscopic behavior and the macro performance of the flow. The porous flow approach will conceptualizes such relationship. The aim of the present study is to model the heterogeneous traffic by using an empirical based approach.

2 Literature Review

Lighthill and Whitham [1] developed the first dynamic traffic flow model to different vehicle types. For each vehicle type developed the separate fundamental diagram. Authors assumed the traffic flow is related to density and conservation law was used to define LWR model.

Hoogendoorn and Bovy [2] developed the mesoscopic gas-kinetic models for heterogeneous traffic. The termed multiple lanes as multi lane multiclass phase space density model.

Heterogeneous traffic is explained by help of vehicular headway. The headway data fits the exponential and log normal distribution to explain the mixed traffic [3].

For model the mixed traffic flow, traffic composition, driver behavior, roadway geometry and maneuverability were considered [4].

Marwah and Singh [5] used the simulation analysis to model capacity of mixed traffic. Authors divided the traffic flow into four level of services.

Heterogeneous traffic flow was explained with a help of speed and headway distribution of the different vehicle types. The developed model used to evaluate traffic management measures like segregation of vehicles on major urban roads, provision of exclusive lanes for buses/bicycles etc. [6]. This research was continued by to quantifying the vehicular interactions in terms of PCU and considering the effect of road width and traffic volume on PCU values of vehicles [7].

Nair and Mahmassani [8] have developed on heterogeneous traffic model based on non lane based traffic flow. The model uses the concept of pores.

3 Methodology for Frame Based Approach

The main criteria considered for this approach was speed of the vehicle is not constant throughout road section i.e., speed of vehicle is changing time to time.

3.1 Location for Data Collection

The location selected was YMCA road. The road link was two lane one way traffic road. The 100 m road link was divided in 10 road sections i.e. length of each road section was 5 m. Digital camera used for capturing the traffic data. Digital camera was positioned on a building in such way that the digital cam was covered the entire road link (Table 1).

Table 1. Details of study locations for data collection

Location no	Location name	Length of section (m)	Width of section (m)	Length trap (m)
1	YMCA road	100	7.5	5

3.2 Retrieval of Data

The process of data retrieval includes transferring of the recorded digital video to computer and then time stamping the video graphs. These video graphs are then used to find out the traffic stream characteristics like areal density and speed. The description of the data retrieval process is given below.

3.2.1 Transferring and Time Stamping of Video Graphs

Traffic data videos are transferred into computer by using data cable. The videos were then time stamped by overlapping it with another video graph which displayed time to an accuracy of 1/100th of a second. This was done using the software Adobe Premier Pro. The videos were then played in Adobe Premier Pro to record the necessary data. The vehicle classification considered as Auto (A), Bus (B), Car (C), Jeep (J), Truck (T) and Two Wheeler (TW).

Traffic video frames were taken with a time lag of approximately 3 s. In the first frame, the frame time was noted. And then type of vehicles and these vehicles crossing at 0 m reference mark i.e. entry time of each vehicles were noted. After that distance at entry time and distance at frame time of vehicles were noted. Next second frame was taken the similar values were note like first frame. But in second frame the entry time of vehicles that were present in first frame were same as frame time of first frame. The similar procedure was followed for next frames.

The main difficult was obtained to note down the distance of vehicle from reference mark when vehicle was in between the tape marks i.e. multiple of 5 m length. For solving that problem a graph between on screen distance versus on ground distance were drawn. That was shown in Fig. 1. From the retrieved data, speed of vehicle, pore space area and areal density were calculated.

3.2.2 Stream Speed

The speed data was obtained from difference in vehicle distance at frame time and entry time divided by time difference in frame time and entry time of vehicles.

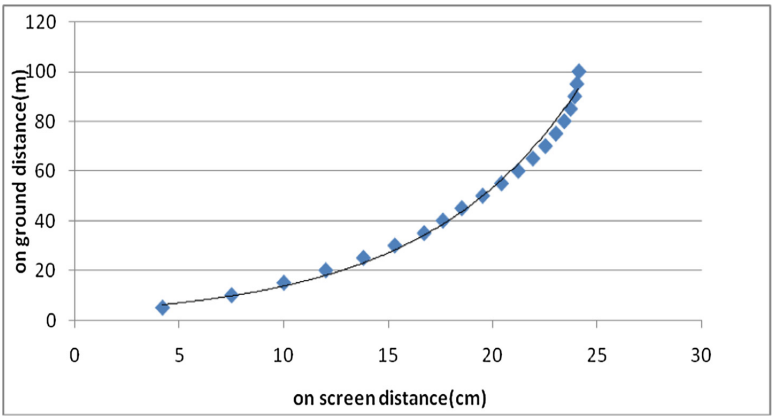

Fig. 1. Ground distance versus screen distance

3.2.3 Pore Space Area

Pore space area is defined as portion of the material (road) that is not occupied by solid material (vehicles). The vehicles length, width and area were shown in Table 2. The composition of vehicles was converted into vehicle areas. Pore space area was obtained by deducting the vehicle area from area of road section.

Table 2. Dimensions of different vehicle classes

Vehicle	Length (m)	Width (m)	Area (m^2)
TW	2.1	0.83	1.74
Auto	2.66	1.32	3.51
Car	3.5	1.50	5.25
Jeep	3.88	1.87	7.25
Bus	10	2.58	25.80
Truck	6.70	2.30	15.41

3.2.4 Areal Density

Areal density was obtained by dividing pore space area with area of road section.

4 Speed-Density-Areal Density Analysis

The speed in km/hr was plotted against areal density in vehicles/m^2. and is shown in Fig. 2 for frame based approach. The model equation and R^2 value is shown in Table 3. It can be observed from the plots that the speed varies linearly with density and there is a considerable scatter in the plot. The average speed range is 50 kmph to 30 kmph and areal density range is 0.01 Veh/m^2 to 0.24 Veh/m^2.

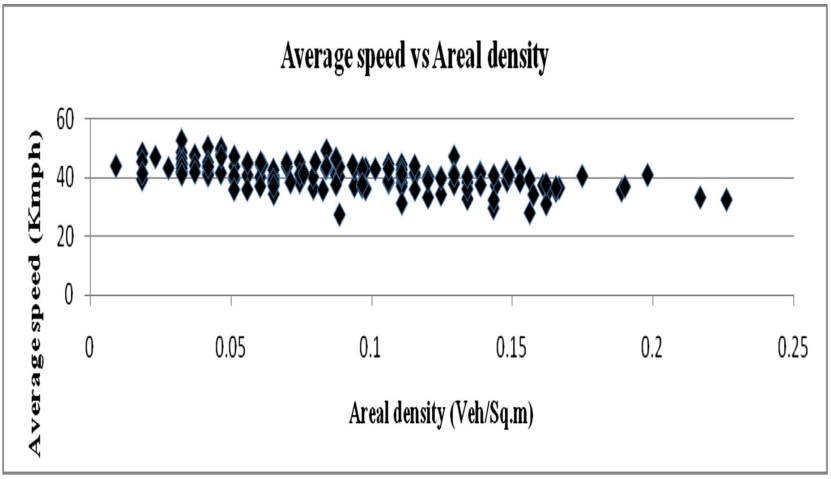

Fig. 2. Average speed versus areal density relationship

Table 3. Development of speed-areal density models

Type of model	Model equation	R-square value
Linear regression model	SPEED = (−53.74 * AREAL DENSITY) + 45.65	0.507

5 Speed-Density Analysis

The speed in km/hr was regressed against density in vehicles/km. The model equation and R-square value are given in Table 4. The speed in km/hr was plotted against density in PCU/km. The plot is shown is Fig. 3 for frame based approach. The model equation and R^2 value are shown in Table 5. It can be observed from the plots that the speed linearly vary with density and there is a wide scatter in the plot. The average speed range is 50 kmph to 30 kmph and density range is 20 Veh/km to 150 Veh/km.

Table 4. Development of speed-density models with density in Veh/km

Type of model	Model equation	R-square value
Linear regression model	SPEED = (−0.055 * DENSITY) + 45.01	0.337

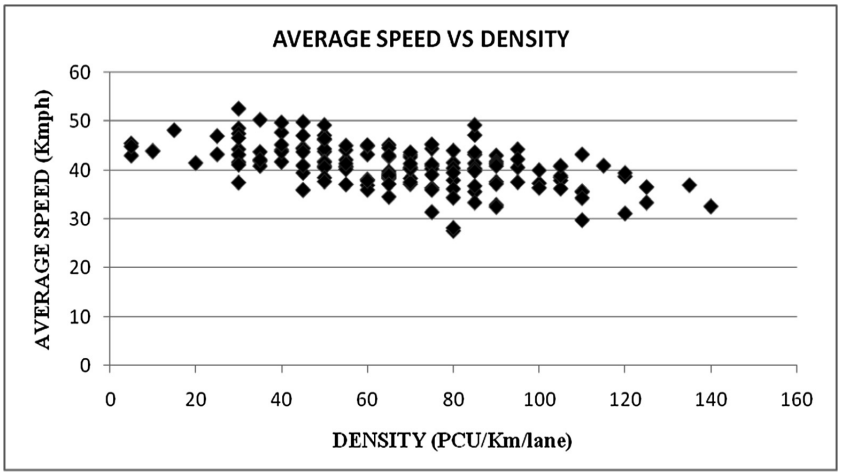

Fig. 3. Average speed versus density relationship

Table 5. Development of speed-density models with density in PCU/km for frame based approach

Type of model	Model equation	R-square value
Linear regression model	SPEED = (−0.853 * DENSITY) + 46.43	0.489

6 Model Development

A linear relationship with speed and areal density for frame based approach was best model equation and the R^2 value obtained was moderately good value. Exponential relationship between speed and areal density was also fitted and the models are shown in Table 6. These relationships also have nearly same R^2 value.

Table 6. Regression models of speed and areal density

Type of model	Model	R-square value
Linear regression model	Speed = (−53.74 * areal density) + 45.65	0.507
Exponential model	Speed = 45.78 * (expo(−1.34 * areal density))	0.500

7 Speed-Porous Area Analysis

The speed in km/hr was plotted against porous area in m^2 for frame based approach. The plot is shown in Fig. 4 for frame based approach. It can be observed from the plot that the speed values do not vary much with density and there is a wide scatter in the plot. Average speed range is 30 kmph to 50 kmph and porous area range is 655 m^2 to

750 m^2 for frame based approach. Average speed range is 30 kmph to 60 kmph and porous area range is 655 m^2 to 750 m^2 for section based approach.

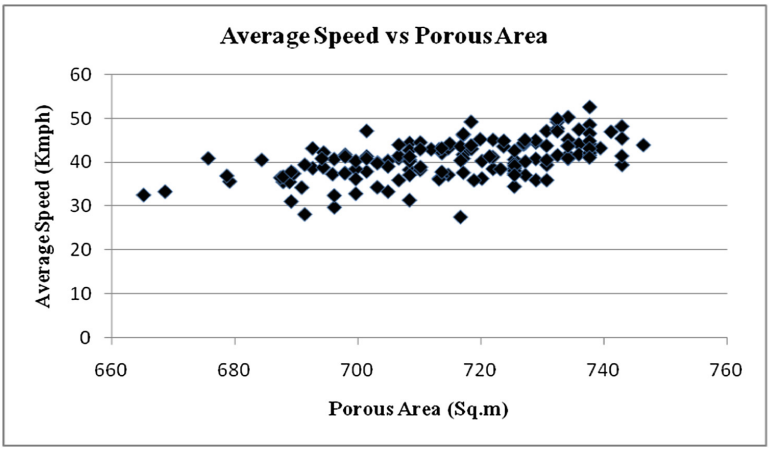

Fig. 4. Average speed versus porous area relationship

8 Porous Space and Headway Distribution Functions

From data regarding porous area are fitted in the distribution. The distribution obtained was GEV distribution. From data regarding space headway are fitted in the distribution. The distribution obtained was log-normal distribution.

9 Conclusions

Data analysis was carried out to find out the relationship between speed, areal density and density, speed and porous area and also pore space and headway distribution. After data analysis speed-areal density and speed-density models were developed. The best model obtained was linear regression model of speed-areal density of frame based approach. The R squared value obtain for linear regression model was 0.507.

From the data analysis conclude that average speed is linearly decreasing with increasing the areal density and speed of vehicles are increasing with more availability of porous area on the road section. The speed density model obtained as linearly decreasing relationship. Areal density parameter explains the heterogeneous disordered traffic system better than the density parameter. The pore space distribution follows the generalized extreme value distribution and headway distribution follows the log-normal distribution. This work makes the contributions to the limited literature on traffic flow theory.

Abstract

This paper deals with buckling analysis of stiffened circular plates through numerical simulation techniques using ABAQUS 6.5. In the present numerical investigation, the effect of aspect ratio (R/T) of a stiffened circular plate on the buckling strength is determined for different mode shapes. Three different geometric shapes namely T, I and HAT are considered to reinforce the plate by way of stiffeners. For all cases studied in the present investigation, a circular plate with radius 0.5m is subjected to in-plain loading. The boundary conditions are such that, the edge is fixed but released in the radial direction during buckling. The results of the analysis for radius to thickness ratio of the plate, in the range from 200 to 250, with four intermediate steps are presented in the form of buckling loads corresponding to different mode shapes in tabular and graphical form.

Key Words: Buckling loads, Circular plates, Ring Stiffeners, Aspect Ratio, Thin shells.

1. Introduction

Thin circular steel plates are widely used in the fabrication of steel structures such cylindrical pressure vessels, storage containers in oil & gas companies, maritime and aerospace industry. While in service, these circular steel plates are subjected to mechanical loads and temperature variations leading to thermo-mechanical loads. As a result, the plates will undergo deformations due to buckling loads. A simple approach to increase the buckling strength of the steel plate is to increase its thickness. However, increasing the thickness of the plate directly increases the weight and cost of the structure. Hence, to increase buckling resistance of the plates, generally stiffeners are attached on the face of the plates. For stiffeners, commercially available steel sections with standard geometric shapes like T, I and HAT are chosen from the open market. Reinforcement of plates with stiffeners increases the buckling strength without adding much to the self-weight for the structure.

Estimation of buckling strength of a thin plate is possible through analytical solutions. But, it becomes difficult to determine the buckling load when stiffeners are attached to the plate. Therefore, one has to resort to either experiments or numerical simulations. It is known that, conducting experiments is not only expensive but also time consuming process. On the other hand, finite element based numerical simulations offer great advantage to incorporate a variety of stiffeners and boundary conditions. These simulations can be repeated several times to investigate the effect of different parameters. In the present investigation, it is proposed to determine buckling load of a circular steel plate with three different stiffeners attached to the face of plate through numerical simulations. For this purpose, ABAQUS is employed, which is one of the powerful FE based software tools for numerical simulations.

2. Literature Review

From the published literature, most pertinent studies conducted by the previous investigators are presented here to give a brief background. Rossettos and Yang [1] presented a treatment of asymmetric buckling problem of ring stiffened circular plates. They indicated a coalescence of the lowest symmetric and asymmetric mode eigen values involving ring torsional stiffness. Grondin et al [2] conducted a parametric study on buckling of stiffened steel plates. They considered stability of stiffened plates using finite element model. In their study, tee-shape stiffeners are used for buckling analysis and parameters included are 1) Initial plate imperfections, 2) direction and magnitude of residual stresses, 3) slenderness ratio of the plate, 4) aspect ratio of the plate and 5) cross-sectional area ratio of plate to stiffener.

Ma and Wang [3] investigated nonlinear bending and post-buckling of a functionally graded circular plate under direct mechanical and thermal loads. They used classical nonlinear von Karman plate theory, for axisymmetric large deflection and bending of a functionally graded circular plate. The types of loads considered in their investigation are mechanical, thermal and combined thermal–mechanical. Brubak and Hellesland [4] conducted an approximate buckling strength analysis for plates reinforced with stiffeners with arbitrary orientation. Ding and Lee [5] gave an analytical solution for a circular plate that is uniformly loaded and clamped at the edges.

Modarresi and Showkati [6] experimentally investigated the failure of diagonally stiffened circular plates to determine ultimate bending capacity. In their experiments, to strengthen the plate, two types of shallow and deep stiffeners of reverse L and rectangular cross-sections were attached. They considered simply supported and clamped edge boundary conditions for a circular plate subjected to lateral loads up to their final collapse. They compare experimental results with non-linear analysis of stiffened circular plates using FEM. The results are presented through load-deflection, load strain curves and volumetric charts. Finally it was concluded that increasing the height of the diagonal stiffener or changing its cross sectional shape may not be an effective way of increasing the load bearing capacity of the diagonally stiffened circular plates. It was recommended that, instead of using one diagonal stiffener, it is better to use two perpendicular diagonal stiffeners with same amount of steel as the first one.

LB Rao and CK Rao [7] presented an exact solution for elastic buckling of circular plates resting on internal elastic ring support and elastically restrained against translation at the outer edge. They used classical plate theory to solve the governing differential equations. Further, they introduced a Mathematica code to estimate the buckling load. Tran et al. [8] studied the buckling behavior of stiffened curved panels under uniform longitudinal compression to address the linear buckling and the ultimate strength of panel which are both influenced by the combined effect of curvature and stiffening. They finally proposed a design methodology for stiffened flat plates to be adopted by European Standards. They concluded that the plate curvature has to be taken in to consideration to optimize the design.

Daniel [9] attempted the stability problem of thin circular plates that are stiffened with thin cylindrical shell on the circumference and also on the plate. In his investigation, an attempt was made to determine the in-plane axi-symmetric critical load with a view to show the effect of cylindrical shell stiffener. Daniel [10] summarized the differential equations for the stability of shell stiffened circular pates and shell stiffened annular plates assuming the deformations are axisymmetric. Chiang-Li Yu et al. [11] focused their attention on the uniaxial ultimate compressive strength of stiffened panels with openings. In their work, experiments were conducted on longitudinal stiffened panels with rectangular openings applying combined loads. Numerical simulations were carried out on stiffened panels considering large elastoplastic deformation behavior using ABAQUS.

From the literature review it is found that, there are a very few papers but not too many focusing on the buckling of stiffened circular plates. But, investigations, concerning the buckling load as a function of plate aspect ratio, particularly when the plate is stiffened, are very much limited in open literature. Therefore, in the present investigation it is proposed to determine the effect of aspect ratio on the buckling load of a stiffened circular plates using the protocols specified in the user's manual of ABAQUS 6.5 [12].

3. Analytical Solution:

In a process industry, thin circular plates are subjected to in-plane radial compressive forces from the supporting structure when there is a change in the working temperature of the medium. As a result, buckling of the circular plates can take place. In the following section governing differential equations for plates subjected to buckling loads are presented.

Circular plate subjected to uniformly distributed in-plane compressive radial forces:

As shown in Fig.1, in the present analysis, a circular plate is considered that is subjected to in-plane radial compressive forces (q_r). In the buckling analysis we include only axisymmetric geometries such a circular plates. Thus, we can use polar coordinate system represented by r and Ø. Equation (1) that represents buckling of a rectangular plate can be transformed to a circular plate for convenience of analysis.

$$\frac{\partial^4 w}{\partial x^4} + 2\frac{\partial^4 w}{\partial x^2 \partial y^2} + \frac{\partial^4 w}{\partial y^4} = \frac{1}{D}\left(N_x \frac{\partial^4 w}{\partial x^2} + 2N_{xy}\frac{\partial^4 w}{\partial x \partial y} + N_y \frac{\partial^4 w}{\partial y^4}\right) \quad (1)$$

For a specific case, when the structure is in equilibrium, for an axi-symmetric loading condition,

We have $$N_x = N_y = N_r = -q_r, \; N_{xy} = 0 \quad (2)$$

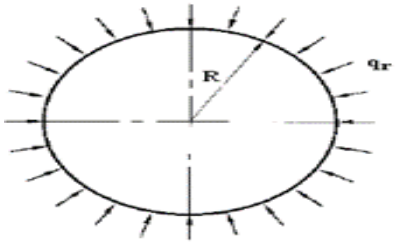

Fig 1: Circular plate subjected to uniformly distributed inplane compressive radial forces

Denoting, $$\mu^2 = \frac{q_r}{D} \quad (3)$$

and using the relations between the polar and Cartesian coordinates, we can derive an equation for axi-symmetric circular plate subjected to circumferential compressive force as shown in Fig.1., is given below.

$$\frac{d^4 w}{dr^4} + \frac{2}{r}\frac{d^3 w}{dr^3} - \frac{1}{r^2}\frac{d^2 w}{dr^2} + \frac{1}{r^3}\frac{dw}{dr} + \mu^2\left[\frac{d_w^2}{dr^2} + \frac{1}{r}\frac{dw}{dr}\right] = 0 \quad (4)$$

Now, let us introduce the following new variable:

$$\rho = \mu r \quad (5)$$

that denotes a non-dimensional polar radius. By means of new variable ρ, it is possible to rewrite the above Eq. (4), in to the form of Eq. (6) given below.

$$\frac{d^4 w}{d\rho^4} + \frac{2}{\rho}\frac{d^3 w}{d\rho^3} + \left(1 - \frac{1}{\rho^2}\right)\frac{d^2 w}{d\rho^2} + \frac{1}{\rho}\left(1 + \frac{1}{\rho^2}\right)\frac{dw}{d\rho} = 0 \quad (6)$$

Eq. (6) is a linear 4th order, homogeneous differential equation. The general solution for Eq (6) is given below.

$$\boldsymbol{w(\rho) = C_1 + C_2 \ln \rho + C_3 J_0(\rho) + C_4 Y_0(\rho)} \quad (7)$$

Where $J_0(\rho)$ is Bessel's function of first kind and $Y_0(\rho)$ is Bessel's function of second kind both for zeroth order. In Eq. (7), above, C_1, C_2, C_3 and C_4 are constants of integration. Since w (ρ) must be finite quantify for all values of ρ, including ρ= 0, then the two terms with ρ and $Y_0(\rho)$, having singularities at ρ=0, must be dropped for the solid plate because they approach an infinity when ρ=0. Thus, for the solid circular plate, Eq. (7) must be taken in the form

$$\boldsymbol{w(\rho) = C_1 + C_3 J_0(\rho)} \quad (8)$$

to determine the critical buckling loads q_r. These loads are assumed to be acting at the mid plane of the circular plate.

4. Finite Element Modelling:

FE modelling of the plate with T, I and HAT stiffeners is carried out using ABAQUS software version 6.5. From ABAQUS library, a 4-node, doubly curved, linear shell element is selected for the geometric modelling of the structure under consideration. To maintain acceptable aspect ratio for the element, shell elements were preferred over three dimensional elements. The choice of the shell elements will also ensures a reasonable mesh density. Stiffeners of three different geometric shapes T, I and HAT are chosen for reinforcement of the circular plate. As shown in Fig.2, on each plate any one type of ring stiffeners are placed at three different radial locations, first one at 0.1m, second one at 0.25m and third one at 0.4m. Mild steel properties are chosen for plate and stiffeners during the analysis. In-plane compressive load of 20 kN is considered acting on the circular plate with stiffeners. As shown in Fig.3, loading and the boundary conditions are such that the plate is fixed along the edge while released in the radial direction. ABAQUS 6.5 is employed to carryout FE analysis on the structure under consideration.

In the present numerical simulations the radius of circular plate is fixed at 0.5m. Thickness of the plate is varied such that the radius to thickness ratio (R/T) is in the range of 200 to 250 with an increment of 10 each. Height and thickness of the stiffeners are held constant at 0.007m and 0.002m respectively.

Material Properties of Mild Steel:

Young's modulus E=200GPa,
Poisson's ratio = 0.3.

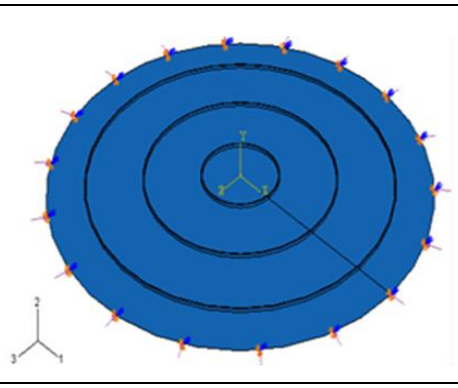

Fig 3: Loading and Boundary conditions for stiffened circular plate

5. Results and Discussion

The results of the simulaton studies to determine buckling load of stiffened circular plate as a function of aspect ratio in the range of investigation from 200 to 250 in steps of 10 are presented in the tables I, II and III. It is observed that, for a given mode of deformation the buckling load decreases with the increase of aspect ratio. It is also observed that for any given aspect ratio in the range of investigation, the buckling load increases with progressive mode of deformation from mode-1 to mode-6. Further, the plate with T-shaped stiffener has lowest buckling strength for all aspect ratios and all modes of deformation. The plate with HAT-shaped stiffener showed largest buckling load for all conditions. The plate with I shaped stiffener has larger buckling loads compared to plate with T-shaped stiffeners but marginally less buckling load when compared to plate with HAT-shaped stiffeners. However, the buckling loads for I-shaped and HAT-shaped stiffeners are closely comparable to each other. One set of results on buckling loads of plate with T, I and HAT shaped stiffeners are presented in Table IV for comparison. Typical sphapes of deformation of plates with T, I and HAT shaped stiffeners are shown in Fig.4, Fig.5 and Fig.6 respectively.

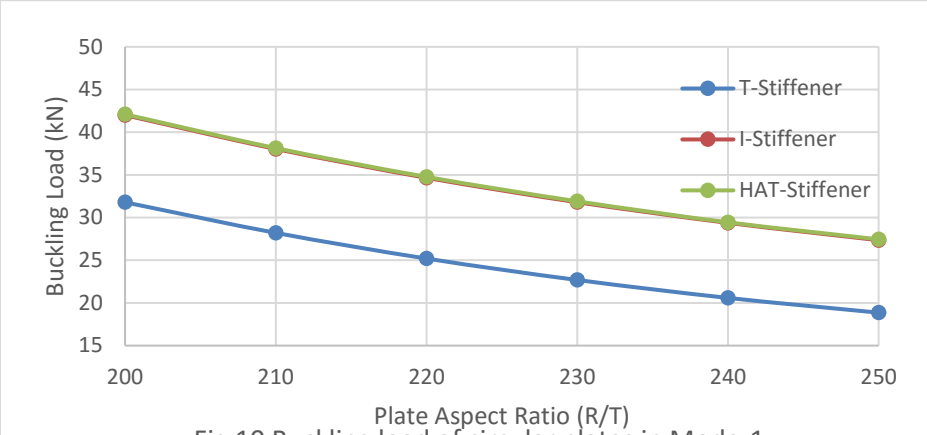

Fig.10 Buckling load of circular plates in Mode-1, with stiffeners of different geometric shapes

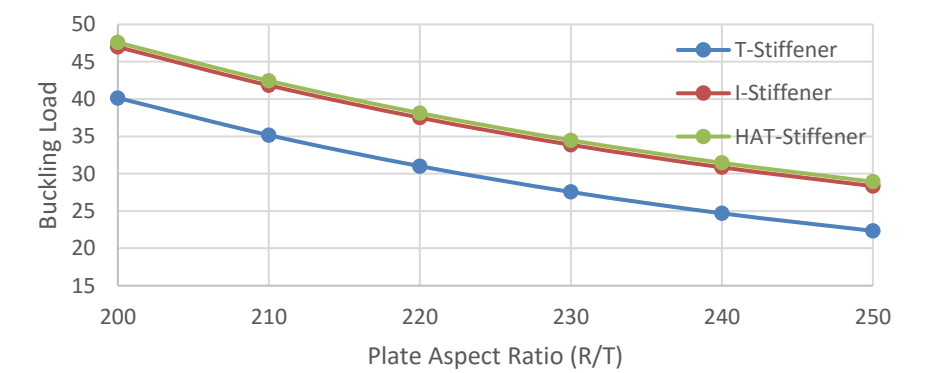

Fig.11 Buckling load of circular plates in Mode-2, with stiffeners of different geometric shapes

From the results in Fig.7, Fig.8 and Fig.9, it is observed that the buckling load curves of the stiffened circular plates are seen in pairs. Buckling load curves for mode-1 and mode-2 are close to each other and appears like a pair of curves. Likewise, buckling load curves for mode-3 and mode-4; mode-5 and mode-6 formed another two pairs of curves. This observation is consistent for all three types of stiffeners considered in the present investigation. Fig.10 and Fig.11 show the variation of buckling load as a function of plate aspect ratio for T, I and HAT-stiffeners in mode-1 and mode-2 respectively. It is further observed that there is not much of a difference between buckling load for plates with I and HAT-stiffeners.

6. Conclusions

In the present investigation buckling load for stiffened circular plates is presented for 6 modes of deformation as a function of plate aspect ratio in both tabular and graphical forms. From the present analysis, it is found that the circular plate with HAT-Shaped stiffener offers highest buckling strength. The plate with T shape stiffener offers lowest buckling strength. However, the plate with I shaped stiffener offered buckling strength in between the plates with T and HAT shaped stiffeners. Further, the buckling strength of plates with HAT shaped and I shaped stiffeners is closely comparable. It is concluded that the geometric shape of the stiffener is very important since it can affect the buckling load and overall buckling behavior of the plate considerably. Through this investigation the capabilities of ABAQUS software are demonstrated to determine buckling loads of stiffened plates. It is understood that the predictive capabilities of the numerical models and software tools greatly depends on the proper definition of the problem and well defined boundary conditions specific to a problem.

Industrial Drives Control based on Self Adaptive Fuzzy PID Controller Using Controller Area Network

N. Rajeswaran, Professor, Department of EEE, Malla Reddy Engineering College (A), Hyderabad, Telangana, India. E-mail: rajeswarann@gmail.com*

S. Arumugam, Professor, Department of EEE, Malla Reddy Engineering College (A), Hyderabad, Telangana, India.

Abstract--- Now a day's modern industrial control technologies are more expected in the control of DC motors and induction motor. In this paper a proposed method of self-adaptive fuzzy PID (Proportional Integral Derivative) logic networked control using CAN (Controller Area Network) bus for dc motor and induction motor is explained and many factors discussed with the help of simulation results. The main aim of fuzzy PID logic controller method is not only to improve the characteristics but also comparing the results with fuzzy, PID and fuzzy PID controller. The simulated results are obtained by using MATLAB/SIMULINK and from the result it is concluded that DC motor can be controlled by self-adaptive fuzzy PID CAN control and for induction motor self-adaptive fuzzy PI CAN based control is the best.

Keywords--- Industrial Drives, PID Control, Fuzzy based Design, Self-Adaptive Approach and Controller Area Network.

I. Introduction

The Networked Control System (NCS) is defined as that the traditional feedback control system is closed through shared communication network with the condition of other nodes outside the control system. The best examples are dc motors, rotors and automobiles. In a normal systems the nodes were connected to the central location through the hard wired connections and also the system is designed such that all the information's collected from the sensors are sent to the central location and the errors and constraints are analyzed continuously and decision were taken and the instructions are passed to the nodes to control the entire system [1-3].

The constraint in the communication such as finite amount of information per unit time, affected the NCSs (Networked Control System) particularly in the Unmanned Aerial Vehicles (UAVs), planetary rovers, sensor networks. The signals after sampling and encoding transmitted as a continuous time signal and it is encoded in the receiver end and in some NCSs the signals are stamped also. Stamped means that the receiver estimates the delaying time and act correct according to the delay. The major difference between NCSs and standard digital control is during the transit the data may be lost through the network and some transmission protocols i.e., like TCP (Transmission Control Protocol), guaranteed will deliver the packet. But in NCSs the old data's are generally not useful [4-5]. Many researchers are trying to integrate control and communications algorithm to meet the unexpected changes in the network service. In NCSs many stations are sharing the network, so network delay is invariable [6-7] and signal must be delayed if another signal is transmitted and at the same time the large delay will affect the performance of the NCSs very badly.

Networked induced delay and data losses are the two major challenges in the NCSs. Because of less expensive, easy design and very effective the dc motors are generally controlled by PID controller limit at the same time mathematical model of the controller and tuning of PID are difficult and generally not used for non-linear systems. The above limitations are overcome by using adaptive PID controller with self-tuning after few mathematical derivations are made in the transfer function model of the motor. The fuzzy modeling is used for self-tuning of PID controllers and modified fuzzy logic controller model is simulated using MATLAB and SIMULINK.

II. Proposed Method

In order to take advantage of the networking, the network implementation should be carefully designed to satisfy real time requirements considering network delays. A network delay caused by more traffic in the communication channel is considered in protocol [8-9]. TCP/IP is a connection oriented protocol. Before transfer between nodes, TCP/IP protocol set up the connections which is time consuming and therefore not suitable for real time operations.

Received: 18 June 2019/Accepted: 30 June 2019

In Token bus protocol, every node selection set the token bus access after a definite interval of time. Among the various protocols for communication we use scan protocol. In case of scan using arbitration, principle node wins the bus access to transmit data. Then the message identifier delivers printing message to transmitter node [10-11]. Price rating is the added advantage of CAN compared to other networks. The block diagram of networked speed control system of DC motor and Induction motor through CAN Bus is shown in the Fig.1.

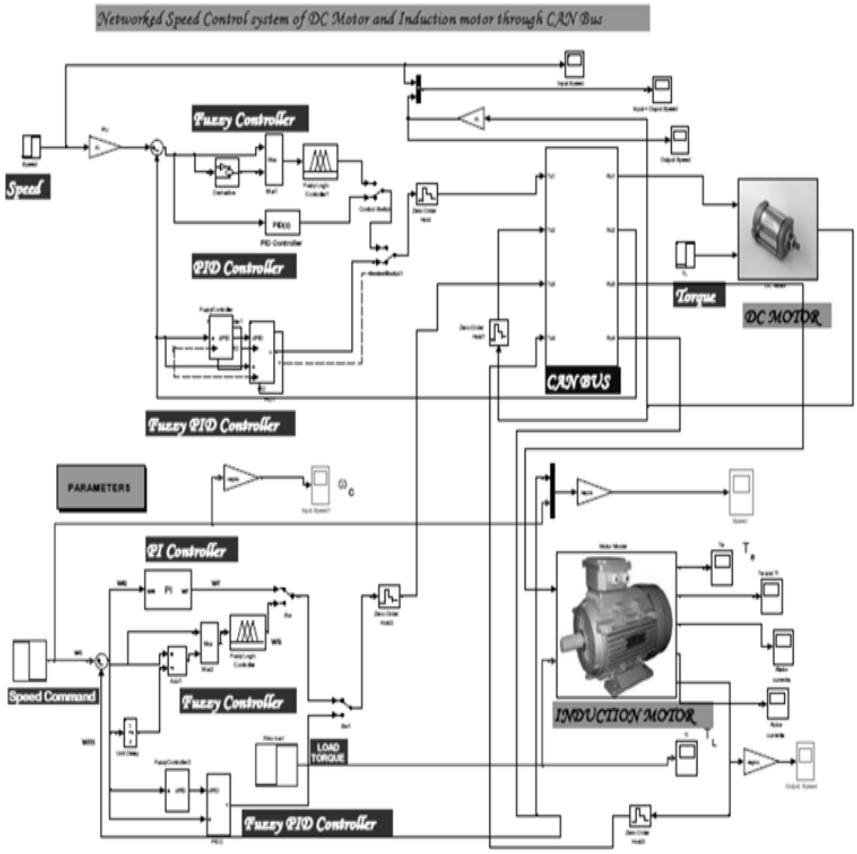

Fig. 1: Networked Speed Control System of DC Motor and Induction Motor through CAN Bus

III. Modeling of DC Motors

The motor variables to be controlled are the speed and the armature current. In the proposed fuzzy logic control scheme, the motor speed error and its error change are used as input variables to Fuzzy speed controller. However, the armature current error and its error change are the input variables to fuzzy current controller. The error and error change for both speed and current are scaled using appropriate scaling factors. These scaled input data are then converted into linguistic variables, which may be viewed as labels of fuzzy sets. For simplicity, the trapezoidal and triangular shaped functions are used in this application. In armature control of separately excited DC motors, the voltage applied to the armature of the motor is adjusted without changing the voltage applied to the field. Figure 2, shows a separately excited DC motor equivalent model.

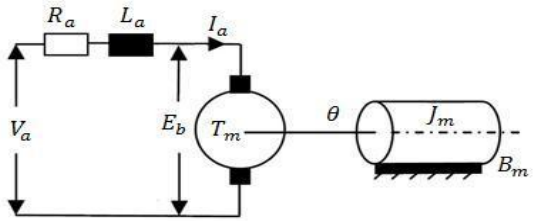

Fig. 2: DC Motor Model

Received: 18 June 2019/Accepted: 30 June 2019

$$T_m(t) = J_m \frac{dw(t)}{dt} + B_m w(t) v_a(t) = R_a i_a(t) + L_a \frac{di_a(t)}{dt} + e_b(t) \quad (1)$$

$$T_m(t) = K_T i_a(t) \quad (2)$$

$$e_b(t) = K_b w(t) \quad (3)$$

Where,

Ra = Armature Resistance, Va =Armature Voltage, La = Armature Inductance

IV.Modeling of DC Motors

The equivalent single phase model transformed to the stator where the magnetic leakages are added and grouped in the rotor and designed by $N_e\omega_s$. The Figure 3, shown below is the resulting model of an Induction Motor.

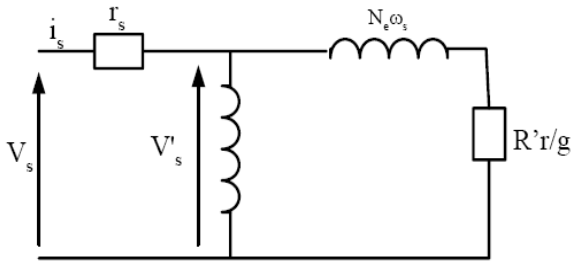

Fig. 3: Equivalent Mono Phase of the Induction Motor Model

It is assumed that the control of the 3-phase induction motor is scalar control using Fuzzy and PI controllers which can be selected using a switch. Scalar control strategy is designed based on the steady state operation of an induction motor.

The mathematical equations involved in dynamics of an induction motor in a synchronous rotating frame are given by

$$vds = rsids - \omega s \Phi qs \quad (4)$$

$$vqs = rsiqs - \omega s \Phi ds \quad (5)$$

$$vdr = rridr - (\omega s - \omega)\Phi qr \quad (6)$$

$$vqr = rriqr - (\omega s - \omega)\Phi dr \quad (7)$$

The d and q axis can be referred in a space vector if they are placed at real and imaginary axis respectively. Hence,

$$vs = vds + jvqs \quad (8)$$

$$is = ids + jiqs \quad (9)$$

$$ir = idr + jiqr \quad (10)$$

$$\Phi s = \Phi ds + j\Phi qs \quad (11)$$

$$\Phi r = \Phi dr + j\Phi qr \quad (12)$$

Deploying (1) and (2) in (5) yields:

$$vs = rsis + j\omega s \Phi s \quad (13)$$

Similarly, the rotor voltage of the induction motor is defined as:

$$vr = rrir + j\omega r \Phi r \quad (14)$$

Based on the equation system and equations (5)-(8), the stator and rotor flux in vector space are given by

$$\Phi s = Lsis + Mir \quad (15)$$

$$\Phi r = Lrir + Mis \quad (16)$$

The scalar induction motor model is:

$$G_m(s) = \frac{k}{1+\tau s} \quad (17)$$

Where k= 0.3478 and τ= 0.5184. τ is the time constant and k is the static gain of the system.

ISSN 1943-023X

Received: 18 June 2019/Accepted: 30 June 2019

$$C(s) = \frac{F(s)}{G_m(s)\,(1-(F(s))} \tag{18}$$

$$C(s) = k_p + \frac{1}{\tau_i(s)} \tag{19}$$

Where k_p= 0.6 and τ_i= 0.0899.

V. Simulation Results

The networked DC motor & induction motor control system are simulated using MATLAB/ SIMULINK under fully controlled environments for Fuzzy Logic Controller, PID Controller and Self-adaptive fuzzy PID CAN based Controller is shown in Figures 4 & 5. In simulation step signal is used as an input and the system running is observed in the oscilloscope. The delays are varied according to different effects of interest. The disturbance and loss of input signal, control signal and the feedback signal are adopted for few milliseconds at each stage and the corresponding results are studied without data losses. In the observation from the graph the self-adaptive fuzzy PID control system is given good response and significant improvements than conventional PID control. The PID controller is attractive for industrial use, because the operators can understand the algorithm and it is also well justified for NCS, since the computational time and memory requirements are fairly low.

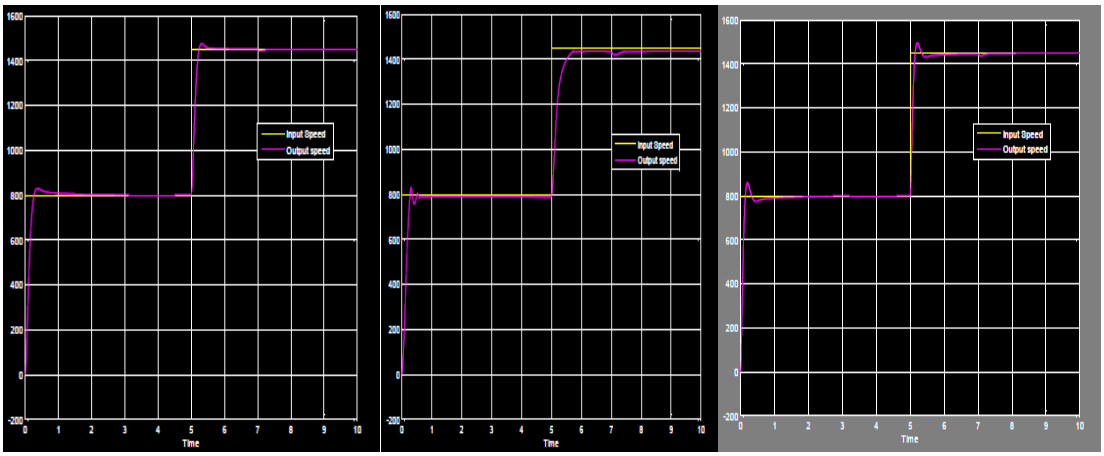

Fig. 4: (a) Fuzzy CAN based DC Motor, (b) Fuzzy PID CAN based DC Motor and (c) PID based DC Motor

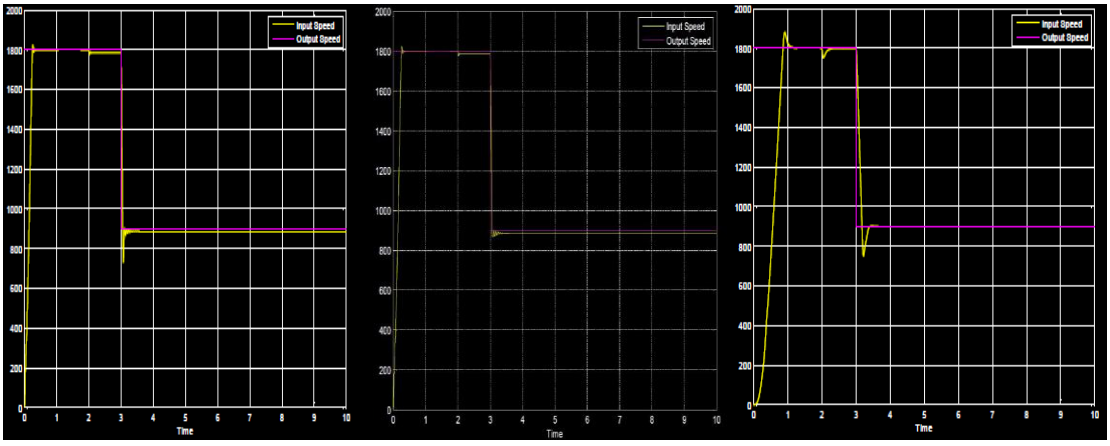

Fig. 5: (a) Fuzzy CAN based Induction Motor, (b) Fuzzy PI CAN based Induction Motor and (c) PI CAN Induction Motor

VI. Conclusion

Industrial drive applications network play a very important role for real time high performance networked control. The PID CAN Based network is used for the control of DC motor and Induction motor. The uniqueness of the performance necessities is very high in dynamic and static characteristics in the results.

Received: 18 June 2019/Accepted: 30 June 2019

The self-adaptive fuzzy PID control algorithm in which the control system, use of PID CAN Based network little fuzzy control theory rules, is simple method and transparent and advantages of self- adaptive learning ability. After carefully analyzing the obtained results particularly settling time, maximum peak over shoot and steady state error, the self-adaptive fuzzy PID CAN based network control suits for DC motors and self-adaptive fuzzy PI CAN based network control suits for Induction Motor.

Application of Modified ALO to Economic Load Dispatch for Coal Fired Stations

A. V. Sudhakara Reddy, N. Rajeswaran, D. Raja Reddy

Abstract*: This manuscript explores the novel Modified Ant Lion (MALO) Optimization to resolve the load dispatch problem optimally. The primary role of Optimal Economic Load Dispatch (OELD) is to obtain an efficient and economical operation of a power system network. The main aim of performing the OELD is for minimizing the fuel cost of the real power generation when the losses are neglected. An Modified Ant Lion (MALO) Optimization is a narrative nature-inspired algorithm and apes the tracking mechanism of ant lions in life. The random walk of ants, building traps, entrapment of ants in traps, catching preys, and re-building traps are the five main steps involved in the hunting process. The principal objective of OELD is to curtail the total generation cost while honoring effective constraints of accessible generating resources. The anticipated Modified ALO technique is utilized on three and six unit test system to various load demands for solving the load dispatch problem economically. A statistical result clarifies that the anticipated MALO method has lowest fuel cost and superior in quality of solution than other optimization techniques accounted in most latest literature.

***Index Terms*: Modified Ant Lion Optimization, Economic Load Dispatch, Fuel Cost, Different Load Demands, Real Power Generation, Coal Fired Station, Without Losses.**

I. INTRODUCTION

Economic Dispatch forms the significant analysis roles dealing with Operation in a power transmission system. Economic Dispatch (ED) is defined as the route of distributing real power generation to the each generating unit, so that the total network load is supplied with most economical manner. In static economic dispatch, the point is to evaluate, the output power of all generating units so that all the loads are energized at minimum cost, while satisfying the various equal and inequality restrictions of the network and the generator limits. Economic Dispatch models the electric power system and dispatch the essential load from the accessible, well, generating units for each control area in the most economic manner or in real-time situation. The point is to reduce the total generation cost (include fuel cost, but exclude the cost of network loss) by meeting the operational constraints.In modern days, different evolutionary and meta-heuristics optimization techniques have been designed for simulating natural phenomena such as: Bat Algorithm (BA) [1], Particle Swarm (PSO) Optimization [2], Moth-Flame Optimization [3, 15], Cuckoo Search Algorithm (CSA) [4], FireFly Algorithm (FA) [5], Real Coded Genetic Algorithm (RCGA) [6], DragonFly Algorithm (DFA) [7], Grey Wolf Optimizer (GWO) [8], Evolution Optimization Swarm Algorithm (EOSA) [9], Sine Cosine algorithm (SCA) [10], Glowwarm Swarm Algorithm (WSA) [11], Hybrid Big Bang-Big Crunch Algorithm (HBBBCA) [12], Ant Lion Algorithm (ALO) [13, 17], Novel Bat Algorithm (NBA) [14], stochastic whale optimization (SWO) [16, 18], Moderate Random Search PSO (MRS-PSO) [19], Multi-Verse (MVO) Optimizer [20] and Sine Cosine Algorithm (SCA) [21]. Some of the heuristics evolutionary algorithms are used to resolve economic dispatch problems, which is reported in published literature as Bat Algorithm (BA), Cuckoo Search Algorithm (CSA) [4], FireFly Algorithm (FA) [5], Real Coded Genetic Algorithm (RCGA) [6], Evolution Optimization Swarm Algorithm (EOSA) [9], Glowwarm Swarm Algorithm (WSA) [11], Hybrid Big Bang-Big Crunch Algorithm (HBBBCA) [12], Ant Lion Algorithm (ALO) [17], Novel Bat Algorithm (NBA) [14], stochastic whale optimization (SWO) [18], Moderate Random Search PSO (MRS-PSO) [19].This manuscript recommends, Modified ALO algorithm is utilized for the elucidation of economic load dispatch to condense the cost of fuel in steam power station for different load demands. The projected Modified ALO has tested on simple 3-unit and 6-unit test systems.

II. PROBLEM FORMULATION

A. Fitness Function

The aptness of the load dispatch hitch is to curtail the cost correlated to total generation while checking the limits of constrictions, when the essential power demand of a network is being supplied. The main objective of this task is to reduce cost given by the subsequent equation.

Minimize $F_T = F_i(P_{Gi}) = F_1(P_{G1}) + F_2(P_{G2}) + \text{-------} + F_n(P_{Gn})$

$$F_i(P_{Gi}) = \sum_{i=1}^{n} F_i(P_{Gi}) \qquad \text{.....(1)}$$

$$F(P_G) = \sum_{i=1}^{n} \left(a_i P_{Gi}^2 + b_i P_{Gi} + c_i\right) \qquad \text{.....(2)}$$

B. Equality Restraint

Revised Manuscript Received on July 9, 2019

Dr. A. V. Sudhakara Reddy, Department of E.E.E, Malla Reddy Engineering College(A), Maisammaguda-500100, Hyderabad, INDIA.
Dr. N. Rajeswaran, E.E.E Department, Malla Reddy Engineering College(A),), Maisammaguda, Hyderabad, INDIA .
Dr. D. Raja Reddy, E.E.E Department, Malla Reddy Engineering College(A),), Maisammaguda, Hyderabad, INDIA.

The total generation of all generators should be meet the required load demand. The power balance equation without losses is given by

$$\sum_{i=1}^{n} P_{Gi} = P_D \qquad \text{.....(3)}$$

C. Inequality Restraint

The active power of all the generators in a coal fired station is to be inhibited within its functional limits.

$$P_{Gi}^{min} \le P_{Gi} \le P_{Gi}^{max} \quad i=1,2,.....n \qquad \text{.....(4)}$$

III. ANT LION OPTIMIZATION

A. Introduction

This article suggested a novel environment motivated algorithm called Ant Lion Optimization [13, 17] as a different practice to crack optimization problems. As the name signifies, Modified ALO algorithm emulates the sharp exploits of antlions in tracking ants in the atmosphere. The life series of AntLions is revealed in Fig. 1 and altered phases engaged while a corner and hunting the prey is publicized in Fig. 2 [13].

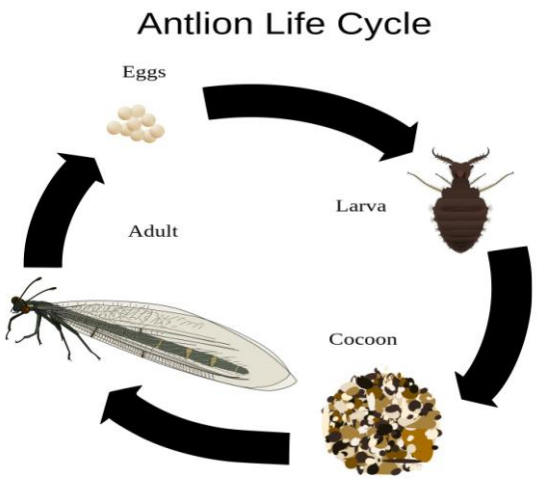

Fig. 1: Existence of an Ant Lions

The life cycle of antlions comprises two phases are of Larvae & Adult. A total lifespan can take up to 3 years, which mostly transpires in larvae. Antlions undergo metamorphosis in a cocoon to turn out to be an adult. Ants typically pursue in larvae and the parenthood era is for reproduction.

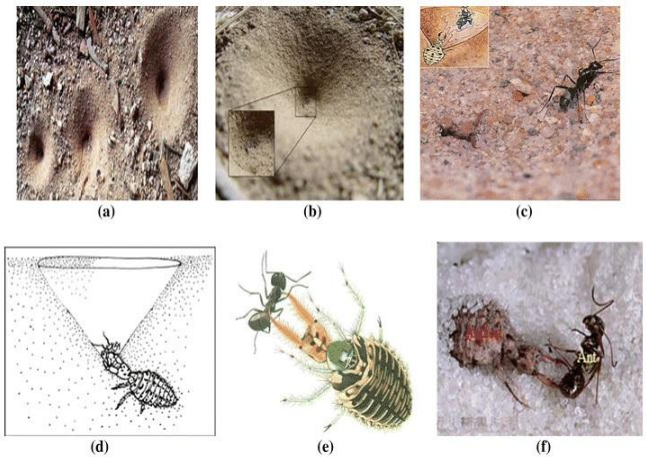

Fig. 2: a–c Erection Traps And Snare Of Ants In Ruses; D–F Contagious The Prey And Re-Building Traps

The ALO mimics relations involving ant-lions and ants in the trap. Since ants voyage stochastically in life when penetrating for groceries, a random walk using roulette wheel is preferred for the modelling ant movement.

The random walks within the search space are kept within boundaries, normalized using min–max normalization.

$$X = \left[0, CumSum\left(2*\left(rand\left(\max_iter,1\right) > 0.5\right) - 1\right)\right]$$

$$RW(i) = X(i) = \frac{\left((X-a).*(d-c)\right)}{(b-a)} + c \qquad \text{.....(5)}$$

$$\text{Where,} \quad a = \min\left(Rand_Walk\right)$$
$$b = \max\left(Rand_Walk\right)$$
$$c = lb\left(dim\right)$$
$$d = ub\left(dim\right)$$

$$ant_pos(i) = \left(ant_pos(i).*\left(\sim\left(Flag4ub + Flag4lb\right)\right)\right) + ub.*Flag4ub + lb.*Flag4lb \qquad (6)$$

Pseudo Code

```
% Initialize input data, search agents and maximum iteration
% Initialize generator coeffecients, lower and upper limits each generator
% Initialize the positions ants
% Initially, evaluate the fitness
for i = 1:n
    for i = 1:dim
        RandomWalk(i) = (d(i) - c(i)) * rand + c(i)
        Calculate Ant_Pos(i) = RA(i) + RE(i) / 2
    end
end
% Boundar checking
% Update positions
% If any antlinons becomes fitter then Update elite position
% Update convergence criteria
display Best_score as Ant_Lion Fitness
```

B. Flow Chart for Optimal Economic Load Dispatch

The flow chart for Economic load dispatch problem by using Modified ALO algorithm is presented in Fig. 3. The ants travel stochastically in nature, while penetrating for food.

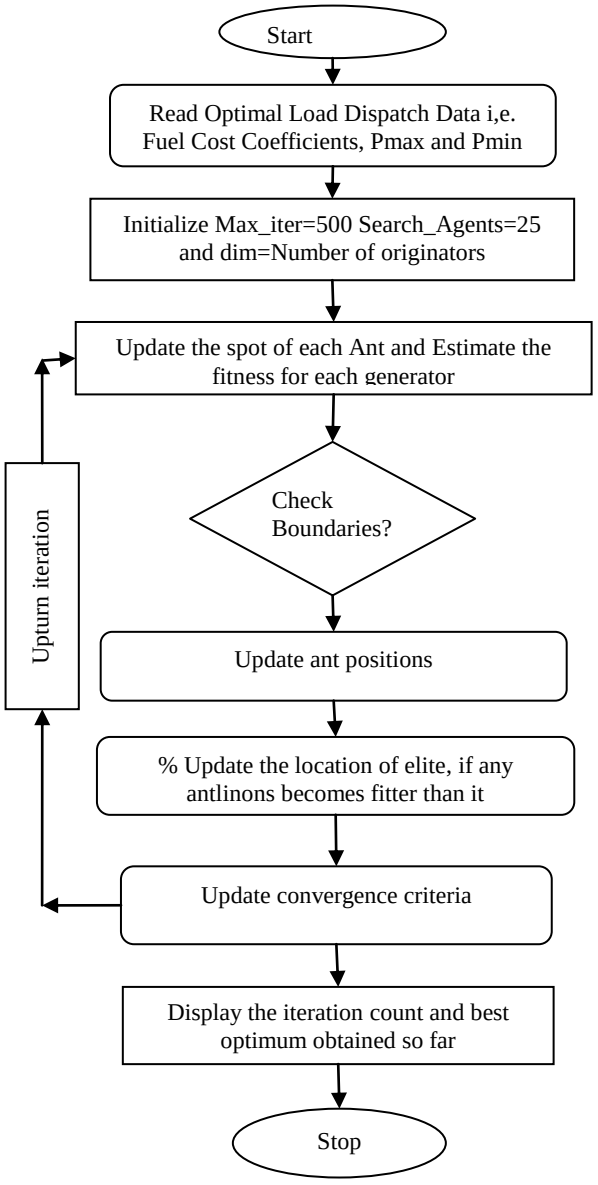

Fig. 3: Flow Chart For ELD Problem Using Modified Ant Lion Optimization

IV. UNITS

The Modified ALO is executed to decipher ELD problem with benchmark 3 and 6 thermal units. The MATLAB code tested on Version R2014a on an Intel, Core™ i3-3227U, CPU@ clock speed of 1.90 GHz, and 8GB RAM, 64-bit OS. The assessment results of the three and six unit systems are revealed. The capricious parameters of Modified ALO are offered in Table. 1.

TABLE I. ALO PARAMETERS

Organize Parameters		
1.	Search Agents	100
2.	Maximum Iterations	500
3.	Dimensions	3 (for 3-Gen system) 6 (for 6-Gen system)

A. Three-Unit System

The generator coefficients and lower, upper boundaries for each generator in a thermal system data are revealed in Table. 2. The planned Modified ALO is realized in the OELD problem when transmission losses are not included and end results of the fuel cost for altered load demands, i.e. 350, 400, 450, 500, 550, 600, 650, 700, 750 and 800 MW are offered in Table. 3.

TABLE II. GENERATOR COEFFFICINTS AND INEQUALITY CONSTRAINTS OF 3-GENERATOR SYSTEM

Unit	a	b	c	Pmin	Pmax
1	0.03546	38.30553	1243.5311	35	210
2	0.02111	36.32782	1658.5696	130	325
3	0.01799	38.27041	1356.6592	125	315

TABLE III. OPTIMUM LOAD DISPATCH RESULTS OF 3-GENERATOR SYSTEM

Load Demand (MW)	P_1 (MW)	P_2 (MW)	P_3 (MW)	Fuel Cost (Rs./hr)
350	64.97302	155.9829	129.0441	18315.5651
400	75.7237	174.0416	150.2347	20480.2969
450	86.47439	192.1003	171.4253	22683.1507

550	107.9758	228.2177	213.8066	27203.2239
600	118.7264	246.2764	234.9972	29520.4433
650	129.4771	264.3351	256.1878	31875.7847
700	140.2278	282.3938	277.3784	34269.2481
750	150.9785	300.4525	298.569	36700.8333
800	163.5053	321.4947	315	39171.2478

B. Six-Unit System

The 6-unit test system generator coefficients, min and maximum limits for real power generation of data are exposed in the Table. 4.

TABLE IV. GENERATOR COEFFFICINTS AND INEQUALITY CONSTRAINTS OF 6-GENERATOR SYSTEM

Unit	a	b	c	Pmin	Pmax

1	0.15240	38.53973	756.79886	10	125
2	0.10587	46.15916	451.32513	10	150
3	0.02803	40.39655	1049.9977	35	225
4	0.03546	38.30553	1243.5311	35	210
5	0.02111	36.32782	1658.5596	130	325
6	0.01799	38.27041	1356.6592	125	315

The planned Modified ALO is realized and the outcomes of the fuel cost for various load demands, i.e. 600, 700 and 800 MW are offered in Table. 5.

TABLE V. OPTIMUM LOAD DISPATCH RESULTS OF 6-GENERATOR SYSTEM

Load Demand (MW)	600	700	800
P1	21.1895	24.97371	28.7579
P2	10	10	10
P3	82.0860	102.6604	123.2360
P4	94.3706	110.6347	126.8982
P5	205.3642	232.6838	260.0032
P6	186.9897	219.0473	251.1047
Cost(Rs./hr)	31445.6229	36003.1239	40675.968

C. Comparison of Six-Unit Test System Results

The test results of 6-unit system are compared with the other meta-heuristic optimization techniques which are previously published articles in the literature under the same operating conditions and presented in Table. 6.

TABLE VI. COMPARATIVE OUTCOMES OF 6-UNIT SYSTEM

Power Demand	FFA [5]	MFA [5]	VSMFA [5]	MFFA [5]	Proposed MALO
600	31489	31447	31576	31481	31446
700	36075	36006	36036	36021	36003
800	40739	40676	40701	40740	40676

From the above comparison, detect that Modified ALO attain the least amount of fuel cost for different power demands as evaluated when the losses are neglected. The convergence criteria is also improved by modified ALO.

The graphical representation of comparative results for 600MW, 700MW and 800MWare exposed in Fig. 3, Fig. 4 and Fig. 5 correspondingly.

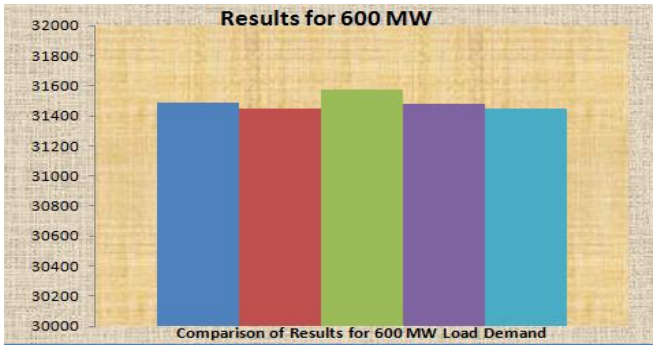

Fig. 4: Graphical Representation For Load Demand 600 MW

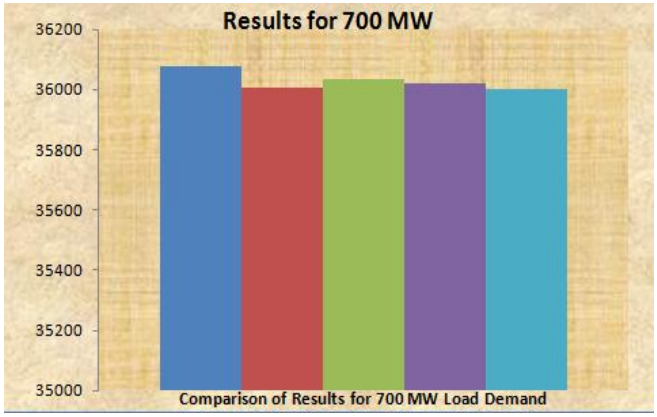

Fig. 5: Graphical Representation For Load Demand 700 Mw

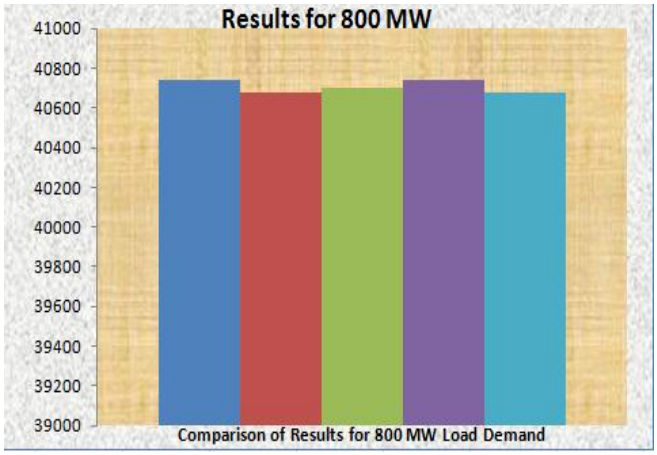

Fig. 6: Graphical Representation Load Demand For 800 MW

ACKNOWLEDGMENT

The investigators are delighted to the Chairmen Sri.Ch.MallaReddy and Principal Dr.S.Sudhakara Reddy, Malla Reddy Engineering College (Autonomous), Hyderabad, India encourages and to do this research work.

AUTHORS PROFILE

Dr. A. V. Sudhakara Reddy has 10 years of experience in Teaching and Research. He did his B.Tech in Electrical and Electronics Engineering from Vaagdevi Institute of Technology & Science (V.I.T.S). He received M.Tech in Electrical Power Systems (E.P.S) from JNTU Pulivendula and Doctor of Philosophy (Ph.D.) in Power Systems from Sri Venkateswara University, India. He has Six Times Qualified in All India GATE Entrance Exam 2010, 2012, 2013, 2015, 2016 and 2017. Presently he is working as Assistant Professor and R&D Coordinator in Electrical and Electronics Engineering at Malla Reddy Engineering College (A)-Main Campus, Hyderabad, India. He has published 20 Research Papers including IEEE conferences, Free, Scopus, Thomson Reuters Indexed and UGC indexed Journals. His area of research interest includes Power Systems, Soft Computing and Machine Learning. He is a life time member of various professional bodies like IEEE, ISTE, IAENG and IEI.

Dr. N. Rajeswaran is presently working as Professor and Head of the Department (HOD) in Electrical and Electronics Engineering at Malla Reddy Engineering College (Autonomous), Hyderabad. He did his Bachelors in Electrical and Electronics Engineering in Government College of Engineering., Bargur (Madras University) and also obtained Masters Degree in Applied Electronics from Anna University Chennai, Tamilnadu. He received doctoral degree from Jawaharlal Nehru Technological University Hyderabad, Telangana, India. He has published more than 35 research papers in various International journals and conferences. His area of research interest includes Electrical Machines, Soft Computing and VLSI Design. He is a life time member of various professional bodies like ISTE, IAENG and IACSIT.

Dr. Raja Reddy. **Duvvuru** has 8 years of experience in teaching and research. He received Ph.D from JNTU Ananthapuramu. Presently he is working as an Assistant Professor & Additional Controller of Examinations at Malla Reddy Engineering College (A)-Main Campus, Hyderabad, India. He has published 25 Research Papers. His area of research interest includes Power Systems and Micro Grid. He is a life time member of various professional bodies like IEEE, ISTE, IAENG and ISRD.

Abstract--- The significant method for the strengthening of the permanence of an AC power distribution system is resolute by the static synchronous compensator. Further most it is castoff in supply level to ease power quality singularities but also at transmission level for voltage control in addition to Power Oscillation Damping (POD). STATCOM by technique of energy storing is previouslymountedbesides it is castoff for power flow controlling then voltage control. POD controller by E-STATCOM has remainedadvanced in an adaptive method in this paper. For approximation areformed RLS algorithm has been castoff and therefore an optimal custom of the existing energy supplyobtainable in this result.

Keywords--- Power Oscillation, STATCOM, Damping, FACTS, POD.

I. Introduction

Static synchronous compensator is a crucial scheme for the strengthening of solidity in an AC controlsystem. Even though characteristically it is used for reactive power booster lone by providing the STATCOM with drive storage, related to the dc-link of the converter additional malleable regulator of the transmission scheme can be attained. Setting up of a STATCOM by means of energy loading is now inductee for power stream board and electrical energy control. Among the countless devices beneath the FACTS family, free of other system parameters a STATCOM is a variable device, which can be used to regulate the movement of reactive power in the system[1].A STATCOM includes three phase inverter (generally a PWM inverter) by SCRs, MOSFETs or IGBTs, a DC capacitor that compromises the D.C voltage intended to the inverter, a connection apparatus relates the inverter production to the ac source cross, strainer apparatuses to sift out the high frequency components owing to that PWM inverter.

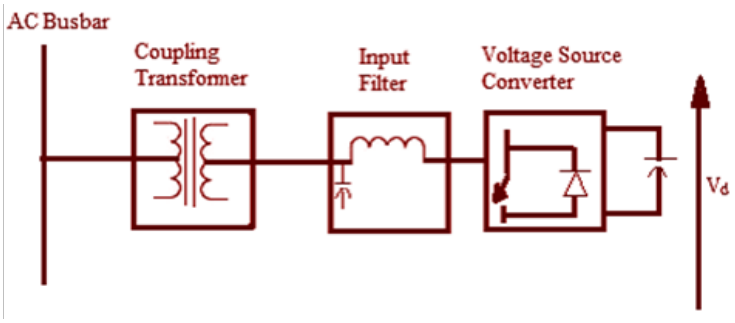

Fig. 1.1: Static Compensator

For two AC sources, which have the similar frequency and are associatedover a series inductance, the dynamic power arrangements starting, and the fore most supply to the casing supply along with the sensitive power streams one subsequently to the advanced voltage scale source to the minor voltage scalesupply [2].Static VAR compensation can be operated to regulate voltage, regulator power factor, and soothe power flow. Static VAR compensators built on a voltage sourced inverter, identified as STATCOM, have been proposed and demonstrated in an exertion to more progress recital, diminution size, and rise flexibility [3-7].

There are two facets to the delinquent of reactive power compensation: load compensation and voltage support. Load compensation entails of improvement in power factor, corresponding of actual power strained to the source, healthier electrical energy control, etc. of great changing loads. Voltage support includes of reduction of voltage fluctuations at a given fatal of the transmission line. Two types of compensation can be used: series and shunt compensation [11]. These quite reasonably do the job of fascinating or making sensitive power through a sooner period reaction also derived under Bendable AC Transmission Systems.

Received: 02 Feb 2019/Accepted: 03 Mar 2019

1.1 Facts

A Flexible Alternating Current Transmission Scheme (FACTS) is a scheme of immobile apparatus castoff and designed for the AC conduction of electrical energy. It is frequently a power electronics-centred system. FACTS are distinctby means of the IEEE as "a power electronic centred scheme besides an extra immobile device that propose regulator of one or additional AC transmission system constraints to enhance controllability and increase power transmission competency." According to Siemens "FACTS upsurge the dependability of AC lattices besides lessen power delivery costs. In modern years, technological advances in power electronics have simplified the progress of electrical equipments that bid the capability to handle large amounts of power [1] [10-12]. The connection of FACTS campaigns (with serial or parallel connections) in a wind farm substation or in the terminals of wind turbines is collective fast owing mainly to the conditions listed in the transmission system operators' grid codes which require that wind turbines should offer ancillary facilities similar to those of conformist synchronous generators.

Numerous non-linear control systems like VSC based STATCOM controller have been useful in power system control for damping multi- mode oscillations [1]. The act of non-linear controllersis subjective by the parameter ambiguity and external disturbance. The planned controllers can deliver worthy hindering in cooperation confined approach as well as inter-zone mode oscillations. Anadvantage is, these controllers can make availablekey damping to both limited mode and put in the groundpart mode oscillations.Drawback of this scheme is area limitations.There are schemes for the integration of battery energy storage and STATCOM [2] [10].The addition of an energy storage system, such as battery energy storing, hooked on a FACTS device can deliver dynamic decentralized active power capabilities and abundant desired litheness for justifying spread level power flow problems. Anadvantage is, it reduces firm state voltage oscillation. Diminishes the inverse power flow. On behalf of hindering of squat rate of recurrence scheme oscillations, there is regulator scheme for full-scale conversion centred on current of airpower plants [3]. Restraining of low frequency power fluctuations is oneof indispensiblecharacteristics of keeping power system stability. Inliterature, it can be found periodicals on damping capability ofextra fed induction generator created wind turbines.The benefit is effective damping controller plan.Including feedback signal variety and regulatorefficacyraises performance.Disadvantage is a massive setup.Energy storage type STATCOM is available for power system stability improvement [4].The energy storing in the STATCOM is aforward-thinkingmalleable BC transmission schemeexpedient, which controls both reactive and active power injection/captivationto the power system. An advantage is innovative flexible ac transmission system device. Control equally reactive and active power injection immersion to the power systems.

Disadvantage of the system is multifaceted computation. Low frequency oscillation suppression in greater part of power system is also carried out by FACTS/ESS [5]. Squatrate of recurrence by its oscillations in the consistentpower schemes are pragmaticaltogetherfor the universe. An advantage is energy storing devices can be castoff and intended to power scheme Squat rate of recurrence by its oscillations due to hindering. Achieve higher efficiency in the system. Disadvantages are, a generator with different directing trend is to be handled differently [8]. Relating the three sinusoidal voltage waveforms with the triangular voltage waveform, the three phase converter voltages can be found [6] [9].

The essential frequency of the converter voltage i.e. f1, modulation frequency, is resolute by the frequency of the regulator voltages, where the converter switching frequency is unwavering by the frequency of the triangular voltage i.e. fs, carrier frequency. Thus, the modulating frequency f1 is alike to the supply frequency in STATCOM. The damping in inter-area oscillations in power systems can be done by STATCOM [7] [9-10]. Rotor of the engine behaves as rigid frames and oscillating energy will be interchange between the machines over transmission line. Native mode oscillations consuming frequency ranges from .7 HZ to 2HZ and these phenomena is related with a single generator or generator plant. Inter mode fluctuationsfrequency ranges from .1 HZ to 8 HZ .An advantage is Modifiable active power movement complete the networks. Drawback are better damping is still needed to well regulation.

II. Proposed System

2.1 Block Diagram

This scheme consists of two dissimilar voltage sources. Then each cause is connected in the transmission lines complete a bus connection. Then STATCOM is allied in the bus segment of the broadcast lines, grounded on feedback mechanism it approximations the influence oscillations in the transmission intermediate.

Received: 02 Feb 2019/Accepted: 03 Mar 2019

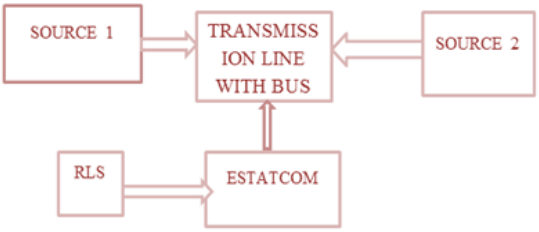

Figure 2.1: Block Diagram

Power flow equation in STATCOM,

$$S = \frac{3V_S V_C}{X_L} Sin\alpha - j3\left[\frac{V_S V_C}{X_L} Cos\alpha - \frac{V_S^2}{X_L}\right] = P - jQ$$

Q is the reactive powerflow,

$$Q = \frac{V_S}{X_L}(V_C - V_S)$$

2.2 RLS

The aim of the algorithm is to approximate the signal module that entails the low frequency oscillation. Evaluate the frequency phase of the contribution signal. Compared with the position signal and finds the variation. Change the frequency, phase of the input signal based upon the fault. Processes are repeat eduntil input signal is inexact equal to the reference signal [5]. Finally, we get the power oscillation damped signal.

2.3 E-STATCOM

The scheme has E-STATCOM, which is connected in the transmission track and the oscillations are condensed. Regulator approach aimed to the E-STATCOM used when Power oscillation occurs. For this, aadapted recursive (RLS)-centered approximation algorithm as predefined in addition it is castoff to abstract the essential regulator indications on or after nearby restrained signal.

III. System Modelling for Controller Design

An easy power system method is showed which is castoff to revise the effect of the E-STATCOM happening in the power scheme underlying forces. The transmission system entails of two transformers considered by their correspondent leakage reactance and a transmission trackby way ofcorresponding reactance. The cutting-edge damages in the transmission scheme are present abandoned for simpler under covert erminologies.

Figure 3.1: Simplified Two-Machine Scheme with E-STATCOM

3.1 Two Machine Scheme Model

The active power generated to the real power, which is used to effort, the electrical signals. Minimizing the effect of reactive power compensation when the power generation variations occur from the generator, the reactive power is unsatisfactory in the transmission lines.This leads to the power oscillation. In order to evade damping, by consuming RLS Algorithm and dropping of power oscillation [9-12].

Received: 02 Feb 2019/Accepted: 03 Mar 2019

When scheming a cascaded controller, the quickness of outer control loop is typically carefully chosen to be ample deliberate than the innermost to guarantee stability. The level of power oscillation damping as long as by the converter hang on how considerable the dynamic power productivity starting to the producers is tempered by means of added current. Doubtfully, the mechanical hindering in the producers is present injured, damping for the inspected scheme is identical to nil.

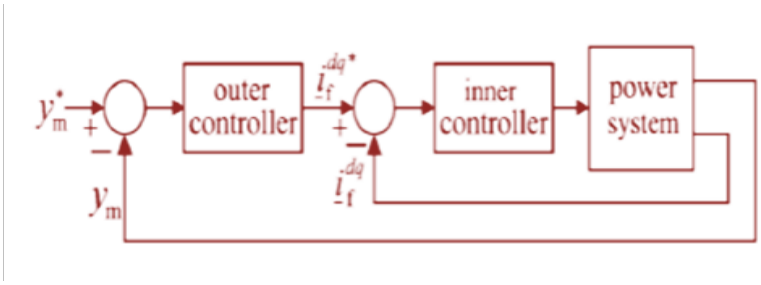

Fig. 3.2: Control scheme

The block diagram consist of

1. Outer controller
2. Inner controller
3. Power system

3.2 Outer Regulator

The external regulator hoop, which would be POD regulator or dc-link voltage, an AC voltage, circles the position current aimed at the inner current regulator [10]. The regulator procedure is applied in d_q-reference mount wherever a phase-locked hoop is castoff to path the lattice power angle starting the lattice voltage trajectory.

3.3 Inner Controller

In inner control loop, the active and reactive powers in the stable state are zero. When scheming cascaded controller, the speed of external control loop is classically selected to be must slower than the inner one to assertion stability. Therefore, the E-STATCOM should be unveiled such as a precise ultimate current source [12].

The near of control oscillation damping on condition that the converter be subject to on, the dynamic power output beginning the producers is cramped by the injected current. The change in active control output after the producer sowing to inserted dynamic besides sensitive power commencing the E-STATCOM.

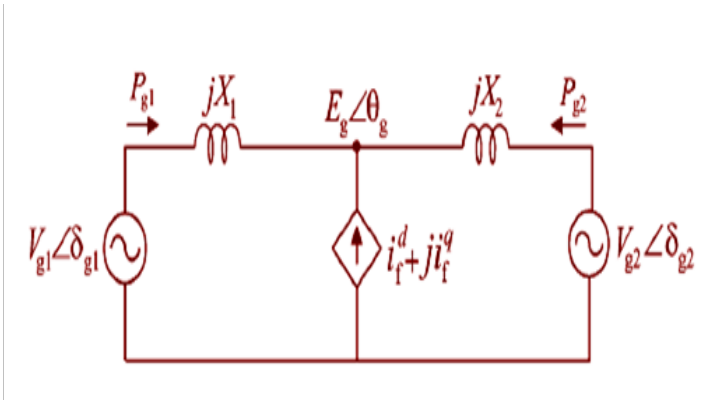

Figure 3.4: Equivalent Circuits for Two-Machine Scheme with

E-STATCOM

Inductors (reactors) are understood to store or absorb reactive power, since they store energy in the form of a magnetic field. Capacitors are said to create reactive power, because they store energy in the form of an electric field. The impedance of transmission outlines and the need for covering VAR by most machines in a generating system, out comes the ingesting of reactive power, thus distressing the stability bounds of the system as well as transmission lines [12].

Received: 02 Feb 2019/Accepted: 03 Mar 2019

3.4 Distribution system

An electric power distribution scheme is the vital stage in the delivery of electric power; it transmits electricity from the transmission scheme to person consumers. Delivery substations connect to the transmission system and lower the transmission voltage to medium voltage extending between 2 kV and 35 kV with the use of transformers. Customers severe a much higherquantity of power may be accompanying directly to the prime distribution level or the subtransmission level [9].

Power factors less than 1.0 necessitate an effectiveness to create much higher than the least volt-amperes compulsory to supply the real power (watts). This increases generation and transmission costs. For instance, uncertainty the capacity power factor be there as squat as 0.7, the seeming power will be 1.4 epochs the actual power castoffby dint of the load. Track current in the circuit moreoverbe there 1.4 epochs thus the current mandatory at 1.0 power factor, consequently the damages in the circuit would be creased (since they are proportional to the square of the current) [11].

IV. Pod Controller Design

4.1 Derivation of Control Input Signals

By means of shortened two-machine system, the dynamic power output after every initiator would alter in amount to the variation in its rapidity to deliver hindering. Commencing a minor-indication fact of assessment in addition to below the declaration that the PCC-voltage scale end to end the track were not take alteration knowingly, the mandatory controller input indicators could be resulting after the PCC-voltage phase as well as transmitted dynamic power.

The PCC-voltage phase has derivative and taken dynamic power exist both reliant that scheduled the rapidity variation of the producers. In addition, the derived of the PCC-voltage phaseis influenced byon the position of E-STATCOM, through the restriction, as well as the mechanical dynamics of the generators [11] [12]. Supercilious equivalent inertia continuous for the two producers, not at all hindering is on situation that by injection of active control by the electrical centre of the track such as the control yield of the two producers might be same then the net impact is zero.

4.2 Alteration of Orthodox RLS Algorithm

The collection of is a trade-off between a good discernment for the estimator and its speed of retort. By cumulative assessment speediness, the rate of recurrence discrimination of the procedure diminishes. Intended to this motive, the orthodox RLS algorithm need to be enhanced in orderto accomplish fast transient estimation [10]. Thus, a frequency reworking mechanismis executed to path the spot-onoscillation frequency of the input from the calculation of the oscillatory section.

4.3 Modification for Multiple Oscillation Modes

The inspected control process has been resulting underneath postulation of a particular oscillation frequency factor in the input signal. Thus, the POD controller can be changed accordingly to control each mode self-reliantly.

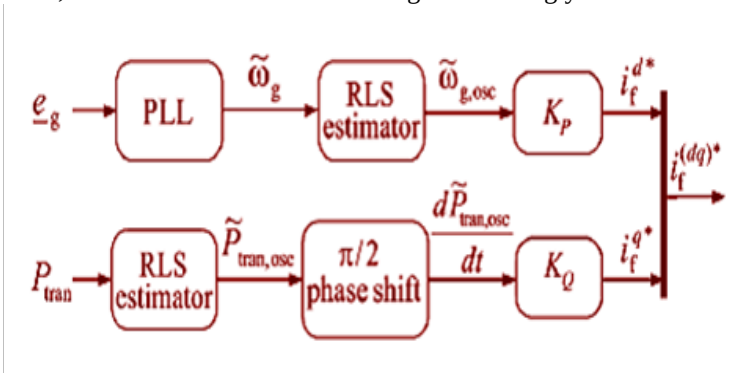

Fig.3.5: POD Regulator-Block Diagram

The POD controller described is confirmed via PSCAD/EMTDC simulation by means of the fine recognized four-machine, two-area scheme. The realized system is rated 20/230 kV, 900 MVA besides the parameters for the generators then transmission system collected with the loading of the system are given in detail [12].

Received: 02 Feb 2019/Accepted: 03 Mar 2019

A three-phase error is useful to the scheme in which one of the transmission tracks bordered by bus 7 then bus 8. The error is vacant later 120ms by separating the criticized track. With the POD controller erection describes the routine of the E-STATCOM succeeding the error by three dissimilar locations.

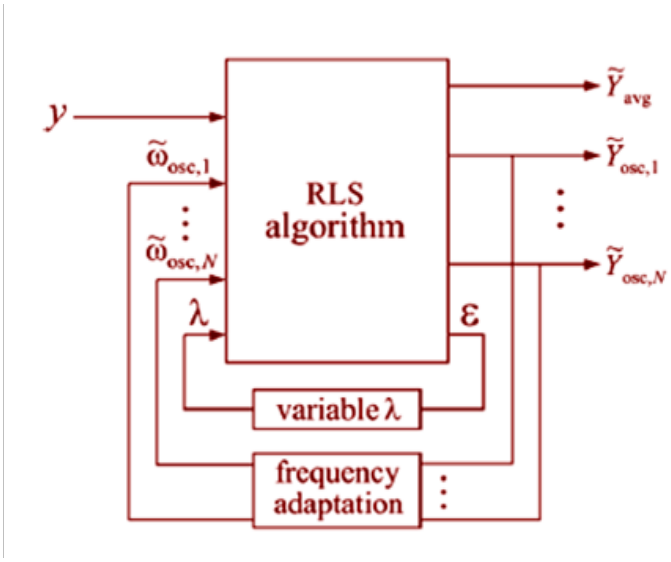

Fig 3.6: Modified RLS Estimator for Multiple Oscillation Modes- Block Diagram

4.4 Proportional & Integral Controllers

PI regulator will eliminate forced oscillations as well as stable state fault subsequent to process of on-off regulator thus to P controller correspondingly. Thus, PI regulator will not increase the speed of response. PI controllers are very often used in industry, expressly when speediness of the rejoinder is not aproblem. A control without D mode is used when:

a. Firm response of the scheme is not essential
b. Large instabilities and noise are existing during process
c. Is only one energy stowing in process (capacitive or inductive)
d. There are huge transport delays in the system

4.5 Adaptive PI Controller

Even though conventional PI/PID (proportional integral/comparative integral derivative) regulators must remained further most usually cast off in HVAC schemes, it takes now and then, being hard to recompense entirely aimed at load commotion besides to retain exact variables near to normal point standards surrounded by the arranged variety. In order to get good regulator possessions, nearby around three communal approaches for modifying the PI/PID regulator in HVAC schemes: physical, self-tuning also adaptive regulator methodologies.

Personality-tuning method of an essential only organizer for thermal load disturbances, most HVAC systems have period changing active appearances in system's limitations are flexible throughout the procedure, so it stays not necessary to use a self-tuning controller [11] [12].

4.6 Constancy Investigation of System Model

To observe the concert of the POD regulator aprecise model of the structure is unconventionally is castoff by expending dynamic in addition to sensitive power accumulation. At the mass-scaled electrical usual of the contour wherever the delaying can be as extended as stays nil.

In circumstance of sensitive power inoculation only, an optimistic damping is one if using the fractious connection relations besides an extreme hindering exists at the electrical intermediate of the contour (i.e., for a balanced system) somewhere scale is supreme. The E-STATCOM program of the poles for the system as a purpose of the setting is shown trendy output [1] [5].With this defined controller policy, injected active power is zero at the fact where the consequence of active power inoculation arranged in hindering is nil. This is atthe electrical norm of this line.

V. Simulation and Results

MATLAB is a high-concert linguistic for technical calculating. It mixes calculation, imagining, and software design in an easy-to-use environment where problems and explanations are articulated in accustomed mathematical representation. MATLAB is acollaborative system whose elementary data element is acollection that does not need dimensioning.

VI. Conclusion

An adaptive POD regulator by E-STATCOM has been technologically advanced in this paper. For this, a reformed RLS algorithm is castoff for assessment of the little-frequency electromechanical oscillation works on or

Received: 02 Feb 2019/Accepted: 03 Mar 2019

after nearby measured signals throughout power system conditions. The strength of the endorsed algorithm in contradiction of system factor fluctuates has also been **complete over** through investigational tests. This is an optimum results that custom the existing energy source.

ABSTRACT

The existence of industrial actions and our communal construction depends on low cost and continuous supply of electrical energy. Even the advancement of a country is self-possessed in positions of per capita intake of electrical energy. The same is in the case of trains, the major network of transport in India. This paper emphasis on the design of electrical energy in the supreme advanced technique. In this paper rotational energy is used for the assembly of electricity. When associated to other procedures of energy like solar, fuel cell etc., the rotational energy has extraordinary efficient ways and means for producing electricity. This paper purposes of setting up miniature power stations at the foul points of the railway rail wherever the fuel supply is limited. The prevailing structure of train wheels are operated in the making of electricity over other minor rollers close-fitting to the rail. These minor rollers rotate and this rotational energy can be amplified and transformed. This obtained electrical energy supply that can be used as unrestricted power supply for railway utilities such as water streaming, charging electrical gadgets, LCD display supply for traveler list, train time scheduling, lighting the podium bulbs, fan, signal lights etc. Most crowded cities like Mumbai, Chennai and Delhi etc. in India such scheme can be definitely implemented. The proposal of the corresponding scheme equally at the entrance and departure path in the railway station or when mounted at intersections nearby rural area, can afford electricity free of cost for minor scale actions.

Original Article

INTRODUCTION

An electric power commencing has an additional source of prime energy in the electricity generation and its development. While considering the electrical efficacy, this is the major method that used in the commutation of clients using electricity [1][3]. Thus in further developments transmission, distribution, in addition electrical power storage and its recovery by means of pumped storage methods are approved by electric power industry. Electrical energy is an utmost produced at power station mainly driven by heat engines fuelled by combustion or nuclear fission by using electromechanical generators. This similar action occurs by an extra means which is comparable to kinetic energy of flowing water and wind [2]. Mainly the energy sources comprise of geothermal power as well as solar photovoltaic.

The main factor of generation of electricity has followed by several methods but depend on the demand and utility it deserves. The region where the generation of the system implemented also has an importance. There

were lots of power plant like hydro electrical, thermal, tidal, nuclear and even based on the renewable sources [4]. Each of these power plants have its own pros and cons. Most of the power plants got developed due to the demand of the energy within source duration. So nowadays power grids ought to change the load on the requirement, but each selection of the base load by the day- to-day minimum usage of power. This affects an interrupted running of the power plant [3][4].

The Indian Railways are the major network of transport, the large quantity in the number of trains; therefore the amount of wheel power that gained in this arrangement is huge. India is a nation by major largest transport system, that i.e.; the trains reach each corner of the nation but have not electricity. Around thousands of villages are immobile of lacking electricity [5]. Likewise Indian Railways merely get well around 57% of cost of travel on a normal.

LITERATURE REVIEW

Indian Railway is one of the prime transportation that brings the revenue to the country. Moreover it is the public transport system that used by all people without considering the financial backup. Considering to any other transport system the train journey provide a feasible amount to pay. This all comes under the control of Ministry of Railways [1][6]. Rather than any other modes of transportation Indian Railway connected to 29 states in India and 7 union territories with around 40,000 miles or 64,373.76 kilometers as per 2014 world census Indian Railways is the fourth major railway in the universe which is carrying around 8435 million commuters. In India, railways are a rebellion in relations of provided an occupation, regular commutation of commuters and carriage of goods and chattels through the length and breadth of the country. Railways have progressed from a period of steam engines to electrically activated engines/ trains [7][8]. The wind energy, solar energy and mechanical energy can be transformed to electrical energy by means of train and podiums as a medium; in a method not supposed by anyone earlier.

STUDY OF EXISTING SYSTEM

Electric railways custom electric engines to drag commuters or goods in distinct cars for electric manifold entities for the customer with their private vehicles. Generation of electricity is usually in huge and compared to any other modes of generating electricity has effectual generating stations and thus it gets transmitted to the railway and further distributed in trains [2] [9]. Nowadays certain electric train has its own generating stations near to the railway station and commonly called as substation with certain voltage rating which usually provides its own distribution lines, switches and transformers. These substations transmit for the electric utility. The railway electrification scheme delivers electric power to railway trains and trams deprived of an involved major mover or limited fuel supply [10]. Dissimilar systems are custom for city and direct zones; certain electric trains can change to diverse supply voltages to consent tractability in the process. Power is delivered to moving trains through a (nearly) constant conductor running sideways of the rail that typically earn one of two arrangements.

In cooperation with overhead wire and third-rail schemes regularly custom the consecutive rails as the reoccurrence conductor however certain arrangements custom an isolated fourth rail for this drive [11]-[13]. Various electric traction schemes offer regenerative braking that tries to change the train’s kinetic energy return into electricity in addition return it to the source system. This is to be cast off using supplementary trains or the complete efficacy of grid [12]. Although diesel locomotives use petroleum, thus electricity is produced commencing miscellaneous sources with numerous amount of carbon dioxide such as nuclear power besides renewable forms for counting wind, geothermal, hydroelectric plus solar [10].

The production of electricity in 2012 there 25,353TWh. Foundations of electricity be present are fossil fuels 68%, renewable energy 18% (mostly hydroelectric, wind, solar as well as biomass), besides nuclear power 12% also supplementary sources remained 4% [2][11]. The mainstream of fossil fuel custom intended for the production of electricity with coal plus gas. Oil stayed 7% as it is the furthermost exclusive communal product that used to yield electrical energy. 95% of renewable energy is there in hydroelectric who trailed by wind at 7% besides geothermal at 2.32%. Solar photovoltaic were 0.89% also solar thermal were 0.008%. Overall energy expended at entire power plants aimed to the production of electricity be there 4,469,768 ktoe (kilo ton of oil equivalent) which has 38% of the aggregate of prime energy sources (TPES) in 2012. Gross electricity amount produced were 1,867,539 ktoe (21,185 TWh), along with efficiency were 41.23%, and in addition to the remaining of 64% were produced heat. A negligible amount (148,251 ktoe, which were 5.5% of the entire input) of the high temperature were employed at coproduction of heat and power plants. The more intake of electricity besides power transmission damages were 290,359 ktoe. The quantities delivered to the ultimate user were 1,445,285 ktoe (15,630 TWh) which stood 34% of the whole energy paid at power plants also high temperature and power co-production (CHP) plants [1]-[9]. Nearly entire electrical power on World is produced by rotational energy by means of water, turbine, compelled by wind, steam or burning gas. The turbine energies an initiating power. Around there were countless dissimilar approaches of emerging mechanical energy, together with heat engines, hydro, wind then tidal power [3].

Meanwhile the Indian Railways has devoted to electrification of traction, it is significant to deliberate the features of effectiveness also carbon discharge, even though it sourcing the power. The conservative technique of sketch power since the dominant grid is wasteful and carbon concentrated. A change to distributed production at several facts resolve not merely to increase the effectiveness and worth of power distributed, on the other hand it drive to diminish the carbon footprint in Indian Railways. 25 kV Single Phase is the greatest favored one and collectively the recognized voltage norm for the overhead traction scheme. To rise overhead voltage. 2×25 kV arrangement is established so that at motor vehicle level, the voltage leftover up to 25 kV [7][8]. Certain Railways need desired system for 50 kV then again the similar is inadequate to heavyweight haul committed the rail structure in which the train likewise it leftover and restricted in that zone. This traction system has no many suppliers.

SYSTEM DESCRIPTION AND WORKING

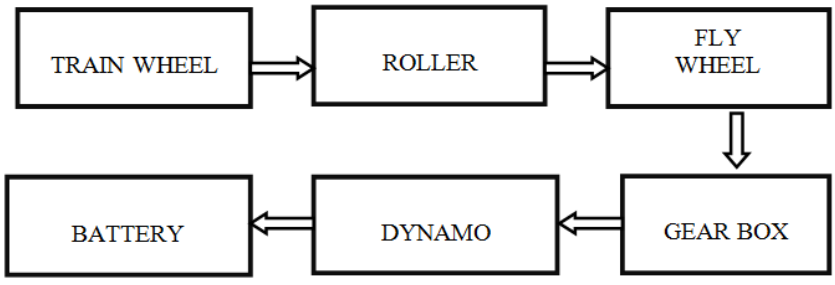

Figure 1: Block Diagram

The energy retained in the train can't be completely enhanced by regenerative braking. This scheme can be effortlessly assumed from the specified block diagram. Overall (Indian railway) while arriving into the railway station, the speediness of the train (irrespective of the type of service) is detach at FOUL MARK. (It is a mark, which is 1200 m gone from the station – Indian railway rules) [7]. Thus the train will travel merely by its own moment of inertia. The energy kept

in the train cannot be abundantly improved by regenerative braking. To hit that wasteful energy to convert it into electrical energy. The rotational energy is transmitted from the train wheel to the static roller. This static roller develops with a flywheel in direction to sudden shoot in the torque rate. Then the mechanical energy is turn into constant by gearbox and it is served to the generator that causes any changes in the mechanical energy which in turns convert to electrical energy. Thus obtained electrical energy is kept stored in battery. The block diagram describes the complete assessment of the paper. The comprehensive work will consist of several elements to be comprised for the endless storage in addition to stream of electricity supplied.

SIMULATION TOOL

The MATLAB SIMULINK (R2015A-version 7.0.14.739) is castoff for simulating as well as defining the possible output of planned paper with an actual time constrictions somewhere the speed of the running train also the conceivable rotation of the rollers that detailed in the software by designing the elements. The direct current is the prime source aiding the rotation of wheels in trains. The simulation is taking place by placing the block of D.C motor which symbolizes the speed of the train. To show the mutual drive of the train wheels in addition to the static roller in touch through the wheel edge of the train, the micro-turbine should designed consequently. This micro-turbine generates the mandatory mechanical torque used for the induction machine where it is attached with the previous one. Therefore the induction machine rotates by means of a papered speed by means to generate the very nearly continuous current which is yet again set to the charging circuit. This is to make stable input current to aid charge the battery positioned then. Additionally an inverter is engaged to get the output current of an identical and an alternate current system which is at last supplied to the grid of the railway sub-station.

EXISTING SYSTEM

The State Electricity Board (SEB) deliveries 11kV to Railway Substation, after there it is step down to 400V by the Delta-Star, 3-phase transformer. There exist two transformers at the railway substation; one is retained as supplementary one. The railway substation deliveries 230V to required podiums by concerning one phase in addition the neutral to the railway podium. In a directive to evade the whole black-out throughout the time of load shedding, the railways so long as an emergency lighting inverter. The arrangement is described over simulation. The elementary form of the Indian railways power distribution network is illustrated in the simulation block diagram. The recent railway subsystem accepts a voltage of 11KV totally drawn as well as exploited from the State Electricity Board during the day. The simulation output in figure 2 displays the graph demonstrating the state electricity board supply voltage and current. The 100V dc output voltage attained after the simulation of the mechanical arrangement is deposited into a battery and can be extra employed in railway podium. Therefore the output voltage created from the running wheels of the train requirements to be transformed, controlled in addition to synchronize the counterpart of the podium restrictions of voltage. A closed loop boost converter is castoff in the simulation apparatus which is controlled by P controllers of suitable gains. The converter boosts up the dc voltage of around 230 V and the controller safeguards 80% state of control in the battery. PI controller orders the voltage to retain it restricted to the vital value of 230V AC. The controlled output is provide into the grid somewhere from the podium receives the power which can one or the other be taken from the SEB or the proposed arrangement.

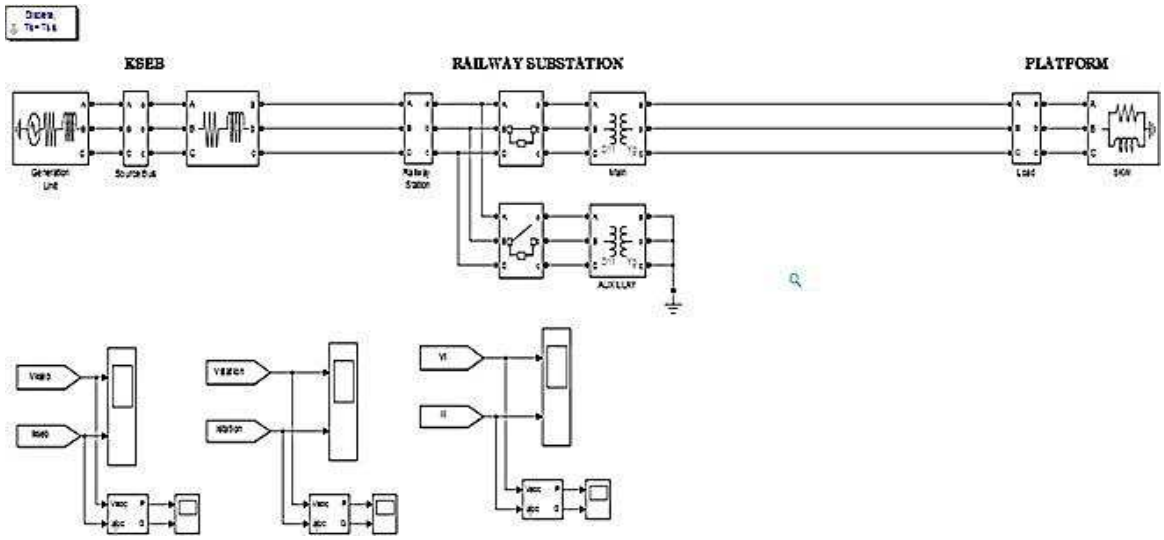

Figure 2: Existing System

MECHANICAL SYSTEM

The mechanical system in this paper is depicted in the simulation by means of elements which comprises of micro-turbine besides flywheel scheming. The output of the micro turbine along with the flywheel is the operative torque produced in the system that is equivalent to the mechanical torque output in the realistic design of the paper [14][15]. The output so found by this setup is once more corrected to portray the dc output that motive which will received from the dynamo in repetition. The output is established to be 100 V.

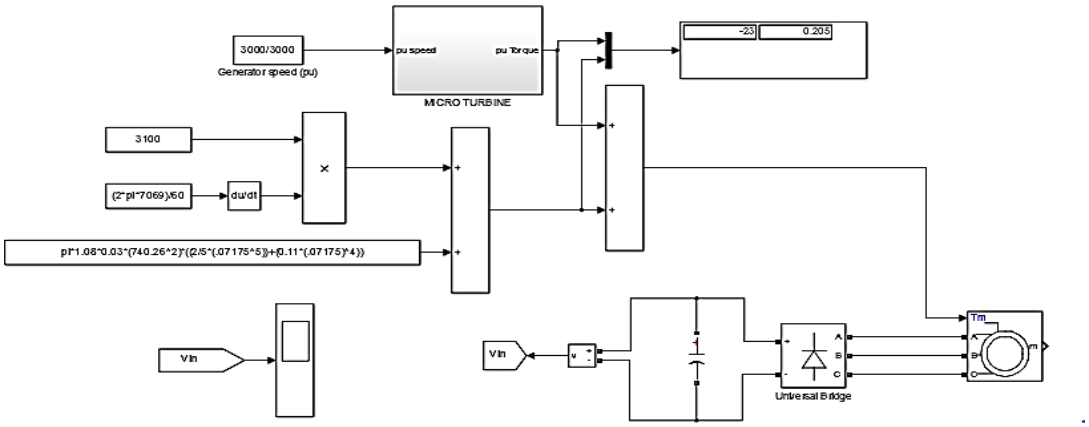

Figure 3: Mechanical System

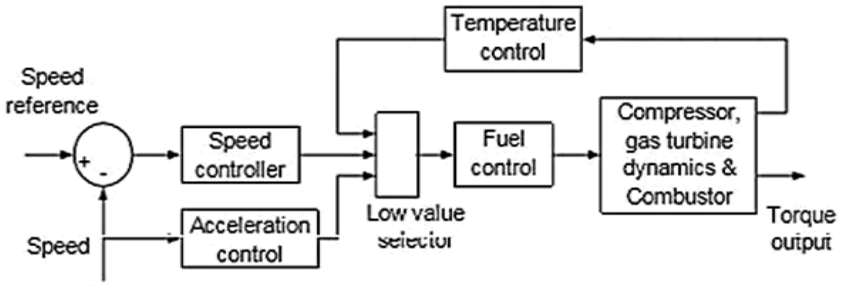

Figure 4: Basic Block Diagram of Micro Turbine

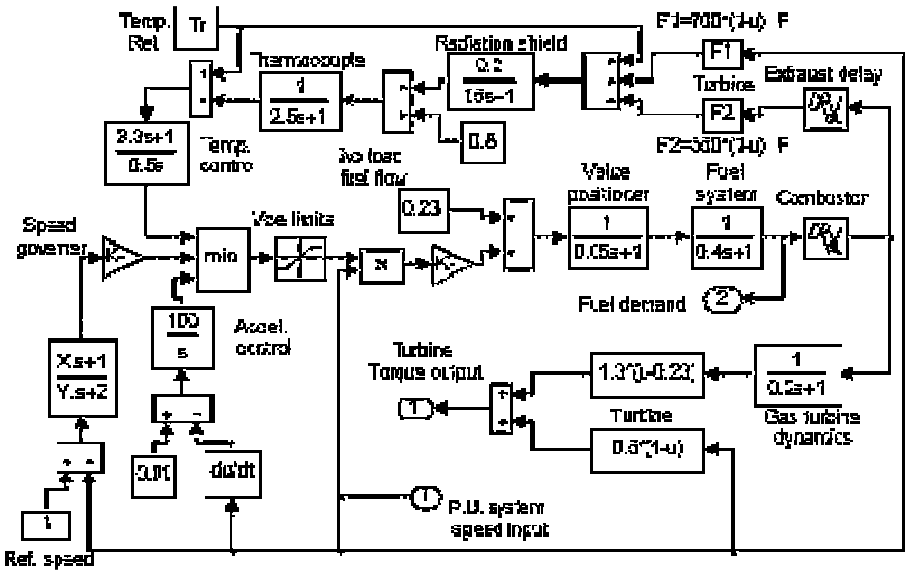

Figure 5: Micro Turbines Simulink Model

It is simply a torque device (AC Induction Motor/generator). The equation that rules the flywheel is simply

$$T = I\omega' + Td \tag{1}$$

Here T is depicted as the shaft torque, while Td is aerodynamic drag torque in the flywheel. Rotational inertia is represented as I in addition to that ω' symbolizes the time derivative of angular velocity, D is the cylindrical by thickness of flywheel, the shear drag coefficient symbolize by CDf , where ρ is the fluid density

$$Design\ Td = \Pi\, \rho\, CDf\, \omega^{4} (2\, r^{4} + Dr^{4}) \tag{2}$$

So here D is the thickness of roller

r is the radius of roller

Roller dia = Height of Rail–Flange Height

= 172mm− 25.5mm

= 143.5mm

Assume, Thickness of roller,

D=(3/4)×Roller dia =.75×143.5mm

= 0.11m

To find Roller speed in rpm, $N1D1 = N2D2$ Where,

$N1$=Wheel speed in rpm,

$D1$=Diameter of wheel

$N2$=Roller speed in rpm

$D2$=diameter of roller

$D1$ =915mm

$N1$= 30kmph = 1109rpm

$D2$=143.5mm

From this we obtain the value of $N2$ = 7069rpm = 53.11mps Inertia I=0.03

$$C_{Df} = \frac{0.455}{(\log(Re)^{2.58})} = 0.03 \quad (3)$$

$$T_d = (\pi * 1.08 \times 0.03 \times (740.2)^2) \times (^2 * (0.07175)^5 + 0.11 * (0.07175)^4) = 0.21Nm \quad (4)$$

ELECTRICAL PART DESIGN

The contribution for boost converter is the output from DC generator/Dynamo. Boost converters are castoff to lift up the magnitude of voltage beginning one level to an additional. Here the output voltage after mechanical part (100V) is boosted to 230V DC [16]. The usefulness in acoustic noise reduction is contingent. For being an united form in the PWM strategy. For error compensation a P controller is also depicted [19].

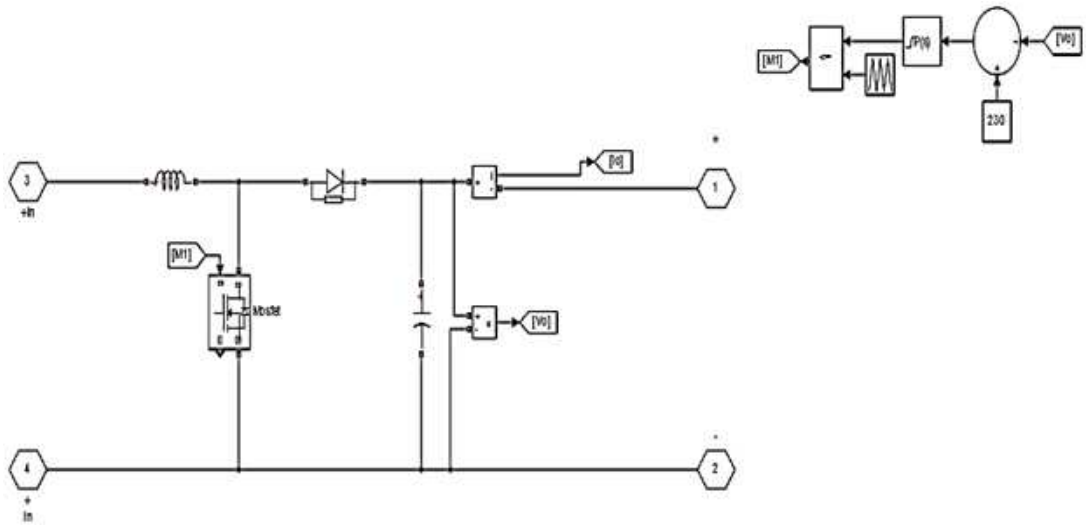

Figure 6: Boost Converter

V_{in}=100V V_o=230V

$D = 1 - Vi/V_0$ =(1-($\frac{100}{230}$))=0.565 (5)

Power output=3000W

$Io = \frac{Po}{Vo}$ (6)

$\frac{300}{230}$=13.04A (Full output current)

Samples F_s = 50 KHz

Inductor selection habitually bounces a series of suggested inductor standards in the data sheets

V_{IN}= nominal used voltage as input

V_{OUT} = desired voltage in the output region

F_s = converters least switching frequency

Ripple current is 20% to 40% of the output current as per estimation for the inductor chosen.

ΔI= ripple current assessed in inductor

$I_{OUT\,(max)}$ = extreme output current used in the application

$$L = \frac{V_{IN} * (V_{OUT} - V_{IN})}{(V_{IN} * (V_{OUT} - V_{IN})} \quad (7)$$

$$\Delta I_l = 0.2 * I_{OUT\,(max)} * \frac{(V_{OUT}}{V_{IN}} \quad (8)$$

$\Delta I_l = (0.2 * 13 * (230/100)) = 5.98$ (9)

$$L = \frac{100 * (230 - 100)}{(5.98 * 50 * 1\,000 * 230)} = 18\ mH \quad (10)$$

- Schottky diodes are used to decrease the losses. The maximum current output is equivalent to the forward current rating. The average rating of Schottky diodes is less but the current rating has a far complex peak [17].

  I_F= average forward current used in the rectifier diode

  V_F = rectifier diodes forward voltage

  $$P_D = I_F * V_F \quad (11)$$

- Existing PWM topologies are used for the good enhancement for the working of the components in simulation, thus it effects the THD minimization and form the deterministic PWM topology [20].

- To custom very low ESR the best method is to decrease the ripple on the output voltage by using capacitors. Generally ceramic capacitors are used for this action if the dielectric material is X5R [17].

- While some of the capacitors charge beyond the suggested limit as per the data sheet that used; the converter will take an exterior compensation however the compensation has to be familiar for the used output capacitance.

  $$Cmin = \frac{I_{OUT\,(max)}}{(fs * \Delta V_{OUT})} \quad (12)$$

  $$\Delta V_{OUT} = \frac{I_{OUT\,(max)}}{(C1 - D) + \left(\frac{\Delta I_L}{2}\right)} \quad (13)$$

  $$\Delta V_{OUT} = \left(\frac{13}{(1 - 0.56)}\right) + \left(\frac{5.98}{2}\right) \quad (14)$$

  $$Cmin = \frac{18.58}{(50 * 2 * 1\,000 * 21.8)} = 4.4\mu F \quad (15)$$

  $R_0 = V_0 / I_0 = 230/13 = 17.65\Omega$ (16)

- In most of the power applications inverters are vibrantly used. Power electronics upgrade to the foremost level for the last two decades.

- According to this inverters that ultimately doing a conversion process which change from DC-AC power [18].

- Thus the system can be further used for the High Voltage DC Transmission (HVDC) that can be generated from the higher voltage DC which is form the single phase AC[22].

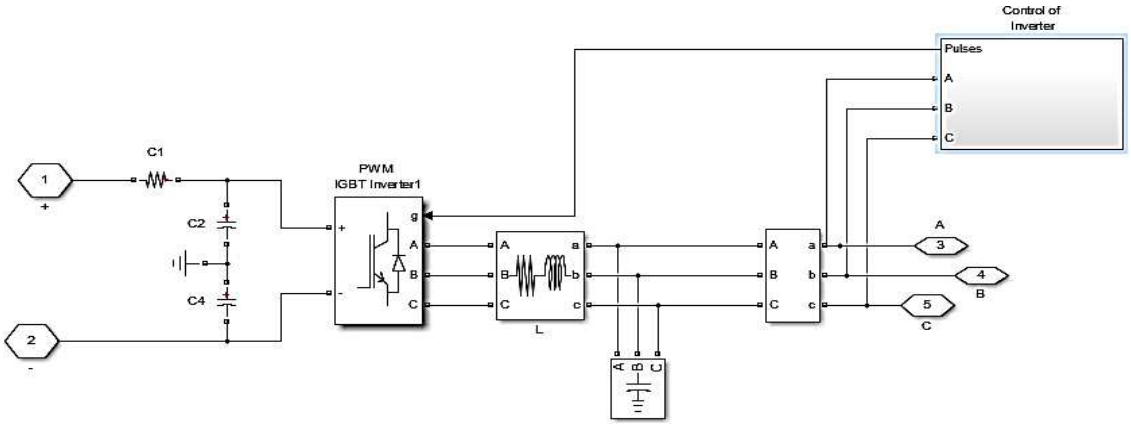

Figure 7: Inverter

In this proposed scheme DC output commencing the boost converter is specified to safekeeping a battery. And it is linked to an inverter. For error compensation a PI controller is presented. In solid state drives with fixed switching frequency, the harmonic power is concentrated in discrete harmonics of the output voltage. The harmonic power is spread as a continuous spectrum in drives with randomly varying switching frequency [22]. Basically an inverter is just a converter which converts DC power to AC power. Most prominently the conversion of DC to AC is taking place in an inverter and Voltage Source Inverters (VSI) are attain. In VSI the fixed voltage from the device is taken (DC supply) and these convert into an AC supply with variable frequency. Using grid voltage the output voltage is synchronized; so that a huge amount of ripple current from the PWM inverter will give to the grid.

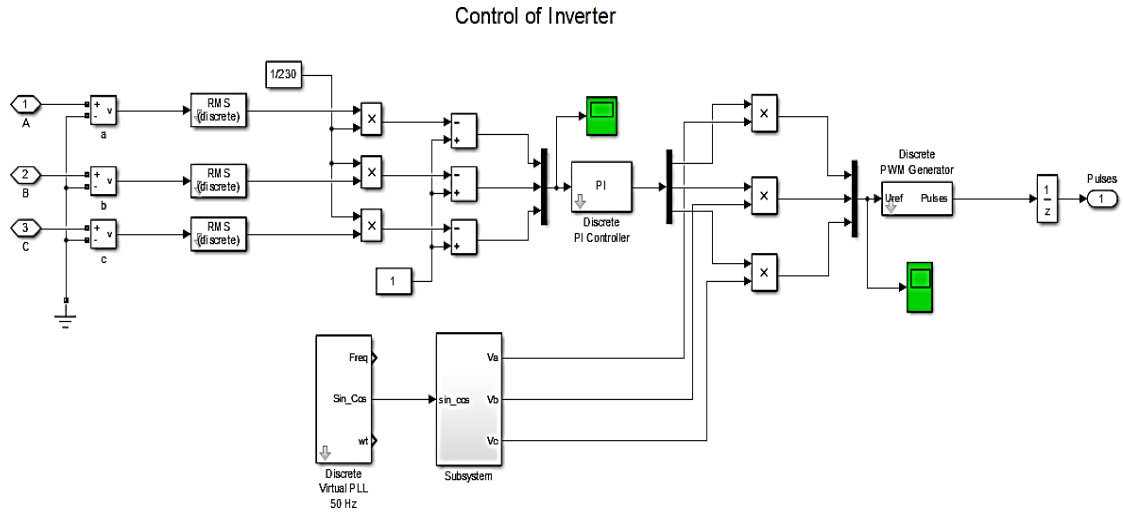

Figure 8: Controlled Inverter

SIMULATION RESULTS

KSEB resolve the source 11KV to the railway substation. In addition to railway locations it is stepped down using a transformer. Current taken from the KSEB is approximately zero. However nearby there happens definite leakage current. Voltage also current waveform in the podium is portrayed. Subsequently in our simulation one railway podium is connected at a period to the railway substation and supplementary podiums are detached through circuit breaker

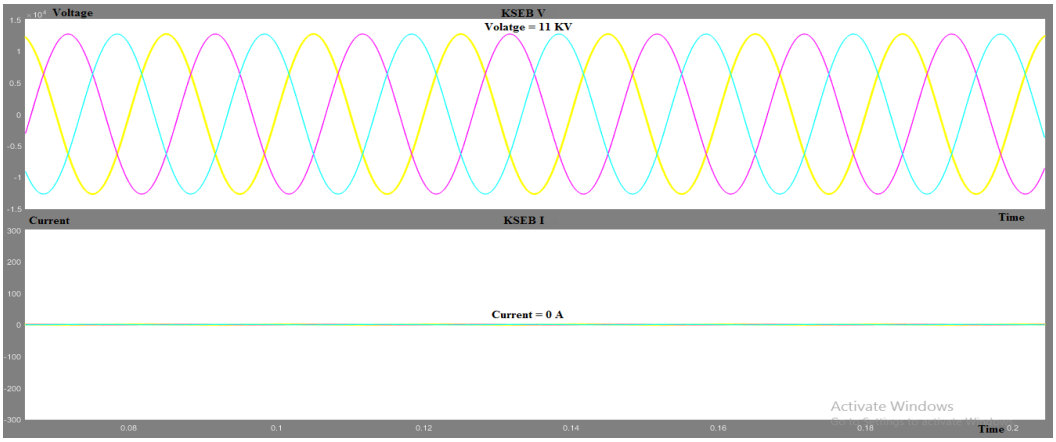

Figure 9: KSEB Supply

For a single phase ac source the dc link voltage fluctuation problem is more serious for an inverter system [21]. The load pulls simply a single phase current. The voltage is 230V in addition Current drawn is 13A.

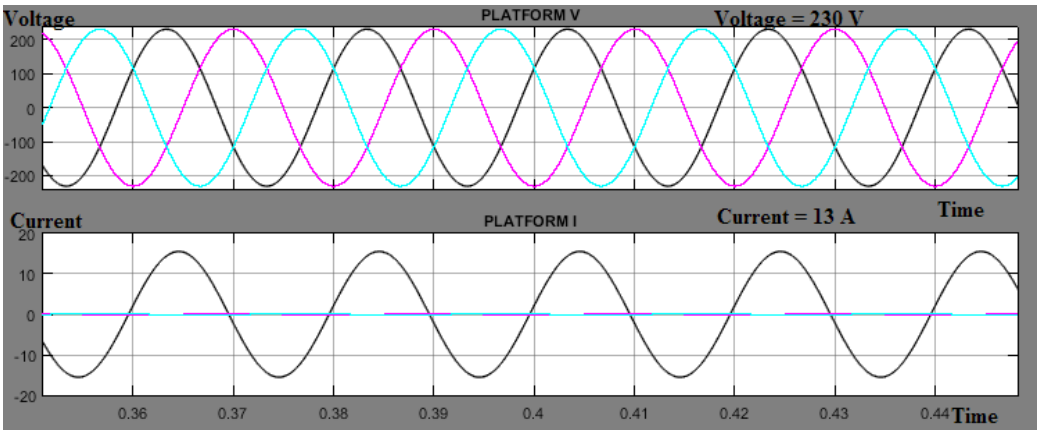

Figure 10: Platform Supply

MECHANICAL OUTPUT

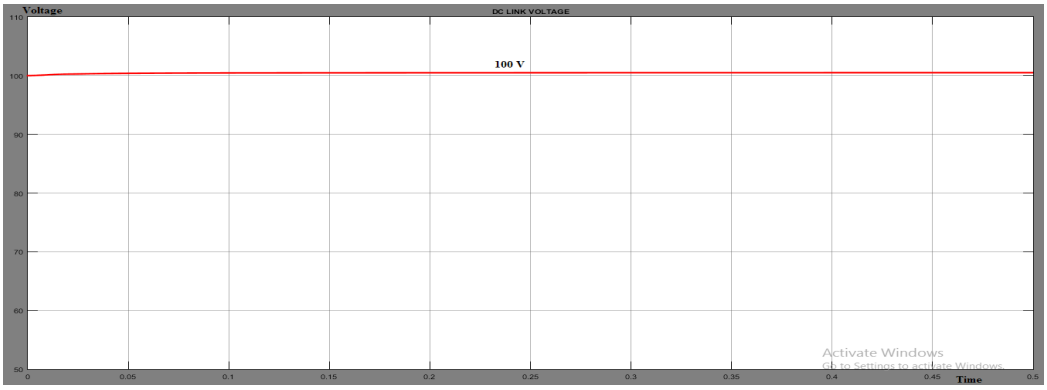

Figure 11: Mechanical Output

From the above Power output at inverter it has been showed that excess current is taken from the inverter portion than State Electricity Board. Since it custom the reactive power pull commencing the proposed scheme is which specifies the power adding to the loads. The voltage at the inverter portion is 230V in addition to Current is 35A.

OUTPUT OF PROPOSED SYSTEM

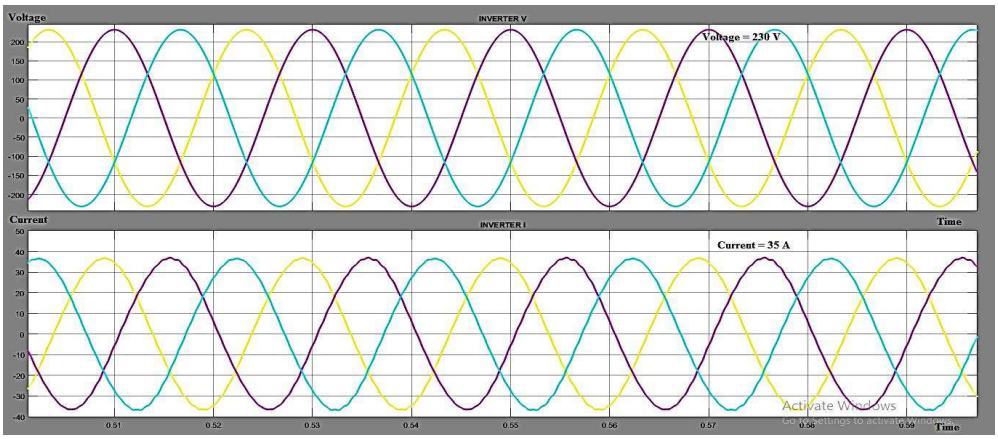

Figure 12: Inverter Voltage and Current

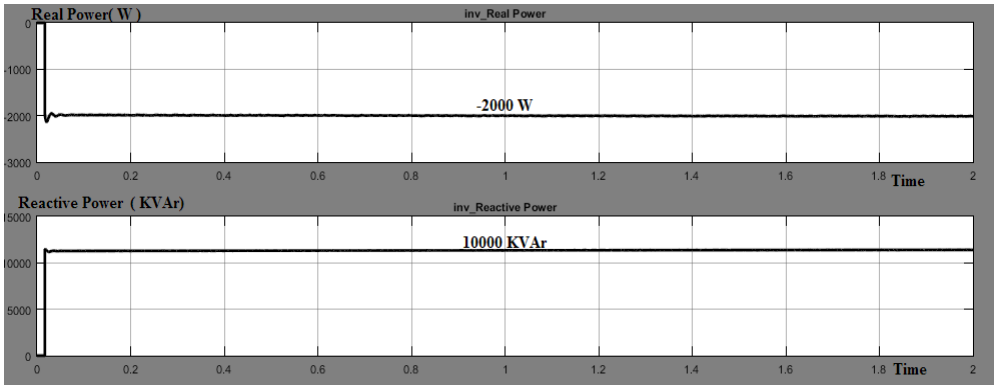

Figure 13: Power Output at Inverter Portion

CONCLUSIONS

In this paper electrical power produced by the train wheels is an extra effective and can be meant for the electrification of the railway station. While comparing to an additional renewable resources like solar energy, fuel cell etc., the rotational energy takes unexpected efficiency of producing electricity. This paper is an emphasis on the novel idea of wheel power that can be put in storage too use modestly. The electrical energy produced by consecutive running wheels of train can be used as an able power source for railway customs such as water stock, to charge cell phones, laptops etc., in the railway podium. The overall expense for this scheme is a smaller amount. So the government of India can effortlessly implement this plan. We expect this technique can be simply accepted in the contemporary era.

Sensor Based Smart Monitoring and Controlling System for Cultivation using Labview

Ch.NarendraKumar, M.Pradeep, N.Rajeswaran, T.SamrajLawrence

Abstract*: Agriculture is the most important back bone of India. Now a day's farmers are reduced because of various problems like water problem, real estate, technology etc. Here our proposed system is to make use of existing technology to improve the farming percentage, gardening and nursery in a smart, effective and accurate method. Our proposed design is an automatic smart monitoring and controlling field system based on IoT which is implemented with NI LabVIEW and NI myRIO interfacing device. NI LabVIEW is a tool for testing, automation, measurement and monitoring system. NI myRIO is an embedded hardware where sensors like Temperature sensor, Moisture sensor, Rain sensor, Humidity sensor, Motor and communication protocols are interfaced with the help of LabVIEW. In this paper, we proposed ground water harvesting though that rain water is stored in the water tank which can be used in future for sprinkling water when soil moisture is less. This proposed design is the best way of economical accuracy and low-cost maintenance system. The concept of IoT in this paper is to monitor the status of the field like water level indicator in the tank, temperature of the field, to know the moisture of the field and detection of rain by using mobile phone or PC or Tab form any part of the world. This research will help the small-scale, mid-scale and high-level forming lands and it will increase the yield percentage and save the agriculture.

***Index Terms*: IoT, NI LabVIEW, NI myRIO, Sensors, Monitoring and controlling system.**

I. INTRODUCTION

In order to make smart field system which helps the farmers for easy farming technique, we used LabVIEW for better programming and accuracy of sensor values [1-2].LabVIEW is a virtual instrument were sensor readings and data's can be monitored and controlled [3]. NI myRIO is an embedded device was we have interfaced all the sensors and myRIO is programmed with LabVIEW. This is the automation process and closed loop system were Moisture sensor, Rain sensor, IR sensor, Temperature sensor and Motor are inter linked with LabVIEW and IOT.

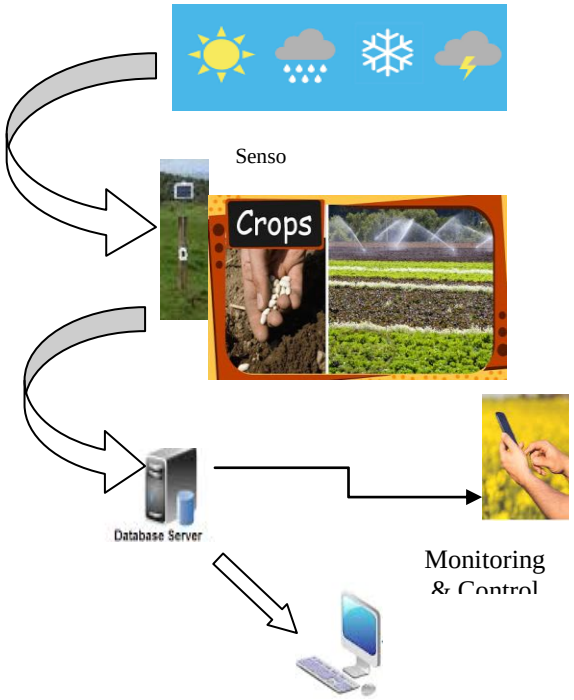

Figure 1: Smart Field System using IoT

In Figure 1 shows the smart filed system integrated with sensors and system. The farmer will get the immediate message from data base server about the weather condition in real time monitoring from remote locations. Based on the information he can able to do the work in the field. This smart field system using IoT reduce the burden of the farmer in weather monitoring and will yield more crops in their fields in better way [4].

II. SENSORS

Thingspeak is clouds sever where you can store you real time data and can be monitored and controlled from any part of the world [5-6]. NI myRIO: NI myRIO is an embedded hardware where sensors like Temperature sensor, Moisture sensor, Rain sensor, Humidity sensor, Motor and communication protocols are interfaced with the help of LabVIEW [7].

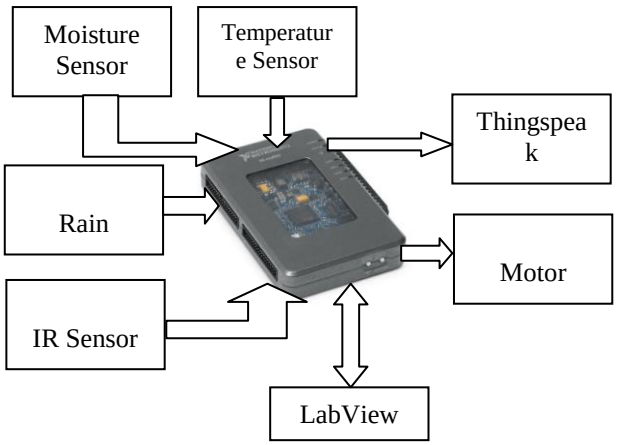

Figure 2 : Block diagram of Interfacing unit

In Figure 3 in our proposal, we used rain sensor to detect weather it is raining or not. If it is raining ground water must be stored in the tank and sprinkler should be off if it is on. Behalf of it we are measuring the rain level and monitored through IoT.

Figure 3: Rain Sensor-HL

In Figure 4, Soil moisture sensor is to detect the moisture of the soil and gives the reading to myRIO. myRIO will send data to cloud.

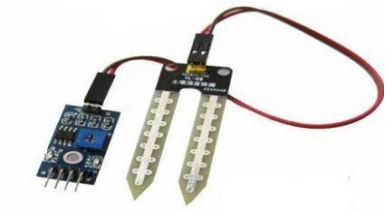

Figure 4: Moisture Sensor-YL69

In Figure 5, our proposal we used IR Sensor to check the tank level. If tank level is less than the threshold value motor is on to fill the water if water reaches the threshold IR sensor will detect and send signal to myRIO to stop the motor.

Figure 5: IR Sensor

The effective distance range 2 ~ 10cm working voltage of 3.3V-5V.The detection range of the sensor can be adjusted by the potentiometer, with little interference, easy to assemble, easy to use features, can be widely used robot obstacle avoidance, obstacle avoidance car assembly line count and black-and-white line tracking and many other occasions.

In Figure 6, the purpose of tank motor is to fill the tank when water level is less than 90%. If it is raining the tank motor will be off.

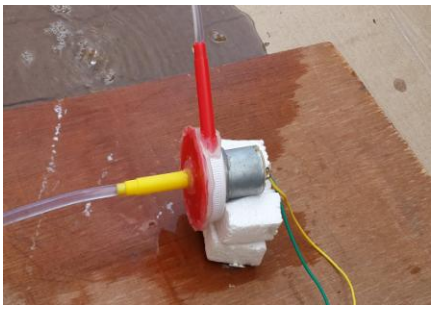

Figure 6: 5v DC Motor

In Figure 7, the purpose of sprinkler is to sprinkle the water automatically when the soil moisture is less than the threshold level.

Figure 7: Sprinkler

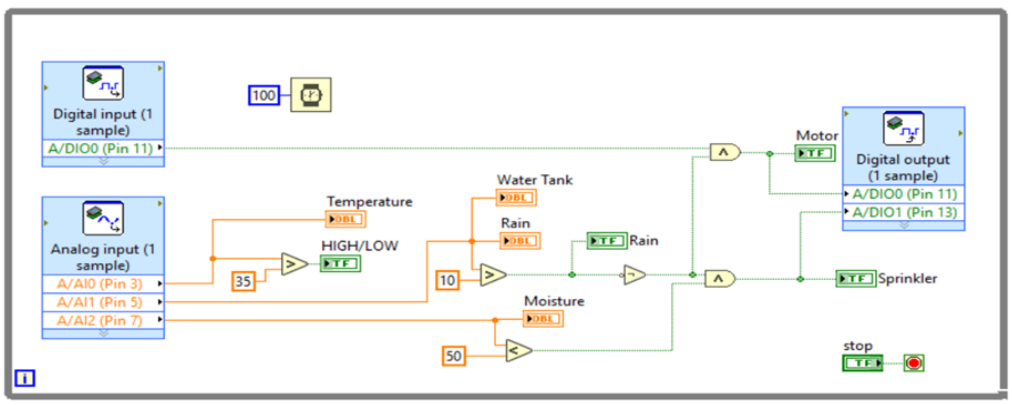

Figure 8: LabVIEW Interface for Proposed Model

I. PROPOSED TECHNIQUE

In Figure: 8 the block diagram of LabVIEW Interface for smart field system is shown. It will give graphical analysis of the rain sensor, temperature sensor and moisture sensor whenever the hardware module of system is connected to software. The motor can also be manually controlled in the Graphical user interface. The status of the motor pump is also shown in the LabVIEW GUI for easy analysis of the moisture and rain sensor module. LabVIEW is a tool which uses Graphical programming language for testing, measuring, monitoring and automation. NI LabVIEW is used to program myRIO to interface sensors [7].

The following steps are the proposed system undergoes.

Step 1: Data Initialization and power supply to interface devices - **START**

Step 2: Read the Temperature(T) range.

Step 3: If T <= Fixed threshold value, the pump in OFF mode i.e, No irrigation in the field.

Step 4: if T > Fixed threshold value, the pump in ON mode i.e, Start irrigation in the field.

Step 5: Read the Moisture (M) level

Step 6: If M > Fixed threshold value, no need to irrigation, the pump will be off.

Step 7 : Read Rain (R) Also if it's raining, repeat step 6.

Step8: : if T > Fixed threshold value, and no rain conditions the pump in ON mode i.e, Start irrigation in the field.

Step 9: Initialization of pump and displaying data on LabVIEW interface and Thingspeak. GUI can also control the motor manually.

Step10: Once the process is completed, it returns back to original state (step3).

Step11: Process **STOP.**

In LabVIEW front panel all the indicators are placed so that farmer can know what is happening in the field through mobile phone. When moisture of the soil is very less the sprinkler motor will automatically starts and prays the water till the moisture of the soil is above threshold point. When there is a rain, the rain sensor will detect the rain and stops the sprinkler motor if it is on and stores the rain water into the water tank through ground water harvesting. IR sensor is used to detect the water level in the water tank, if the water in the tank is less than 90% the motor with automatically on to fill the tank. This project is a feedback system in which all the sensors interfaced with myRIO will communicate with each other and works accordingly. The Table 1 shows the different range of setting used in the LabView module for the simulation.

Table 1: Simulation Parameters

Sl.No	Parameters	Range
1.	Digital Input	0 or 1 Logic
2.	Analog Output	0 to 5 V
3.	Temperature Sensor	0 to 5 V
4.	Rain Sensor	0 to 5 V
5.	Moisture Sensor	0 to 5 V
6.	Water Tank	0 to 5 V
7.	Motor	0 or 1 Logic
8.	Sprinkler	0 or 1 Logic

II. RESULTS & DISCUSSIONS

Table 2 shown the experimental setup connected to myRIO and sensors.

Table 2: Experimental Output

Type of Soil	Time	Dry Condition (V)	Wet Condition (V)	Temperature (C)

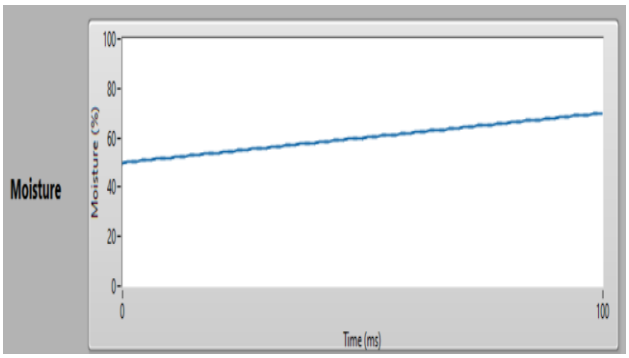

Figure 9: Experimental setup

In Figure 9 graph indicates the soil moisture percentage range with respect to time, when its percentage range is less than 40% the sprinkler will automatically switch on, when the moisture percentage is more than 40% the sprinkler will be automatically switched off.

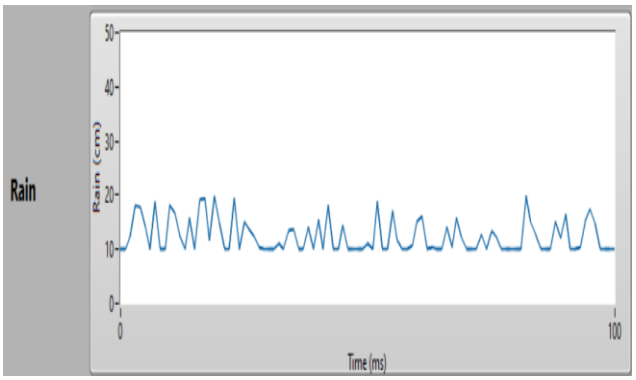

Figure 10: Experimental setup

In Figure 10, graph indicates the detection of rain. When there is rain there will be change in graph or else constant line will be displayed.

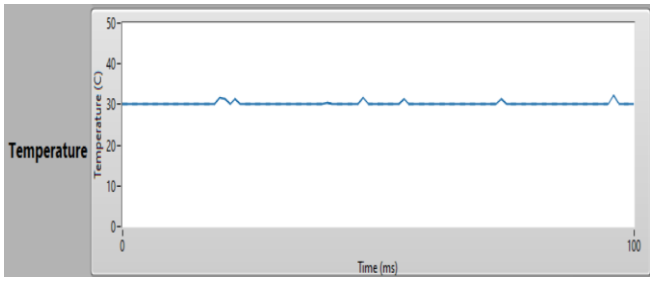

Figure 11: Temperature monitoring

In Figure 11 graph indicates the field temperature. Based on high /low indicator in the front panel the former can do the necessary actions to be performed.

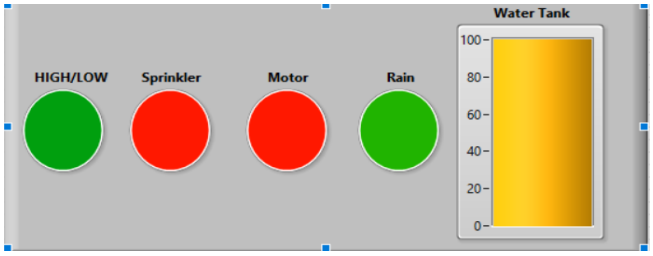

Figure 12: Level of Indicators

In Figure 12, different level of indicators indicates whether temperature is in range or not, sprinkler is on /off, Motor is on /off, is it raining or not and rain water and motor water will be stored in water tank.

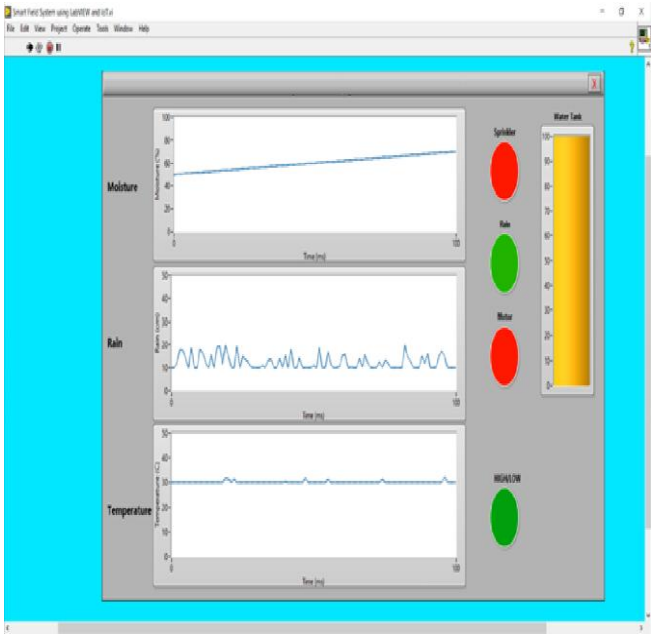

Figure 13: Monitoring and Controlling system

In Figure.13 the front panel screen which is displayed to farmer in mobile phone through cloud. Based on this the farmer can do agriculture from home are from office. This is the reason making this forming as smart field system.

III. CONCLUSION

This concept is a similar design technique of monitoring and controlling the farming parameters using LabVIEW. Providing valuable tools that need to build any measurement or control application graphically in less time, LabVIEW is the unique development tool for innovation, discovery and accelerated solution for human problems. We have combined the power of LabVIEW software with reconfigurable hardware myRIO to overcome the ever - increasing complexity involved in providing measurement and control systems on right time and less cost. The rain sensor is very important to avoid unnecessary power wastage by motor as well as saving the water. Moisture measuring is critical in agriculture to help farmers manipulate their irrigation process more successfully. This paper will help the farmers to use less water to grow a crop though increase growth in yields. Embedded system for computerized irrigation of agriculture gives a real-time solution to assist web page- precise irrigation control which permits farmers to increase their productivity and develop the nation.

AUTHORS PROFILE

Mr. Ch. Narendra Kumar has completed B.Tech in Electrical and Electronics Engineering from Jawaharlal Nehru Technological University Hyderabad in 2002 and M.Tech in Power Electronics and Drives from Bharath Institute of Higher Education and Research, Chennai in 2008. Currently, he is working as Associate Professor at Electrical and Electronics Engineering Department, Malla Reddy Engineering College (A), Secunderabad. He is a CLAD (Certified LabVIEW Associate Developer) from National Instruments. His research Interests includes Power Electronics, Power Systems and Applications of Electrical Drives.

Dr.M.Pradeep received his B.Tech. in Instrumentation Engineering Branch from V R Siddhartha Engineering College, Vijayawada in 2002, M.Tech. in Communication Engineering from Vellore Institute of Technology, Vellore in 2004 and Ph.D. in Image Processing area from Andhra University,Visakhapatnam in 2018.He started his teaching career as Assistant Professor in Electronics& Communication Engineering Department, Shri Vishnu Engineering College for Women(A), Bhimavaram in the year 2005. Later he promoted as Associate Professor in 2010. He has about more than 25 publications in various International, National Conferences/Journals. His areas of interests are Image Processing, Embedded systems. He is a member of professional bodies like IETE, ISTE& MIE (India).

Dr.N.Rajeswaran is presently working as Professor in Electrical and Electronics Engineering at Malla Reddy Engineering College (Autonomous), Hyderabad. He did his Bachelors in Electrical and Electronics Engineering in Government College of Engineering,
Bargur (Madras University) and also obtained Masters Degree in Applied Electronics from Anna University Chennai, Tamilnadu. He completed doctoral degree from Jawaharlal Nehru Technological University Hyderabad, Telangana, India. He has published more than 35 research papers in various International journals and conferences. His area of research interest includes Electrical Machines, Soft Computing and VLSI Design. He is a life time member of various professional bodies like ISTE, IEI, IAENG and IACSIT.

An Efficient Technique to Remove Gaussian Noise and Improve the Quality of Magnetic Resonance Image

N.Rajeswaran, T.Samraj Lawrence, R.P.Ramkumar, N.Thangadurai

Abstract*: Medical Resonance Imaging (MRI) is very useful in different medical applications for diagnosis the diseases in human body. But the main problem arising in MRI images is presence of various noises. These noises are affecting the originality of the MRI images and producing erroneous results. Here Brain MRI images are used for analysis of noise. Brain images are fractal in nature and especially those images are affected by various noises. In this paper we discussed about the Gaussian noise in brain MRI image. The effect of this noise is reduced by wavelet based thresholding techniques. They are namely Visu shrink, SURE shrink and Bayes shrink. These three methods are applied to the brain MRI images and obtained results are compared by PSNR(Peak signal to Noise ratio), MSE(Mean Square Error),Absolute error, Fractal dimension, IEF(Image Enhancement Factor),Normalized cross correlation and structural content.

***Index Terms*: MRI Images, Gaussian Noise, Wavelet Thresholding, PSNR,MSE, NK, and IEF.**

I. INTRODUCTION

Many researchers are focusing the medical image processing for removal of noises. Because, the noise affected MRI images produced the erroneous result and misleading the user for false observation of diseases. Image restoration technique is used to deal larger part of image processing with or image denoising, denoising the noise affected images plays a major role to diagnose the diseases in a proper manner and to retain the image up to its quality[1-2]. One of the best method suggested many researcher by image denoising and this will helpful for the reduction of noises in MRI images. The different fields this technique applicable and tradeoff between the image features and noise reduction must be taken into account while denoising. Many soft computing techniques are recently used for removal of noises in MRI [3]. MRI (Magnetic Resonance imaging) is used for taking medical images. CT (Computed Tomography) and Ultrasound imaging techniques are also used in medical images. Among these MRI sounds better in giving high resolution images of the soft tissues in human body. Human brain is the soft and most complex organ of human body. An image of human brain consists of several complex patterns that are independent of scales. Thus brain image is a self similar structure and is fractal in nature [4-5]. Salt and pepper noise, Gaussian noise, speckle noise and fractional Brownian motion noise (fBm noise) are also affected the MRI images [6-7].

II. PROPOSED TECHNIQUE

Now days, wavelet transform technique is most popular because of accuracy and classification of images. Here, DWT (Discrete Wavelet Transform) is used [8-9]. Using this technique can represent an image with high resolution. To remove the noise presented in brain MRI images Wavelet denoising technique is proposed in this paper. Also it preserves the image details without considering the frequency content of the image and so it suits well for medical images. In DWT the brain MRI image is considered to be consisting of small functions called wavelets [10]. The three wavelet techniques are explained below,

A. Visu Shrink

Here fixed threshold is applied and is given by the equation,

$$T_u = \sigma_n^2 \sqrt{2 \log N}.$$

Where N is the size of the image and the median absolute deviation of noise σn2 is given by,

$$\sigma_n^2 = \left[\frac{median(HH1(n,m))}{0.6745}\right]^2 \qquad (2)$$

Here n and m are the pixel indices of the sub band HH1 which is obtained by the first level of wavelet decomposition.

Visu shrink considers only the images of size N and the standard deviation of the noise. Visu shrink threshold value increases as the number of pixels in the image increase and as a result, the significant coefficients are killed. Visu shrink minimizes the overall error in the denoised image and produces overly smoothened estimation. This method does not work properly if there are discontinuities in the signal.

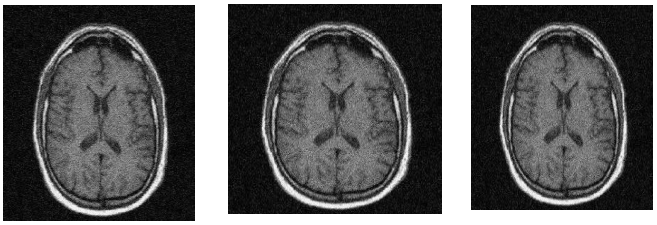
B. SURE Shrink

The combination of universal threshold and the Stein's unbiased risk estimator constitutes SURE shrink. Each sub-band is having separate threshold here. This is best suited to image with sharp discontinuities. This performs well in denoising the image and it has minimum value for mean square error. The threshold function is given by,

$$T_S = \min(T, \sigma_n^2 \sqrt{2 \log N}) \qquad (3)$$

Here T is the value that minimizes the Stein's unbiased risk estimator.

C. Bayes Shrink

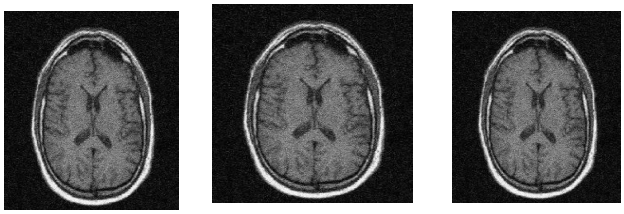


Bayes shrink models the wavelet coefficients with general gaussian distribution. This adapts to both signal and noise characteristics. The threshold is given by the relation,

$$T_B(\sigma_x) = \frac{\sigma_n^2}{\sigma_x} \qquad (4)$$

Here σx denotes the standard deviation of the image in each wavelet sub band.

III. Simulation Results and Discussions



The wavelet based thresholding techniques are implemented by using MATLAB (R20111a) and the simulation results for Visu shrink are given in the Fig. 1. The Fig. 1(a) shows the original image. The Fig. 1(b) shows the noisy image. The Fig. 1(c) shows the denoised image. Here in the noisy image the value of the Hurst parameter is 0.11 (for a classical Brownian motion, the Hurst parameter h=0.13).

(a) (b) (c)

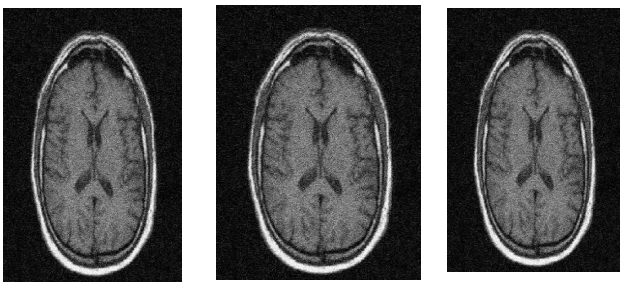


Fig.1. Simulation results for Visu shrink

The simulations results for SURE shrink are given in the Fig. 2. The Fig. 2.(a) shows the original image. The Fig. 2.(b) shows the noisy image. The Fig. 2.(c) shows the denoised image. Here also the noisy image takes the value of 0.11 for H.

(a) (b) (c)

Fig.2. Simulation results for SURE shrink

(a) (b) (c)

Fig. 3.Simulation results for Bayes

The simulation results for Bayes shrink are given in the Fig.3. The Fig.3. (a) shows the original image. The Fig.3.(b) shows the noisy image (with Hurst parameter of 0.11). The Fig.3.(c) shows the denoised image.

The performances of all the three thresholding techniques are listed in the following Table. 1.

Table 1: Comparison of wavelet thresholding techniques

S.No.	Performance Metrics	VISU Shrink	SURE Shrink	BAYES Shrink
1	MSE (Mean Square Error)	0.6465e+02	0.2525e+02	0.1854e-02
2	PSNR (Peak signal to Noise ratio)	30.9852	50.2565	80.0658
3	FD(Fractal Dimension)	1.9844	1.9526	1.9965
4	IEF(Image Enhancement Factor)	1.2365	1.4424	9.000
5	SSIM (Structural Similarity Index)	1.000	0.6556	1.000
6	NK(Normalized Cross correlation)	0.6554	0.9912	0.9932
7	AD(Average Difference)	236	165	46
8	SC (Structural Content)	1.0000	1.0000	1.0000
9	MD(Maximum Difference)	251	228	254
10	NAE(Normalized Absolute Error)	0.6545	0.0563	0.0053
11	Time Elapsed when attempt to denoise	1.2604 sec	8.1924 sec	1.0801 sec

The following figures (Fig. 4 to Fig. 8) show the comparison graph for all the performance metrics for various samples of brain MRI images.

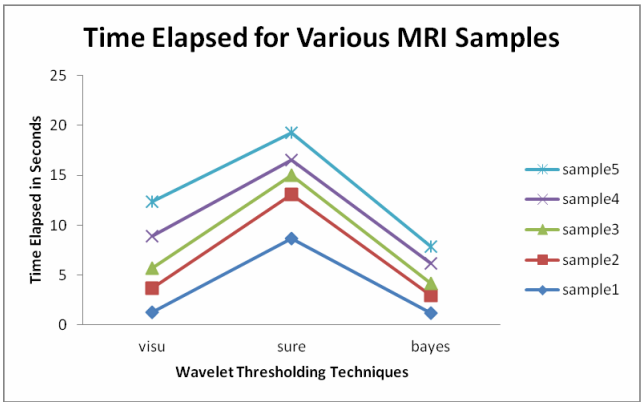

Fig.4. Chart for MSE

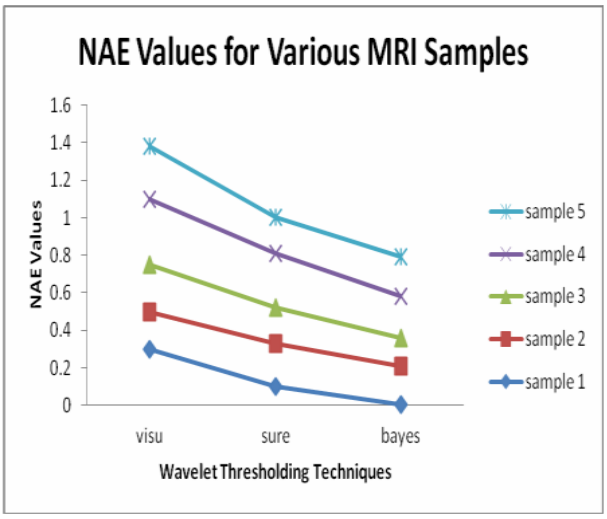

Fig.5. Chart for Normalized Absolute Error-NAE

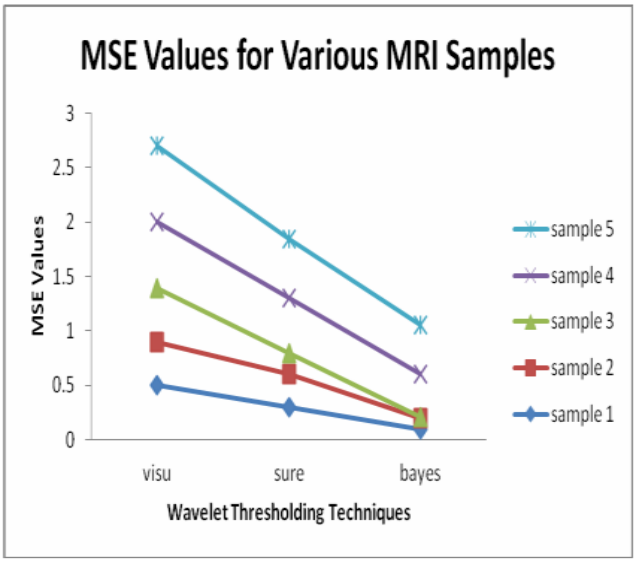

Fig.6. Chart for Cross Correlation-NK

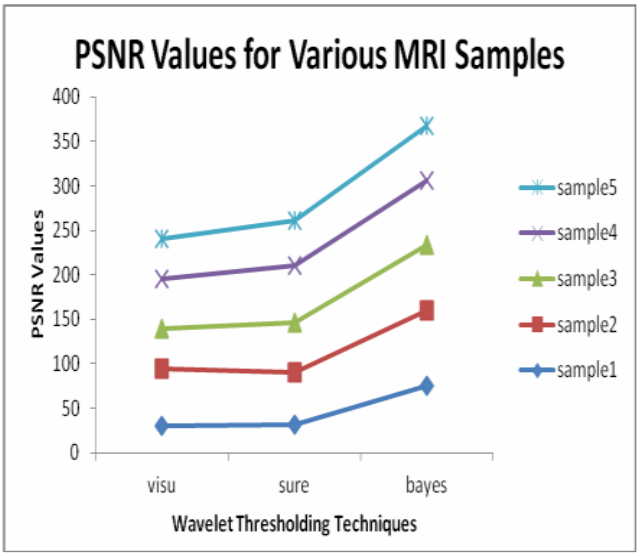

Fig.7. Chart for PSNR

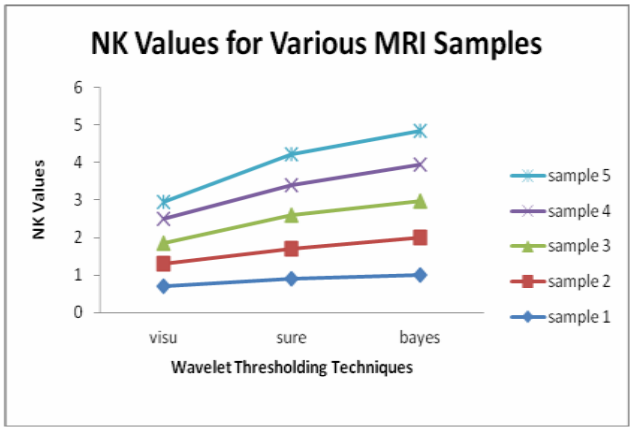

Fig.8. Chart for Time Elapsed to produce denoised image

IV. CONCLUSION

The inference from all these implementations are that Bayes shrink performs better in terms of all performance metrics. It has high PSNR ratio, lowest MSE and lower Normalized Absolute Error. In future this work may extend to analyze and implement by different filters for removing noise in MRI images. The conventional noise removal technique uses only the homomorphic filtering approach. The future scope also aims to propose a new type of filter that best suits to remove the noises and to test the performance of the filters using various evaluation metrics.

Position Tracking of ML System using CSA Based PID Controller

P. Ananthababu, K. Rama Sudha

Abstract*: The classical proportional integral derivative (PID) controllers are still use in various applications in industry. Magnetic levitation (ML) systems are rigidly nonlinear and sometimes unstable systems. Due to inbuilt nonlinearities of ML systems, tracking of position of ML Systems is still difficult. For the tracking purpose of position, PID controller parameters are found by choosing Cuckoo Search Algorithm (CSA) of optimization. The ranges of parameters are customized by z-n method of parameters. Simulation results show the tracking of position of ML systems using conventional and optimized parameters obtained with the CSA based controller.

***Keywords*: Conventional Controllers, Nonlinear Magnetic Levitation System, Optimization algorithms, z-n method**

I. INTRODUCTION

ML is a method to levitate the object in free space against the direction of gravitational force with support of magnetic field [1] [2]. Position tracking of a levitated object becomes more difficult with conventional controllers. Conventional controllers fail in producing perfect performance when the systems are nonlinear and uncertain. Zhenyu Yang et al, [3] designed an automatic Conventional controller using Non-dominated Sorting Genetic Algorithm (NSGA-II) for one dimensional Non-linear Magnetic Levitation system (NMLS). Pallav S K et al, [4] developed a conventional controller for MLS with the derivative filter concept. Marria Hypiusova et al, [5] proposed a robust PID controller to stabilize the NMLS using frequency domain approach. In this approach, the controller chosen does not guarantee stability conditions; if it fails then the controller design has to be repeated. Witchupong W et al, [6] proposed state PI controller to achieve the control over the states of the MLS. Chang-Hyun Kim [7] proposed a robust air-gap controller considering disturbance force produced by magnetic suspension for MLS.

Optimization has gained superior power and influence in many applications like industrial design and engineering. The main objective of optimization is to be maximize or minimize the main function. Hongpo Wang et al, [8] designed a controller using optimizing the control algorithms for the MLS based on the state observer. R. J. Wai et al, [9] proposed a PSO PID controller for transportation system by controlling the ML system. I. Ahmad et al, [10] designed PID controller for MLS based on GA for the parameters of the conventional controller. Literature show, that CSA satisfies the convergence requirements in global when compared with other optimization techniques, so it can guarantee the global convergence properties [11]. Civiciglu, P et al, [12] and Dhivya, M et al, [13] have made an attempt to shown CSA is very efficient for the applications of data fusion and wireless sensor networks and also mentioned the CSA produces more robust results when compared with other algorithm, PSO, ABC etc. In this paper an attempt has been made to control the MLS, by using cuckoo search based PID controller. Section II describes the real time ML system. III Section describes the design of PID controller based on cuckoo search algorithm. IV Section describes performance of cuckoo search based PID controller for position tracking of ML system, and finally section V contains our conclusions.

II. REAL TIME MAGNETIC LEVITATION MODEL

The MLS mainly consists of Levitated steel ball, position IR sensor, controller & actuator. The levitated ball is controlled by current in the primary electrical circuit. The net force acting on the levitated ball is due to the current in the coil and distance y between coil & centre of the steel ball [2]. Fig. 1 shows the experimental setup of MLS.

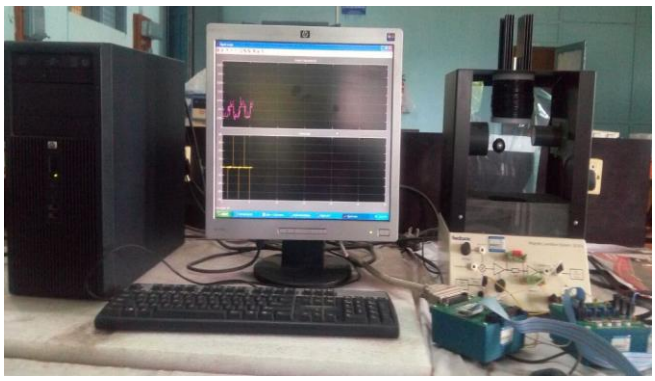

Figure 1 Real time setup of MLS

The non-linear model of ML system, which is expressed in current 'i' in the coil and the position 'y' of the levitated object as

$$m\ddot{y} = mg - K\frac{i^2}{y^2} \quad \ldots (1)$$

Revised Manuscript Received on September 05, 2019.

K. Rama Sudha, Department of Electrical Engineering, Andhra University College of Engineering (A), Andhra University, Visakhapatnam-530003, India. Email: arsudhaa@gmail.com

Where K is the constant, depends on parameters of the coil, m mass of the levitated object, g is gravitational constant.

The maglev system in (1) is of nonlinear type, it is linearized in and around equilibrium point $i_0 = 0.8\ A$ & $y_0 = 0.009$ meters.

$$f(i,y) = K\frac{i^2}{y^2} \quad \ldots (2)$$

The linearized maglev system as

$$\Delta\ddot{y} = \left(\frac{\partial f(i,y)}{\partial i}\Big|_{i_0,y_0}\Delta i + \frac{\partial f(i,y)}{\partial i}\Big|_{i_0,y_0}\Delta h\right) \quad \ldots (3)$$

Using (3), calculating partial derivatives and taking the laplace transforms,

$$\frac{\Delta y}{\Delta i} = \frac{-k_i}{s^2 - k_y} \quad \ldots (4)$$

Where k_i and k_y are constants for the MLS and those are

$$k_i = \frac{2g}{i_0},\ k_y = \frac{2g}{y_0}, \quad \ldots (5)$$

With reference to electrical circuit, the current in the circuit is proportional to the control voltage V

$$i = k_1 V \quad \ldots (6)$$

Where, 'k_1' is proportional constant. transfer function of Maglev system is turned into

$$\frac{\Delta y}{\Delta V} = \frac{-k_1 k_i}{s^2 - k_y} \quad \ldots (7)$$

In above transfer function, ΔV is change in voltage.

Adding sensor gain to above transfer function, overall transfer function of the maglev system as

$$\frac{\Delta y_{so}}{\Delta V} = \frac{-k_1 k_2 k_i}{s^2 - k_y} \quad \ldots (8)$$

Here , Δy_{so} is output voltage at the sensor

For any value of the parameter of ML system without feedback has transfer function of 2nd order. The ML system has oscillations in its closed loop response. Due to closed loop response of ML systems, levitated object will fall down or will attract to electromagnet. In order to meet the performance specifications there is a need of controller.

III. PID Controller Design based on Cuckoo Search Algorithm

In general, conventional controllers are preferred for Industry application, parameter of controller are searched in a certain space. Parameters found in search space satisfies the required performance indices, those are best parameters of controller. These parameters ranges can be extended based on the parameters obtained with Z-N Method [14].

In order to get optimal parameters of PID Controller, nature inspired metaheuristic algorithm is required i.e. Cuckoo search algorithm [15]. CS uses levy flights for its global search, so that it can extends the search space effectively [16]. The steps involved in finding the optimal parameters of PID controller are as follows.

A. Cuckoo Search Algorithm

Step 1:- Confirm the function to be minimum $f(x), x = (x_1, x_2, \ldots, x_{nd})^T$, where nd is the number variables. Objective function as integral square error.

Generate the set of values for each variable in the function to be minimum, i.e., $x_i (i = 1,2, \ldots, m)$ randomly, and the other parameters - size, number of variables, probability to be maximum P_k and max. no. of iteration a;

Step 2:- with reference to the function to be minimum, confirm the solution function $p(x)$, $x = (x_1, x_2, \ldots, x_{nd})^T$, calculate the solution for each value of the variable, and note it.

Step 3:- record the best solution of each parameter value in every generation, using the function be minimum in Step 1 to get suboptimal values.

Step 4:- Compare the every best parameter value with the best one in last generation, and also keep the optimal value.

Step 5:- if the solution is not changed upto max. no. of iterations a or changes less than value 0.05 in max. no. of iterations a, then go for next step, Otherwise, skip the next step.

Step 6:- In each iteration, cuckoos can founds the good parameter value & bad parameter value, replace the poor parameter value form an intermediate group with an optimal parameter value generated during the previous iteration. Mutate the optimal parameter value by solution obtained in 2 step, regarding the parameter values except the optimal one as sub-optimal parameter values & mutate the sub-optimal parameter values by 3 step.

Compare the solutions of current and previous optimal, if current solution is best, then indicate current solution is optimal and also update it as optimal solution, otherwise, repeat the process. If max no. of times the variation is not successful, then execute 8 step.

Step 7:- compare probability to be maximum P_k with an arbitrary value $r \in (0,1)$ if $r > P_k$, then change arbitrary $x_i^{(a+1)}$. If no change, then hold the best group of parameter values.

Step 8:- terminate condition, to meet the max no.iterations a or did not met the minimum error ε condition. If do not attained, then return to 2 step. Otherwise execute the global optimal values.

IV. Simulation Results

In this, Conventional controller is designed for position tracking of ML System. The electromagnetic coil is placed on top of the ML System. IR sensor is placed on opposite sides of the levitated object. It is easy to sense the position of levitated object. If the levitated object is near to electromagnetic coil, it will experience an attractive force. Otherwise it will fall down.

Controller is required to maintain the levitated object in free space, i.e to control the force due to electromagnetic coil, so that position tracking of ML system can be achieved. The response of ML system is undamped and oscillatory. The designed controller should be capable of improving the response requirements. The parameters of conventional controller obtained with z-n method are $k_p = 4.0$, $k_i = 0.05$ and $k_d = 0.2$. The other parameters used in simulations as well as in real time application are in table 1

Table 1 Maglev system parameters

Parameter	Value	observation
m	0.011 kg	Mass of levitated object
y_0	0.0078 m	Equilibrium Position
i_0	0.421 A	Equilibrium current
k_i	0.4678 N/A	Current amplification gain
k_1	0.1 A/V	Control voltage gain
k_2	Aprox. 33333 V/m	sensor gain

CSA is utilized to find optimal parameters of the conventional controller by minimizing the objective functions like ISE, IAE etc. [14-15]. In this paper integral square error (ISE) performance index is chosen as objective function. The search space for the CSA is chosen based on the parameters tuned using Z-N method and also used these parameters for first iteration. The remaining parameters are chosen randomly around alpha by a guess. In order to get global optimum solution, care should be taken while choosing search space.

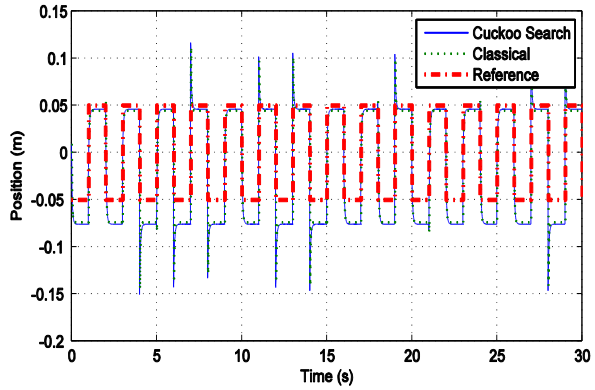

Figure 2 position tracking comparison of ML system in simulation

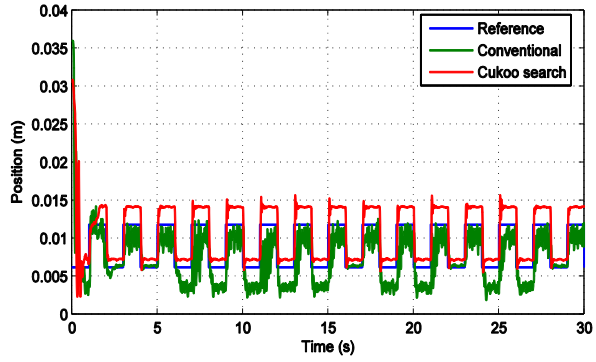

Figure 3 position tracking comparison of Real Time ML system

The comparison of position tracking response of the ML systems with PID controller using CSA and Z-N Method are in Figure 2. For the same parameters of the PID controllers has been implemented for real time ML system, which is shown in Figure 3.

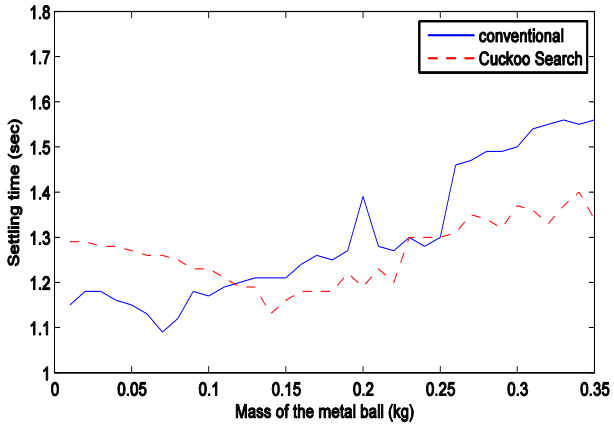

Figure 4 settling time comparison of ML system in real time

Fig. 4 shows the settling time variation of ML system for different values of mass of the levitated object. Conventional controller produces large variation in settling time as increasing the mass of the ball from minimum to maximum. As compared with conventional controller, cuckoo search based PID controller produces small variation in settling time as increasing the mass of the ball from minimum to maximum. Conventional controller needs to change the design parameters, if there is any variation in the system parameters. Cuckoo search based PID controller do not need any variation in the design parameters.

V. CONCLUSIONS

CSA based PID controller is designed for position tracking of ML system. The parameters obtained with CSA are optimized which are used in simulation as well as real time. CSA based PID controller guarantees the improvement in performance required, by minimising the integral square error of the ML system. The results are made comparison with conventional controller and CSA based PID controller. The conventional controller needs continuous updation if there is any change in the ML system parameters. CSA based PID controllers provides better performance when there is any change in ML system parameters.

AUTHORS PROFILE

Dr. P. Ananthababu received his B.Tech in Electrical and Electronics Engineering from Acharya Nagarjuna University, Guntur and ME in Control Systems from Andhra University, Visakhapatnam in 2005 and 2008 respectively. He was awarded his doctoral degree in Electrical Engineering by Andhra University in 2018. Currently, he is working as Associate professor at Department of Electrical and Electronics Engineering, Malla Reddy Engineering College (A), Secunderabad. His research interests include neural networks, fuzzy logic, control systems and control applications to drives.

Dr. K. Rama Sudha received her B.E in Electrical and Electronics Engineering and M.E in Power Systems from Andhra University, Visakhapatnam in 1991 and 1994. She was awarded her Doctorate in Electrical Engineering by Andhra University in 2006. During 1994–2006, she worked with GITAM Engineering College and presently she is working as Professor in the Electrical Engineering Department, Andhra University College of Engineering (A), Andhra University, Visakhapatnam, India. Her research interest includes Fuzzy logic, Power flow studies, Energy systems and controller applications.

Performance of Distributed Power Flow Controller in Transmission System Based on Fuzzy Logic Controller

Rajareddy.Duvvuru, N.Rajeswaran, T.Sanjeeva Rao

Abstract*: *Many of the Power Flow Controlling Devices are mostly used in the Transmission Lines in order to monitor the real as well as reactive power-flow variations. In this work provide an innovative power flow controlling device such as Distributed Power Flow Controller, this device also belongs to the FACTS family. This device is emerged from the Unified Power Flow Controller, there is a small differentiation between both these devices that is the common dc-link. In case of DPFC there is no existence of the dc link which connects both the converters. By design a DPFC device in MATLAB/Simulink to analyze the transmission line parameters.

Keywords* : *electronics devices, Unified Power Flow Controller ,Distributed power flow controller.

I. INTRODUCTION

The increasing difficulty of the current power systems is largely due to the everyday change in the system arrangement in organize to meet the ever growing demand of electrical energy, through the development of installation of new units of generation, interconnectivity of the transmission lines, extra high voltage tie line etc. The combined controllers of FACTS and Power-Electronics are one of the most appropriate devices which are utilized in managing power-flow [1]-[2]. The series-compensated FACTS controller is known as UPFC which can be treated as one of the commanding Power Flow Controlling Devices which can be used to control the all parameters [3].

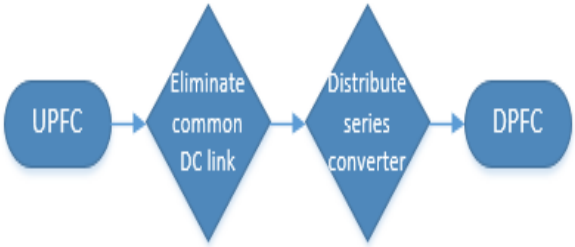

Figure 1. Conversion from UPFC-device to DPFC-device

Enlarging the Unified-PFC into the innovative controller known as Distributed-PFC is ended by apart from the common DC-link and series converter distribution as given away in Fig. 1.The new concept Distributed FACTS is employed in the series converter design. Here many number of low power rating converters are adopted as a replacement for a large 3-phase rated converter which results in low cost and increases the reliability [4].

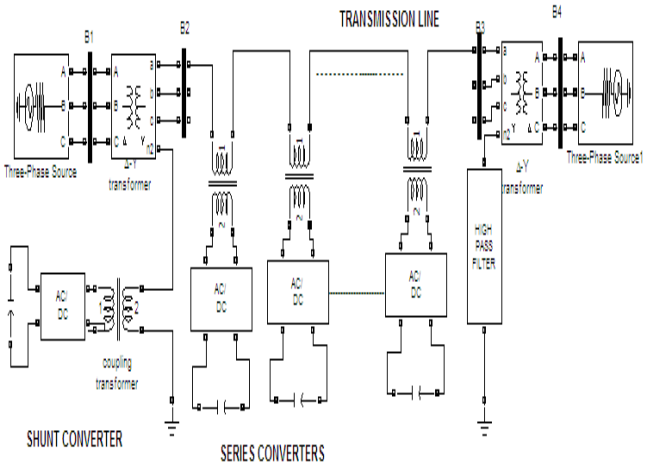

Figure 2. DPFC configuration

These are considered as the most important advantages of DPFC compared to UPFC. Figure 2 shows the configuration of Distributed-PFC consisting shunt along with series converters as in case of UPFC. In DPFC each-converter have their individual DC-capacitor that contributes necessary DC-voltage.

II. DPFC PRINCIPLE

Ac terminals of shunt-converter are connected with series converter via transmission line through which active power is interchanged. Power-theory of the non-sinusoidal components is adopted in this method. In Fourier analysis the non-sinusoidal current and voltage is articulated as summation of sinusoidal-functions in different frequencies by means of dissimilar amplitudes. This results in the true-power as shown in equation (1).

$$P=\sum_{i=1}^{\infty} V_i I_i \cos\phi_i \qquad (1)$$

Where I_i ,V_i are current as well as voltage at the i^{th}-harmonic-frequency correspondingly, where as ϕ_i be the phase-angle among the current as well as voltage. DPFC mainly comprises of a many number of low power rating series-converters and also a shunt-converter is also utilized. Here shunt-device is operated as the Static-compensator where as the series converter acts as a Distributed-FACTS controller [5]. Using the PWM (Pulse Width Modulation) technique inject the current into the shunt converter to organize reactive-power and also the voltage is injected into the series converter through a dc link to monitor real-power variations in order to inject voltage into the series

converter. There are many advantages regarding D-FACTS controller, the price of the apparatus gets minimized and the reliability of the system is improved [6]. By using a single bulky controller with high rating, there is an availability of using number of low rated controllers so this the cost the equipment may get reduced.

Each and every Distributed-FACTS component is self employed and they are monitored tenuously by the PLC's (power-line communications) or wireless communication. Since the unit does not need support of phase to ground isolation, it is capable of adopted at all voltage levels. During single module failure, the Distributed-FACTS redundancy offers an unremitting process, thus giving higher reliability compared to other FACTS devices [7].

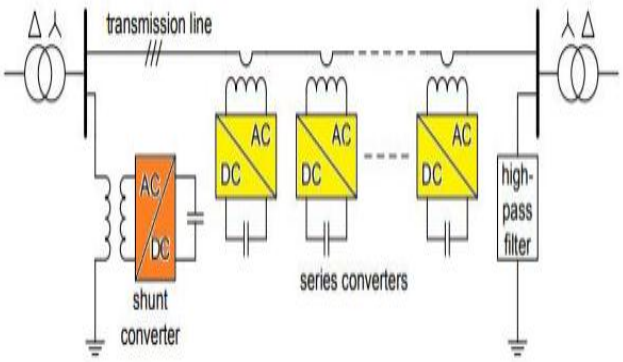

Figure 3. Block diagram of DPFC control

III. DPFC CONTROL

Fig. 3 shows the 3- types of controllers, namely series controller, shunt controller and central control. The constraints that are used in shunt in addition to series control is sustained by themselves sometimes is called a local controllers. By the side of the system's level the central control regulates the DPFC functions [8].

3.1. Central Control

Mainly in this control is adopted to produce the ref signals to other controllers. These are generated next to the fundamental-frequency. Reactive current signal and voltage reference signal is provided for the shunt converter along with the series-converters respectively. At power system level, the central-control is used to minimize the systems oscillations, and also monitors the power-flows and also balances the components which are asymmetrical.

3.2 . Series Control

This control in adopted in DPFC in order to inject the voltages into the line when required. Here the voltage is inserted into the at the 3rd harmonic-frequency. Here Vector control principle used to maintain the voltage across capacitor.

3.3 . Shunt Control

In order to transfer the real-power, 3rd harmonic-current is inserted into the three phases of the transmission line with the help of the transformer which is connected to the AC terminals of the shunt-device. This is the main objective of this control technique. And also it maintains the constant voltage-levels across the dc-capacitor [9].

IV. COMPARISON OF PI AND FUZZY CONTROLLER

Here fuzzy as well as PI controllers are utilized. The responses obtained by both the controllers are studied under this section.

4.1. Proportional Integral Controller

The controller is utilized; the DC link voltage is observed at normal intervals and is correlated with a ref value. Here an error signal can be generated which is handled in a PI controller as shown in figure below [10]-[11].

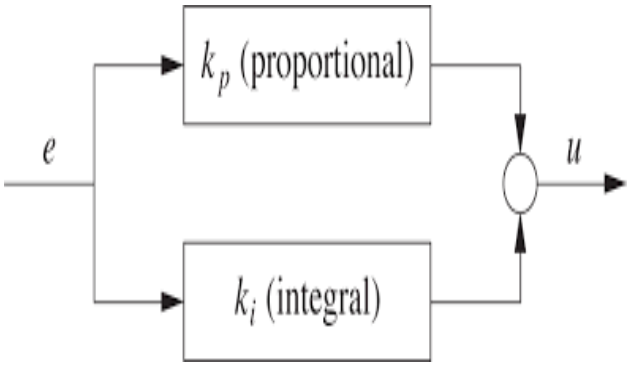

Figure 4. Block diagram of PI controller

4.2. Comparision of PI and Fuzzy Logic Controller (FLC)

The following are some the advantages of fuzzy- logic controllers when compared with the proportional integral (PI) controllers,

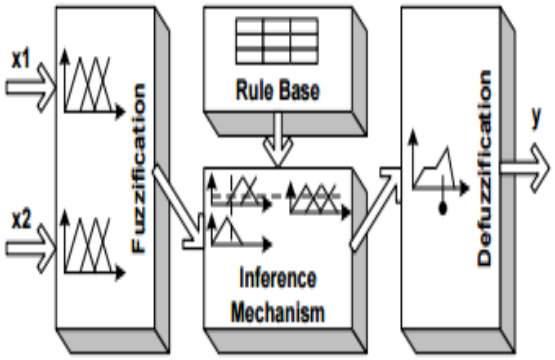
- perfect mathematical model is not mandatory
- Fuzzy controllers can handle the inputs which are unknown.
- Fuzzy controllers have enough capability to work with non-linearities.

Fuzzy-inference systems are applied in numerous applications namely computer-vision techniques, control-data categorization etc. Mainly the FIS are classified into two types they are as follows;

- Mamdani-techique and
- Sugeno-techique

Among both the methods, Mamdani' technique is adopted frequently when compared to sugeno method and also this method gives more accurate results when compared with PI controller.

The sampling time of this method is very low so due to this reason we are not adapting this method for real time applications. Block diagram of fuzzy-logic controller is given away in Fig.4. The control-action that is carried out by fuzzy-logic controller is determined by evaluating the linguistic rules. The different components of a fuzzy control system are fuzzification, rule base, defuzzification, and inference mechanisms.



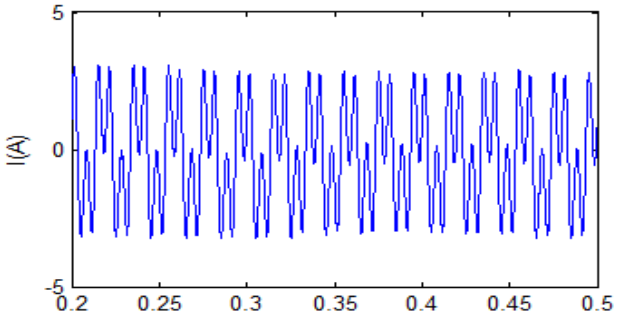


Figure 5. Block diagram of Fuzzy controller

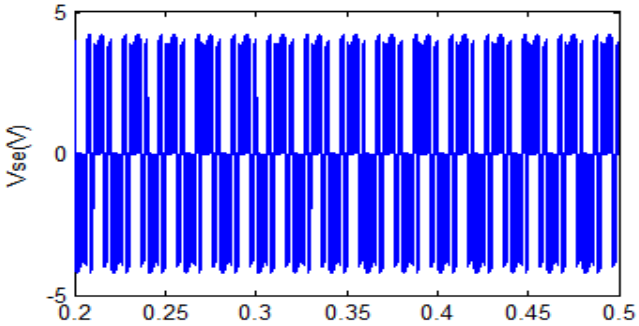
Under fuzzification procedure the crisp-values are transformed to fuzzy-values. Where as in de-fuzzification procedure fuzzy-values are changed to crisp-values. Rule base consists of different rules which are applied to solve a problem. Inference mechanism mainly consists of two techniques such as mamdani and sugeno techniques by considering these two techniques we will solve a problem [12]-[13].



V. SIMULATION RESULTS

Simulation is carried out in MAATLAB/SIMULINK software. Here mainly we are analyzing two situations they are steady-state in addition to step-response conditions. In first case using series control we are inserting a voltage -vector with d-axis and q-axis components, namely *V*se,d,ref=0.30V and *V*se,q,ref=−0.10V. The responses of DPFC under the steady-state are shown in figures 6(a), 6(b), 6(c) where only the waveforms of one phase are shown for clarity. When a fault occurs on a power system a third harmonic current component is produced in order to eliminate the third frequency component by using a shunt converter we are introducing another third frequency component in the negative direction now both of the harmonics currents gets cancelled out then the fault can be easily rectified.

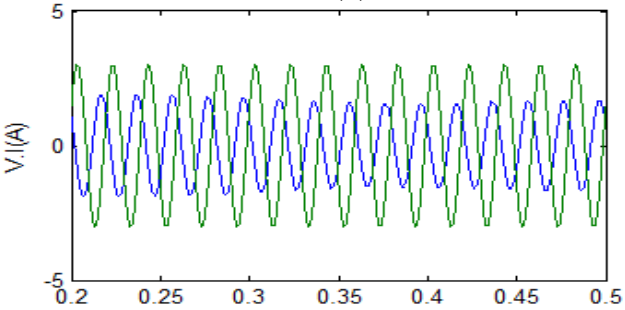


Fig 6(a) represents the 3rd harmonic current, subsequent to nullify the component of harmonic current by use of shunt converter the results are shown in fig.6(c). It is observed that fig 7.(a) step-change of a series converter ref-voltage is shows real as well as the reactive power variation and Direct Current voltage is alleviate previously and after the step changes. fig.7 (b) and 7(c) are power from the voltages and currents which are measured.

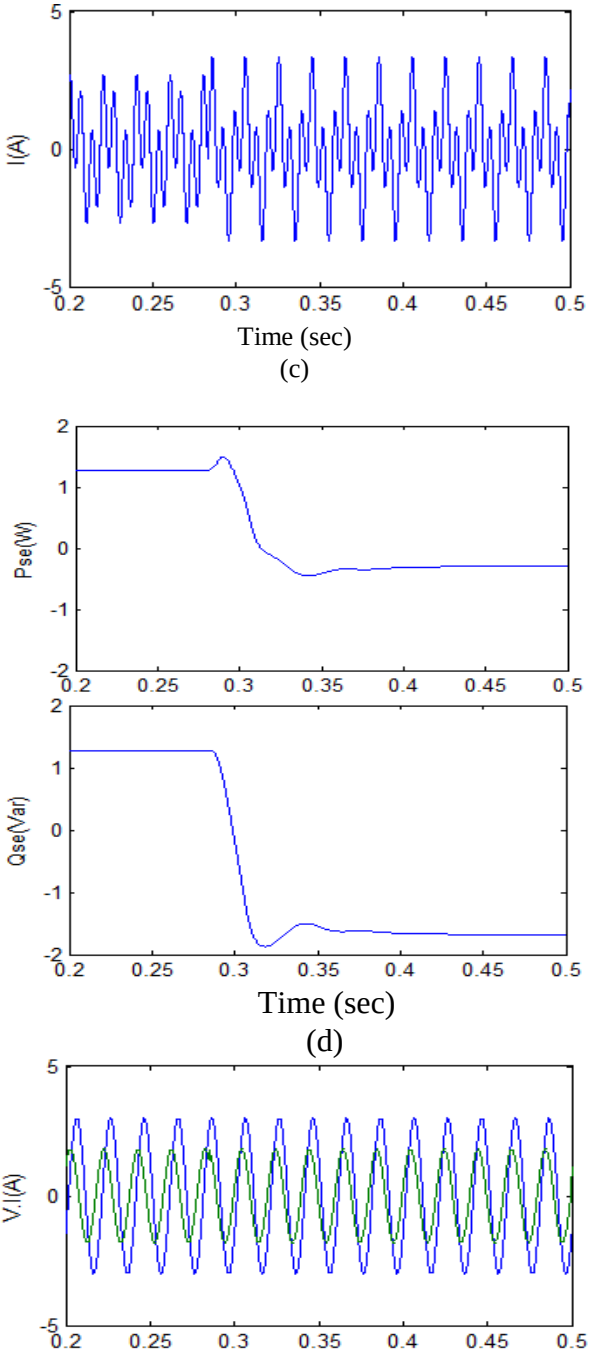

Figure 6. Steady-state operation of DPFC (a) line- current (b) voltage of series converter (c) bus voltage magnitude and current

(a)

(b)

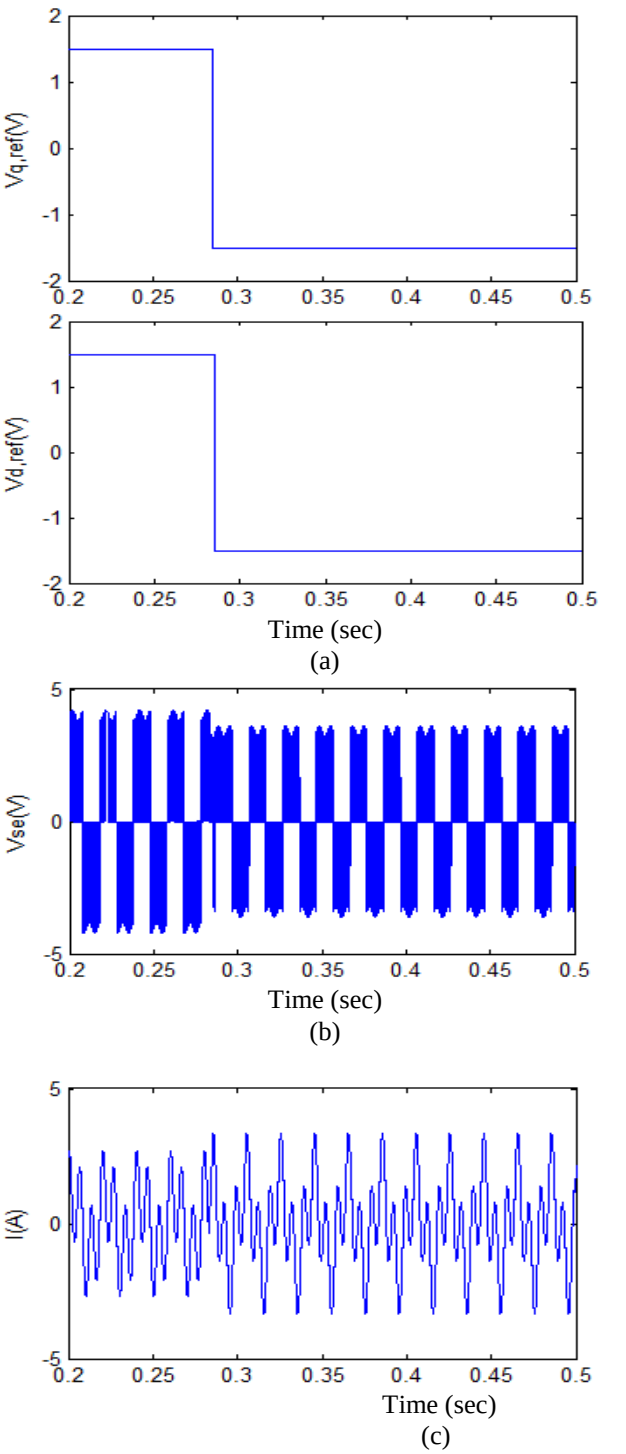

Figure 7. Step-response of DPFC: (a) ref voltages (b) series-Converter voltage (c) line-current (d) active & reactive powers (e) bus voltage and current of PI controller

The data is measured in 3 phases but only 1- phase data is progressed in computer system using MATLAB software. A LPF (low-pass filter) with 50-Hz cut-off frequency filters the measured data containing harmonic distortion in order to examine the current along with voltage at fundamental-frequency.

This filter causes a 1.5 cycle delay of calculated voltage and current to the real values thus cause of delay of measured real-power in addition to reactive-power. Fig.7.(d) shows the series-converter injecting real-power along with reactive-power at fundamental- frequency. The receiving end side waveforms are represented in fig.7 (e).

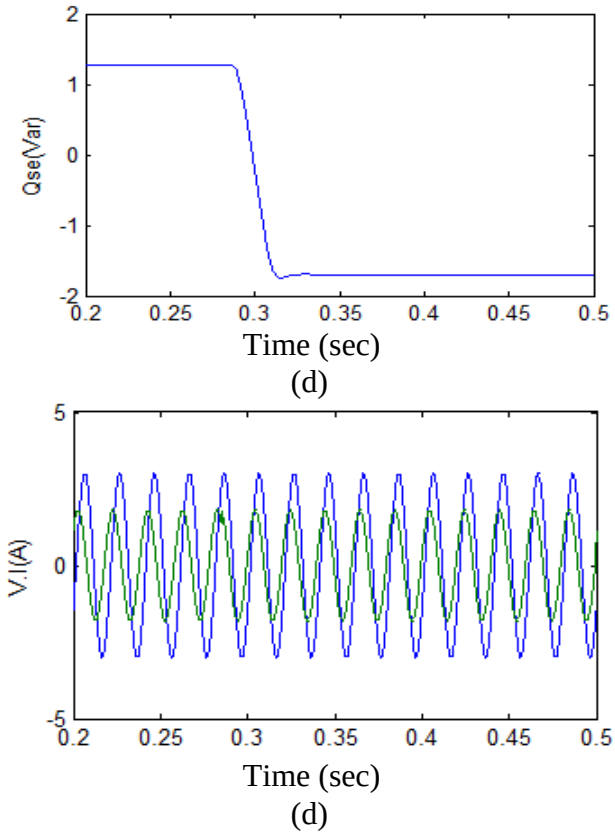

Figure 8. Step-response of the DPFC: (a) ref voltages (b) series converter voltage (c) line current (d) active & reactive powers (e) bus voltage and current of Fuzzy controller

Above fig.8 (a), 8(b), 8(c), 8(d), 8(e) demonstrate the step response of the DPFC using fuzzy logic controller. Here the delay of measured active and reactive power is reduced compared to PI controller.

VI. CONCLUSION

In this work a new PFCD from FACTS Family called DPFC was presented. Here using Fuzzy Logic Controllers instead of using Conventional Proportional Integral (PI) Controllers, these Fuzzy Controllers gives better response and we get accurate results compared with conventional PI Controllers. Fuzzy Controllers control the real-Power, Reactive-Power; bus Voltages along with bus currents. The D-FACTS concept is operated in the DPFC resulting in cost reduction and high reliability compared to UPFC.

Flower Pollination Algorithm to Solve Dynamic Economic Loading of Units with Practical Constraints

Y V Krishna Reddy, M Damodar Reddy, A V Sudhakara Reddy

Abstract*: Dynamic economic load dispatch (DELD) aims to obtain optimum generation schedule of the committed generating units' output over a certain timing horizon , sustaining practical restrictions and power demands in each period. Valve-point effect, the ramp up/down limits, prohibited operation zones (POZs), and power losses form the DELD as a complex, non-linear liable problem. The Flower Pollination Algorithm (FPA) is therefore anticipated in this paper to solve such a complex issue. The practicality of the proposed FPA method is assessed by conducting simulations at different load patterns on standard 5-unit and 10-unit systems for a 24-hour schedule. The FPA's simulation results are related to other previously published biography techniques. These results clearly show that the skill and robustness of the proposed FPA method to solve the non - linear DELD problem has been restricted.

Keywords* : Dynamic economic load dispatch, Valve-point effect, Ramp up/down limits, Prohibited operation zones, Flower Pollination Algorithm.

I. INTRODUCTION

The system which can deals with power generation, transmission and distribution in order to supply the consumer on an economical basis known as power system. Dynamic economic load dispatch (DELD) in the power system is one of the most important issues of optimization. DELD's goal is to allocate optimal generator outputs for a given variety of load demands in order to reduce overall operating costs over a given period of time, impose equality and various inequality constraints on system operation through generator ramp-rate limits. The operating cost function of generators are obtained using input-output characteristics, finally obtain quadratic function as cost function [1]. The operating cost function consist non-convexity due to steam turbines admission valves, hence the DELD problem becomes complex due to the valve-point loading in finding optimal solution. Many classical methods to evaluate the DELD problems with valve-point loading like Lagrangian relaxation [2], dynamic programming [3] and Maclaurin series [4] but these methods does not provide global optimal solution because of non-linearity and non-convexity features in the generating units. Due to the stability limits or machine components, generating units are restricted to operate certain operating zones.Therefore, due to consideration of valve point effects and POZs in objective function, DELD becomes nonconvex optimization problem.

Recently, in [5], Chaotic Quantum GA (CQGA) is used to solve the DELD problem, taking into account the effect of wind production. DE algorithms focused on solving DELD issues [6 - 9]. Other methods of empirical search include Quantum GA (QGA)[10], Artificial Bee Colony (ABC)[11], Artificial Immune System (AIS)[12], PSO[13,14], Enhanced Cross - Entropy (ECE)[15], and Multiple TS (MTS) algorithm[16] to solve DELD problems over the past decade. Hybrid methods such as hybrid swarm - based HAS [17], hybrid AIS - SQP [18], hybrid EP - SQP method [19], hybrid SOA - SQP [20], hybrid PSO - SQP [21], and AIS [22] have been found to be effective in solving complex optimization problems such as DELD.

This paper proposes an algorithm for flower pollination (FPA) to solve restricted non - convex DELD problems. Xin - She Yang recently proposed FPA [23]. This algorithm is an optimization algorithm inspired by nature based on universe pollen transfer. FPA has shown good action in solving optimization problems in various areas, as there is only one key parameter p (switch probability) that makes the algorithm faster to reach the optimal global solution. In addition, this transfer switch between local and global pollination can ensure an escape from the minimum local solution. The results of FPA method to solve DELD problem for test systems, shown that FPA can find better results compared to other exploratory algorithms.

II. DELD PROBLEM FORMULATION

The objectives function for DED problem as follows:

$$\min TC = \sum_{t=1}^{T}\sum_{i=1}^{N} C_{it}(P_{it}) \qquad (1)$$

Where C_{it} : Fuel cost of unit i at time t (in \$/h), N: Number of generation units, P_{it} : Power output of i^{th} unit at time t (in MW), T: Total number of hours.

Revised Manuscript Received on September 15, 2019

Y V Krishna Reddy*, Eee Department, Sri Venkateswara College Of Engineering, Tirupati, India Email: Yvkrishnareddy36@Gmail.Com

Dr. M Damodar Reddy, Eee Department, Sri Venkateswara University College Of Engineering Tirupati, India Email:Mdreddy999@Rediffmail.Com

Dr. A V Sudhkara Reddy, Eee Department, Malla Reddy Engineering College, Maisammaguda, Hyderabad, India Email: Sreddy4 Svu@Gmail.Com

Due to involvement of valve-point the fuel cost of a generation unit defined as:

$$C_{it}(P_{it}) = a_i P_{it}^2 + b_i P_{it} + c_i + \left| e_i \sin(f_i (P_i^{min} - P_{it})) \right| \quad (2)$$

The DELD problem objective function maintains the following constraints should be minimized:

2.1. Real power balance

By considering network transmission losses, the equality constraint of the given network is written as:

$$\sum_{i=1}^{N} P_{it} = P_D(t) + P_{loss}(t) \qquad t = 1, 2, ..., T \quad (3)$$

Where $P_{loss}(t)$: Total transmission loss of the system (in MW), $P_D(t)$: Total power demand of the system at time t (MW). The power loss calculated using coefficients of the B matrix as follows:

$$P_{loss}(t) = \sum_{i=1}^{N}\sum_{j=1}^{N} P_{it} B_{ij} P_{jt} \qquad t = 1, 2, 3, ..., T \quad (4)$$

2.2. Generation limits of units:

$$P_i^{min} \le P_{it} \le P_i^{max} \qquad i = 1, ..., N, \; t = 1, 2, ..., T \quad (5)$$

Where P_i^{min} and P_i^{max} (in MW) are the minimum, maximum power outputs of i^{th} unit.

2.3. Ramp up and ramp down constraints:

The generation unit ramp rate limits are stated as follows:

$$P_{it} - P_{it-1} \le UR_i \qquad i = 1, ..., N, \; t = 1, 2, ..., T \quad (6)$$

$$P_{it-1} - P_{it} \le DR_i \qquad i = 1, ..., N, \; t = 1, 2, ..., T \quad (7)$$

Where UR_i: Ramp up limit, DR_i: Ramp down limit of the i^{th} generator (MW/h). Due to involvement of ramp rate limits power limits can be modified as follows:

$$\max(P_i^{min}, P_{it-1} - DR_i) \le P_{it} \le \min(P_i^{max}, P_{it-1} + UR_i)$$
$$i = 1, ..., N, \; t = 1, 2, ..., T \quad (8)$$

2.4. Prohibited operation zone limits (POZ):

Due to stability concerns or limitations of machine components generating outputs have certain delimited operation zone. The generation unit acceptable operation zone can be defined as:

$$P_{it} \in \begin{cases} P_i^{min} \le P_{it} \le P_{i,1}^{l} \\ P_{i,j-1}^{u} \le P_{it} \le P_{i,j}^{l} \qquad j = 2, 3, ...M_i \\ \qquad\qquad i = 1, ..., N \quad t = 1, 2, ..., T \\ P_{i,M_i}^{u} \le P_{it} \le P_i^{max} \end{cases} \quad (9)$$

Where $P_{i,j}^{u}$ and $P_{i,j}^{l}$ are the upper and lower limits of the j^{th} POZs of unit i, respectively. M_i is the number of POZs of unit i.

III. FLOWER POLLINATION ALGORITHM

3.1. Introduction

In this section, new nature inspired optimization algorithm based on flower fertilization process has been proposed and implemented on DELD problem. Xin-She Yang [23] developed FPA method in 2012. There are namely two types of fertilization processes known as biotic and abiotic. Majorly (90%) the transfer of pollen occurs due to the biotic pollination by using pollinators as bats, birds, insects and other animals. Wind and diffusion help in the abiotic fertilization (10% occur) rather than using pollinators.

Cross - fertilization or self - fertilization can achieve flower fertilization. First, one is due to the pollen fertilization of a different plant flower. Second, one occurs because one flower is fertilized from pollen of the same flower or other flowers of the same plant.

For FPA, the following four rules are used:

1. To find the global fittest, biotic and cross-fertilization considered, as pollen – carrying pollinators fly following Levy flights.
2. To find the local fittest, abiotic fertilization and Self-fertilization used.
3. Generally, insects can develop flower perseverance; this probability of reproduction is proportional to the similarity of the two flowers involved.
4. The switch probability of $P \varepsilon [0,1]$, is used to control interaction of local and global fertilization, which is slightly biased toward local pollinator.

3.2. Mathematical representation of FPA

Global fittest (g_*) can be formulated using first rule, and it can be represented mathematically as Eqn. (10),

$$X_i^{t+1} = X_i^t + L(X_i^t - g_*) \quad (10)$$

Where X_i^t the solution is vector X_i at iteration t, and g_* is the current iteration best solution. L is the strength of fertilization should be greater than zero.

Levy distribution can be represent as Eqn. (11)

$$L \sim \frac{\lambda \Gamma(\lambda) * \sin(\pi\lambda/2)}{\pi} \left(\frac{1}{S^{1+\lambda}}\right) \qquad (S \gg S_0 > 0) \quad (11)$$

Where Γ (λ): Standard gamma function distribution is valid for large steps S > 0.

For the local fertilization, both Rules 2 and 3 can be signified as shown in Eqn. (12).

$$X_i^{t+1} = X_i^t + \varepsilon (X_j^t - X_k^t) \quad (12)$$

Here X_j^t and X_k^t are pollens from the different flowers of the same plant species. Here ε is drawn from a uniform distribution as [0, 1]. In both local and global searches, flower pollination can occur. If there are two similar solutions, the search may be local; while there are two different solutions, the search will be global. The two parameters in this algorithm are population size n and probability switch (p[0,1]).

From our reproductions, found that probability switch= 0.75 for solving DELD problem. The flower pollination flowchart shown if Fig. 1, and algorithm to the proposed method discussed in below.

Implementation of Flower Pollination Algorithm:

Step 1: The algorithm begins by setting the initial population size(n), the switch probability(p), the maximum number of iterations, the search variables dimension (dim), the cost of generation coefficients, the B - matrix, the upper & lower limit and the load demand for 24 hours.

Step2: Initialize the population or solutions of flower randomly.

Sol (i, :) =Lb+ (Ub-Lb).*rand (1, dim).

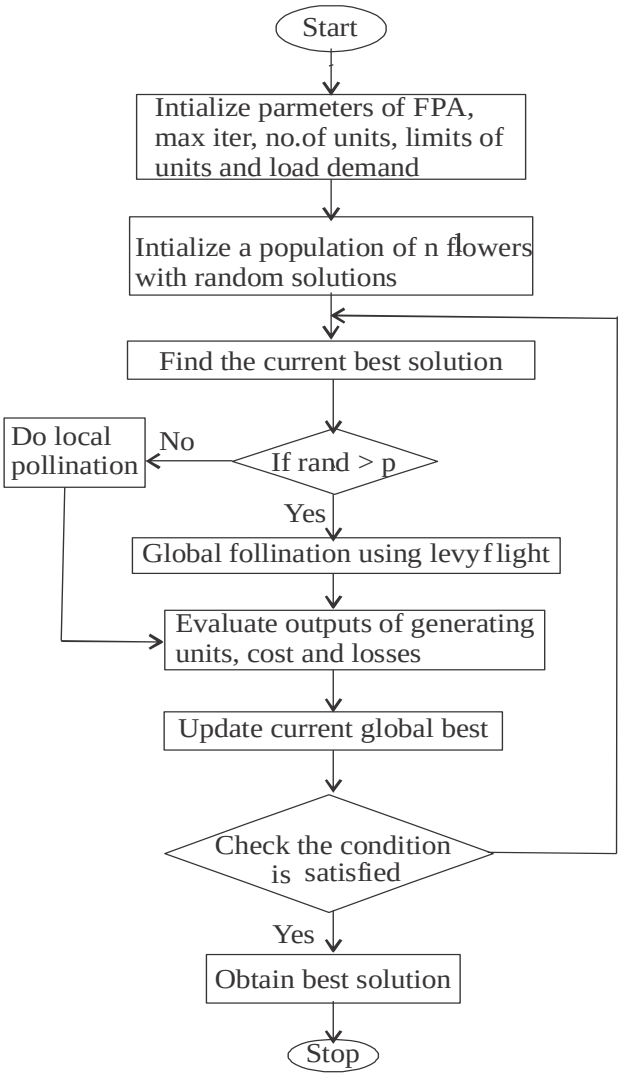

Fig. 1. Flowchart of FPA to solve ED

Step3: Find the current best solution g_* in the initial population.

[Fmin, I]=min (Fitness).

Step4: Start the iteration count i=1.

Step5: Check the limits that are simple. If random is larger than p, use equation (10) to draw a step vector that obeys a levy distribution. Use Eqn. (11) to make the global pollination.

Step6: Draw a uniform distribution in [0, 1] randomly select j & k among all solutions if random is less than p. Use equation to do local pollination (12).

Step7: Check to see if all the restrictions are met if they are not met go to step 4. Assess new solutions (unit generation outputs, costs and losses).

Step8: Update the global fittest and its position.

Step9: Run the program up to meet the tolerance (0.00001). Display the results such as generation cost, power generations, transmission losses and total power generation for 24 hours.

IV. SIMULATION RESULTS

The FPA method is examined on two test systems with five and ten number of units in this section. MATLAB programs are executed on a PC with 4 GB RAM using MATLAB R2014a to solve DELD issues. 30 Trails are considered in order to evaluate the robustness of the proposed FPA method for each system. The number of pollens in all test systems is 40. The stop criteria are defined in this paper as reaching the tolerance of 0.00001. DELD problem is solved for three different load patterns, taking into account valve-point effects, losses and POZs, resulting in a convex quadratic programming problem.

4.1. Five unit test system

From [8], the 5-unit test system data is adapted. Valve - point loading, power losses and ramp rate limitations are considered for this test system. The total time period of one day was divided into 24 intervals and three different load patterns were considered. Table 1 presents the simulation results obtained for this test system. The proposed FPA provided a minimum cost of 42267.4315 ($) production. The test results are correlated to other methods placed in literature in terms of statistical analysis for cost over 30 runs presented in Table 2. By examining the 5 unit system results shown in Table 2, it can be noticed that the results attained by FPA method better as compare with other methods cited.

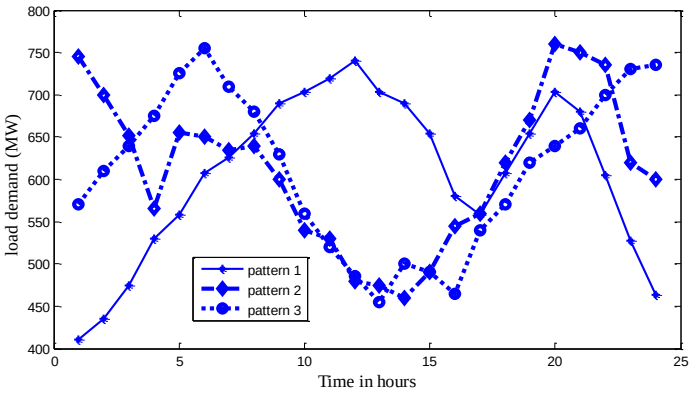

Fig. 2. Five unit test system different load patterns

From Table 2, it can be concluded that the minimum production cost of the proposed FPA is 42267.4315 ($) compared with ABC[11], AIS[12], APSO[13], HHS[17] and SOA[20] for load pattern 1.

Table 1: Best generation dispatch results obtained by FPA for 5-unit system for load pattern 1.

4.2. Ten unit test system

From [8], the data of the 10-unit test system is adapted. Valve - point loading, power losses and ramp rate limitations are considered for this test system. The total one - day time period was divided into 24 intervals, three different load patterns were considered and shown in the appendix in Figure 4. Table 4 presents the simulation results obtained for this test system. The proposed FPA provided a minimum cost of production of $1012349.2247. The proposed FPA provided a minimum cost of $1012349.2247 production. The test results are correlated to other methods placed in literature in terms of statistical analysis for cost over 30 runs presented in Table 5. By examining the 10 unit system results shown in Table 5, it can be noticed that the results attained by FPA method better as compare with other methods cited.

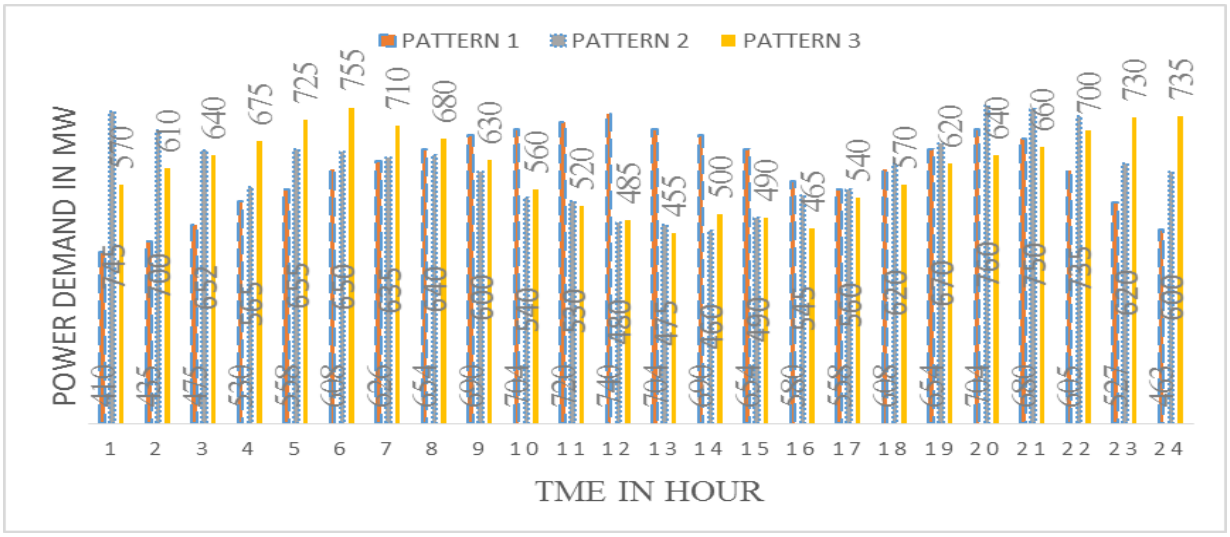
V. CONCLUSION



This paper uses the Flower Pollination Algorithm (FPA) to solve the DELD problem, taking into account the effects of the valve - point and ramp - rate limits. Five and ten-unit test systems for different load patterns for 24-hour time interval demonstrated the feasibility of the proposed method. The test results show that the optimal dispatch solution obtained through the proposed FPA method is superior to other methods presented in the literature to determine the optimal solution to solve the problem of DELD. The proposed approach outperforms the methods used by MDE, ABC, ECE, PSO and Hybrid to solve DELD problems with better performance in terms of solution quality.

AUTHORS PROFILE

Y. Venkata Krishna Reddy has one year experience in teaching and research in Graduate and Post Graduate level. He has received M.Tech in the specialization of Power Systems from JNTUACE, Anantapur. Six times qualified in All India GATE entrance exam from 2012-2016. Presently working as assistant professor in sri Venkateswara college of engineering, Tirupati, India

Prof. M. Damodar Reddy has 25 years of experience in teaching in Post Graduate level and 20 years of experience in Research. He has received M.Tech and Ph.D from S. V. University College of Engineering, Tirupati, India, 1992 and 2008 respectively. He has a Life Member of ISTE. Presently he is working as a Professor at S.V.University, Tirupati, India. He has published 63 Research (Journals-**48**, Conferences-**32**) Papers. Presently guiding 8 Ph.D. Scholars and 2 of them are in submission. His Research area is Power system optimization & reactive power compensation

Dr. A V Sudhakara Reddy has five year experience in teaching and research in Graduate and Post Graduate level. He has received M.Tech in the specialization of Power Systems from JNTUCE, Pulivendula. Five times qualified in All India GATE entrance exam from 2011-2017 Presently he is working as assistant professor in Malla Reddy College of Engineering, Maisammaguda, Hyderabad, India.

Voltage Control and Power Loss Reduction in Distribution Networks using Distributed Generation

Sabarinath.G, T.Gowri Manohar, A.V.Sudhakara Reddy

Abstract*: Distributed generation (DG) units can provide many benefits when they are incorporated along the distribution network/system. These benefits are more if DG units are connected at suitable nodes with appropriate rating otherwise, they may cause to increased power loss and poor voltage profile. In this work, optimal allocation (both location and size) problem is solved by considering power loss minimization as an objective function. An analytical method "index vector method (IVM)" is applied to find DG location. A new optimization algorithm "Whale Optimization Algorithm (WOA)" is employed to determine the DG rating. Two popularly known test systems "IEEE 33 & IEEE 69"bus systems are used to evaluate the efficacy of IVM and WOA.

***Keywords:* Distributed generation, Distribution system, Index vector method, Power loss reduction, Whale optimization algorithm.**

I. INTRODUCTION

Distribution network/system is an integral part of power system that joins high voltage sub-transmission system to the low voltage consumers. With ever increasing demand for electrical energy, distribution network needs continuous expansion to meet the increasing load demand. According to Indian records 20% of total power generation is wasting at distribution level. Distributed Generation (DG) is the main and one of the alternatives to meet ever increasing load demand and decrease power loss at distribution level. Integration of DG units into the distribution network can provide numerous environmental, technical and economic benefits to the consumers as well as distribution companies. Many studies proved that the above said benefits can be achieved only if the DG units are placed at optimal locations with optimal size otherwise DG leads to negative impacts. DGs are categorized as follows [1]:

Type-1 DG: These DGs can inject only P (active power) into the system.

Type-2 DG: These DGs can inject only Q (reactive power) into the system.

Type-3 DG: These can inject P in to the system and consume Q from the system.

Revised Manuscript Received on October 05, 2019.

Type-4 DG: These can inject P as well as Qin to the system.

So in this work optimal sitting and sizing problem in distribution network is solved by taking power loss reduction as main objective function. This paper is organized as follows: section one gives the introduction about distribution network, DG and also presents literature survey. Section two presents the analytical method called index vector method used to identify the optimal DG locations. Section three explains and models the whale optimization algorithm used to find the optimal rating of DG unit. Section four presents the simulation results and finally section five gives the final conclusions.

II. INDEX VECTOR METHOD

In this work, optimal DG locations (bus or node) in a given distribution network are found by using index vector method [1]. Index vector values at each bus excluding reference bus of a system are found by using equation (1). The normalized voltages calculated by the given equation (2) at each and every bus of a network are also considered to select the optimal DG locations. The bus with the highest index value and normalized voltage less than 1.01 will be on top priority to place DG. The index vector of a given system can be calculated as follows:

$$\text{Index Vector}(n)=\frac{1}{V(n)^2}+\frac{I_q(k)}{I_p(k)}+\frac{Q_{eff}(n)}{Q_{total}} \quad (1)$$

Normalized voltages are determined as follows:

$$\text{Normalized voltage, } V_{nor}(n)=\frac{V(n)}{0.95} \quad (2)$$

Where

Index vector (n) = index value at bus 'n'

V(n) = voltage magnitude of bus 'n'

Ip(k) = Real component of current flowing through branch 'k'

Iq(k) = Imaginary component of current flowing through branch 'k'

Qeff(n) = Effective reactive load at bus 'n'

Qtotal = Sum of reactive loads of system

III. WHALE OPTIMIZATION ALGORITHM

Whale optimization algorithm (WOA) [2] is a new bio inspired, population based optimization technique developed in 2016 by the scientists namely S. Mirjalili and Lewis. Whales are the biggest mammals in the planet and they will not move fast enough to follow and catch a school fish during hunting. Therefore, they exhibit a unique hunting method called "bubble net hunting technique" to catch a school of fish or pray. In this method, humpback whales generate air bubbles around the prey or a school of fish along the circular or spiral shaped path. As it can be viewed in "Fig. 1" [3], the radius of the bubble net continuously decreases towards the water surface. The humpback whales forces or directs a school of fish towards the surface of the water and attacks them when they are close to the surface of water. Therefore, this unique technique simplifies the hunting process. The bubble net hunting technique has been simulated in WOA.

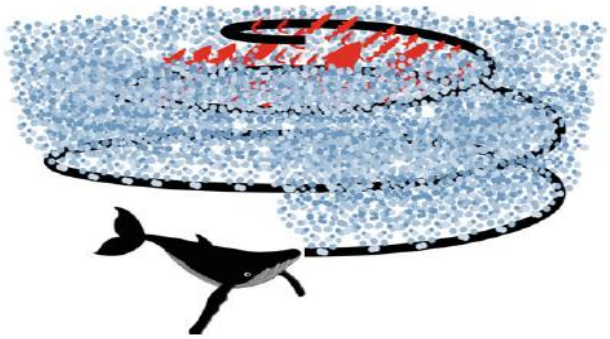

Fig.1. Bubble net feeding technique

The hunting behavior of humpback whales can be explained and modeled in three sections as follows:

A. Encircling Prey

Humpback whales can predict the location of prey and encircle them. At starting, humpback whales assume the current best candidate solution as the location of prey and the remaining whales update their position towards the best solution. This behavior is modeled as follows:

$$\vec{D}=\left|\vec{C}.\vec{X}^{*}(t)-\vec{X}(t)\right| \quad (3)$$

$$\vec{X}(t+1)=\vec{X}^{*}(t)-\vec{A}.\vec{D} \quad (4)$$

The values of vectors '$\vec{A}$' and '$\vec{C}$' are determined using equations (36) and (37)

$$\vec{A}=2.\vec{a}.\vec{r}-\vec{a} \quad (5)$$

$$\vec{C}=2.\vec{r} \quad (6)$$

Where't' denotes the current iteration '$\vec{A}$' and '$\vec{C}$' represents coefficient vectors X $\vec{}$* is position vector of the prey or best solution '$\vec{X}$' is current position. Where '$\vec{a}$' value linearly decreases from 2 to 0 over the succeeding iterations and '$\vec{r}$' is a random vector in [0,1].

B. Bubble net attacking method

In this phase, humpback whales (search agents) moves closer to the prey (best solution agent). The bubble net attacking technique can be mathematically modeled using the following two approaches:

1) Shrinking encircling mechanism

This SEM presented in "Fig.2" is achieved by decreasing the value of '$\vec{a}$' in expression (5) and hence the value of '$\vec{A}$' also decreases by '$\vec{a}$'. Now, the next position of a search agent (whale) can be assigned anywhere in between the original position of the search agent and the position of the existing best agent by assigning random values for '$\vec{A}$' in [−1,1].

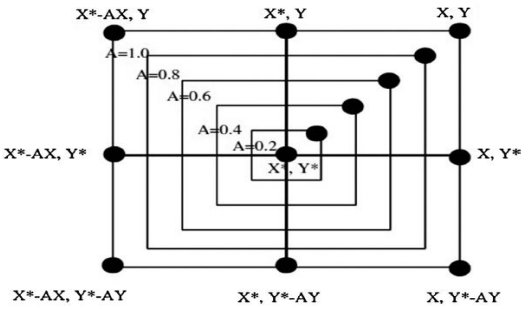

Fig.2. Shrinking encircling mechanism

2) Spiral updating position

In this phase presented in "Fig.3", the distance between the (X, Y) (whale position) and (X*, Y*) (prey position) is calculated and then a spiral equation is formed using expression (7).

$$\vec{X}(t+1)=D'.e^{bl}.\cos(2\pi l)+\vec{X}^{*} \quad (7)$$

Where 'D'=$\left|\vec{X}^{*}-\vec{X}(t)\right|$' represents the distance between the (X, Y) and (X*, Y*) and variable 'l' is a random number between -1 and 1.

During hunting process, humpback whales moves in spiral shaped as well as shrinking circle path simultaneously and hence we consider 50% probability between both shrinking circling and spiral model. Now the updated position is determined using the below equation (8).

$$\vec{X}(t+1)=\begin{cases}\vec{X}^{*}(t)-\vec{A}.\vec{D} & \text{if } P<0.5\\ D'.e^{bl}.\cos(2\pi l)+\vec{X}^{*} & \text{if } p^{3}0.5\end{cases} \quad (8)$$

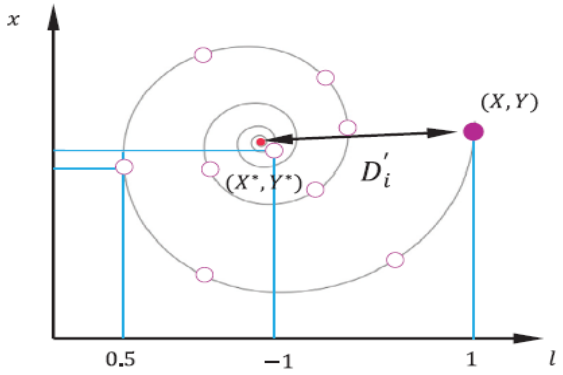

Fig.3. Spiral updating position mechanism

C. Search for Prey

To make the algorithm global optimizer when less than one or greater than one the search agent (whale) is updates its position according to a randomly selected search agent instead of the best search agent.

$$\vec{D} = |\vec{C}.\vec{X}\text{rand} - \vec{X}| \quad (9)$$

$$\vec{X}(t+1) = \vec{X}\text{rand} - \vec{A}.\vec{D} \quad (10)$$

IV. RESULTS AND ANALYSIS

Two popularly used test systems in the literature are used to test and evaluate the efficacy of proposed techniques.

Test system#1: A popularly known IEEE 33-bus system is considered as test system 1. The data including branch and load data are taken from [1]. It consists of one feeder, 33 nodes/buses, 32 lines/braches and operates at 12.66 KV. The sum of real and reactive loads of system is 3.715 MW and 2.3 MVAr, respectively. Without any compensation, the real and reactive losses are 210.99 KW and 143.03 KVAr. Index vector values of this test system are graphically presented in "Fig.4". As it can be viewed from "Fig.4", the bus 30 is having the highest index value and its normalized voltage in "Fig.5 is also less than 1.01 and hence it is selected as candidate node/bus to connect DG.

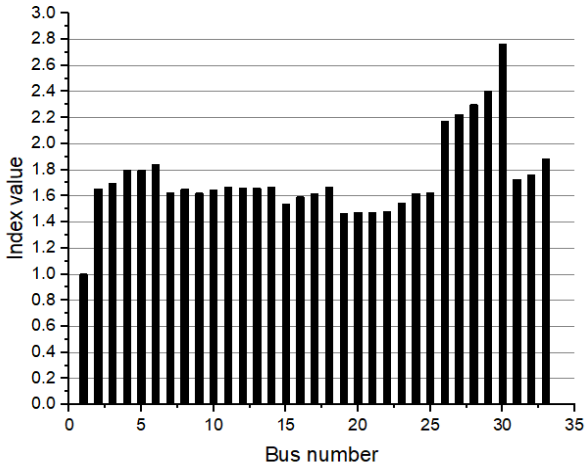

Fig.4. Index vector profile for IEEE 33-bus system

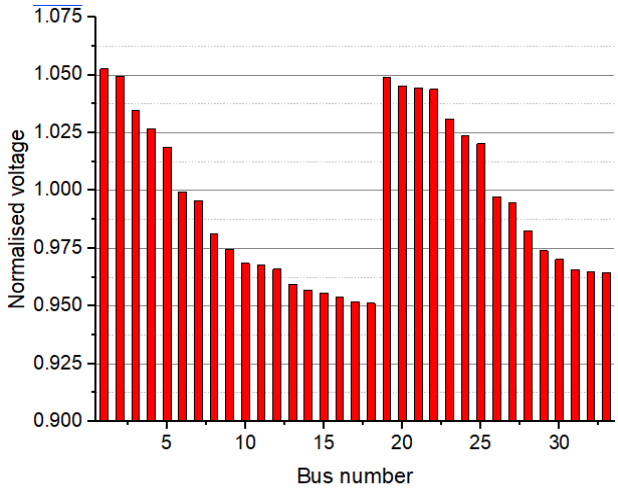

Fig.5. Normalised voltage profile of IEEE 33-bus system

The optimized results of IEEE 33-bus system with the proposed WOA algorithm are recorded in "Table-I". The results include DG size in kilowatts, real power loss (Ploss), reactive power loss (Qloss), minimum voltage level (Vmin) and total voltage deviation (Vdevi). From the results it is clear that the power losses after the placement of type-4 DG is very less when compared to other types of DGs. Power losses are very less with type-4 DG because it injects active power as well as reactive power at connected bus. The actual reduction in real power loss after the placement of type-1, 2, 3 and 4 DGs are 40.67%, 28.25%, 7.18% and 65.12%, respectively. The minimum voltage level at bus 18 is greatly improved with type-4 DG when compared to other DG types. The reduction in total voltage deviation is also superior with type-4 DG unit. Figure 6 shows the graphical representation of voltage profile of IEEE 33-bus system with and without DG.

Table-I: Results of IEEE 33-bus system

	Without DG	With DG			
		Type-1	Type-2	Type-3	Type-4
DG location	NA	30	30	30	30
DG size	NA	1542.67 KW	1257.99 KVAr	631.83 KVA	1976.20 KVA
P_{loss}(KW)	210.99	125.16	151.37	195.84	73.59
Q_{loss}(KVAr)	143.03	89.28	103.81	134.00	55.68
Vmin (p.u)	0.9038	0.92723	0.91648	0.9086	0.93941
Vdevi	1.8051	1.1137	1.4263	1.6637	0.74551

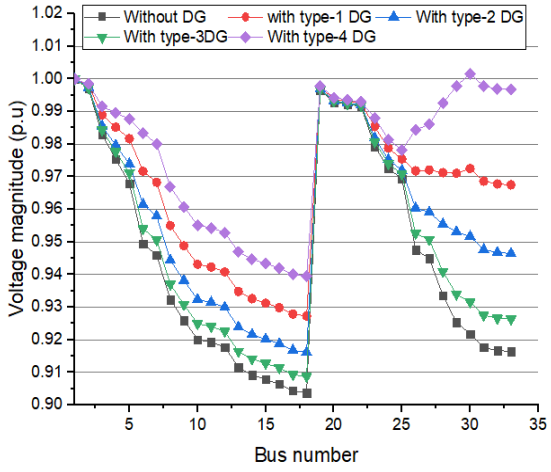

Fig.6. Voltageprofile of IEEE 33-bus system

"Fig.7" visualizes the convergence curves of a WOA when applied for test system 1. From the convergence curves it is clear that the proposed WOA can converge in very less number of iterations.

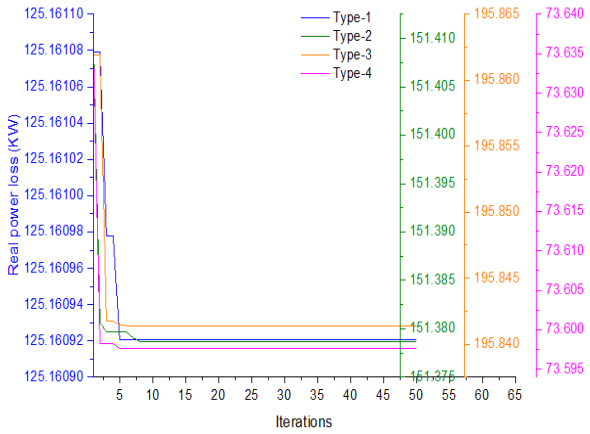

Fig.7. Convergence characteristics of WOA for IEEE 33-bus system

Test system#2: IEEE 69-bus system is taken as second test system. The system data including line/branch data and load/bus data is obtained from [1]. It consists of 69 nodes/buses, 68 branches/lines and operates with 12.66 KV. Total network loads are 3802.19 KW and 2694.6 KVAr. "Fig. 8" and "Fig. 9" represents index vector profile and normalized voltage profile of a IEEE 69-bus system. From the index vector profile it is very clear that bus 61 is having highest index value and from normalized voltage profiles its normalized voltage is also less than 1.01. Hence, bus 61 is selected to place DG units.

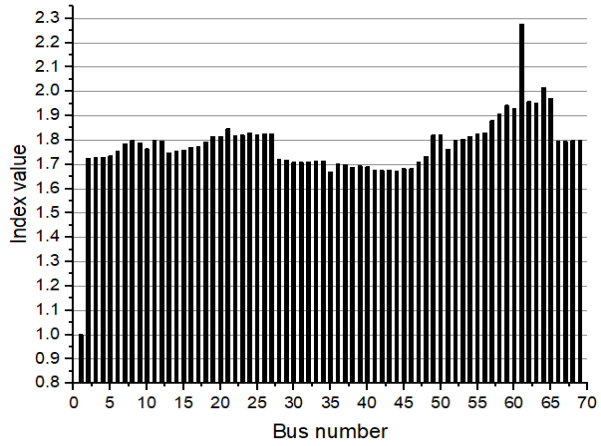

Fig.8. Index vector profile for IEEE 69-bus system

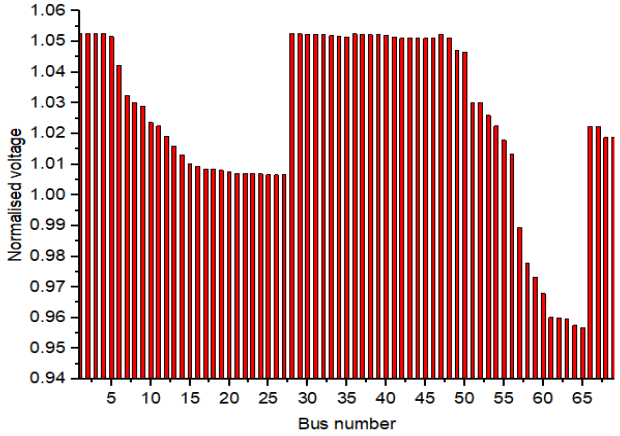

Fig.9. Normalized voltage for IEEE 69-bus system

The optimized results of IEEE 69-bus system with the proposed WOA algorithm are recorded in "Table-II". The results include DG size in kilowatts, real power loss (Ploss), reactive power loss (Qloss), minimum voltage level (Vmin) and total voltage deviation (Vdevi). From the results it is clear that the power losses after the placement of type-4 DG is very less when compared to other types of DGs. Power losses are very less with type-4 DG because it injects active power as well as reactive power at connected bus. The actual reduction in real power loss after the placement of type-1, 2,3 and 4 DGs are 63.01%, 32.42%, 12.43% and 89.70%, respectively. The minimum voltage level at bus 65 is greatly improved with type-4 DG when compared to other DG types. The reduction in total voltage deviation is also superior with type-4 DG unit. "Fig. 10" shows the graphical representation of voltage profile of IEEE 69-bus system with and without DG.

Table-II: Results of IEEE 69-bus system

	Without DG	With DG			
		Type-1	Type-2	Type-3	Type-4
DG location	NA	61	61	61	61
DG size	NA	1872.70 KW	1329.99 KVAr	813.41 KVA	2223.86 KVA
P_{loss}(KW)	225	83.22	152.04	197.63	23.16
Q_{loss}(KVAr)	102.17	40.52	70.49	90.28	14.37
Vmin (p.u)	0.90918	0.96831	0.93072	0.92598	0.97247
Vdevi	1.8388	0.8822	1.5093	1.6147	0.5867

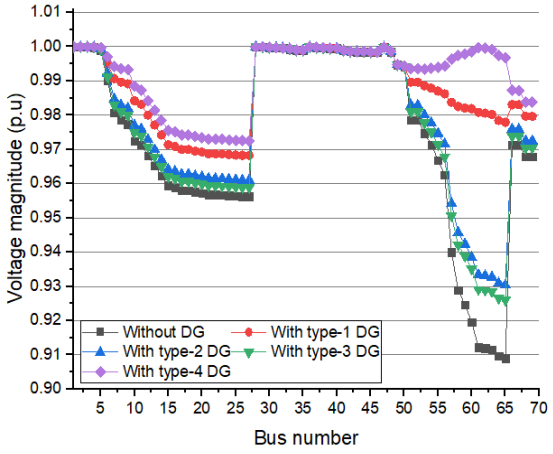

Fig.10. Voltage profile of IEEE 69-bus system

"Fig. 11" visualizes the convergence curves of a WOA when applied for test system 2. From the convergence curves it is clear that the proposed WOA can converge in very less number of iterations.

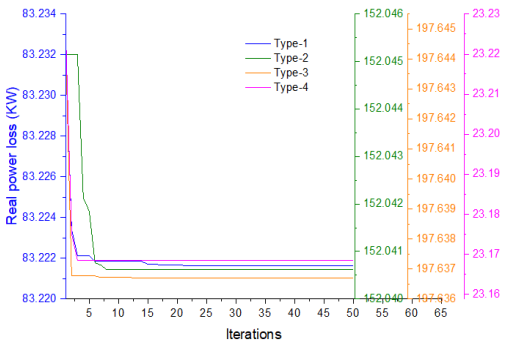

Fig.11. Convergence characteristics of WOA for IEEE 69-bus system

V. CONCLUSION

Power loss reduction and voltage control are considered as main objectives in this work. This objectives are reached by optimal placement and sizing of different types of DG units. Optimal DG locations are found by using analytical method called index vector method (IVM) and optimal rating are found by optimization technique called 'whale optimization algorithm' (WOA). The proposed IVM and WOA are tested on two popularly used test systems namely IEEE 33 & 69 bus systems. Finally, it is observed from the results that type-4 DG performs well as compared to other types of DGs in view of power loss reduction and voltage profile improvement.

A Hybrid Diesel Wind PV Based Energy Generation System

A. V. Sudhakara Reddy, Balla Shiva Kumar, Ch. Narendra Kumar

Abstract*: Imperativeness increase of network to compelled districts is connected with specific and modest. Enabled examination abuse age manageable power.Test displays execution an unbiased miniaturized scale matrix topology relying upon a lone. Miniaturized scale matrix structure is empowered with various maintainable power sources to be explicit breeze and sun orientated PV group. Regardless, vitality amassing structure in like manner saves the trustworthiness. Upside blurred trading key oversee. Realized supply. Breeze daylight essentially based hotshots resources identified with association.Appliedon associate with rouse quick vitality steadiness underneath exact conditions.Nearby the system compromise, the VSC moreover can possibly slight the vitality extraordinary inconveniences, for example, consonant streams, load altering and voltage principle. By utilizing cushioned method of reasoning controller in this system to diminish the deviations inside the waveforms. A broad gathering copy is shown uncover all.

Keywords* : eyewitness, manage exceptional, independent micro grid, voltage tenet.

I. INTRODUCTION

Most extreme reasonable for a wild revision because of trapezoidal returned EMF. On the off peril that the winding streams are in like manner made semi rectangular wave, by then a low wave torque is made and the contraption works effectively. This component isn't made semi rectangular streams. What's more, the essentialness thickness of the PMBLDC machine is unreasonable which makes it little in size, in this way incredible inclination for post mounting utility. Unflinching outstanding appraisal of a breeze diesel-battery based absolutely system is represented, wherein wind vitality trade structure trustworthiness is gotten thinking about the breeze fluctuations and component trouble. Furthermore, the reliability research of the entire structure is likewise performed by method for taking diesel, wind and battery. The control of a PMSG (Permanent Magnet Synchronous Generator) basically based WECS (Wind Energy Conversion System) related with an inverter with battery going around as structure is advertised. The vitality created by methods for WECS is used to control the SOC of battery. In the more a piece of the structures depicted in the composition, variable pace wind power trade system attempts to isolate the most extreme serious power from the breeze. Wind vitality is detached vitality at the action mastermind, so it is valuable to remove the best quality and to develop the adequacy and utilizing WECS. It Dreams starting capital charge, yet. Various systems figuring like incline climbing, the mechanical sensor considerably less MPPT estimation contemporary sensor less computation lifts. Figuring related side interest repeat, directing top notch issues consolidating aircon. Various estimations represented inside composition. A moved estimation reliant onlooker represented. Spectators applied isolate symphonious portions sign a short time later the evacuated significant is also applied in this oversee figuring. This assignment execution dwindled wind-sunshine based -essentially unprejudiced little scale grid structure.

A version enduring those factories being developed. breeze sunlight based basically based PV structures are ceaselessly toiled at their most extreme serious power factor using help converters and the DG is worked inside a predefined quality assortment to improve the ability join assets resources vitality development potential great ability. sensor less recollect utilized a lazy absolutely estimation sunlight based situated structure. In the moving toward years, all living arrangements could have its extremely possess uninterruptible manageable power source structures that may can likely figure in statute methods Of hobby, as an example, network related mode and islanded mode. This strategy might be sound for gathering a simple, relentless change among those modes with the guide of abuse. Landing district and resynchronization algorithmic core value could be something tangled. Each approach of progress power cycle is respected inside the Figure. There are two strategies for exercises as respected in observe underneath, fair-minded and system related. At the point when the capacity is shut far away from the utility grid, the system goes to the islanded mode and once the limit is to be had from the application network, the structure can synchronize and may be related with the application cross section. Yield oversee from the electrical cell is accessible for interfacing hybrid electrical vehicle (PHEV) system. Bidirectional Power Device (BPD) controls two parameters, dynamic present and dynamic/responsive control. In autonomous mode, BPC supervises two parameters, AC repeat and voltage.

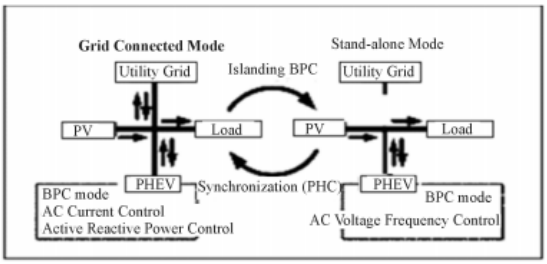

Fig. 1. Mode of operation

The going with segment explains working general of those modes. There are progressive alterations with the country of atmosphere and speed of wind. Dependent upon these conditions, wind and grand bodies work. These systems must be adoptable. This deduces these systems should change of employable parameters in accordance with the movements in climatic circumstances. These parameters are hugely fanciful. These parameters can't be common even with the guide of the chairmen inside the structure and cannot predict the speed of wind and light hours Conditions for photograph voltaic cell develops decisively. The yield of those frameworks differs forever and administrator ought to be horribly careful within the lattice. In any case, there are various unique troubles which can be difficult to be illuminated.

II. LITERATURE SURVEY

A. R. Sebastian

Gives the Wind diesel cross breed frameworks is remote frameworks that be a piece of diesel generators with wind turbine turbines to diminish the fuel utilization. Noteworthy fuel speculation properties are most likely doable if the machine is in structure for strolling with the diesel turbines not running (Wind Only mode). This becomes the control multifaceted nature and requires extra gadget. Directly simultaneously as the breeze oversee isn't open, the diesel generator need to stock the basic capacity to the device. To lessen the measure of start forestall cycles in the diesel processes a speedy lived noteworthiness collecting machine is sizeable. Batteries are essential in wind diesel cream structures in view of the reality they might be the basic inclination for mid-term criticalness aggregating. This paper shows up at the gigantic alternatives for the case of batteries as at the present time vitality gathering. The battery fundamentally based totally significance putting away device utilizes a three-establishment interface related with the remote instrument that takes after the main power references.

Proposes a stand-apart independent crossover control age device, utilizing instigated control procedures, supported by methods for method for 4 quality property: wind control, sun masterminded vitality, gathering battery, and diesel motor generator, and which isn't constantly connected with a business oversee structure. Astonishing exertion changed into situated into the improvement of dynamic responsive vitality and advance off oversee controls. Contrasting power resources May be interconnected any place on a relative electrical connection, terrifying adaptable structure headway. It is anticipated that this blend control age machine, into which regular hugeness is merged, will include to worldwide natural assurance separated islands and in common zones without a reliance on modern business venture oversee frameworks.

III. PROBLEM FORMULATION

Also, an oversee depend is expected related endeavor rehash moderating charming issues combining cooling things. Different key control figuring's are spoken to inside the structure. An induced control calculation contemplating composite passerby is spoken to. Composite observers are utilized to seclude consonant factors from any flag and after that the expelled essential is in like manner utilized on this control depend. This undertaking offers utilization decreased -sun sorted out totally independent little scale network structure plants hesitance suffering those plants being developed. breeze sun fundamentally based structures normally toiled most extreme incredible utilizing help worked internal predefined control improve general execution utilized set up resources vitality development limitation top notch exchange limit. A mechanical sensor less MPPT calculation is utilized for WECS and an enduring conductance based MPPT depend is utilized for sun oriented based absolutely PV device.

IV. HYBRID SYSTEM

If you Between relationship of as a base two wellsprings of Renewable ages like breeze control, picture voltaic quality, electric controlled portable and littler scale turbine generator to give ability to close by load or most likely interfacing with organize/scaled down scale structure frameworks Hybrid Energy Systems. By virtue of qualities of daylight based absolutely vitality imperativeness, quality age group moreover breeze relating relentless top notch of joined vitality age which is much better while appeared differently in relation to the vitality made by an individual stock. An across the board required bunch. As of past due, DC systems are resurging a final product of the headway and relationship of limitless DC control resources and the favored situation for DC stacks in business undertaking, mechanical and individual applications. To include with the remarkable appropriated turbines DC small scale network has been proposed. Regardless, AC sources should be altered over related with system required customary hundreds. At the factor when vitality can be completely given with the guide of the boundless power sources. HV extensive detachment transmission is not the slightest bit again indispensable. Cooling Micro networks are proposed to rouse the relationship of limitless quality assets to AC systems. In any case, photovoltaic (PV) board's DC yield vitality must be changed over utilizing supporters interface with system. System, required for novel household working environments offer particular. A portion of half AC/DC littler scale system is proposed In this paper to diminish various methodologies of turnaround alterations in a man or lady framework rouse inexhaustible what's more, assets hundreds quality. Plans greatest limitless debilitate move among structures, save up steady enthusiasm underneath part commercial center leisure activity conditions when the

hybrid system works system moved equipment advancements used make predetermination stacks increasingly wonderful. In light of the manner in which that daylight basically based fanciful, better invasion in sort's framework should manufacture specific frail frameworks live particular structures right gathering capacity. Planning 2 limitless assets into a perfect blend, the effect of the variable thought of sun powered based and wind things could be in the fundamental settled and the general system ends up being routinely strong and moderate to run. Every wellspring of intensity makes diverse quality pointers, for example Photovoltaic portable produces DC and wind produces AC. Adaption is must be required between them. This adaption is alluded to as coupling. Coupling should be feasible in two specific habits: AC or DC. They might be utilized as a touch of each on-network, off-cross section and additionally fit as a fiddle. In AC-coupling and DC-coupling the amount of components are for all intents and purposes same yet the important differentiation is dump weight is used in DC simultaneously as WTG inverter in AC-coupling.. Noteworthy is the way that the WTG inverter a terrible parcel of the time is made With a breaking chopper, basically a DC-DC supplanting noxious present day-day and voltages directly into a resistor making warmth, to comfortable the inverter as opposed to a unload load.

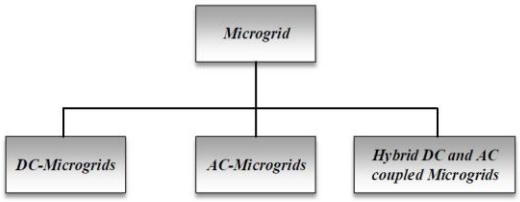

Fig. 2. Three types of grids

Voltage and repeat substitute, and music are full-size power astounding issues for every network related and keep on being singular systems with additional impact inside the occasion of weak cross section. This can bere fathomed to a decent estimated degree by means of having real shape, pushed brief response oversee work environments, and advancement of the blend systems.

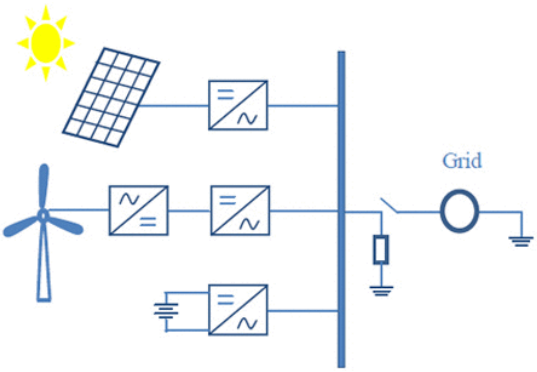

Fig. 3. Hybrid gadget with AC Micro network

Small scale framework is another thought in charge age. The Micro network thought changed into a gathering of hundreds and littler scale resources functioning as a lone controllable system that offers every quality and warmth. A couple of models ought to portray the fragments of a Micro system.

V. MODELING SYSTEM

Sun oriented orientated principally fair little scale grid with the battery vitality amassing to keep up the nearby masses. The all out system topology is showed up in Fig. 4. A by method for RG is applied breeze plants picked intentionally in light of the going with turbines decrease upkeep close with.

By methods for RG is applied customary counselor and AVR is depleted at this point the voltage and rehash of the structure are directed. Pushed methods for a breze. Regarded Fig in. 4, the relationship lift is most proper a wild change because of trapezoidal again EMF.

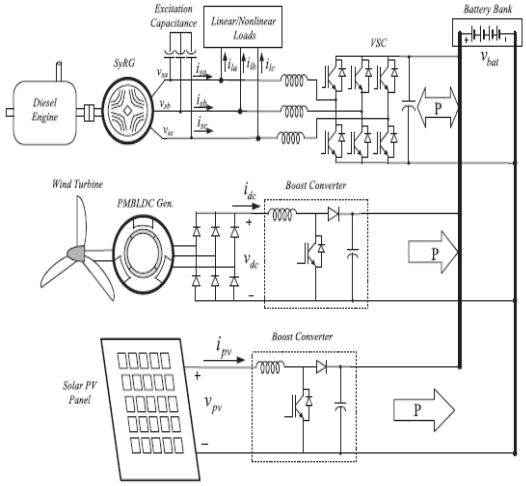

Fig.4 proposed unmarried VSC and the brushless age fundamentally based free little scale cross section structure

If the winding streams are in like manner made semi rectangular wave, by then a low-swell torque is brought and the gadget works easily. This angle isn't made semi rectangular streams the essentialness thickness contraption little long, hereafter phenomenal open door for distribute mounting programming. The proposed topology additionally conveys sun arranged PV structure, which is likewise connected with the dc association of the VSC for power stream to the forced air system side wherein weights are to be had. As discussed sooner than, to keep up the power leveling and steadfast best of the store, the battery vitality accumulating machine is required. In this way, additionally presented association structure severa assets, gadget as made improve as well as eco-benevolence or as upgrade the free of extraction imperativeness helpful. As well as DG rule aircon supply inside the structure, so the system and the stack stop repeat is perceived with the action of the DG since it were. A customary repeat of the structure suggests the consistent speed of the generator (as the generator is by RG). It is communicated that with consistent speed movement of the diesel engine, the fuel use doesn't exchange bounty from its motivating force at complete weight, along those strains as making it as engine diesel eco-agreeableness terrible at lighter weights. as the diesel vehicles compositions may sensible super viability among eighty–a hundred% stacking. Here, the control technique is delivered for the DG to works of art it regularly inside a foreordained

stacking assortment as respected in Fig. Five. The as well as rating full as weight rating isn't as well as required there is maintainable power supply property and the battery essentialness accumulating framework is out there.

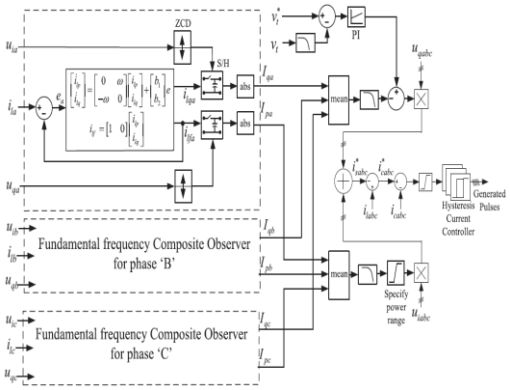

Fig. 5. VSC for strategy Control

As well as WECS comprises for as generator PMBLDC, 3-arrange rectifier diode partner diode or as converter lift. It is inductor as well as utilized as well as to made of the dc present day in every way that really matters suffering which shows as semi square waveform of current revealing in genuine time conditioner viewpoint that is good for the movement of PMBLDCG as examined beforehand. The development of the WECS is advanced with the guide of getting out the need of any mechanical sensor for MPPT. A MPPT figuring is used which calls for simply identifying of VDC and IDC. This MPPT computation is proportionate to issue and watch that is used for most extreme exceptional power extraction in sun based absolutely PV system.

VI. SIMULATION RESULTS

For Sensor Mechanical MPPT. A MPPT estimation for used may requires essentially identifying as VDC and IDC. As well as MPPT computation of comparable to issue and watch that is used for greatest exceptional vitality extraction in sun based PV system.

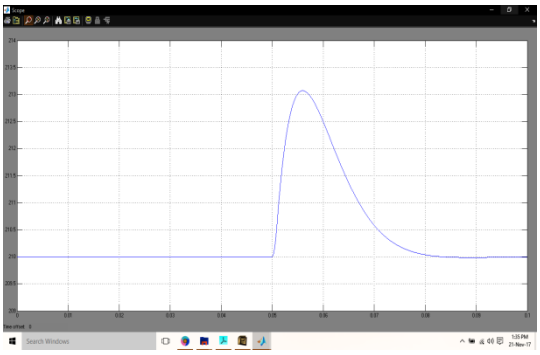

Fig. 6(a). VDC

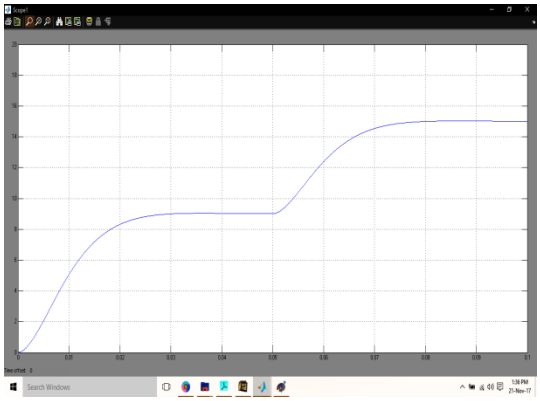

Fig. 6(b) IDC

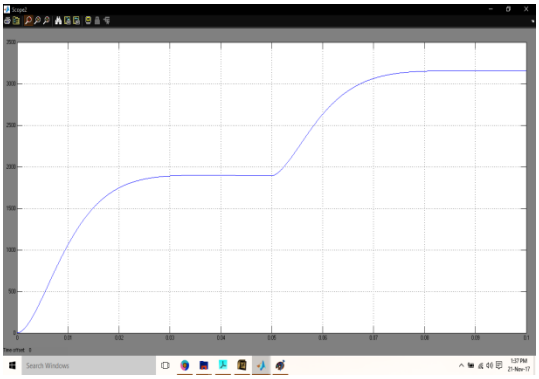

Fig. 6(c) PDC

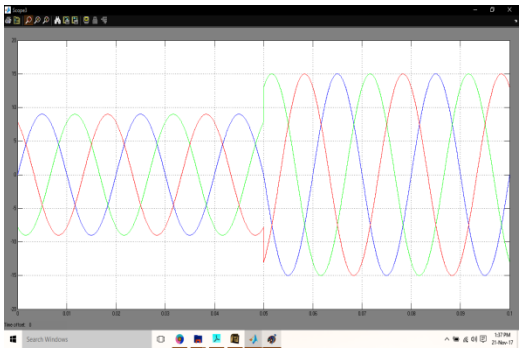

Fig. 6(d) Ipm-bldc

Fig. 6. As Performance for varying wind under WECS speed

As relating to execution as for MPPT count underneath thing wind movement is appeared in Fig. 6. The impacts with steady wind speed are appeared in Fig. 6 until t= zero.05s. The breeze pace is adjusted from 7 to 12 m/s at t = zero.05 s. The dynamic conduct of the structure is appeared during such assortment in wind speed. From those outcomes, it is noticeable that with an assortment inside the breeze speed, the vitality yield of the WECS increases and in addition it might be unmistakable that the PMBLDCG present day has similarly expanded.

Fig. 7. Performance faulted under condition System

The territory gives as succinct cognizance be ways as structure shall keep on underneath some trouble circumstances. The blemish events are made and separated utilizing reenactment apparatus. First case is taken where the trouble is made reporting in real time conditioner shipping. Current through the converter is controlled inside the control check number. As the streams are no Sinusoidal, a hard present day factor of constringent is applied to comfortable the gadgets and the system. On the off danger that the trading contraptions have their extremely possess guarantee structure (like desideration for IGBTs), at that factor a roundabout present day control might be applied, which requires simply supply streams. Nevertheless, the ones protections are hook capable (shutdown the structure), so it's miles more astute to restrict the cutting edge without requesting the interest. That is the thought process a quick present day control merging compensator streams for used. as outcomes it appeared an Fig. 7. As showed up in Fig. 7, the responsive as for at most extreme part gave the guide of the converter and with the deficiency reporting in real time conditioner line, the open vitality possesses inconvenience way breakdown. Regardless, while the need is cleared, the generator gets once more. Another piece of breathing space on that structure as well as it's far as framework fundamentally system based or from now on at generator prominently adds at that issue contemporary, with have as monster brisk out score appeared differently in relation to the semiconductor contraptions.

VII. CONCLUSION

Hybrid vitality structures (HES) can convey circumstance pleasant and monetarily adroit essentialness courses of action with higher unfaltering charming and vitality five star. As opposed to standard vitality, impartial sun based principally based breeze diesel based absolutely HES can supply no longer too awful convey of electrical power in faraway regions. In these days, HES is a money related truth to bring down the dependence network systems. As well as diesel driven control generator at normally given the remote HES of the event of electrical unavailability in the unavailability vitality for economical quality. Additionally, can HES significantly lessen as fuel use or outpouring appeared differently in relation to the customary vitality structures. Regardless, a considerations boggling vitality the official's methodology is required to

guarantee suitable quality phenomenal sources or streamline as quality. The compact report interest as locked in on that investigation will a mean to collect a vitality the board strategy and control structures for stay lone sun essentially based breeze diesel half of breed essentialness frameworks (SWDHES). The proposed little scale network topology with a singular voltage source converter and brushless generators has been practiced underneath unmistakable running conditions. An included movement of oversee estimations is moreover endeavored for structure's voltage and repeat control, cure of force agreeable issues, oversee balance inside the total system under novel disrupting influences stretching out from full-size weight territory to maintainable vitality source supply vulnerability. Some thought of battery rate release oversees and flaw investigation is additionally talked about. Matlab/simulink impacts have affirmed the appropriateness of this topology for rustic/segregated districts in light of the fact that the topology is simple and expense compelling.

AUTHORS PROFILE

Dr. A. V. Sudhakara Reddy has 10 years of experience in Teaching and Research. He received Doctor of Philosophy from Sri Venkateswara University, India. Presently he is working as Assistant Professor and R&D Coordinator in Electrical and Electronics Engineering at Malla Reddy Engineering College (A)-Main Campus, Hyderabad, India. He has published 23 Research Papers including IEEE conferences, Free, Scopus, Thomson Reuters Indexed and UGC indexed Journals. His area of research interest includes Power Systems, Soft Computing and Machine Learning. He is a life time member of various professional bodies like IEEE, ISTE, IAENG and IEI.

Balla Shiva Kumar has has completed Bachelor of Engineering in Electrical and Electronics Engineering from Matrusri Engineering College, Osmania University, Hyderabad, Telangana State, INDIA in 2016. Presently, he is studying as Post Graduation in Electrical Power System at Electrical and Electronics Engineering Department, Malla Reddy Engineering College (A), Secunderabad.

Mr. Ch. Narendra Kumar has completed B.Tech in Electrical and Electronics Engineering from Jawaharlal Nehru Technological University Hyderabad in 2002 and M.Tech in Power Electronics and Drives from Bharath Institute of Higher Education and Research, Chennai in 2008. Currently, he is working as Associate Professor at Electrical and Electronics Engineering Department, Malla Reddy Engineering College (A), Secunderabad. He is a CLAD (Certified LabVIEW Associate Developer) from National Instruments. His research Interests includes Power Electronics, Power Systems and Applications of Electrical Drives.

A review of Fingerprint Recognition Based Automatic Attendance System

Mrs. Y Sudha Reddy[1], Mrs. P Pooja[2]

Assistant Professor, EEE, MREC[1,2]

Abstract: Our paper aims at designing a student attendance system which could effectively manage attendance of students at institutes like NIT Rourkela. Attendance is marked after student identification. For student identification, a fingerprint recognition-based identification system is used. Finger prints are considered to be the best and fastest method for biometric identification. They are secure to use, unique for every person and do not change in one's lifetime. Fingerprint recognition is a mature field to- day, but still identifying individual from a set of enrolled fingerprints is a time taking process. It was our responsibility to improve the fingerprint identification system for implementation on large databases e.g. of an institute or a country etc. In this paper, many new algorithms have been used e.g. gender estimation, key based one to many matching, removing boundary minutiae. Using these new algorithms, we have developed an identification system which is faster in implementation than any other available today in the market. Although we are using this fingerprint identification system for student identification purpose in our paper, the matching results are so good that it could perform very well on large databases like that of a country like India (MNICPaper).

This system was implemented in Matlab10, Intel Core2Duo processor and comparison of our one too many identification was done with existing identification technique i.e. one to one identification on same plat form. Our matching technique run sinO (n+N) time as compared to the existing O(Nn2). The finger print identification system was tested on FVC2004 and Verifinger databases.

Keywords: Attendance Management Systems, MATLAB, Fingerprint Recognition, Matching Techniques

I. INTRODUCTION

Designing a student attendance management system based on fingerprint recognition and faster one to many identification that manages records for attendance in institutes like NIT Rourkela**.** Every organization whether it be an educational institution or business organization, it has to maintain a proper record of attendance of students or employees for effective functioning of organization. Designing a better attendance management system for students so that records be maintained with ease and accuracy was an important key behind motivating this paper. This would improve accuracy of attendance records because it will remove all the hassles of roll calling and will save valuable time of the students as well as teachers. Image processing and finger print recognition are very advanced today in terms of technology. It was our responsibility to improve fingerprint identification system. We decreased matching time by partitioning the database to one-tenth and improved matching using key based one too many matching.

Biometric Identification Systems are widely used for unique identification of humans mainly for verification and identification. Biometrics is used as a form of identity access management and access control. So use of biometrics in student attendance management system is a secure approach. There are many types of biometric systems like fingerprint recognition, face recognition, voice recognition, iris recognition, palm recognition etc. In this paper, we used fingerprint recognition system. A fingerprint is the pattern of ridges and valleys on the surface of a fingertip. The endpoints and crossing points of ridges are called minutiae. It is a widely accepted assumption that the minutiae pattern of each finger is unique and does not change during one's life. Ridge endings are the points where the ridge curve terminates, and bifurcations are where a ridge splits from a single path to two paths at a Y-junction. Figure1 illustrates an example of a ridge ending and a bifurcation. In this example, the black pixels correspond to the ridges, and the white pixels correspond to the valleys.

When human finger print experts determine if two fingerprints are from the same finger, the matching degree between two minutiae pattern is one of the most important factors. Thanks to the similarity to the way of human fingerprint experts and compactness of templates, the minutiae-based matching method is the most widely studied matching method.

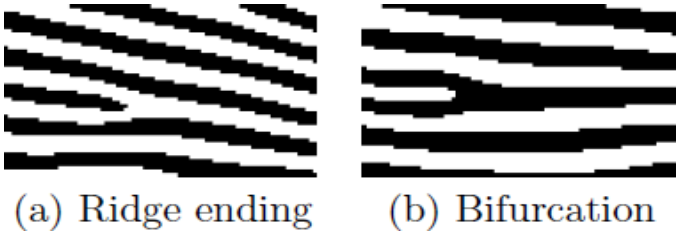

Fig 1: Example of a ridge ending and a bifurcation

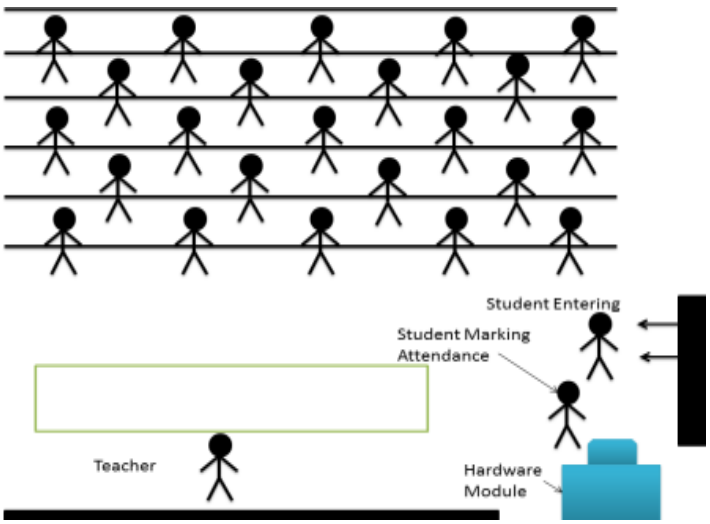

Fingerprints are considered to be the best and fastest method for biometric identification. They are secure to use, unique for every person and do not change in one's lifetime. Besides these, implementation of fingerprint recognition system is cheap, easy and accurate up to satisfiability. Fingerprint recognition has been widely used in both forensic and civilian applications. Compared with other biometrics features, fingerprint-based biometrics is the most proven technique and has the largest market shares. Not only it is faster than other techniques but also the energy consumption by such systems is too less.

II. USING FINGERPRINT RECOGNITION SYSTEM ATTENDANCE MANAGEMENT

Managing attendance records of students of an institute is a tedious task. It consumes time and paper both. To make all the attendance related work automatic and on-line, we have designed an attendance management system which could be implemented in NIT Rourkela. It uses a fingerprint identification system developed in this paper. This finger print identification system uses existing as well as new techniques in fingerprint recognition and matching. A new one to many matching algorithm for large databases has been introduced in this identification system. This paper has been organized into introduces with our paper, explains the proposed design of attendance management system. Explains the fingerprint identification system used in this paper, explains enhancement techniques, explains feature extraction methods, explains our database partitioning approach work. Explains matching technique, explains experimental work done and performance analysis, includes conclusions and introduces proposed future work.

III. ATTENDANCE MANAGEMENT FRAMEWORK

Manual attendance taking and report generation has its limitations. It is well enough for 30-60 students but when it comes to taking attendance of students large in number, it is difficult. For taking attendance for a lecture, a conference, etc. roll calling and manual attendance system is a failure. Time waste over responses of students, waste of paper etc. are the disadvantages of manual attendance system.

Moreover, the attendance report is also not generated on time. Attendance report which is circulated over NITR webmail is two months old. To overcome these non-optimal situations, it is necessary that we should use an automatic on-ine attendance management system. So we present an implementable attendance management framework. Student attendance system framework is divided into three parts: Hardware/Software Design, Attendance Management Approach and On-line Report Generation. Each of these is explained below.

Hardware - Software Level Design

Required hardware used should be easy to maintain, implement and easily available. Proposed hardware consists following parts:
(1)Fingerprint Scanner, (2) LCD/Display Module (optional), (3) Computer, (4) LAN connection

Table 1: Estimated Budget

Device Name	Cost of One Unit	No. of Units Required	Total Unit Budget
Scanner	500	100	50000
PC	21000	100	2100000
Total			21,50,000

Fingerprint scanner will be used to input fingerprint of teachers/students into the computer software. LCD display will be displaying rolls of those whose attendance is marked. Computer Software will be interfacing fingerprint scanner and LCD and will be connected to the network. It will input fingerprint, will process it and extract features for matching. After matching, it will update database attendance records of the students.

Fig 2: Hardware present in classrooms

Estimated Budget Estimated cost of the hardware for implementation of this system is shown in the table 2.1. Total number of classrooms in NIT Rourkela is around 100. So number of units required will be 100.

This part explains how students and teachers will use this attendance management system. Following points will make sure that attendance is marked correctly, without any problem:

(1) All the hardware will be inside classroom. So outside interference will be absent.
(2) To remove unauthorized access and unwanted attempt to corrupt the hardware by students, all the hardware except fingerprint scanner could be put inside a small cabin. As an alternate solution, we can install CCTV cameras to prevent unprivileged activities.
(3) When teacher enters the classroom, the attendance marking will start. Computer software will start the process after inputting fingerprint of teacher. It will find the SubjectID, and Current Semester using the ID of the teacher or could be set manually on the software. If teacher doesn't enter classroom, attendance marking will not start.
(4) After sometime, say20minutes of thisprocess, no attendance will be given because of late entrance. This time period can be increased or decreased as per requirements.

Database for attendance would be a table having following fields as a combination for primary field: (1)Day, (2)Roll, (3)Subject and following non-primary fields: (1)Attendance, (2)Semester. Using this table, all the attendance can be managed for a student. For on-line report generation, a simple website can be hosted on NITRourkela servers, which will access this table for showing attendance of students. The sql queries will be used for report generation. Following query will give total numbers of classes held in subject.

Network and Database Management

This attendance system will be spread over a wide network from classrooms via intranet to internet. Using this network, attendance reports will be made available over internet and e-mail. A monthly report will be sent to each student via email and website will show the updated attendance.

In ER diagram, primary fields are Roll, Date, SubjectID and TeacherID. Four tables are Student, Attendance, Subject and Teacher.

Using wireless network instead LAN and bringing portability
We are using LAN for communication among servers and hardwares in the classrooms. We can instead use wireless LAN with portable devices. Portable device will have an embedded fingerprint scanner, wireless connection, a microprocessor loaded with a software, memory and a display terminal, see figure2.5. Size of device could be small like a mobile phone depending upon how well the device is manufactured.

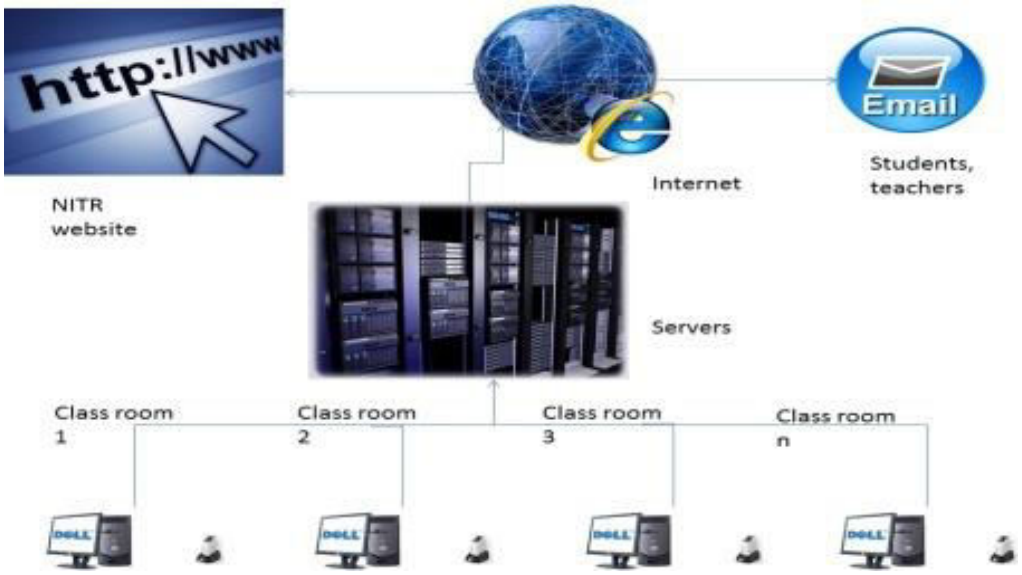

Fig 4: Components of Portable device

This device should have a wireless connection. Using this wireless connection, attendance taken would be updated automatically when device is in network of the nodes which are storing the attendance records. Database of enrolled fingerprints will be in this portable device. Size of enrolled database was 12.1 MB when 150 finger- prints were enrolled in this paper. So for 10000 students, at least 807MB or more space would be required for storing enrolled database. For this purpose, a removable memory chip could be used. We cannot use wireless LAN here because

IJIREEICE

ISSN (Print) 2321-5526

International Journal of Innovative Research in
Electrical, Electronics, Instrumentation and Control Engineering

Vol. 7, Issue 10, October 2019

fetching data using wireless LAN will not be possible because of less range of wireless devices. So enrolled data would be on chip itself. Attendance results will be updated when portable device will be in the range of nodes which are storing attendance reports. We may update all the records online via the mobile network provided by different companies.Today3G network provides sufficient through put which can be used for updating attendance records automatically without going near nodes. In such case, the need of database inside memory chip will not be mandatory. It will be fetched by using 3G mobile network from central database repository. The design of such a portable device is the task of embedded system engineers.

The device may either behaving touch screen input/display or buttons with lcd display. A software specially designed for the device will be running on it. Teachers will verify his/her fingerprint on the device before giving it to students for marking attendance. After verifying the teacher's identity, software will ask for course and other required information about the class which he or she is going to teach. Software will ask teacher the time after which device will not mark any attendance. This time can vary depending on the teacher's mood but our suggested value is 25 minutes.

There are various other kind of student attendance management systems available like RFID based student attendance system and GSM-GPRS based student attendance system. These systems have their own pros and cons. Our system is better because first it saves time that could be used for teaching. Second is portability. Portability has its own advantage because the device could be taken to any class wherever it is scheduled. While GSM-GPRS based systems use position of class for attendance marking which is not dynamic and if schedule or location of the class changes, wrong attendance might be marked. Problem with RFID based systems is that students have to carry RFID cards and also the RFID detectors are needed to be installed. Nonetheless, students may give proxies easily using friend's RFIDcard. These problems are not in our system. We used fingerprints as recognition criteria so proxies cannot be given. If portable devices are used, attendance marking will be done at any place and anytime. So our student attendance system is far better to be implemented at NITR.

Matching

Matching means finding most appropriate similar fingerprint to query fingerprint. Fingerprints are matched by matching set of minutiae extracted. Minutiae sets never match completely, so we compute match score of where q_j and p_i are the coordinates of j^{th} minutiae of database minutiae set and i^{th} minutiae of query minutiae set respectively. Using these $<\delta x, \delta y, \alpha_k>$ values ,whole query minutiae set is aligned. This aligned minutiae set is used to compute pairing score. Two minutiae are said to be paired only when they lie in same bounding box and have same orientation. Pairing score is(number of paired minutiae)/(total number of minutiae).The i,j,k values which have highest pairing score are finally used to align minutiae set.Existing Matching Techniques

Most popular matching technique of today is the simple mindedn^2 matching where n is number of minutiae. In this matching each minutiae of query fingerprint is matched with n minutiae of sample fingerprint giving total number of n^2 comparisons. This matching is very orthodox and gives headache when identification is done on large databases.

One to Many matching

Few algorithms are proposed by many researchers around the world which are better than normal n2 matching. But all of them are one to one verification or one to one identification matching types.

IV. CONCLUSION

In this paper, we have presented a fingerprint-based attendance management system.

The developed system is an embedded system that is part of a fingerprint recognition/authentication system based on minutiae points. The system extract the local characteristic of a fingerprint which is minutiae points in template based. Templates are matched during both registration and verification processes. For improved quality control during the registration or verification process, a matching score was used to determine the success of the operation. The matching score was specified so that only sets of minutiae data that exceed the score will be accepted and data below the score will be rejected. Therefore, Fingerprint Recognition using Minutia Score Matching method was used for matching the minutia points before attendance is recorded.

The developed system is very helpful in saving valuable time of students and lecturers, paper and generating report at required time. The system can record the clock in and clock out time of students and workers in a very convenient manner using their fingerprint to prevent impersonation and reduce level of absence. Also, it reduces most of the administrative jobs and minimizes human errors, avoids proxy punching, eliminates time-related disputes and helps to update and maintain attendance records.

Abstract:*The main aim of this project is multilevel inverter associated UPQC for power quality enhancement. UPQC having 2 controllers namely series controller&another one is shunt controller. These controllers are associated with the DC link capacitor. Dc voltage is produced by PV source. In this project multilevel inverters are used in series&shunt controller for producing accurate sinusoidal wave shape. The series controller is connected at grid side for grid power quality improvement. In this project grid side voltage sag/swell reduced by series controller. The shunt controller regulate the reactive power compensation as well as reduced the load current harmonics. These controllers are regulated by expending synchronous reference frame theory (SRF). The advantages of proposed system is high efficiency&enrichment of quality power. The simulated results of proposed system is verified by MATLAB/Simulink environment.*

Key word: PV, UPQC, Power quality, harmonics, Synchronous reference frame theory,

I. INTRODUCTION

In recent days usage of renewable energy source are very popular & there is also enhancing emphasis on unpolluted energy generation via connection of rooftop-PV structures in small scale apartments and as well as profitable buildings [1]. Due todiscontinuousnature-of PV, an improved penetration of such frameworks, mostly in weak-circulation networksleads-to power quality issues i.e., voltage swell & voltage sag, which ultimatelyinsecurity in grid [2]. These issues also lead-to frequent false tripping of power electronic frameworks, damaging & false triggering of electronic structures &increases heating of capacitor banks etc [3]. In the Power quality issue on together load side& at grid side is main problem are faced between in modern distribution systems. The three stage multi-functional solar energytransformation network, which compensate-into load side power-quality issue was proposes in [4]. The single-phase solar PV inverter along within activepowerfiltering ability as well-known proposed as [5]. The main researched works are done into integrate at cleaned energy generations among the shuntactive filters. While shuntactive filters is capable as together load voltage-regulation,&has been coming into the cause ofinjects into reactive powers. In shunt-active filter are not regulates in PCC voltages as known in maintained in grid current unit power factor into equal time, as well as the stringent-voltage quality-requirements formelectronic load, in the used in series-active filter have propose form used into little apartment&profitable building[6]. The solar-photovoltaic systems are integrate into the dynamic voltages at restorer are proposed in [7]. Comparing at shunt &series-active power filters, at unify power quality-conditioner (UPQC), when it is have been together series or shunt compensator may be performed into load voltage regulations on maintaining at grid current sinusoidal at aunity power factor into same time. Integrating PV array as well as UPQC, giving to the two benefit in thecleaned energy generations into universals active. This integration on PVarray within unify power quality-conditioner have been reported in [8]. Compared between conventional grid connected inverters, in the PV integrated unify power quality-conditioner was many benefit into such improves in power quality in the grid, protecting critical loads for gridside conflictseparately in increases in the faults rides among the capability to converter throughout transients. With the increasestress on distribution generations& micro grids, here on renewable interested intounify power quality-conditioner systems [9]. Mention signal-generations are main tasks into control of the PV-UPQC. References signal generation technique may broad dividing astime domains at frequencies as domain technique. Time-domain method is common uses in between inthe lower computational requirement into real time implementation. Which are common using methods includes inreactive-power theories, synchronous-reference frames theory (DQ theory). The majorissue in use inthe synchronous referenced with frames theory base on technique as due to loadsdisturbed conditions, at double harmoniccomponent are presented at the D-axis currents. Because of this, lowpass filter at low cut off frequency is uses into filterout double harmonic-component. In the project is, a moves average filter (MAF) at uses in filter at the D axis

current to obtaining fundamental loads active currents. And giving as optimal-attenuation inwithin reduces the bandwidth in the controls [10]. Later, MAF is apply into improving performance of DC-link controls are known into grid synchronization used to phase locked loop. In the project, is the design & performance analysis of a three phase PV-UPQC are presented. Here the single phase inverter is replaced by cascaded multilevel inverter (CMLI-UPQC) for reducing the harmonics&improve the wave shape of inverter. These major benefits of the proposing system as following,

- Integrated into the clean energy generation&power quality improvements.
- Simulated into voltages or currents quality improves.
- The performing into load current compensate because of uses into MAF as DQ controls in CMLI-UPQC.

These improvements are the proposed systems are analyzing extensively below at two dynamic & stable state condition using into Matlab/Simulink softwares.

II. EXISTING SYSTEM

Fig.1 indicates the existing system configuration with 2 level inverters. The framework PV-UPQC has series controller&shunt controller& DC link capacitor it is connected with PV source. The shunt controller associated with load side for reduction of load current harmonics & reactive power compensation & here filters are used for smoothing the ac wave. The series controller associated with grid side for improvement of gird power quality i.e., voltage sag/swell. The main drawback of this system is high harmonics are produced because of 2 level inverters.

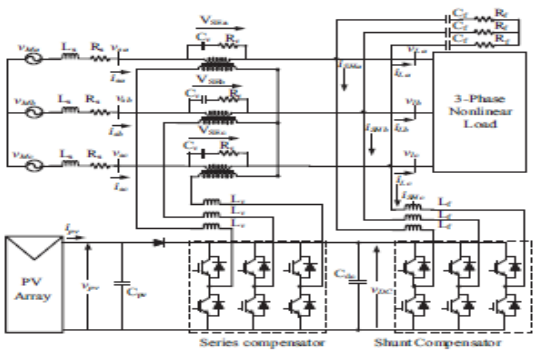

Fig. 1. Configuration PV-UPQC with 2 level inverter

III. PROPOSED SYSTEM

Because of 2 level inverter getting higher THD. So this is the major drawback of existing framework. In the proposed system the 2 level inverter is replaced by multilevel inverter namely CMLI-UPQC. The main benefit of cascaded multilevel inverter is to generate the accurate sinusoidal shape of the ac wave. In this framework series&shunt controllers are replaced by multilevel inverter via dc associated capacitor. The function series CMLI-1 is to compensate power quality problems at gird side i.e. voltage sag/swell. This controller is operated by synchronous reference theory by taking feedback as grid side voltages as discussed in control strategy. The function of shunt CMLI-2 is to compensate the load current harmonics produced by nonlinear or unbalanced load. It is regulated by synchronous referenced frame theory as discussed in below segment.

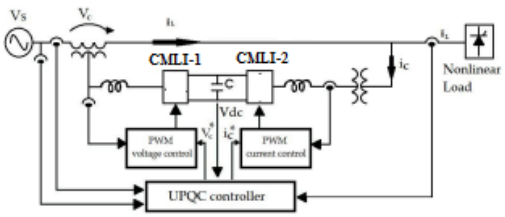

Fig 2 ProjectedSystem of CMLI –UPQC

Cascaded Multilevel Inverter

The below figure.3 indicates the cascaded multilevel inverter. This inverter consists of dc link capacitors & each dc link capacitor associated with on full bridge inverter connected in cascaded with h shape.

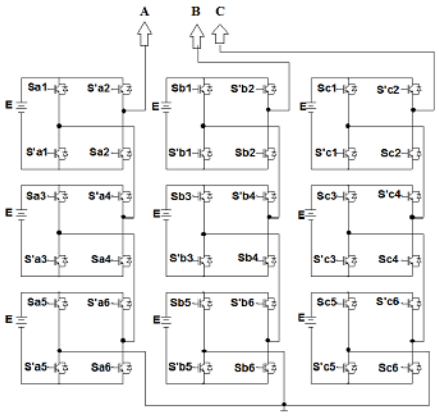

Fig 3 Three phase H Bridge cascaded Multilevel Inverter

Every single inverter employed a dc-interface voltage to sortanaltered voltage at yield terminals. The entire yield voltage is acquired by total of every individual yield voltage is picked up by the cumulative of the separate yield voltage

IV. PROPOSED CONTROL STRATEGY

A. Control of Shunt Compensator

The control block diagram of shunt compensator is indicates in fig.4. As per synchronous reference frame theory the load side currents taken as feedback signals i_{La}, i_{Lb}, i_{Lc} are transformation in to dqo. Assumed that active component is taken as reference signal this signal known as i_{Ld} is passes through the moving average filter for harmonic elimination. The final signal $I_{lf}$is addition with i_{Loss} & subtracted with I_{pvg}. Here i_{Loss} is getting form PV source by employing P&O MPPT algorithm. The final signal is Id. The dq0 is transformation in to Currents as reference signals these reference singles pass through the hysteresis current controller. In this controller reference currents are compared with measured load currents for producing pulses. These pulses are given to the shunt controller for operating.Here to take out DC portion without dividing the dynamic execution, a MAF isapplied to separateDCdivider.

The exchange furthest reaches of moving commonplace filters are assumed at,

$$MAF(s) = \frac{1 - e^{-T_w^S}}{T_w^S} \ldots.1$$

Where T_w are the windows lengths in the moved into typical filters.T_w is timespan.

In equivalent current part owing to PV group is known as,

$$I_{pvg} = \frac{2}{3}\frac{P_{pv}}{V_s} \ldots..2$$

Where P_{pv} is the PV exhibit power&Vs issize of the PCC voltages. The references framework currentsset as

$$I_{sd}^* = I_{Ldf} + I_{loss} - I_{pvg} \quad \ldots\ldots\ldots\ldots..3$$

I^*_{sdis} changed over to abc territory reference structure streams.

CONCLUSION

In the proposed PV-UPQC framework multilevel inverters are used in series&shunt controllers. The series controller is connected at grid side for grid power quality i.e., voltage sag/swell. The shunt controller reduced the load current harmonics. This may located the PV unify power qualityconditioner arehigh-quality resolution meant in recent circulation structure among incorporating circulated generation for enhancement of powerquality. The series&shunt controllers are regulated by synchronous reference frame theory. The simulated results are studied&verified by MATLAB/Simulink environment.

Abstract— In this paper we are add the capacitor add Dynamic Voltage Restorer (DVR) for life of the battery and performance increase in the system. We can reduce the distortions in the grid . This study examines the use of superconducting magnetic and battery hybrid energy storage to compensate grid voltage fluctuations. The superconducting magnetic energy storage system (SMES) has been emulated by a high current inductor to investigate a system employing both SMES and battery energy storage simulation. The design of the simulation is described in detail, which consists of a series-connected three phase voltage source inverter used to regulate AC voltage, and two bidirectional DC/DC converters used to control energy storage system charge and discharge. 'DC bus level signaling' and 'voltage droop control' have been used to automatically control power from the magnetic energy storage system during short-duration, high power voltage sags, while the battery is used to provide power during longer-term, low power under-voltages. Energy storage system hybridisation is shown to be advantageous by reducing battery peak power demand compared with a battery-only system, and by improving long term voltage support capability compared with a SMES-only system. Consequently, the SMES/battery hybrid DVR can support both short term high-power voltage sags and long term undervoltages with significantly reduced superconducting material cost compared with a SMES-based system.

Index Terms-- Dynamic Voltage Restorer (DVR), Energy Storage Integration, Sag, Superconducting Magnetic Energy Storage, Battery, capacitor.

I. INTRODUCTION

THE improvement of power quality is an important objective for electrical utilities and industrial and commercial consumers. Highly intermittent distributed generation, rapidly changing loads, and direct-off-line power electronic systems all contribute to reduced power quality causing equipment downtime, overload and failure leading to lost revenue [1]. Voltage disturbance is a common problem and under voltage conditions have been seen to occur more frequently than overvoltage conditions [2]. Short-term under-voltage sags are defined in IEEE Std. 1159-1995 [3] as a decrease to between 0.1 and 0.9 p.u. (per unit) r.m.s voltage for durations of 0.5 cycles to 1 min. They occur more frequently than long term under-voltages with significant costs to industry [4]. Long-term under-voltage events are defined as a measured voltage less than 0.8-0.9 p.u. r.m.s voltage, lasting longer than one minute [3] and can lead to load shedding and potentially to voltage collapse [5]. The study below presents a means by which both short-term and long-term voltage fluctuations can be mitigated at the load using short-term magnetic energy storage and long-term battery energy storage.

II. POWER QUALITY

The power quality definition, standards, causes and effects of harmonic distortion in a power system.

2.1 DEFINITION OF ELECTRIC POWER QUALITY

In recent years, there has been an increased emphasis and concern for the quality of power delivered to factories, commercial establishments, and residences. This is due to the increasing usage of harmonic-creating non linear loads such as adjustable-speed drives, switched mode power supplies, arc furnaces, electronic fluorescent lamp ballasts etc.[1]. Power quality loosely defined, as the study of powering and grounding electronic systems so as to maintain the integrity of the power supplied to the system. IEEE Standard 1159 defines power quality as [2]: The concept of powering and grounding sensitive equipment in a manner that is suitable for the operation of that equipment. In the IEEE 100 Authoritative Dictionary of IEEE Standard Terms, Power quality is defined as ([1], p. 855): The concept of powering and grounding electronic equipment in a manner that is suitable to the

operation of that equipment and compatible with the premise wiring system and other connected equipment. Good power quality, however, is not easy to define because what is good power quality to a refrigerator motor may not be good enough for today‟s personal computers and other sensitive loads.

2.2 DESCRIPTIONS OF SOME POOR POWER QUALITY EVENTS

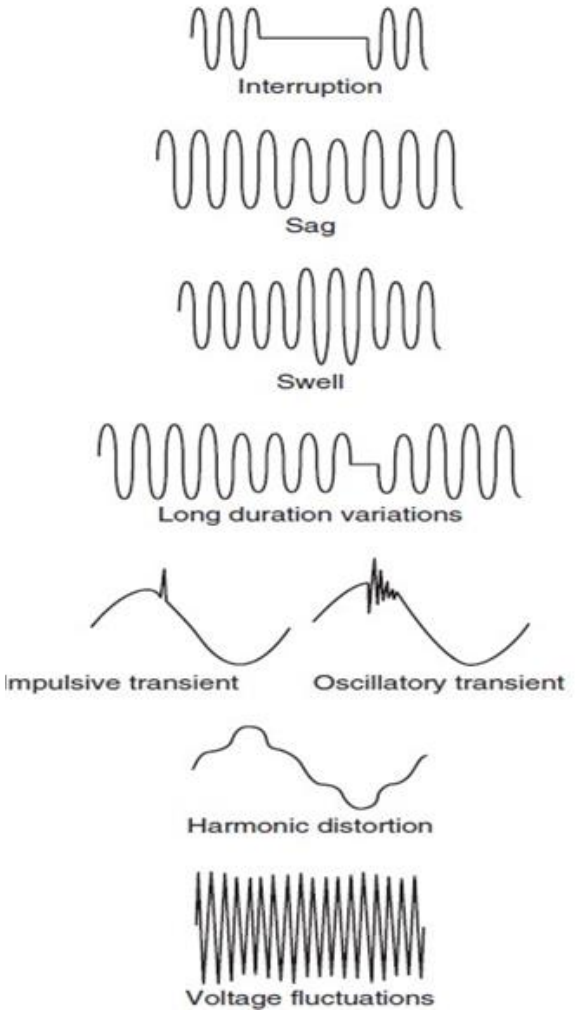

Fig. 1 Typical power disturbances.

The following are some examples and descriptions of poor power quality events

■ A voltage sag/dip is a brief decrease in the r.m.s line-voltage of 10 to 90 percent of the nominal line-voltage. The duration of a sag is 0.5 cycle to 1 minute. Common sources of sags are the starting of large induction motors and utility faults.

■ A voltage swell is a brief increase in the r.m.s line-voltage of 110 to 180 percent of the nominal line-voltage for duration of 0.5 cycle to 1 minute. Sources of voltage swells are line faults and incorrect tap settings in tap changers in substations.

■ An impulsive transient is a brief, unidirectional variation in voltage, current, or both on a power line. The most common causes of impulsive transients are lightning strikes, switching of inductive loads, or switching in the power distribution system. These transients can result in equipment shutdown or damage, if the disturbance level is high enough. The effects of transients can be mitigated by the use of transient voltage suppressors such as Zener diodes and MOVs (metal-oxide varistors).

■ An oscillatory transient is a brief, bidirectional variation in voltage, current, or both on a power line. These can occur due to the switching of power factor correction capacitors, or transformer ferroresonance.

■ An interruption is defined as a reduction in line-voltage or current to less than 10 percent of the nominal, not exceeding 60 seconds in length. Another common power-quality event is “notching,” which can be created by rectifiers that have finite line inductance.

■ Voltage fluctuations are relatively small (less than 5 percent) variations in the r.m.s line-voltage. These variations can be caused by cyclo converters, arc furnaces, and other systems that draw current not in synchronization with the line frequency. Such fluctuations can result in variations in the lighting intensity due to an effect known as “flicker” which is visible to the end user.

■ A voltage “imbalance” is a variation in the amplitudes of three-phase voltages, relative to one another.

III. HARMONICS AS POWER QUALITY PROBLEM

Harmonic disturbances come generally from equipment with a non-linear voltage/current characteristic. Nowadays a large part of industrial, commercial and domestic loads is non-linear, making the distortion level on the low-voltage supply network a serious concern. As time goes on, more and more equipment is being used that creates harmonics in power systems. Conversely, more and more equipment is being used that is susceptible to malfunction due to harmonics. Computers, communication equipment, and other power systems are all susceptible to malfunction or loss of efficiency due to the effects of harmonics. For instance, in electric motors, harmonic current causes AC losses in the core and copper windings. This can result in core heating, winding heating, torque pulsations, and loss of efficiency in these motors. Harmonics can also result in an increase in audible noise from motors and

transformers and can excite mechanical resonances in electric motors and their loads.

Harmonic voltages and currents can also cause false tripping of ground fault circuit interrupters (GFCIs). These devices are used extensively in residences for local protection near appliances. False triggering of GFCIs is a nuisance to the end user. Instrument and relay transformer accuracy can be affected by harmonics, which can also cause nuisance tripping of circuit breakers. Harmonics can affect metering as well, and may prompt both negative and positive errors. High-frequency switching circuits such as switching power supplies, power factor correction circuits, and adjustable-speed drives create high-frequency components that are not at multiples of line frequency. Harmonic distortion can be considered as a sort of pollution of the electric system which can cause problems if the sum of the harmonic currents exceeds certain limits.

3.1 Individual Harmonic Distortion (IHD)

It is the ratio between RMS value of individual harmonic and the rms value of the fundamental component of a wave form.

$$IHD_n = \frac{I_n}{I_1} \times 100 \quad (1.1)$$

where I_n is the amplitude of current harmonic „n" and I_1 is the amplitude of fundamental current .

3.2 Total Harmonic Distortion(THD)

The ratio of r.m.s. value of the sum of all the harmonic components up to a specified order to the r.m.s. value of the fundamental component is called total harmonic distortion and can be represented as

$$THD = 100 \sqrt{\sum_{n=2}^{\infty} \frac{I_n^2}{I_1^2}} \quad (1.2)$$

I_1, I_2, I_3, I_4,..... I_n, are r.m.s. values of harmonics 1,2,3,4,….n. Normally „n" is limited to 50. If risk of resonance is less at higher orders then „n" is limited to 25.This parameter is used in low voltage, medium-voltage or high-voltage systems. Conventionally, current distortion parameters are suffixed with „I", e.g. 35 % THDI, and voltage distortion figures with „V", e.g. 4 % THDV .

IV. DYNAMIC VOLTAGE RESTORER

Voltage sags of short duration may not cause much harm other than cause a slight flickering of lights to a domestic and non-sensitive loads whereas, the temporary sag is bound to have a greater impact on the industrial customers with sensitive loads. Voltage sags lasting only 4 to 5 cycles may cause wide range of sensitive equipment consumer to dropout. It ultimately leads to wastage of resources (both material and human) as well as financial losses.

The latest trends in the power market and the declining profits have made it important for the power utilities to recognize the significance of high power quality. This is possible only by ensuring that uninterrupted flow of power is maintained at proper voltage levels. Electric utilities are looking forward to appropriate solutions to ensure high quality power supply to their consumers. The DVR is one of the important solutions in the present scenario.

A DVR is a device that injects a dynamically controlled voltage in series to the bus voltage by means of a booster transformer. It is normally installed in a distribution system between the supply and the critical load feeder, Jindal (2008). Its primary function is to rapidly boost up the load-side voltage in the event of a disturbance in order to avoid any power

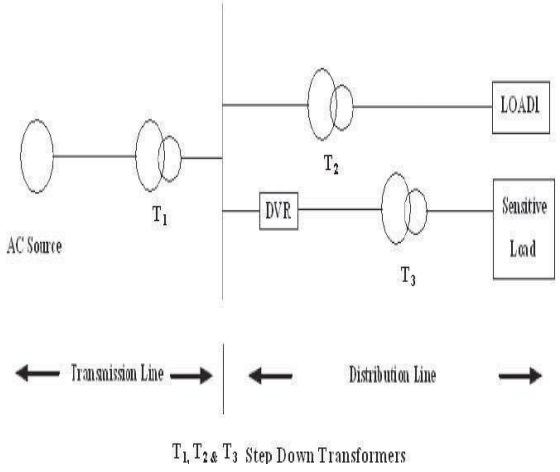

Figure 2 Location of DVR

disruption to that load Sng et al (2004). There are various circuit topologies and control schemes that can be used to implement a DVR. In addition to voltage sags and swells compensation, DVR can also added other features such as: line voltage harmonics compensation, reduction of transients in voltage and fault current limitations. The Figure 2.1shows the location of the DVR

4.1 Injection / Booster Transformer

The Injection / Booster transformer is a specially designed transformer that attempts to limit the coupling of noise and transient energy from the primary side to the secondary side, Kularatna (1998). It has the following functions: x connects the DVR to the distribution network via the HV-windings x

transforms and couples the injected compensating voltages generated by the voltage source converters to the incoming supply voltage x isolating the load from the system (VSC and control mechanism)

V. METHODOLOGY AND CONTROL DESIGN

The SMES has been emulated by a 15mH, 100A inductor. During a voltage error a three-phase inverter is used to generate the compensation voltage at the primary of the injection transformers (T1-T3) so that the load voltage remains close to nominal. DC/DC converters are used to interface the battery and SMES-emulator to the DC bus. An auxiliary supply (Aux. Supply) is used to support the DC bus during standby operation and charge the energy storage devices. The auxiliary supply is disconnected and the energy storage devices provide the necessary power for the inverter to support the load during a voltage error.

A. DVR Control

The objective of the DVR control system is to minimise supply voltage variations at the load terminals. This is achieved by generating a compensating voltage at the series injection transformer terminals. The phasor diagram in Fig. 2(a) shows various DVR voltage control techniques. 'In phase compensation' causes the compensating voltage to be in phase with the incoming supply voltage and has been shown to result in the lowest DVR power ratin. 'Pre-sag compensation' preserves the phase of the incoming supply at the time a sag occurs which can be beneficial in protecting loads that are sensitive to phase disturbances. 'Energy optimal' control is used to minimise DVR energy storage requirement by injecting a voltage in quadrature to the load current. 'In phase compensation' and 'Pre-sag compensation' have been considered in this study. The control scheme was implemented in the synchronous reference frame as shown in Fig. 2(b) by converting three phase AC quantities to equivalent two phase quantities:

$$\begin{bmatrix} V_{s\alpha} \\ V_{s\beta} \end{bmatrix} = \frac{2}{3}\begin{bmatrix} 1 & -1/2 & -1/2 \\ 0 & \sqrt{3}/2 & -\sqrt{3}/2 \end{bmatrix}\begin{bmatrix} V_{sa} \\ V_{sb} \\ V_{sc} \end{bmatrix} \quad (1)$$

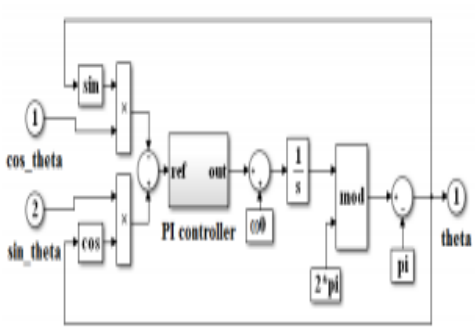

Figure3. Simulink implementation of PLL algorithm where ω0 is the fundamental output frequency in rad/s.

$$\begin{bmatrix} V_{sd} \\ V_{sq} \end{bmatrix} = \begin{bmatrix} \cos\theta_{pll} & \sin\theta_{pll} \\ -\sin\theta_{pll} & \cos\theta_{pll} \end{bmatrix}\begin{bmatrix} V_{s\alpha} \\ V_{s\beta} \end{bmatrix} \quad (2)$$

where Vsa,b,c, Vsa,b, Vsd,q are the supply voltages and θpll is the estimated supply phase angle.

A phase-locked loop (PLL) was used to determine the phase angle θpll of the incoming supply based on an algorithm which is robust in the presence of harmonics, non-symmetry and transients. Fig. 3 shows a Simulink implementation of the PLL algorithm. This algorithm minimises the sine of the phase error term causing the control system to be non-linear. For this reason, the PI controller gains were tuned empirically. The PLL algorithm requires the cosine and sine of the incoming supply angle as inputs which can be obtained geometrically using the orthogonal reference frame voltages from (1) as:

$$\cos(\theta) = \frac{V_{s\alpha}}{\sqrt{{V_{s\alpha}}^2 + {V_{s\beta}}^2}} \quad (3)$$

$$\sin(\theta) = \frac{V_{s\beta}}{\sqrt{{V_{s\alpha}}^2 + {V_{s\beta}}^2}} \quad (4)$$

The PLL controller can be tuned to preserve the phase of the incoming supply before a sag event with phase jump or, alternatively, the PLL can be made to track the phase of the incoming supply during a sag with phase-jump. Consequently, by changing the PLL gains the system can be controlled to provide 'in phase' or 'pre-sag' compensation. Fig. 4 illustrates the results of tuning the PI controller in this way,

To detect the presence of a voltage error, the following inequality was used

$$\sqrt{\left(V^*_d - V_{s,d}\right)^2 + \left(V^*_q - V_{s,q}\right)^2} \geq V_{threshold} \quad (5)$$

where Vs,d,q is the measured load voltage and V*d,q is the desired nominal voltage in the synchronous reference frame. Inequality (5) was also used to trigger the disconnection of the DC bus auxilliary power supply (see Fig. 1).

The compensation voltage Vrefd,q is determined, based on the error between the desired nominal voltage and the supply voltage:

$$V_{refd,q} = V^*_{d,q} - V_{d,q} \qquad (6)$$

The PWM phase reference voltages Vrefa,b,c were generated by transforming the required compensation voltage to the rotating three phase reference frame:

$$\begin{bmatrix} V_{ref\alpha} \\ V_{ref\beta} \end{bmatrix} = \begin{bmatrix} \cos\theta_{pll} & -\sin\theta_{pll} \\ \sin\theta_{pll} & \cos\theta_{pll} \end{bmatrix} \begin{bmatrix} V_{refd} \\ V_{refq} \end{bmatrix} \qquad (7)$$

$$\begin{bmatrix} V_{refa} \\ V_{refb} \\ V_{refc} \end{bmatrix} = k\frac{3}{2} \begin{bmatrix} 2/3 & 0 \\ -1/3 & 1/\sqrt{3} \\ -1/3 & -1/\sqrt{3} \end{bmatrix} \begin{bmatrix} V_{ref\alpha} \\ V_{ref\beta} \end{bmatrix} \qquad (8)$$

The injection voltages, Vref_a,b,c, were multiplied by a feedforward constant, k to compensate for losses within the power stage.

Sine-wave pulse width modulation (SPWM) or space vector modulation (SVM) were considered for generating the inverter output voltage. SVM is advantageous due to better utilisation of the DC bus voltage and which allows deeper sag compensation. However, SPWM allows the possibility to mitigiate unbalanced faults so this technique was implemented in this study.

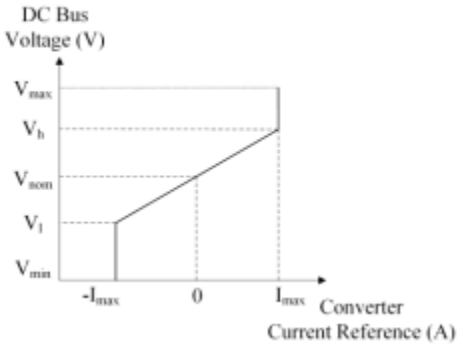

Figure4. Energy storage systems active current droop control.

B. Energy Storage top-Level Control

The objective of the top-level energy storage control strategy was to control the charge/discharge of each energy storage device. A current vs. voltage active droop characteristic was chosen as this strategy has been shown to provide good stability and active power sharing. The converter reference currents are based solely on the level of the DC bus voltage which is advantageous as high-bandwidth communication between the three different converters is not necessary. The charge or discharge priority of an energy storage device can be adjusted raising or lowering its nominal DC bus voltage using a technique known as "DC bus signaling". The system was configured to prioritise the SMES-emulator to charge/discharge before the battery. By always prioritising the short term energy storage, battery power cycling is reduced which can improve battery lifetime .

The current droop characteristic for each device is shown in Fig. 5, and is made up of three regions of operation. When the DC voltage is above voltage level Vh(x) (where x refers to energy storage system 1 or 2) or below below Vl(x),, the converter current is limited to Imax(x) or -Imax(x). In between Vh(x) and Vl(x), current is controlled based on the linear current vs. voltage relationship:

$$I_x = (V_{nom} - V_{bus})k_x \qquad (9)$$

where kx is a droop coefficient (A/V) and Ix is the energy storage converter reference current.

C. SMES-Emulator System

To reduce costs and be able to evaluate a SMES-battery hybrid DVR control platform, the SMES device was emulated by using a 15mH iron-core inductor in this study. The SMES converter was based on the asymmetric H-bridge configuration shown in Fig. 6. This converter was rated at up to 220A continuous current using forced air cooling. During charge, Q2 is held ON and Q1 is modulated whereas during discharge Q1 is held off and Q2 is modulated. The relationship between DC bus current, inductor current and duty ratio, is given by (12) and (13) for charge and discharge, respectively [16].

$$I_{csmes} = I_{smes} D_1 \qquad (10)$$

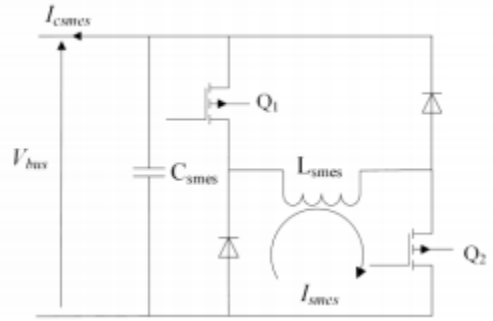

Figure 5. SMES DC/DC converter

$$-I_{csmes} = I_{smes}(1 - D_2) \qquad (11)$$

For active current droop control according to (9), the desired converter output current Icsmes is given by (12).

$$I_{csmes} = (V_{bus} - V_{nom_smes})k_{smes} \quad (12)$$

where ksmes is the gradient of the droop controller and Vnom_smes is the nominal voltage of the droop controller.

D. Battery System

A bidirectional synchronous-buck converter rated at 40A output current with hysteresis current control was used to control battery current. This topology has been previously reported for use with interfacing an ultra-capacitor energy storage system to the DC bus in DVR application [13]. However, the proposed system differs from previous studies [13] in that a variable-frequency hysteresis current control has been used. This is advantageous as it features cycle-by-cycle current limiting, making it tolerant to short circuit faults. Also, the proposed technique is shown below to be globally stable over the operating range whereas typical current mode control techniques described previously [13] require slope compensation to ensure global stability [28]. Further advantages include good dynamic current-tracking capability, and robust performance despite variation and uncertainty in operating conditions [29].

Assuming lossless, ideal components, the inductor current in Fig. 7 is given by (13). Figure 6. SMES DC/DC converter. Figure X1. Measured

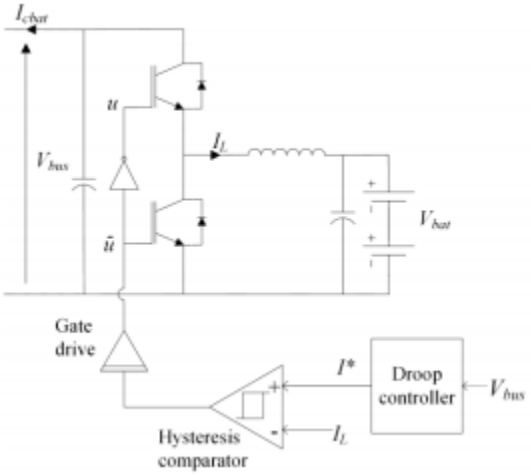

Figure 6. Battery DC/DC converter.

VI. SIMULATION RESULTS

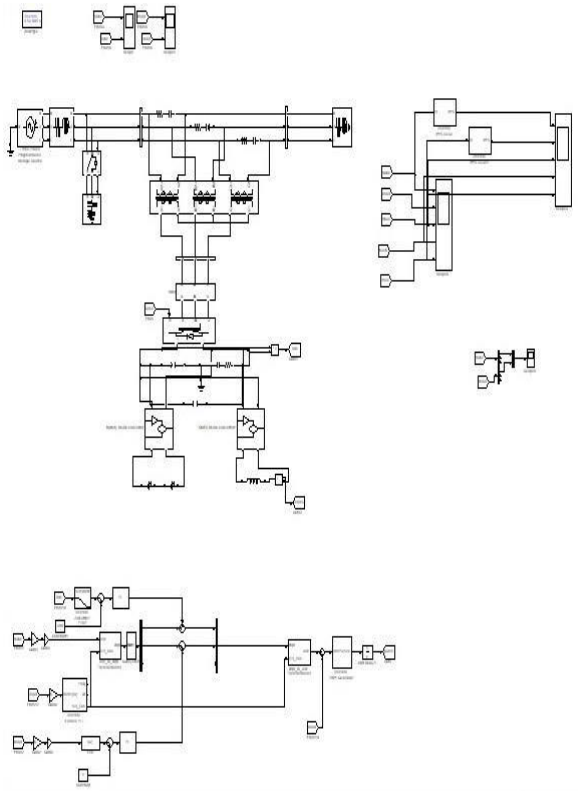

Fig.7 simulink diagram capacitor added dvr hybrid model

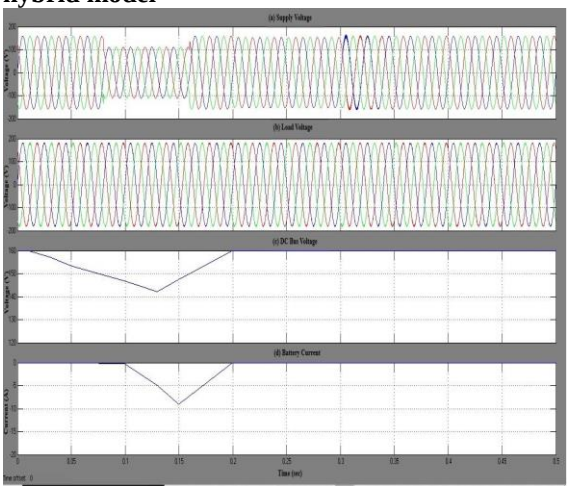

Figure 8. Capacitor added DVR Battery System Experimental results: 0.1s Three phase sag to 35% of nominal voltage. (a) Supply voltages (b) Load voltages (c) DC Link Voltage (d)Battery Current.

The SMES-emulator was then removed from the system and the test was repeated. The system response to the same three phase sag with only battery energy storage is shown in Fig. 8. As the DC bus voltage falls below 140Vdc (the battery system nominal voltage) the battery is discharged to support the DC bus. The peak battery current is

9.85A in this case and the DVR system can be seen to effectively mitigate the voltage sag. By adding capacitor the battery peak current was reduced to 9.85A.

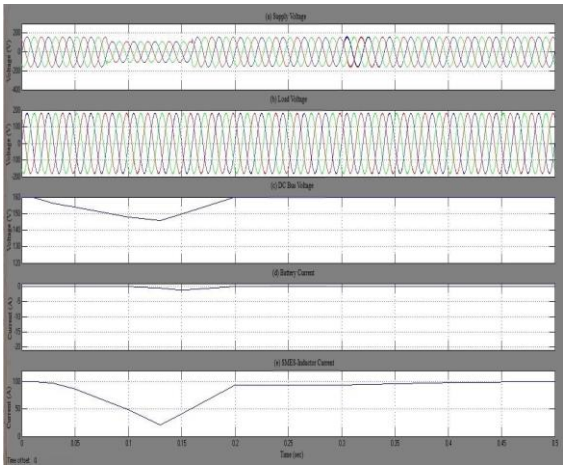

Figure9. capacitor added DVR Hybrid System Experimental results: 0.1s Three phase sag to 35% of nominal voltage. (a) Supply voltages (b) Load voltages (c) DC Link Voltage (d) Battery Current (e) SMES-inductor current.

Initially a three-phase voltage sag to 35% of nominal voltage, lasting 100ms was used to demonstrate the response of the DVR and energy storage systems. From Fig. 9 it can be seen that the hybrid DVR system mitigates the voltage sag effectively during the sag event. The battery is discharged momentarily at -1.2A at the end of the sag when the inductor energy has been depleted.

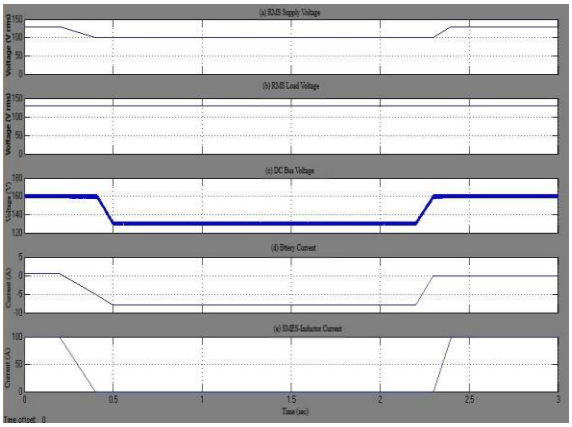

Figure 10. Capacitor added DVR Hybrid System Experimental results: Long-term three phase under voltage (a) RMS supply phase-voltage. (b) RMS load phase voltage (c) DC Bus Voltage (d) Battery Current (e) SMES-inductor current.

By use of the SMES-emulator hybrid system, the peak battery current response during a three-phase sag to 35% of nominal was reduced to 1.2A from 9.85A compared with the battery-only system. This reduction in battery peak current can have significant benefits in terms of improved battery life, which is negatively affected by discharge current magnitude .

From Fig. 10, it can be seen that the long-term under voltage performance of the system has been improved by the introduction of battery energy storage. One of the main shortcomings limiting the usage of SMES systems is the high cost of the superconducting material. By integrating a battery, the hybrid DVR can be of significantly reduced cost compared with a SMES only DVR and still be capable of compensating a variety of short-term sags and long-term under-voltages. In order to estimate the potential scale of the cost reduction, the prototype system used in this study has been considered. The SMES-inductor was emulated to give L= 15mH at 100A DC. The energy capacity of an equivalent SMES can be calculated

VII. CONCLUSION

The performance a novel hybrid capacitor added DVR system topology has been assessed experimentally and shown to effectively provide voltage compensation for short-term sags and long-term under-voltages. A prototype system has been developed which demonstrates an effective method of interfacing SMES and battery energy storage systems to support a three phase load. The system has been shown to autonomously prioritise the use of the short-term energy storage system to support the load during deep, short-term voltage sags and a battery for lower depth, long-term under-voltages. This can have benefits in terms of improved voltage support capability and reduced costs compared with a SMES-based system. Additional benefits include the capacitor dicharges during voltage sag before battery discharge. Then reduced battery power rating requirement and an expected improvement in battery life compared with a battery-only system due to reduced battery power cycling and peak discharge power.

Abstract – The need of safety can be achieved by making locks which can be electrical or mechanical with one or a few keys, but for locking a big area many locks are required. As everyone knows old fashioned locks are heavy weight and fragile also depending on the tools therefore electronic locks are given more value than those of mechanical locks. Nowadays every device's operation is based on digital technology. For example, technology based identity devices are used for automatic door unlocking or locking. These locking systems are used to control the movement of door and are functional without requiring a key to lock or unlock the door. These locking systems are controlled by a keypad and are installed at the side hedge of the door. The main objective of this project is to give safety at every common places like home, public places. In this user would give a known password. The information will be stored in database. When the correct passcode will be entered, the microcontroller will give instruction to servo motor. Servo motor will perform the action on door unlocking. Thus, what we want is digital technology to construct an integrated and well customized safety system at a price which is reasonable.

I. INTRODUCTION

Password Based Door Lock System is designed using ARDUINO UNO where in once the correct code or password is entered, the door is opened and the concerned person is allowed access to the secured area. Password Based Door Lock System using Arduino UNO is a simple project where a secure password will act as a door unlocking system. Old fashioned lock systems use mechanical locking and these can be replaced by new advanced techniques of locking systems. These methods are a combination of mechanical and electronic devices and are highly intelligent. One of the distinct features of these intelligent lock systems is their simplicity and high efficiency. Such an automated lock system consists of electronic control assembly, which controls the output load through a password. The example of this output load can be a motor or a lamp or any other mechanical/electrical load.

Here, we made an electronic code lock system using Arduino UNO, which provides control to the actuating the load. It is a simple embedded system with takes input from the keyboard and the output being actuated accordingly.

This system demonstrates a Password based Door Lock System using Arduino UNO, wherein once the correct code or password is entered, the door is opened and the concerned person is allowed access to the secured area. If another person arrives, it will ask to enter the password again. If the password is wrong, then door would remain locked, denying access to the person.

Main idea behind this project is of a door-latch opening using a password entered through keypad. As well as turning on the Buzzer when passcode is entered wrong for multiple times. User can modify this password anytime he/she wishes using a keypad. The main component in the circuit is Arduino UNO which is basically used to send a text message to owner of the house about the breach of security.4*4 keypad is used to enter the password. The entered password is compared with the known password. If it is correct password, the system opens the door by servo motor and displays the status of door on LCD. If the password is wrong then door remains closed and displays "WRONG PASSWORD" on LCD.

II. MATERIALS AND METHODS

A. *Arduino UNO*

This microcontroller is based on the ATmega328P. There are total of 20 pins (0-19) out of which 6 are analog inputs, 14 are digital input output pins(6 pins provide PWM voltage) which can also be used as general purpose pins, a ceramic resonator of frequency 16 MHz, an USB connection, a power jack and a reset button. It has an operating voltage of 5V. It cotains everything needed to support a microcontroller.

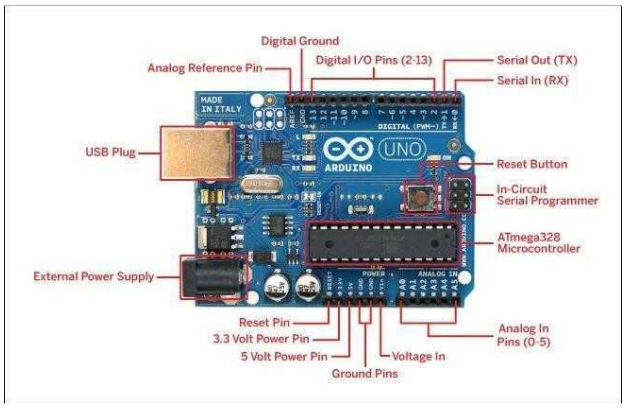

Figure1Arduino Uno

B. *LCD*

Liquid Crystal Display, which we are using in our project is 16*2 LCD. This display consists of 16 columns and 2 rows. This is programmed using the library <LiquidCrystal.h>

Figure 2 16*2 LCD

C. *Membrane Keypad*

In our project we will be using 4X4 matrix membrane keypad. This 16 button keypad will provide user interface component for Arduino project. This is programmed using the library <Keypad.h>

Figure 3 4*4 Keypad

D. *Servo Motor*

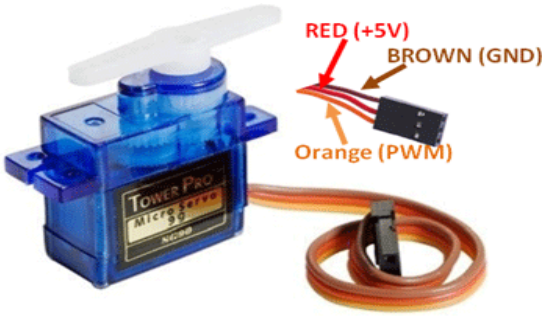

Figure 4 Servo Motor

E. *Buzzer*

In our project the buzzer is used for beep sound indicating the entry of wrong password.

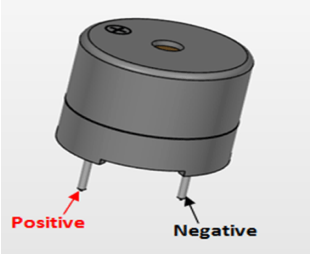

Figure 5 Buzzer

F. *Potentiometer*

In our project we have used a potentiometer of 10Kohm resistance in order to adjust the contrast of the Liquid crystal display

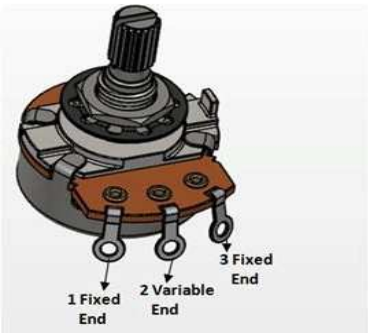

Figure 6 Potentiometer

G. *GSM Module*

A GSM module is a device which can be either a mobile phone or a modem device which can be used to create a computer or any other processor to communicate over a network. A GSM module needs a SIM card to be operated and operates over a network range subscribed by the network operator.

Figure 7 SIM 800L GSM Module

III. **METHODOLOGY**

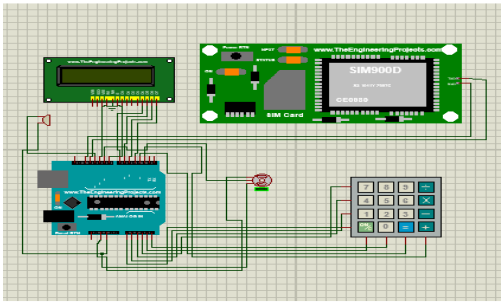

Figure 8 Circuit Diagram

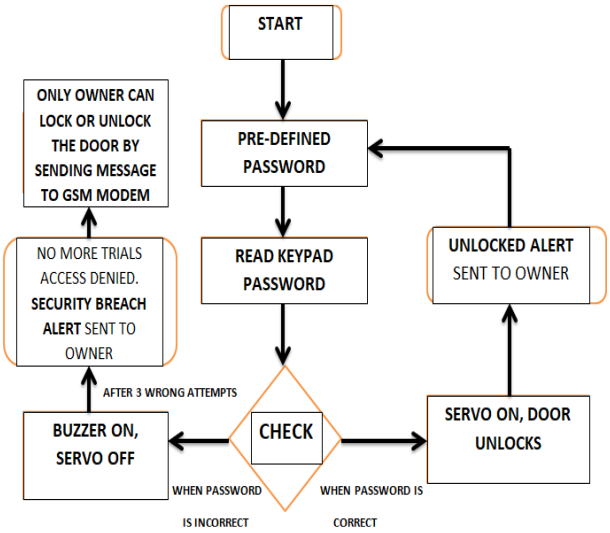

Figure 9 Flowchart

The above flowchart gives a brief idea as to how the project works. Initially the password is known. When the device is turned on, it resets the servo angle to lock the door. Now the user is prompted to enter the password. The user enters the passcode through a keypad which is read by the Arduino. Now the entered password is checked with the known password. If the password matches, then the servo motor deflects and the door unlocks for 10 seconds else the buzzer beeps indicating the invalidity of the password.

Owner do gets the information too about the locking and unlocking of door through SMS sent to his smart phone by GSM modem.

After 3 wrong attempts, the system automatically gets locked showing “NO MORE TRIALS ACCESS DENIED”. Now, the password won’t be entered through keypad but only the owner who knows some pre-defined code will be able to unlock or lock the door through SMS sent by his phone to the sim which is connected in GSM modem.

IV. **RESULTS**

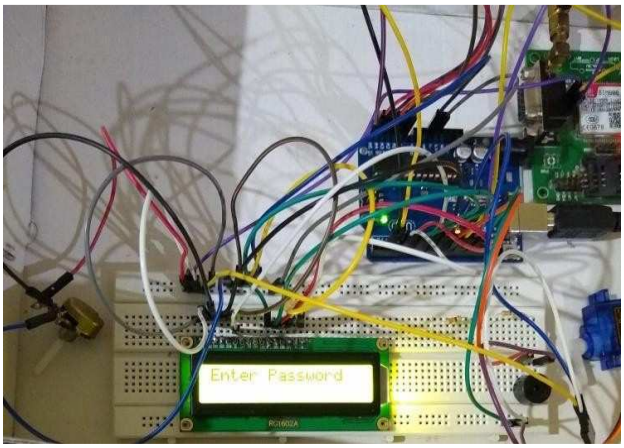

Figure 10 Showing user to enter the password

In the above figure, Fig-10 the LCD displays the user “ENTER PASSWORD”. The entered password is displayed as characters on the LCD.

In the figure, Fig-11, the user has entered the correct password and the LCD shows “ACCESS GRANTED” on the LCD.
The servo motor deflects thus unlocking the door.

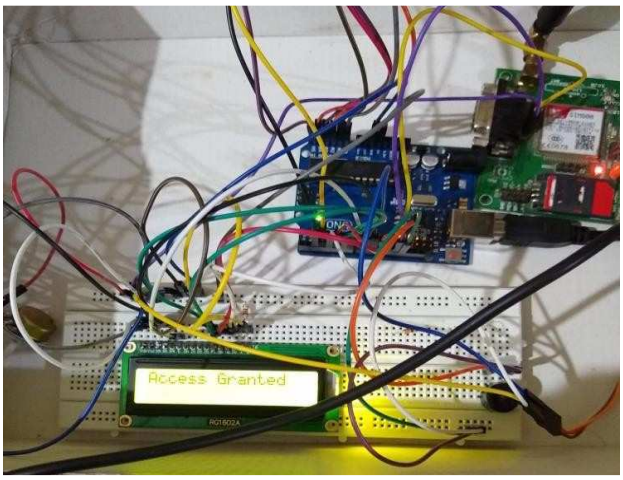

Figure 11 Access is granted and the door unlocks

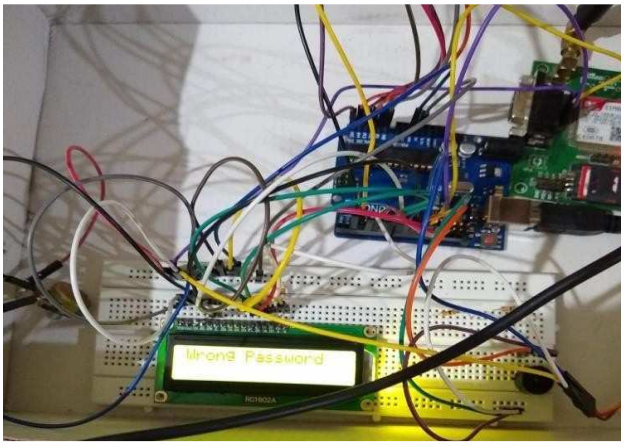

Figure 12 Showing user wrong password when the password entered does not match with the pre- defined password

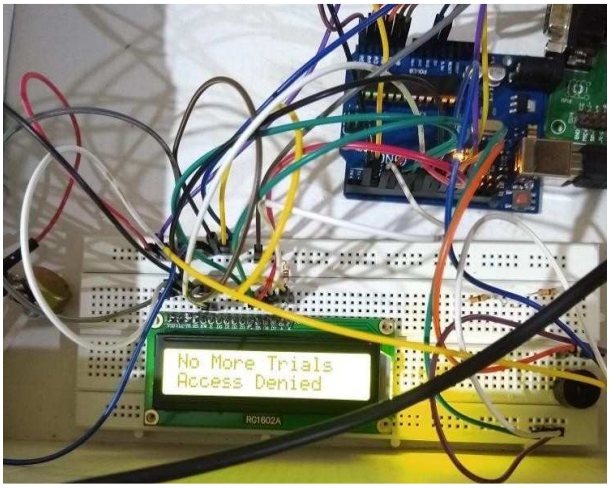

Figure 13 After 3 wrong attempts, system gets locked

When the system gets locked, password cannot be entered through keypad. Now only owner has the power to unlock or lock the door with the password he knows.

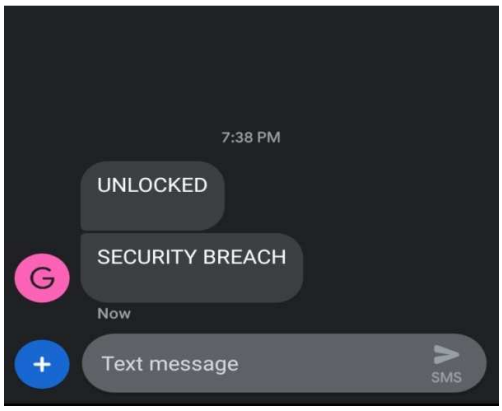

Figure 14 Owner getting information when the door is unlocked and on three wrong attempts

V. FUTURE SCOPE

The security level can be increased by adding a biometric fingerprint scanner. We can interface sensors like Fire, LPG, PIR motion detector to microcontroller in case of any accident so that door will open automatically**.** We can interface camera to the micro controller so that it could capture the picture of the thief who is trying to breach the security. This simple circuit can be used at places like home to ensure better safety. With a slight modification, this project can also be used to control the switching of loads through password. It can also be used at organizations to ensure authorized access to highly secured places.

VI. CONCLUSION

This project is productive in providing enough security as long as the password is not shared. In future this "code based Door Lock System" can be provided maximum security by the above enhancements in order to completely satisfy user's needs. Hence, a common man can afford to buy such locking system in minimal cost to keep his valuables safely without any worries.

Abstract - This project shows the design of the automatic sliding door operator and power supply for module circuit. Automatic sliding door operator performs for opening or closing the door automatically. Automatic door is an automated movable barrier installed in the entry of a room or building to restrict access, provide ease of opening a door or provide visual privacy. Automatic doors are specially designed to reduce congestion and increase access and can make the door use easier. Sensors are detected when people approach the doors and trigger them to slide open. When someone enters in front of the sensors inside or outside the room, control module in door operator receives the signal and controls through the motor which drives the door sliding.

Keywords -.PIC 16F887 Microcontroller, DC Motor, H-Bridge (L298), Sensors, Sliding Door.

I. INTRODUCTION

Nowadays, Security has always been a major concern for all of us and there are many Hi tech and IoT based security and surveillance system are available in the market. Intruder or Burglar Alarm is one of the classic and popular projects among the Electronics students and hobbyists. We have also built many Burglar Alarms based on various technologies:

- Laser Security Alarm Circuit
- IR Based Security Alarm
- Burglar Alarm using PIR
- GSM Based Security System

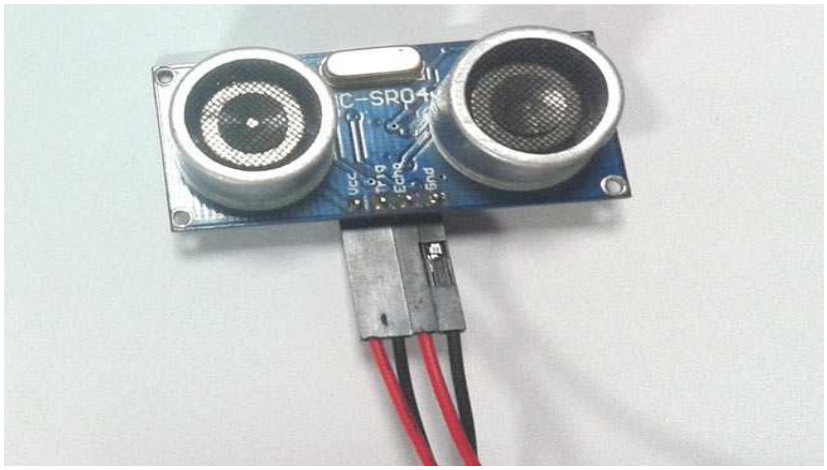
Today we are adding one more Security Alarm in our list which is based on Ultrasonic Sensor. This Arduino Controlled Door alarm can be installed near the door to detect the presence of anybody at the door. Whenever somebody comes in the range of Ultrasonic sensor, buzzer starts beeping. You can adjust the sensor detection range according to your door. This system can also serve the purpose of Motion Detector.

II. REQUIRED COMPONENTS

- Breadboard
- Ultrasonic Sensor
- Buzzer
- Arduino Mega (any model)
- Jumper Wires
- USB cable for Arduino or 12v, 1A adapter.

Ultrasonic Sensor Module:

Ultrasonic sensor HC-SR04 is used here to detect the presences of any person at the door. The sensor module consists of ultrasonic transmitter, receiver and the control circuit. Ultrasonic Sensor consists of two circular eyes out of which one is used to transmit the ultrasonic wave and the other to receive it.



Ultrasonic sensor HC-SR04 is used here to detect the presences of any person at the door. The sensor module consists of ultrasonic transmitter, receiver and the control circuit. Ultrasonic Sensor consists of two circular eyes out of which one is used to transmit the ultrasonic wave and the other to receive it.

We can calculate the distance of the object based on the time taken by ultrasonic wave to return back to the sensor. Since the time and speed of sound is known we can calculate the distance by the following formulae.

Distance = (Time x Speed of Sound) / 2

The value is divided by two since the wave travels forward and backward covering the same distance. But in this project we have used NewPing.h library, and this library takes care of this calculation and we just need to use some key words, explanation is given in programing section below.

Check the below project to measure the distance of any object and to properly understand the Ultrasonic sensor working:

- Arduino Based Distance Measurement using Ultrasonic Sensor
- Distance Measurement using HC-SR04 and AVR Microcontroller

III. RESULTS AND DISCUSSION

In this project, LDR's are working as light detectors. Before we go into detail, we will have to understand how the LDR's work. LDR (Light Dependent Resistor) also known as photo resistor is the light sensitive device. Its resistance decrease when the light falls on it and that's why it is frequently used in Dark or Light Detector Circuit. Check the various circuits based on LDR here.

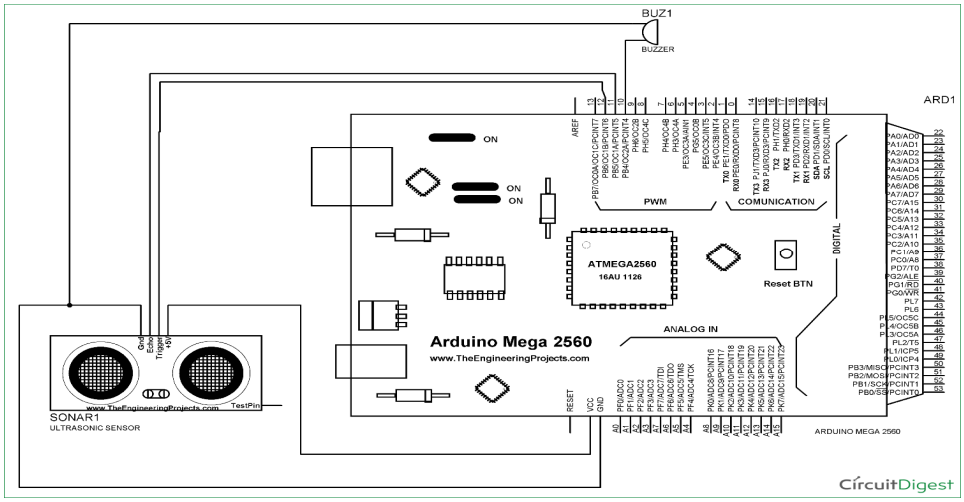


Fig. 1. Circuit Diagram And Explanation

Circuit connections for this Ultrasonic Alarm are very simple. Trigger pin of ultrasonic sensor is connected to pin no. 12 of Arduino and Echo pin of sensor is connected to pin no 11 of Arduino. Vcc of sensor is connected to 5V pin of Arduino and GND of sensor is connected to GND of Arduino. One pin of buzzer is connected to GND of Arduino and the other pin is connected to 8th pin of Arduino.

IV. RESULTS AND DISCUSSION

To make the prototype, you will have to follow the below steps:

Fig. 2. Working Model

Working Explanation:

Working this Arduino Door Alarm is very easy. Whenever anyone comes in the path/range of Ultrasonic Sensor, microcontroller detects the distance of object from the sensor and if the object is in the defined range, it sends the High signal to the buzzer and buzzer starts beeping.

The working principle of this circuit is, when light falls on the light dependent resistor, then its resistance will be decreased, which results in an increase of the voltage at pin2 of the 555 IC. This 555 IC is inbuilt with a comparator, which associates between the i/p voltage from pin2 of the IC and 1/3rd of the power supply voltage. When i/p falls below 1/3rd then o/p is fixed to high otherwise it is fixed to the lower.

The proposed circuit is built with ATmega microcontroller, DS1307 IC, LDR, LCD, PIR sensor, Array of LED. This circuit is very useful in our day to day life like highways, real time street lights, the parking areas, restaurants and hotels.

V. CONCLUSION

The test the circuit by putting any thing in front of sensor within the range, check the Video for demonstration. This function of Ultrasonic Sensor can also be used to build Obstacle Avoiding Robot.

Abstract - The project is to designed detect vehicle movement on highways to switch ON only a block of street lights ahead of the vehicle, and to switch OFF the behind lights to save energy. During night all the lights on the highway remain ON for the vehicles, but lots of energy is wasted when there is no vehicle his movement. This proposed system provides a solution for energy saving. This is achieved by sensing an approaching vehicle and switches ON a block of street lights ahead of the vehicle. As the vehicle passes by the behind lights switch OFF automatically. So when there are no vehicles on the highway, then all the lights remain OFF. Sensors used on either sides of the road send logic commands to microcontroller to switch ON/OFF the LEDs. Intensity control is also possible by Pulse Width Modulation (PWM) generated by the microcontroller. Thus this way of dynamically changing intensity ON/OFF helps in saving a lot of energy.

Keywords -. Microcontroller, Sensor, Street Light.

I. INTRODUCTION

Raindrop sensor is basically a board on which nickel is coated in the form of lines. It works on the principal of resistance. Rain Sensor module allows to measure moisture via analog output pins and it provides a digital output when a threshold of moisture exceeds. The module is based on the LM393 op amp. It includes the electronics module and a printed circuit board that "collects" the rain drops. As rain drops are collected on the circuit board, they create paths of parallel resistance that are measured via the op amp.

II. PRINCIPLE OF OPERATION

The sensor is a resistive dipole that shows less resistance when wet and more resistance when dry. When there is no rain drop on board it increases the Resistance so we gets high voltage according to V=IR.

When rain drop present it reduces the resistance because water is a conductor of electricity and presence of water connects nickel lines in parallel so reduces resistance and reduces voltage drop across it.

Specifications

- Adopts high quality of RF-04 double sided material.
- Area: 5cm x 4cm nickel plate on side,
- Anti-oxidation, anti-conductivity, with long use time;
- Comparator output signal clean waveform is good, driving ability, over 15mA;
- Potentiometer adjust the sensitivity;
- Working voltage 5V;
- Output format: Digital switching output (0 and 1) and analog voltage output AO;
- With bolt holes for easy installation;
- Small board PCB size: 3.2cm x 1.4cm;
- Uses a wide voltage LM393 comparator

III. RESULTS AND DISCUSSION

Rain Sensor Module

Pin	Description
Vcc	+5 Volts Power Source
GND	Ground or negative power source
D0	Digital Output. Goes low when moisture exceeds set threshold.
A0	Analog Output – Zero to five volts. The lower the voltage, the greater the moisture
POWER LED	Indicates that power is applied

OUTPUT LED Illuminates when moisture has exceeded threshold set by sensitivity adjustment.
Sensitivity Adjustment Clockwise is more sensitive. Counterclockwise is less sensitive.

Connecting with Arduino

Arduino Rain Sensor – Circuit Diagram

Source Code

Arduino Code

```
const int sensorMin = 0;
const int sensorMax = 1024;
void setup()
{
  Serial.begin(9600);
}
void loop()
{
  int sensorReading = analogRead(A0);
  int range = map(sensorReading, sensorMin, sensorMax, 0, 3);
  switch (range)
    {
      case 0:
        Serial.println("RAINING");
        break;
      case 1:
        Serial.println("RAIN WARNING");
        break;
      case 2:
        Serial.println("NOT RAINING");
        break;
    }
  delay(1000);
}
```

Code Explanation

Initialize the lowest and highest sensor readings with type as an integer and variable name.

```
const int sensorMin = 0; // sensor minimum
const int sensorMax = 1024; // sensor maximum
```

The setup() routine runs once when we reset it or power the board. Here we are initializing serial communication at 9600 baud rate.

```
void setup()
{
  Serial.begin(9600);
}
```

The loop function runs over and over again forever. Firstly this code reads the analog signal at A0 pin from Rain sensor and maps those measured value with initialized values.

```
void loop()
{
  int sensorReading = analogRead(A0);
  int range = map(sensorReading, sensorMin, sensorMax, 0, 3);
```

Checks the measured value with pre-stored condition and displays the weather condition like RAINING, RAIN WARNING & NOT RAINING.

```
  switch (range)
  {
    case 0: // Sensor getting completely wet
      Serial.println("RAINING");
```

```
    break;
   case 1: // Sensor getting partially wet
    Serial.println("RAIN WARNING");
    break;

   case 2: // Sensor dry
    Serial.println("NOT RAINING");
    break;
 }
 delay(1000);
}
```

Working

Make connections according to the above circuit diagram.

- Connect VCC pin of sensor to 5V power supply of Arduino,
- Connect GND pin of sensor to GND of Arduino and
- Connect Analog output pin of sensor to A0 pin of Arduino.

Upload the above code into Arduino IDE and test the result on Serial Monitor by soaking the rain sensor into water.

IV. CONCLUSION

In Proposed The serial monitor displays the below result based on the amount water drop on the rain sensor module.If the Rain Sensor Board is completely soaked; “case 0” will be activated and “RAINING” will be sent to the serial monitor.If the Sensor Board has water droplets on it; “case 1” will be activated and “RAIN WARNING” will be sent to the serial monitor. If the Sensor Board is dry; “case 2″ will be activated and “NOT RAINING ” will be sent to the serial monitor.

Abstract - Recent studies show that all over the world, there has been a rapid increase in vehicle numbers. The latest statistics show that there are approximately 1 million licensed vehicles in the year 2014. As a result traffic problems has increased in the last few years and the present traffic light controllers have limitations because it uses the predefined hardware that does not have the flexibility of modification on real time basis. Due to the fixed time intervals of green, orange and red signals the waiting time is more. To make this traffic light controlling more efficient we exploit the emergence of new technique called as "Smart Traffic Control System". This makes use of sensors along with embedded technology .The timings of the red and green lights will be smartly decided based on the traffic on adjacent roads. As compared to fixed mode traffic light controller this new system is more efficient and flexible. It also has an intelligent traffic control system to pass the emergency vehicles such as ambulance, fire brigade etc. and also detect and track the stolen vehicles. The design also has scope for further expansion. Density of the road is calculated using IR sensors. IR sensors are used to detect the number of vehicles based on the IR sensor; the traffic light is operated. IR sensors are less cost and more effective.

Keywords - Arduino, LED, Selective Sensor, Traffic, Density, IR sensors.

I. INTRODUCTION

Smart letter In modern life we have to face with many problems one of which is traffic congestion becoming more serious day after day. It is said that the high volume of vehicles, the inadequate infrastructure and the irrational distribution of the development are main reasons for increasing traffic jam[1]. The major cause leading to traffic congestion is the high number of vehicle which was caused by the population and the development of economy. Due to the massive growth in urbanization and traffic congestion, automatic based traffic light controller is needed to reduce the traffic delay and travel time especially in developing countries. Traffic congestion is now considered to be one of the biggest problems in the urban environments. Traffic problems will be also much more widely increasing as an expected result of the growing number of transportation means and current low-quality infrastructure of the roads [2] . In addition, many studies and statistics were generated in developing countries that proved that most of the road accidents are because of the very narrow roads and because of the destructive increase in the transportation means. This idea of controlling the traffic light efficiently in real time has attracted many researchers to work in this field [3] with the goal of creating automatic tool that can estimate the traffic congestion and based on this Variable, the traffic signal can be varied.

II. COMPONENTS USED

2.1 ARDUINO

Arduino is an open-source project that created microcontroller based kits for building digital devices and interactive objects that can sense and control physical devices. The project is based on microcontroller board designs, produced by several vendors, using various microcontrollers. These systems provide sets of digital and analog input/output (I/O) pins that can interface to various expansion boards (termed shields) and other circuits. The boards feature serial communication interfaces, including Universal Serial Bus (USB) on some models, for loading programs from personal computers. For programming the microcontrollers, the Arduino project provides an integrated development environment (IDE) based on a programming language named Processing which also supports the languages C and C++. The first Arduino was introduced in 2005, aiming to provide a low cost, easy way for novices and professionals to create devices that interact with their environment using sensors and actuators. Common examples of such devices intended for beginner hobbyists include simple robots, thermostats, and motion detectors. Arduino boards are available commercially in preassembled form, or as do-it-yourself kits. The hardware design specifications are openly available, allowing the Arduino boards to be produced by anyone. Ad fruit Industries estimated in mid-2011 that over 300,000 officials Arduino had been commercially produced, and in 2013 that 700,000 official boards were in users' hands.

2.2 LED

A light-emitting diode (LED) is a two-lead semiconductor light source as shown in figure2.It is a p–n junction diode, which emits light when activated. When a suitable voltage is applied to the leads, electrons are able to recombine with electron holes within the device, releasing energy in the form of photons. This effect is called electroluminescence, and the color of the light (corresponding to the energy of the photon) is determined by the energy band gap of the

semiconductor. An LED is often small in area (less than 1 mm2) and integrated optical components may be used to shape its radiation pattern. Appearing as practical electronic components in 1962, the earliest LEDs emitted low-intensity infrared light. Infrared LEDs are still frequently used as transmitting elements in remote-control circuits, such as those in remote controls for a wide variety of consumer electronics. The first visible light LEDs were also of low intensity, and limited to red. Modern LEDs are available across the visible, ultraviolet, and infrared wavelengths, with very high brightness. Early LEDs were often used as indicator lamps for electronic devices, replacing small incandescent bulbs. They were soon packaged into numeric readouts in the form of seven segment displays, and were commonly seen in digital clocks. Recent developments in LEDs permit them to be used in environmental and task lighting. LEDs have many advantages over incandescent light sources including lower energy consumption, longer lifetime, improved physical robustness, smaller size, and faster switching. Light emitting diodes are now used in applications as diverse as aviation lighting, automotive headlamps, advertising, general lighting, traffic signals, camera flashes and lighted wallpaper. As of 2016, LEDs powerful enough for room lighting remain somewhat more expensive, and require more precise current and heat management, than compact fluorescent lamp sources of comparable output. They are, however, significantly more energy efficient and, arguably, have less environmental concerns linked to their disposal.

III. SELECTION OF SENSOR

3.1 Proximity sensor:

A proximity sensor is a sensor able to detect the presence of nearby objects without any physical contact. A proximity sensor often emits an electromagnetic field or a beam of electromagnetic radiation (infrared, for instance), and looks for changes in the field or return signal. The object being sensed is often referred to as the proximity sensor's target. Different proximity sensor targets demand different sensors. For example, a capacitive or photoelectric sensor might be suitable for a plastic target; an inductive proximity sensor always requires a metal target. The maximum distance that this sensor can detect is defined "nominal range". Some sensors have adjustments of the nominal range or means to report a graduated detection distance. Some know this process as "thermo sensation". Proximity sensors can have a high reliability and long functional life because of the absence of mechanical parts and lack of physical contact between sensor and the sensed object. Proximity sensors are commonly used on smart phones to detect (and skip) accidental touch screen taps when held to the ear during a call. They are also used in machine vibration monitoring to measure the variation in distance between a shaft and its support bearing. This is common in large steam turbines, compressors, and motors that use sleeve-type bearings. A proximity sensor adjusted to a very short range is often used as a touch switch. The main disadvantages are that a significant part of the measurement is external (i.e.) no metallic part intrusion within 3-inch spherical radius" of the sensor. Hence IR sensors are used to detect the density of traffic.

3.1 IR sensor

IR Transmitter

IR transmitter looks like an LED. This IR transmitter always emits IR rays from it. The operating voltage of this IR transmitter is 2 to 3V. These IR (infra red) rays are invisible to the human eye. But we can view these IR rays through camera. Infrared is an invisible radiant energy, electromagnetic radiation with longer wavelengths than those of visible light, extending from the nominal red edge of the visible spectrum at 700 nanometers (frequency 430 THz) to 1000000 nm (300 GHz) (although people can see infrared up to at least 1050 nm in experiments). Most of the thermal radiation emitted by objects near room temperature is infrared. Infrared radiation is used in industrial, scientific, and medical applications. Night-vision devices using active near infrared illumination allow people or animals to be observed without the observer being detected. Infrared astronomy uses sensor-equipped telescopes to penetrate dusty regions of space such as molecular clouds, detect objects such as planets, and to view highly red-shifted objects from the early days of the universe. Infrared thermal imaging cameras are used to detect heat loss in insulated systems, to observe changing blood flow in the skin, and to detect overheating of electrical apparatuses.

IR Receiver (Photodiode):

A photodiode is a semiconductor device that converts light into current. The current is generated when photons are absorbed in the photodiode. A small amount of current is also produced when no light is present. Photodiodes may contain optical filters, built-in lenses, and may have large or small surface areas. Photodiodes usually have a slower response time as their surface area increases. The common, traditional solar cell used to generate electric solar power is a large area photodiode. Photodiodes are similar to regular semiconductor diodes except that they may be either exposed (to detect vacuum UV or X-rays) or packaged with a window or optical fiber connection to allow light to reach the sensitive part of the device. Many diodes designed for use specifically as a photodiode use a PIN junction rather than a p–n junction, to increase the speed of response. A photodiode is designed to operate in reverse bias.

IV. RESULTS

The working of the project is divided into three steps

- If there is traffic at all the signal, then the system will work normally by controlling the signals one by one.

- If there is no traffic near a signal, then the system will skip this signal and will move on to the next one. For example, if there is no vehicle at signal 2, 3 and currently the system is allowing vehicles at signal 1 to pass. Then after signal 1, the system will move on to signal 4 skipping signal 2 and 3.
- If there is no traffic at all the 4 signals, system will stop at the current signal and will only move on the next signal if there will be traffic at any other signal.

V. CONCLUSIONS

Nowadays, the technology and science is in progress day by day new technologies are invented and new things are created by human. In this system we have studied a smart letter box system that notifies the letter is received in the letter box. In our daily life it is not possible for us to check the letter box we proposed this system that the system notifies the user by sending message that letter is arrived. In this paper we conclude that science is non stoppable, new things arrive and growth of smart system.

Abstract –Home fires have been taking place frequently and the threat to human lives and properties is growing in recent years. Liquid petroleum gas (LPG) is highly inflammable and can burn even at some distance from the source of leakage. Most fire accidents are caused because of a poor-quality rubber tube or the regulator is not turned off when not in use. Therefore, developing the gas leakage alert system is very essential. Hence, this paper presents a gas leakage alert system to detect the gas leakage and to alarm the people onboard.

Keywords –Arduino Pro Mini, LPG Gas Sensor Module, Buzzer

I. INTRODUCTION

Password While LPG is an essential need of every household, its leakage could lead to a disaster. To alert on LPG leakage and prevent any mishappening there are various products to detect the leakage. Here we have developed an Arduino based LPG gas detector alarm. If gas leakage occurs, this system detects it and makes an alert by buzzing the buzzer attached with the circuit. This system is easy to build and anyone who have some knowledge of electronics and programming, can build.

II. COMPONENTS

2.1 Main Components:

1. Arduino Pro Mini
2. Lpg Gas Sensor Module
3. Buzzer
4. Bc 547 Transistor
5. 16x2 Lcd
6. 1k Resistor
7. Bread Board
8. 9 Volt Battery
9. Connecting Wires

2.2 LPG Gas Sensor Module:

This module contains a MQ3 sensor which actually detects LPG gas, a comparator (LM393) for comparing MQ3 output voltage with reference voltage. It gives a HIGH output when LPG gas is sensed. A potentiometer is also used for controlling sensitivity of gas sensing. This module is very easy to interface with microcontrollers and arduino and easily available in market by name "LPG Gas Sensor Module". We can also build it by using LM358 or LM393 and MQ3.

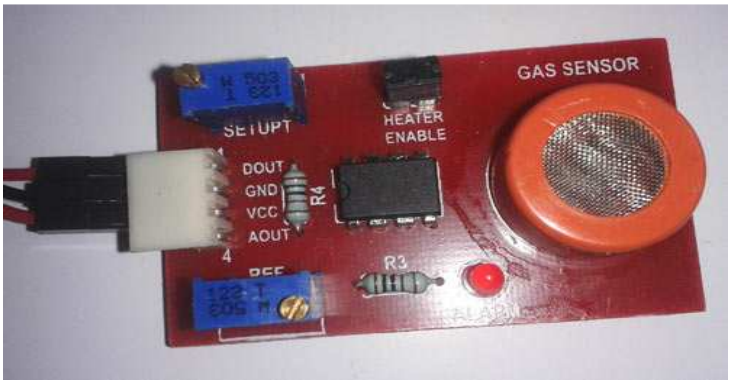

Fig. 1 Design of LPG leakage detection

III. WORKING PRINCIPLE

We have used a LPG gas sensor module to detect LPG Gas. When LPG gas leakage occurs, it gives a HIGH pulse on its DO pin and arduino continuously reads its DO pin. When Arduino gets a HIGH pulse from LPG Gas module it shows "LPG Gas Leakage Alert" message on 16x2 LCD and activates buzzer which beeps again and again until the gas detector module doesn't sense the gas in environment. When LPG gas detector module gives LOW pulse to arduino, then LCD shows "No LPG Gas Leakage" message.

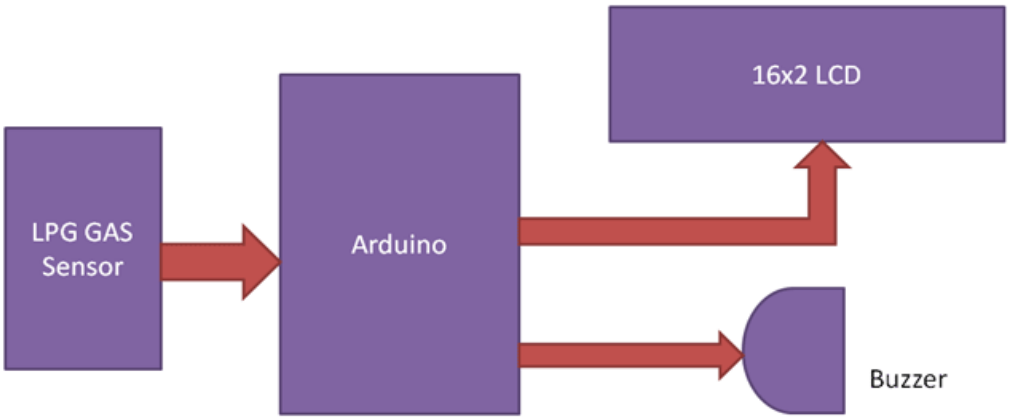

Fig. 2 LPG leakage detection and alert system

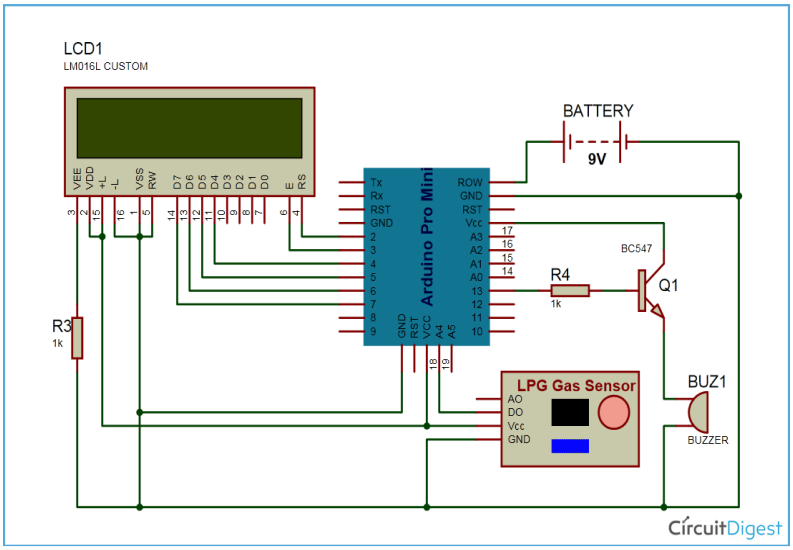

Fig. 3 Circuit Diagram and Description

As shown in the schematic diagram above, it contains Arduino board, LPG GAS Sensor Module, buzzer and 16x2 LCD module. Arduino controls the whole process of this system like reading LPG Gas sensor module output, sending message to LCD and activating buzzer. We can set sensitivity of this sensor module by inbuilt potentiometer placed on it.

LPG gas sensor module's DO pin is directly connected to pin 18 (A4) of Arduino and Vcc and GND are connected to Vcc and GND of arduino. LPG gas sensor module consist a MQ3 sensor which detects LPG gas. This MQ3 sensor has a heater inside which needs some heater supply to heat up and it may takes up to 15 minute to get ready for

detecting LPG gas. And a comparator circuit is used for converting Analog output of MQ3 in digital. A 16x2 LCD is connected with arduino in 4-bit mode. Control pin RS, RW and En are directly connected to arduino pin 2, GND and 3. And data pin D0-D7 are connected to 4, 5, 6, 7 of arduino. A buzzer is connected with arduino pin number 13 through a NPN BC547 transistor having a 1 k resistor at its base.

IV. CONCLUSIONS

Gas leakage leads to severe accidents resulting in material losses and human injuries. Gas leakage occurs mainly due to poor maintenance of equipments and inadequate awareness of the people. Hence, LPG leakage detection is essential to prevent accidents and to save human lives. This paper presented LPG leakage detection and alert system. This system triggers LED and buzzer to alert people when LPG leakage is detected. This system is very simple yet reliable.

Smart Waste Management System

Mechineni Sindhuja[1], Gunji Pravalika[2], Ganesh Pashikanti[3] and V.Ganesh Kumar[4]

[1, 2] Final Year B.Tech, Department of Electrical and Electronics Engineering, Malla Reddy Engineering College (A), India
[3,4] Assistant Professor, Department of Electrical and Electronics Engineering, Malla Reddy Engineering College (A). India.
E-Mail: ganeshp5891@gmail.com

Abstract - Garbage! In our daily life, we see the pictures of garbage bins being overfull and all the garbage smells out. This leads to the number of diseases as large number of insects and mosquitoes breed on it. A big face up to the smart cities is solid waste management, not only in India almost all the countries in the world

Keywords - Arduino microcontroller through RS232, LCD, Arduino Software (IDE)

I. INTRODUCTION

This project gives the most efficient ways to keep our environment clean and green. The upcoming large number of smart cities, large numbers of responsibilities is also required to be fulfilled. The most important need of a smart way of life begins with cleanliness and cleanliness begins with smart dustbin. A people will get its waste dispatch properly only if the dustbins are placed well and collected well. The main problem in the current waste management system in most of the cities is the damaging status of dustbins. So, by using the new technology we send the information to the concern persons and display boards are arranged in the concern offices. The progress of waste across the entire city can be tracked and thus can be monitored by a single system efficiently and concretely. This system can prove to be a revolution for the whole waste management system of future smart cities.

.

II. MATERIALS AND METHODS

Hardware Requirements

The hardware requirements for the system are as follows.

Ultrasonic Sensors: Detecting the level of Garbage. The Ultrasonic Sensor sends out a high-frequency sound pulse and then times how long it takes for the echo of the sound to reflect back. The sensor has 2 openings on its front. One opening transmits ultrasonic waves, the other receives them. The speed of sound is approximately 341 meters (1100 feet) per second in air. The ultrasonic sensor uses this information along with the time difference between sending and receiving the sound pulse to determine the distance to an object.

It uses the following mathematical equation:

Distance = (Time x Speed of Sound)/2

Time = the time between when an ultrasonic wave is transmitted and when it is received.

To measure the distance to an object, the time from transmission of a pulse to reception is measured and converted into arrange by knowing the speed of sound. This signal together with noise is then passed through various forms of signal processing, which for simple sensors may be just energy measurement. It is then presented to some form of decision device that calls the output either the required signal or noise. This decision device may be an operator with headphones or a display, or in some systems this function may be carried out by software. Further processes may be carried out to classify the target and localize it, as well as measuring its velocity. Some ultrasonic sensors have multiple beams to provide all round cover while others only cover an arrow arc, although the beam may be rotated, relatively slowly, by mechanical scanning.

GSM Modem: GSM Modem can accept any GSM network operator SIM card and act just like a mobile phone with its own unique phone number. Advantage of using this modem will be that you can use itsRS232 port to communicate and develop embedded applications. Applications like SMS Control, data transfer, remote control and logging can be developed easily using GSM as shown below.

The modem can either be connected to Arduino microcontroller through RS232. It can be used to send and receive SMS or make/receive voice calls. It can also be used in GPRS mode to connect to internet and do many applications for data logging and control. This GSM modem is a highly flexible plug and play quad band SIM900A GSM modem for direct and easy integration to RS232applications. Supports features like Voice, SMS, Data/Fax, GPRS and integrated TCP/IP stack.

Liquid Crystal Display: To display the dustbin location.

A liquid crystal display (LCD) is a display module with liquid crystals and backlight by LEDs. A 16x2 LCD display consists of two rows of display with each row consisting of 16 characters. LCD Module has 16 pins and operates

with 5V. Power pins i.e. pins 1, 2, 3, 15 and 16 are used to supply for the module as well as the backlight LEDs. The voltage to the Contract Adjust Pin (Pin 3 or VEE) is usually given from a Potentiometer and will or battery to get started. The major advantage is control multiple appliances with a single board.

Software Requirements:

Arduino IDE: The Arduino is open source Integrated Development Environment or Arduino Software (IDE). It contains a text editor for writing code, a message area, a text console, a toolbar with buttons for common functions and a series of menus.

Writing Sketches: Programs written using Arduino Software (IDE) are called sketches. These sketches are written in the text editor and are saved with the file extension .ino. The message area gives feedback while saving and exporting and also displays errors. The console displays text output by the Arduino Software (IDE), including complete error messages and other information. The bottom right hand corner of the window displays the configured board and serial port. The toolbar buttons allow you to verify and upload programs, create, open, and save sketches, and open the serial monitor. Arduino Language is user friendly and for programming is merely a set of C/C++ functions that can be called from your code.

III. DESIGN AND IMPLEMENTATION:

The project can be divided into two modules, one is detection of garbage level and then the second module is send the information to the corresponding officials through GSM.

Description of project: Garbage level detection is the done by ultrasonic sensors (HC-SR04).The ultrasonic sensors is placed on top of the dustbin facing the bottom. The sensors continuously emits the sonic waves, when the sonic waves hit the object and reflect back, the echo in the sensors senses the waves and calculates the distance of the object. Arduino Mega 2560 is used for controlling whole the process detecting garbage in different places and depending on the program first display in LCD to reminding the garbage level in the bin even though the garbage is not take out from the bin then the particular bin information is sent to higher officials through GSM.

IV. CONCLUSION

Garbage monitoring systems are the needs of Smart buildings. Smart waste monitoring and management is the keen idea of smart city planners. Garbage monitoring systems is a new idea of implementation which makes a normal dustbin smart using sensors for garbage level detection and sending message to the user updating the status of the bin. As soon as the dustbin is full it gives the information in LCD and sent the message to corresponding officials.

Abstract - This project employs a solar panel mounted to a time-programmed stepper motor to track the sun so that maximum sun light is made incident upon the panel at any given time of the day. This is better compared to the light sensing method that may not be accurate always – for example, during cloudy days. With the impending scarcity of non-renewable resources, people are considering to use alternate sources of energy. Barring all the other available resources, the solar energy is the most abundant and it is comparatively easy to convert into electrical energy. The usage of solar panel to convert Sun energy into electrical energy is very popular, but due to the transition of sun from east to west, the fixed solar panel may not be able to generate optimum energy. The proposed system solves this problem by an arrangement for the solar panel to track the Sun. This tracking movement is achieved by coupling a stepper motor to the solar panel such that the panel maintains its face always perpendicular to the sun to generate maximum energy. This is achieved by using a programmed microcontroller to deliver stepped pulses in periodical time intervals for 12 hours for the stepper motor to rotate the mounted panel in one direction and then return to the start point for next day light as desired. The Arduino controller used in this project is from the Arduino family. The Stepper motor is driven by an interfacing IC as the controller is not capable of handling the power requirements of the stepper motor. Furthermore, this project can be enhanced by using an RTC (Real Time Clock) to follow the sun. This helps in maintaining the required position of the panel even if the power is interrupted for some time.

Keywords - Solar Panel, Stepper motor, Programmed Microcontroller, Real Time clock, 89C51.

I. INTRODUCTION

In this article we are going to make a Sun Tracking Solar Panel using Arduino, in which we will use two LDRs (Light dependent resistor) to sense the light and a servo motor to automatically rotate the solar panel in the direction of the sun light. Advantage of this project is that Solar panel will always follow the sun light will always face towards the sun to get charge all the time and can provide the supply the maximum power. The prototype is very easy to build. Below you will find the complete description of how it works and how the prototype is made.

II. COMPONENTS AND METHODS

- Servo Motor (sg90)
- Solar panel
- Arduino Uno
- LDR's X 2 (Light Dependent Resistor)
- 10K resistors X 2
- Battery (6 to 12V)

III. RESULTS AND DISCUSSION

In this project, LDR's are working as light detectors. Before we go into detail, we will have to understand how the LDR's work. LDR (Light Dependent Resistor) also known as photo resistor is the light sensitive device. Its resistance decrease when the light falls on it and that's why it is frequently used in Dark or Light Detector Circuit. Check the various circuits based on LDR here.

The two LDR's are placed at the two sides of solar panel and the Servo Motor is used to rotate the solar panel. The servo will move the solar panel towards the LDR whose resistance will be low, mean towards the LDR on which light is falling, that way it will keep following the light. And if there is same amount of light falling on both the LDR, then servo will not rotate. The servo will try to move the solar panel in the position where both LDR's will have the same resistance means where same amount of light will fall on both the resistors and if resistance of one of the LDR will change then it rotates towards lower resistance LDR. Check the Demonstration Video at the end of this Article.

IV. RESULTS AND DISCUSSION

To make the prototype, you will have to follow the below steps:

Step 1:

First of all, take a small piece of cardboard and make a hole at one end. We will insert the screw in it to fix it with the servo later on.

Step 2:

Now fix two small pieces of cardboard with each other in a V shape with help of glue or hot gun and place solar panel on it.

Step 3:

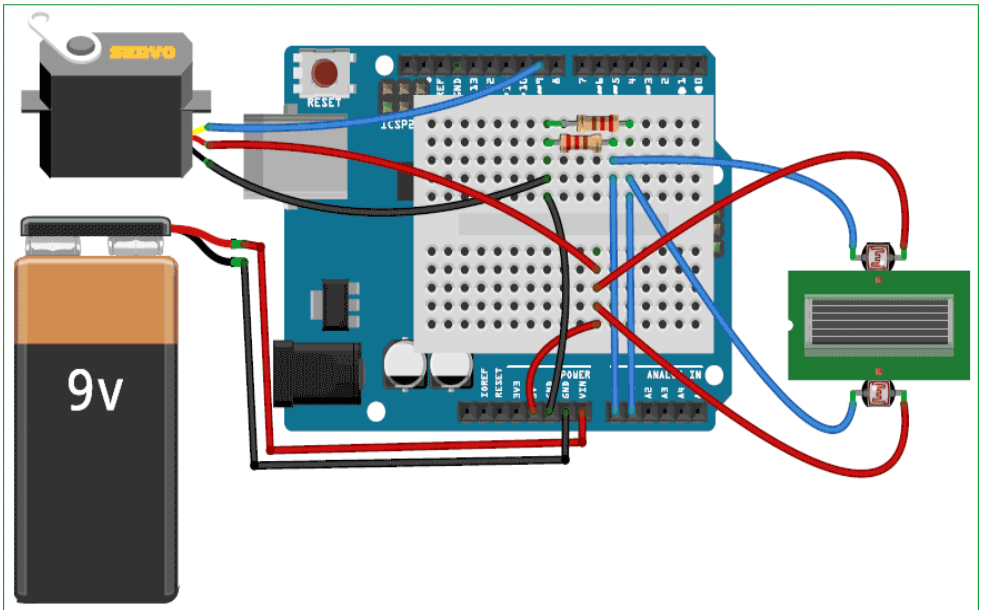
Then attach the bottom side of the V shape to the other end of small piece of cardboard in which you made a hole in first step.

Step 4:

Now insert the screw in the hole you made on card board and insert it through the hole into the servo. The screw comes with the servo motor when you buy it.

Step 5:

Now place the servo on another piece of cardboard. The size of the cardboard should be larger enough so that you can place a Arduino Uno, a breadboard and a battery on it.



Step 6:

Attach the LDRs on the two sides of the solar panel with the help of glue. Make sure you have soldered the wires with the legs of the LDR's. You will have to connect these with the resistors later on.

Step 7:

Now place the Arduino, battery and the breadboard on the cardboard and make the connection as described in the Circuit diagram and Explanation section below. The final prototype is shown below.

In this Arduino Solar Panel Tracker, Arduino is powered by the 9V battery and all the other parts are powered by the Arduino. Arduino recommended input voltage is from 7 to 12 volts but you can power it within the range of 6 to 20 volts which is the limit. Try to power it within the recommended input voltage. So connect the positive wire of the battery to the Vin of the Arduino and the negative wire of the battery to the ground of the Arduino.

Next connect the servo to the Arduino. Connect the positive wire of the servo to the 5V of Arduino and ground wire to the ground of the Arduino and then connect the signal wire of Servo to the digital pin 9 of Arduino. The servo will help in moving the solar panel.

Now connect the LDRs to the Arduino. Connect one end of the LDR to the one end of the 10k resistor and also connect this end to the A0 of the Arduino and connect the other end of that resistor to the ground and connect the other end of LDR to the 5V. Similarly, connect the one end of second LDR to the one end of other 10k resistor and also connect that end to the A1 of Arduino and connect the other end of that resistor to ground and connect the other end of LDR to 5V of Arduino.

V. CONCLUSION

In this project, the sun tracking system is developed based on 89C51 microcontroller. The microcontroller 89C51 based circuit is used in this system with a minimum number of components and the use of stepper motors enables accurate tracking of the sun. It has been shown that the sun tracking systems can collect maximum energy than a fixed panel system collects and high efficiency is achieved through this tracker, it can be said that the proposed sun tracking system is a feasible method of maximizing the light energy received from sun. This is an efficient tracking system for solar energy collection.

Keywords - Microcontroller, Sensor, Street Light

I. INTRODUCTION

Nowadays, street lighting systems in industries or cities are growing rapidly. The important considerations in the field of different technologies like electrical and electronics are cost effective, automation and power consumption. There are different street lighting systems are developed to maintain and control the lighting systems. These lighting systems are used to control and decrease energy consumption. This article illustrates the street light that glows on detecting vehicle movement. Street light controlling is one of the most developing systems in India to conserve the energy.

Generally, street light controlling system is a simple concept which uses a transistor to turn ON in the night time and turn OFF during the day time. The entire process can be done by a using a sensor namely LDR (light dependent resistor). Nowadays conserving the energy is an essential part and day by day energy resources are getting decreased. So our next generations may face a lot of problems due to this lack of resources. This system doesn't need a manual operation to turn ON/OFF the street lights. The street light system detects whether there is need of light or not.

II. COMPONENTS AND METHODS

- Servo Motor (sg90)
- Solar panel
- Arduino Uno
- LDR's X 2 (Light Dependent Resistor)
- 10K resistors X 2
- Battery (6 to 12V)

III. RESULTS AND DISCUSSION

In this project, LDR's are working as light detectors. Before we go into detail, we will have to understand how the LDR's work. LDR (Light Dependent Resistor) also known as photo resistor is the light sensitive device. Its resistance decrease when the light falls on it and that's why it is frequently used in Dark or Light Detector Circuit. Check the various circuits based on LDR here.

The two LDR's are placed at the two sides of solar panel and the Servo Motor is used to rotate the solar panel. The servo will move the solar panel towards the LDR whose resistance will be low, mean towards the LDR on which light is falling, that way it will keep following the light. And if there is same amount of light falling on both the LDR, then servo

will not rotate. The servo will try to move the solar panel in the position where both LDR's will have the same resistance means where same amount of light will fall on both the resistors and if resistance of one of the LDR will change then it rotates towards lower resistance LDR. Check the Demonstration Video at the end of this Article.

IV. RESULTS AND DISCUSSION

To make the prototype, you will have to follow the below steps:

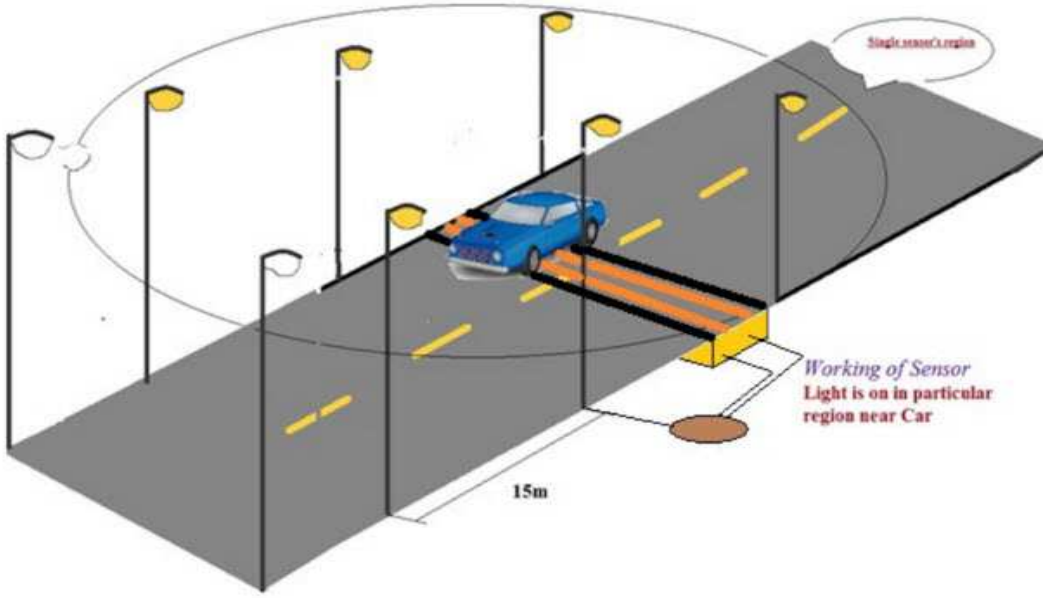

Fig.1 Street Light that Glows on Detecting Vehicle Movement Circuit

The working principle of this circuit is, when light falls on the light dependent resistor, then its resistance will be decreased, which results in an increase of the voltage at pin2 of the 555 IC. This 555 IC is inbuilt with a comparator, which associates between the i/p voltage from pin2 of the IC and 1/3rd of the power supply voltage. When i/p falls below 1/3rd then o/p is fixed to high otherwise it is fixed to the lower.

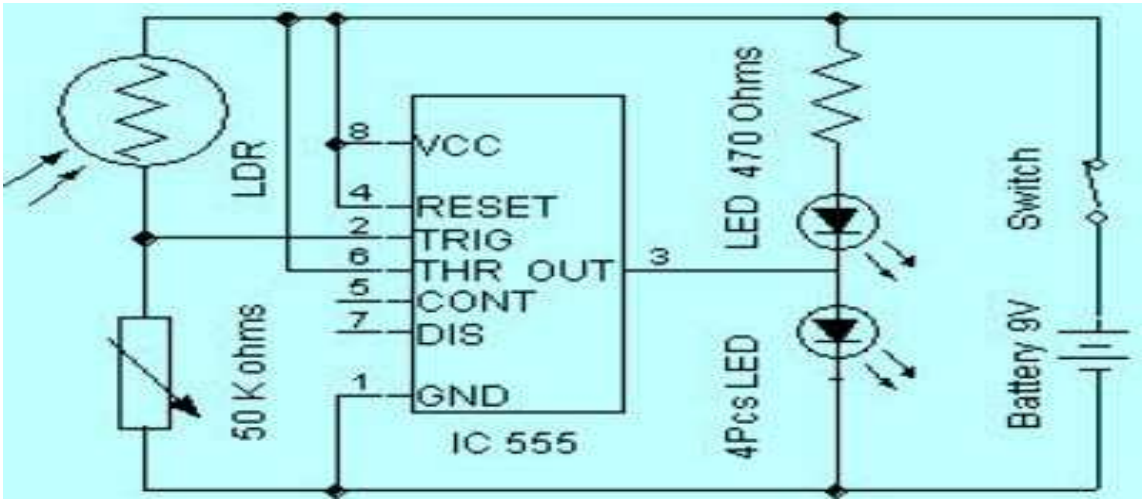

Fig. 2. Street Light that Glows on Detecting Vehicle Circuit

The proposed circuit is built with ATmega microcontroller, DS1307 IC, LDR, LCD, PIR sensor, Array of LED. This circuit is very useful in our day to day life like highways, real time street lights, the parking areas, restaurants and hotels.

V. CONCLUSION

In Proposed system is power saving mechanism for street lights by using LED lamps as replacement of normal lamps and using special power savings mechanism for microcontroller. It turns out most reliable and time efficient way to switch ON/OFF streetlights. It provides an effective measure to save energy by preventing unnecessary wastage of electricity, caused due to manual switching or lighting of street-lights when it is not required..

Smart Dustbin Using ARDUINO, Ultrasonic Sensor & Servo Motor

Pavan Kumar Reddy chinthakunta[1], R Shiva Sai Rama Krishna[2], K. S. S. Naga Teja[3] and S. Sunanda[4]

[1, 2] Final Year B.Tech, Department of Electrical and Electronics Engineering, Malla Reddy Engineering College (A), India
[3,4] Assistant Professor, Department of Electrical and Electronics Engineering, Malla Reddy Engineering College (A). India..
E-Mail: kssnteja@gmail.com

Abstract - Mostly in our daily life we encounter dustbins that are excessively full and garbage spilling out of them. This kind of situation is neither good for our environment nor for our advancement. This problem leads to huge number of diseases as large number of insects and mosquitoes breed on the waste accumulated in this garbage. Hence, we developed a project to control the overfilling of the dustbin by making the dustbin smart enough to notify itself for its cleaning. In this project the smart dustbin management system is built on the microcontroller based system having ultrasonic sensors on each of the four dustbins that will show the current status of garbage on the LCD screen as well as on the mobile.

Keywords -. ATMEGA328P, Ultrasonic Sensor, ESP8266, IR Sensor, PIR sensor

I. INTRODUCTION

In this project, I will show you How to Make a Smart Dustbin using Arduino, where the lid of the dustbin will automatically open when you approach with trash. The other important components used to make this Smart Dustbin are an HC-04 Ultrasonic Sensor and an SG90 TowerPro Servo Motor.

II. LITERATURE SURVEY

Since smart cities are becoming centre of attraction for the advancement of developing countries and without the removal or solution to the garbage problem these cities will be not that attractive. Therefore, large number of projects and research is going on in the area of smart dustbins for smart cities and to implement such projects typically use microcontroller based real time bin monitoring system, RFID technology, GPS, GSM, RF module etc. Yusof et al. [2], presented an Arduino Uno micro controller based smart garbage monitoring system to ascertain the level of waste in the garbage bin in real-time and before there is overflow in garbage bin the system sense out and alert through SMS municipality for the bin to be emptied an garbage to be collected immediately.

III. COMPONENTS AND METHODS

- Concept behind Smart Dustbin using Arduino
- How to Build a Smart Dustbin using Arduino?
- Connecting the Servo
- Connecting the Ultrasonic Sensor
- Wiring up the Components
- Circuit Diagram
- Components Required
- Code
- Working
- Output Video
- Conclusion

IV. RESULTS AND DISCUSSION

In this Dustbins (or Garbage bins, Trash Cans, whatever you call them) are small plastic (or metal) containers that are used to store trash (or waste) on a temporary basis. They are often used in homes, offices, streets, parks etc. to collect the waste. In some places, littering is a serious offence and hence Public Waste Containers are the only way to dispose small waste. Usually, it is a common practice to use separate bins for collecting wet or dry, recyclable or non-recyclable waste. In this project, I have designed a simple system called Smart Dustbin using Arduino, Ultrasonic Sensor and Servo Motor, where the lid of the dustbin will automatically open itself upon detection of human hand. The two LDR's are placed at the two sides of solar panel and the Servo Motor is used to rotate the solar panel. The servo will move the solar panel towards the LDR whose resistance will be low, mean towards the LDR on which light is falling, that way it will keep following the light. And if there is same amount of light falling on both the LDR, then servo will not rotate. The servo

will try to move the solar panel in the position where both LDR's will have the same resistance means where same amount of light will fall on both the resistors and if resistance of one of the LDR will change then it rotates towards lower resistance LDR. Check the Demonstration Video at the end of this Article.

V. RESULTS AND DISCUSSION

To make the prototype, you will have to follow the below steps:

Fig. 1. Experimental Kit Diagram

VI. CONCLUSION

In Proposed system, the implementation of smart dustbin management system using IOT as a hardware and ionic framework as our software insures the cleaning of dustbins soon when the garbage level reaches its maximum. If the dustbin is not cleaned in specific time, then the record is sent to the higher authority in our case the admin who can take appropriate action against the concerned employee.

E-Mail: ganeshp5891@gmail.com

Abstract - Mostly in our daily life we encounter dustbins that are excessively full and garbage spilling out of them. This kind of situation is neither good for our environment nor for our advancement. This problem leads to huge number of diseases as large number of insects and mosquitoes breed on the waste accumulated in this garbage. Hence, we developed a project to control the overfilling of the dustbin by making the dustbin smart enough to notify itself for its cleaning. In this project the smart dustbin management system is built on the microcontroller based system having ultrasonic sensors on each of the four dustbins that will show the current status of garbage on the LCD screen as well as on the mobile.

Keywords -. ATMEGA328P, Ultrasonic Sensor, ESP8266, IR Sensor, PIR sensor

I. INTRODUCTION

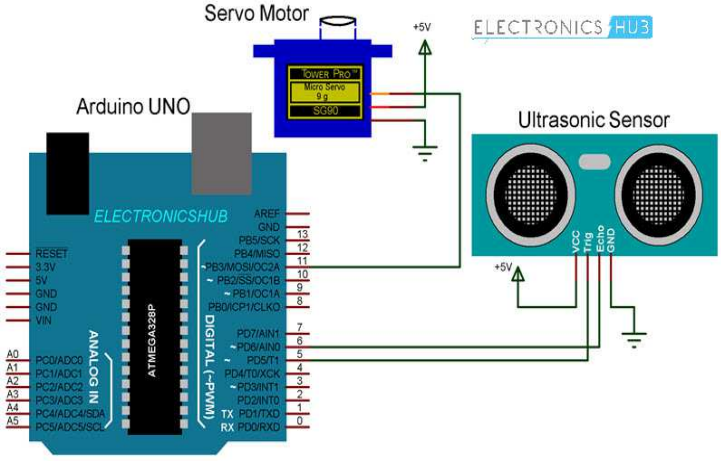
The main concept behind the Smart Dustbin using Arduino project is Object Detection. I have already used Ultrasonic Sensor in **Object Avoiding Robot**, where upon detecting an object, the Robot will change its course of direction.A similar methodology is implemented here, where the Ultrasonic Sensor is placed on top of the dustbin's lid and when the sensor detects any object like a human hand, it will trigger Arduino to open the lid. In this project, I will show you How to Make a Smart Dustbin using Arduino, where the lid of the dustbin will automatically open when you approach with trash. The other important components used to make this Smart Dustbin are an HC-04 Ultrasonic Sensor and an SG90 TowerPro Servo Motor.

For this mechanism to be able to open the lid of the dustbin, it must be placed near the hinge where the lid is connected to the main can. From the following image, you can see that I have fixed the servo motor on the can. Also, make sure that the lifting arm is parallel to ground under closed lid condition. **NOTE:** According to the Laws of Physics, you will require more energy to push the lid from the hinge than at the extreme end. But in order to open the lid and not have any obstacle, this is the only place to fix the servo motor with its arm.

II. COMPONENTS AND METHODS

- Concept behind Smart Dustbin using Arduino
- How to Build a Smart Dustbin using Arduino?
- Connecting the Servo
- Connecting the Ultrasonic Sensor
- Wiring up the Components
- Circuit Diagram
- Components Required
- Code
- Working
- Output Video
- Conclusion

Connecting the Ultrasonic Sensor:
Once the servo is in position, you can move onto the Ultrasonic Sensor. Make two holes corresponding to the Ultrasonic Sensor on the lid of the dustbin, as shown in the following image.



III. RESULTS AND DISCUSSION

In this Dustbins (or Garbage bins, Trash Cans, whatever you call them) are small plastic (or metal) containers that are used to store trash (or waste) on a temporary basis. They are often used in homes, offices, streets, parks etc. to collect the waste. In some places, littering is a serious offence and hence Public Waste Containers are the only way to dispose small waste.

WARNING: You have to use a sharp object with a lot of force to make these holes. Be careful.

All the wires from both the components i.e. Ultrasonic Sensor and Servo Motor are connected to respective pins of Arduino. This finishes up the build process of the Smart Dustbin.
The two LDR's are placed at the two sides of solar panel and the Servo Motor is used to rotate the solar panel. The servo will move the solar panel towards the LDR whose resistance will be low, mean towards the LDR on which light is falling, that way it will keep following the light. And if there is same amount of light falling on both the LDR, then servo will not rotate. The servo will try to move the solar panel in the position where both LDR's will have the same resistance means where same amount of light will fall on both the resistors and if resistance of one of the LDR will change then it rotates towards lower resistance LDR. Check the Demonstration Video at the end of this Article.

IV. RESULTS AND DISCUSSION

To make the prototype, you will have to follow the below steps:

- Working
- After setting up the Smart Dustbin and making all the necessary connections, upload the code to Arduino and provide 5V power supply to the circuit. Once the system is powered ON, Arduino keeps monitoring for any object near the Ultrasonic Sensor.

- If the Ultrasonic Sensor detects any object like a hand for example, Arduino calculates its distance and if it less than a certain predefined value, Arduino will activate the Servo Motor and with the support of the extended arm, it will list the lid open. After certain time, the lid is automatically closed.

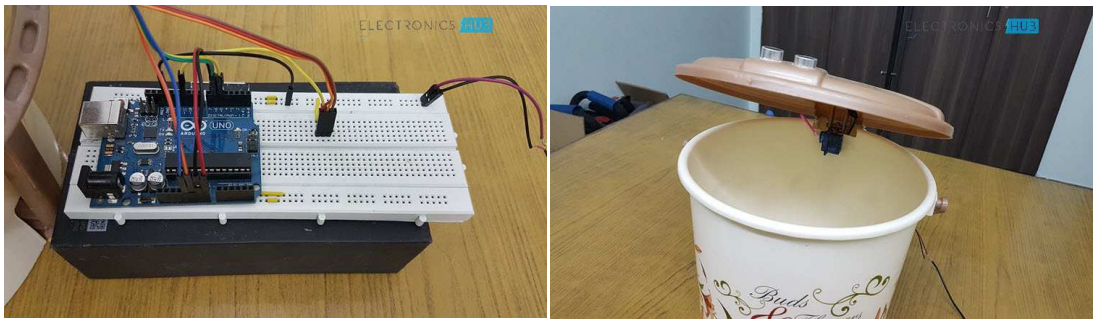


Fig. 1. Experimental Kit Diagram

V. CONCLUSION

A simple but useful project called Smart Dustbin using Arduino is designed and developed here. Using this project, the lid of the dustbin stays closed, so that waste is not exposed (to avoid flies and mosquitos) and when you want dispose any waste, it will automatically open the lid. If the dustbin is not cleaned in specific time, then the record is sent to the higher authority in our case the admin who can take appropriate action against the concerned employee.

Sensor Based Street Lightening for Vehicle Movement

Dravya mulkala[1], Chelkala Nikhitha[2], Mr. B. Sampath Kumar[3] and Mr. Pujari Vamshi[4]

[1, 2] Final Year B.Tech, Department of Electrical and Electronics Engineering, Malla Reddy Engineering College (A), India
[3,4] Assistant Professor, Department of Electrical and Electronics Engineering, Malla Reddy Engineering College (A). India..
E-Mail: sampath3505@gmail.com

Abstract - The project is to designed detect vehicle movement on highways to switch ON only a block of street lights ahead of the vehicle, and to switch OFF the behind lights to save energy. During night all the lights on the highway remain ON for the vehicles, but lots of energy is wasted when there is no vehicle his movement. This proposed system provides a solution for energy saving. This is achieved by sensing an approaching vehicle and switches ON a block of street lights ahead of the vehicle. As the vehicle passes by the behind lights switch OFF automatically. So when there are no vehicles on the highway, then all the lights remain OFF. Sensors used on either sides of the road send logic commands to microcontroller to switch ON/OFF the LEDs. Intensity control is also possible by Pulse Width Modulation (PWM) generated by the microcontroller. Thus this way of dynamically changing intensity ON/OFF helps in saving a lot of energy.

Keywords -. Microcontroller, Sensor, Street Light.

I. INTRODUCTION

Street lighting provides a safe night time environment for all road users including pedestrians. Providing street lighting is one of the most important and expensive responsibilities of a city. Lighting can account for 10–38% of the total energy bill in typical cities worldwide. Street lighting is a particularly critical concern for public authorities in developing countries because of its strategic importance for economic and social stability. Inefficient lighting wastes significant financial resources every year, and poor lighting creates unsafe conditions. Energy efficient technologies and design mechanism can reduce cost of the street lighting drastically. The main objective of the present project is to reduce the power consumption and efficient utilization of renewable sources for the application of street lightening and traffic signalling. Hence, this paper is aimed at design and implementation of an automatic system to control the traffic and reduce energy consumption of streets public lighting system up to the maximum possible extent. The density of traffic is sensed by using an array of Infrared Sensors (IR), which senses the traffic movement.

II. COMPONENTS AND METHODS

- Servo Motor (sg90)
- Solar panel
- Arduino Uno
- LDR's X 2 (Light Dependent Resistor)
- 10K resistors X 2
- Battery (6 to 12V)

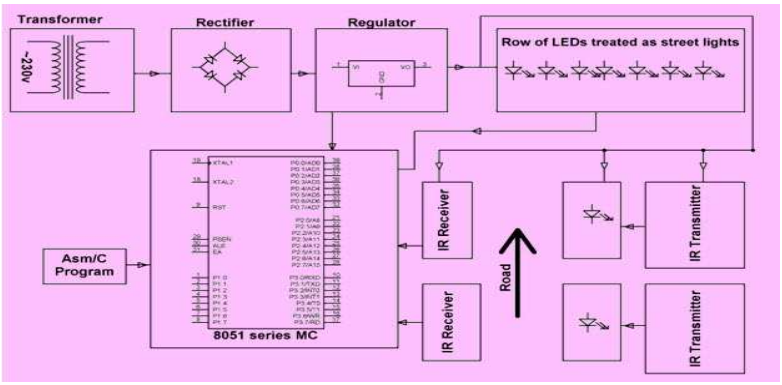

Fig. 1 Circuit Diagram

III. RESULTS AND DISCUSSION

In this project, LDR's are working as light detectors. Before we go into detail, we will have to understand how the LDR's work. LDR (Light Dependent Resistor) also known as photo resistor is the light sensitive device. Its resistance decrease when the light falls on it and that's why it is frequently used in Dark or Light Detector Circuit. Check the various circuits based on LDR here.

The two LDR's are placed at the two sides of solar panel and the Servo Motor is used to rotate the solar panel. The servo will move the solar panel towards the LDR whose resistance will be low, mean towards the LDR on which light is falling, that way it will keep following the light. And if there is same amount of light falling on both the LDR, then servo will not rotate. The servo will try to move the solar panel in the position where both LDR's will have the same resistance means where same amount of light will fall on both the resistors and if resistance of one of the LDR will change then it rotates towards lower resistance LDR. Check the Demonstration Video at the end of this Article.

IV. RESULTS AND DISCUSSION

To make the prototype, you will have to follow the below steps:

The power supply of this project comprises of a step-down transformer, which steps down the voltage from 230v to 12V AC. This is transformed to a DC using a Bridge rectifier. A capacitor is used to remove the ripples using a capacitive filter, and it is then regulated to +5V from 12v using a 7805 IC voltage regulator, which is compulsory for the microcontroller as well as other components.

Furthermore, this project can be extended by using suitable sensors for detecting the street light failure, and then sending an SMS to the control department through a GSM modem for suitable action.

By using this project a lot of energy can be saved. The proposed system uses LEDs instead of other lamps. The project is especially designed for street lighting in remote rural and urban areas where the traffic is low at times. The system is multipurpose, extendable and totally variable to user needs. The applications of this street light that glows on detecting vehicle movement mainly involve in highways, real time street lights, hotels, parking areas and restaurants, etc. The advantages are; low cost, more life span and energy can be saved.

Thus, this is all about street light that glows on detecting vehicle movement circuit and it working. We hope that you have got a better understanding of this concept of the information which we have given in the above. Furthermore, any queries regarding this topic or microcontroller based projects, please give your valuable suggestions by commenting in the comment section below.

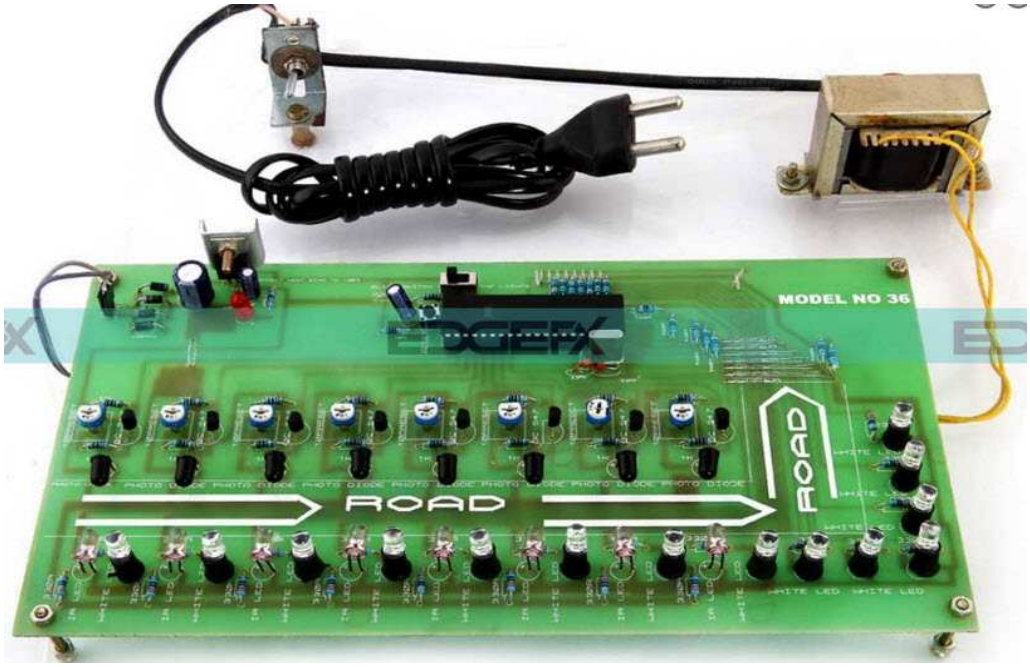

Fig. 2. Sensor Based Street Lightening Kit

V. CONCLUSION

In Proposed system During the night time all the lights on the highway road remain on throughout the night, so the energy loss will be high when there is no movement of vehicles. This project gives a solution for saving the energy. This is attained by detecting an approaching vehicle by turning ON the street lights. As the vehicle passes away from the street light, then the lights get turn OFF. If there are no vehicles on the road, then all the lights will turn OFF.

Abstract - Mostly in Road traffic accidents and deaths caused by them are most critical issues now a days. It is also impacting the country's economy. Research in this paper includes important issues like road accident and their impacts, causes of this accident, effect of accident, prevention and control that we can improve this situation. Also it is not safe now a days to cross the ghat while having any long journey. Percentage of accident in ghat area is increasing day by day. Severity of this accidents are non-reparable. Road traffic accidents (RTA) are responsible for 1.2 million deaths worldwide each year. So it is first important to control this scenario and have some safety measures in ghat area. This paper includes some solutions and ideas to improve safety in ghat areas.

Keywords -. Accident, Road safety, Ghat Section,.

I. INTRODUCTION

Today, road traffic injuries are one of the leading causes of death, disabilities and hospitalization in the country. Road network in India, of about 56 lakh km in March 2016, is one of the largest in the world. A total of 4,64,910 road accidents have been reported by States and Union Territories (UTs) in the calendar year 2017 claiming 1,47,913 lives and causing injuries to 4,70,975 persons. These figures translate, on an average, into 1274 accidents and 405 deaths every day or 53 accidents and 17 deaths every hour in the country. There are many dangerous roads in the world like mountain roads, narrow curve roads, T roads. The problem in these curve roads is drivers can't able to see the vehicle or obstacles coming from other end of the curve. If the vehicle is in very speed then it is difficult to control and there are chances of falling to cliff. The solution for this problem is alerting the driver about the obstacle or vehicle. Usually horn is used for this purpose but it is not a valid. To avoid these problems in curve roads or T roads we are introducing sensor based accident prevention system. That is we are keeping ultrasonic sensor in one side of the road before the curve and keeping a LED light after the curve.

Mostly, in the hilly areas of Northern India, accidents due to poor development of national highways and hazard zones. In India the rate of accidents in ghat section is increasing day by day. In India 1 out of 6 serious victim's dies, but in the U.S.A. the figure is 1:200. It will become the third largest contributor to the Global burden of the disease. It is estimated that 60,000 are killed on the roads every year.

- Preventive measures
- Engineering measures
- Enforcement of regulation.
- Educators of public in traffic laws.

Road design, road lighting, penance of the defective vehicles taken to decrease the rate of accidents. Speed control, traffic control, training and supervision, section observance of law and regulation and medical check up to all these points were included in the enforcement of regulation. It is necessary to provide education related to traffic laws to educate the road user regarding the necessary safety precaution taken while using the road.

II. SURVEY

Some road conditions responsible for accident
Road crossing
Potholes
Damaged road
Diversions
Illegal speed breakers
Merging of rural road with highways
Signal crossing
Narrow width of road at bridge section
Ghat section

III. METHOD

Arduino Uno is a microcontroller board based on the ATmega328P. It has 14 digital input/output pins (of which 6 can be used as PWM outputs), 6 analog inputs, a 16 MHz quartz crystal, a USB connection, a power jack, an ICSP header and a reset button. It contains everything needed to support the microcontroller, simply connect it to a computer with a USB cable or power it with an AC to-DC adapter or battery to get started. The power for Arduino can be derived from Nonconventional sources like solar energy.

Ultrasonic sensors

Ultrasonic sensors are “based on the measurement of the properties of acoustic waves with frequencies above the human audible range” often at roughly 40 kHz. They typically operate by generating a high-frequency pulse of sound, and then receiving and evaluating the properties of the echo pulse. In the presence of vehicle the sensor senses the vehicle; the light will glow at the other end of the curve. In the absence of the vehicle the sensor will not sense and the light will not glow. This process repeats continuously.

3.1 Causes of road accidents in ghat section

1. This happens while a vehicle tries to overtake other vehicle when entering village town and suddenly a road divider starts.
2. For increasing number of accident is overloading vehicle
3. So many times while driving drivers are drunk
4. Lack of connectivity between villages Occur due to drivers losing control over the vehicle at sharp bends
5. 25% of accident have occur because of drunken driving.
6. Also the enforcement of police is weak
7. Topography nature of ground is another reason for spread in accident.
8. It is observed that 50% accidents have occurred while negotiating the sharp bends.
9. A majority of drivers are not properly trained and many drivers not even have their licence.
10. Basic elements in accident on road user’s vehicle road and its condition environmental factors etc.
11. Drivers pedestrian’s element of surprise passenger vehicle defects road condition Road design whether animal’s other causes are also the cause of accident.

IV. RESULTS AND DISCUSSION

Ultrasonic sensor has 4 pins. They are +5V VCC, GND, Trig pin and Echo pin. Here Trigger pin is output pin and Echo pin is input pin. Ultrasonic sensor sends the signal in the form of pulses from trigger pin. When this signal hit the object it will get reflected back and is received by the echo pin. From echo the signal is sent to microcontroller Arduino UNO. Microcontroller Arduino UNO processes this data and operates the LED which is connected to output pin of the microcontroller Arduino UNO. LED is operated according to the command. In this study, we got to know about the accident which occurs on the road at Ghat section. We understand the causes and effect of accidents and then founded out a solution introducing a new technique to avoid such accident.

V. CONCLUSION

The new technique consists of two CCTV cameras and two LCD screen which displays the live scene captured from the CCTV. This help in reducing the accidents and to enjoy the safer ride. Life is important than any other thing, once gone cannot be regained. So, to save this valuable life, this method have important role. It can help Road users at Ghats from being killed in a serious injury.

Abstract - This system presents a low cost, less time consuming, safe and effective implementation of Smart Letter Box System through the wireless sensor networks which makes the use obstacle sensor. A special device, called hardware kit is realized and design for this purpose. Obstacle sensors has IR transmitter and IR receiver.IR transmitter transmit the rays. When the rays fall on to the object then it gets reflected to IR receiver, it results that the object is detected. In existing system user is notified by sending a text message through a SIM card, but here we introduce Android Application which gives the notification through the internet. The paper illustrates the description of this device, the android application which receives the notification .This system reduces the Human efforts. The additional component of the current system is a battery backup which is used to avoid power failure of the system. The final aim is to minimize the human efforts, reduce cost as well as power failure.

Keywords - Smart Sensor Box, Sensor , Hardware Kit, Android, MySQL

I. INTRODUCTION

Smart letter box is the new and the latest technology that have been involved from recent times. The use of letter box is largely finding in government post box, courier system, and home letter box system in societies. Such letter box are use to post the letter. In this smart letter box system it involves five parties: the admin who has the highest authority. The area manager, pick-upper, operator and user. The area manager is given different areas. Pick-upper and operator are under area manager. Pick-upper is supposed to pick up the letters from the letter box and operator installs the letter box on the hardware kit. The hardware kit include obstacle sensor. Obstacle sensors has IR transmitter and IR receiver.IR transmitter transmit the rays. When the rays fall on to the object then it gets reflected to IR receiver, it results that the object is detected. Then the notification is send to user using internet connection on android application. The android application is used to receive the notification from the kit. The hardware kit also include SIM card which is used for internet connection. Battery backup is provided to the kit so the power failure problem will not occur. Here MySQL database is used to store the data. Data in sense it stores the count of the letters that has been dropped in letter box. The address from where the letter has been received. The existing system reduces the human efforts as well as cost. This system is the best approach in IoT. Fig:-Basic diagram of letter box.

II. LITERATURE SURVEY

Geometric filter algorithm uses geometric objects such as line segment, points and circle to represent shadowed links ,possible target locations which reduces the number of computations and storage.GF uses the prior information to improve the tracking results making it most robust to noise. To remove the outlier links and points a circular prior region is used. It maintains the computational efficiency and improve the location estimate. The prior region is used to assign the weights to maintain computational efficiency and it improves the location estimate. The weight are based on the amount of swallowing experienced by the links. And distance of intersection point to the prior location estimate. The problems that comes in t-tracking in two aspects. One aspect is to investigate more practical issues using the concept of faces as localized areas for tracking, mainly in the case of a target localization by two nodes. Another aspect is to check the proposed scheme in different tracking situations.

For instance, intruders like people are moving toward the fence (or border) of a surveillance region and are taking different directions. In this instance, it can be consider the edge crossing between the monitor and backup as the border crossing of the surveillance region[2]. An efficient target tracking mechanis m(ETT) for a single target which dynamically wake up in a distributed manner with the minimal number of working sensors in which the user-defined tracking quality is satisfied. Energy conservation when the target not entering the monitoring region: In the initialization phase the ETT only wakes up boundary sensors. For energy conservation. All the other sensors stay in sleeping state In addition, the boundary sensor that monitors the longer boundary segment has assigned the higher priority to participate in the monitoring task to minimize the number of working boundary sensors. Most works did not consider the situation that target does not enter the monitoring region.

III. WORKING PRINCIPLE

There are four major parts in this system.

1. Sensing circuit: Sensing circuit is a comparator which is builds using Im 358 ic. Output of this comparator is directly connected to the digital pin number 3. In thiscircuit IR transmitter and IR receiver are placed in letter box in the same direction when any obstacle or inserted into the letter box comparator detects the obstacle then it send signal to Arduino.
2. Controller circuit:- After getting signal from comparator, Arduino sends command to GSM module for sending a notification message to a specified number.
3. GSM Module:- Rx and Tx pins of GSM are directly connected with Tx and Rx pins of Arduino respectively. And ground pins of both modules should be connected to each other.4
4. Real time clock:- This RTC clock is used here for running the time and when delivery , if letter occurred, letter delivery time of RTC is saved in EEPROM of Arduino.. Android Application Android application system: Android is an open handset Alliance. It is a mobile operating system and is developed by Google which is based upon linux kernel. Software stack in android operating system consist of java application which is based on object oriented-application. A smart letter box system is access anywhere and at any time .The record can be accessed using android mobile operating system .The report generated message is stored in server database. Mobile application is developed and installed in the mobile and the message generated with the hardware kit which hasGSM in build in it. C.DATABASE My SQL database is used at server side and is connected through GPS to Mobile Android Application . Literature Survey Letter box system is actually an indication system, it shows indications whenever there arrives letter in the letter box It works using on the concept of Obstacle detection. In this arrangement IR Transmitter and IR Receiver are placed near to each other, whenever any obstacle (i.e Letter) comes in front of the obstacle sensor the rays gets reflected and thus we get the output as HIGH Thus the letter have been detected in the Letter the Box. Thus the letter have been detected in the Letter the Box In the days of technology postman still comes to our house to deliver the letters, courier and parcels. Because the things courier and parcels cannot be sent via email and by any other electronic media. So to get notification of letter delivery in our mail box here we design an intelligent letter box that provides notification of delivery of letters in our mail box through the message to our smart phone our GSM mobiles. This system uses IR pair that is used to sense the incoming letter in the letter box and a GSM module is used to send message to our phone. And a 16x2 LCD display displays time and letter box status (empty or not), delivery time, date and a real time clock circuit is also used in this system. LED is configured to indicate that letter box is empty or not. When any person insert letter in the letter box, IR sensor sense the obstacle that is letter and then Arduino send the command to GSM module to send notification message to the certain phone number. Than we can collect the letter if possible otherwise after some time. When we collect letters we have to press the reset button that clears the entries of letters, we add an additional feature in which data will not be lost after power failure. Because in this system Arduinos EEPROM is used to store the delivery time of letter and date. This system is designed to save only 6 delivery reports of letters.

The mobile application is used to receive the notification. Here the obstacle sensor is used to detect the object (letter). The RTC clock is used to store the time the delivery of the letter. GSM module is used to send the notification through message and the GPS detects the location at which address the letter has been received. We have used Android operating system in this system which has lot of features integrated in it. MySQL database is used to store the records. This database is easy to maintained records.

IV. CONCLUSION

Nowadays, the technology and science is in progress day by day new technologies are invented and new things are created by human. In this system we have studied a smart letter box system that notifies the letter is received in the letter box. In our daily life it is not possible for us to check the letter box we proposed this system that the system notifies the user by sending message that letter is arrived. In this paper we conclude that science is non stoppable, new things arrive and growth of smart system.

Abstract - Robot is a re-programmable, multi functional device which is primarily designed to do work like human such as pick and place, loading and unloading, surveillance, health care, industrial, aerospace application. Robots can perform dangerous and accurate work to increase the productivity as they can work 24 hours without rest. This paper deals with the design and control of automated vehicle type robot which can move in desired direction and captures pictures and videos of required location. An android application has developed using MIT App inventor and a Bluetooth communication is made with robot which interfaces with microcontroller to control its speed and direction. Aim of this work is to design and control the motion of robot using Bluetooth device of an Android phone.

Keywords -HC-05 ,MATLAB ,Arduino UNO, L298N Motor Driver Module

I. INTRODUCTION

The design and develop a Bluetooth Controlled Robot using Arduino, HC-05 Bluetooth Module and L298N Motor Driver Module. On the other end of the Bluetooth Communication, I will be using a Smart Phone and a simple Android App to control the Robotic Car. Robots are always a fancy topic for students, hobbyists and DIYers. If you are beginner, then building a robot (like a car or an arm) is probably one of the important projects to do after learning about the basics.

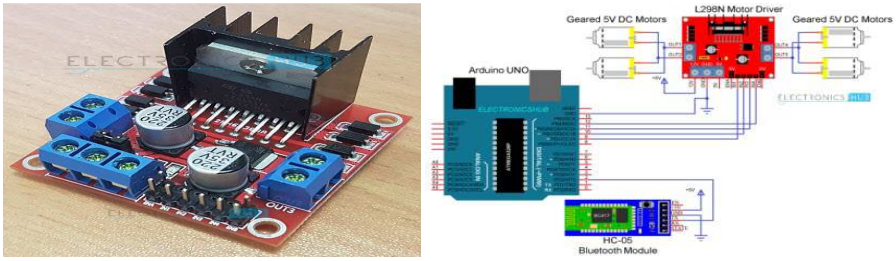
HC-05 Bluetooth Module

Implementing Bluetooth Controlled Robot using Arduino and a few other components and build a simple robotic car that can be controlled using an Android Phone (through an App) over Bluetooth Communication.

Prerequisites for Bluetooth Controller Robot

Apart from Arduino, which is the main controlling module of the project, there are two other important modules that you have to be familiar with in order to implement the Bluetooth Controlled Robot project.

They are the HC-05 Bluetooth Module and the L298N Motor Driver Module.



The HC-05 Bluetooth Module is responsible for enabling Bluetooth Communication between Arduino and Android Phone.

L298N Motor Driver Module

The L298N Motor Driver Module is responsible for providing the necessary drive current to the motors of the robotic car. I have provided information about L298N Module in an earlier project called Arduino DC Motor Control using L298N. So, refer to ARDUINO DC MOTOR CONTROL USING L298N for more information on interfacing L298N with Arduino.

Circuit Diagram of Bluetooth Controlled Robot

The following is the circuit diagram of Bluetooth Controlled Robot using Arduino, L298N and HC-05.

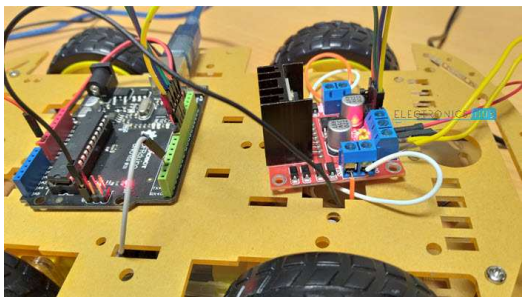
II. COMPONENTS REQUIRED

- Arduino UNO
- L298N Motor Driver Module
- HC-05 Bluetooth Module
- Robot Chassis
- 4 x 5V Geared Motors
- Connecting Wires
- Battery Holder
- Power Supply
- Android Phone
- Bluetooth Controller App

I have used L298N Motor Driver Module to drive the motors of the robot. You can use either this one or L293D Motor Driver Module. If you are using L293D, then check out for the connections.

Circuit Design: I wouldn't go into the details of the construction of the robot as your robot chassis might be different from mine and you can easily figure it out how to build the robot from the available parts and possible cable management for making the robot more appealing. Coming to the design of the circuit, first is the HC-05 Bluetooth Module. The +5V and GND pins of the Bluetooth Module are connected to +5V and GND of Arduino. Since I will be only transmitting data related to the Robot's movement from Android Phone to Bluetooth Module and do not intend to receive any data from Arduino, I will connect only the TX pin of the Bluetooth Module to RX Pin of Arduino. This RX pin of Arduino is based on Software Serial library (Pin 2 and Pin 3 are configured as RX and TX on Arduino). The RX pin of the Bluetooth is left open. Now, the L298N Motor Driver Module. Digital I/O Pins 9 through 12 of Arduino are configured as Input pins of the Motor Driver and are connected to IN1 through IN4 of the L298N Motor Driver Module. Both the Enable Pins are connected to 5V through provided jumper. The robot chassis which I am using in this Bluetooth Controlled Robot Car project is supplied with 4 geared motors. Since L298N has slots for only two motors, I have joined the left side motors as one set and the right side motors as other set and connected both these sets to the output of L298N Module.

III. WORKING



Assemble the robot, make the necessary connections and upload the code to Arduino.

If you understood the HC-05 Bluetooth Module tutorial, then understanding the Bluetooth Controlled Robot project is very easy.

First, in the Android App, I have used 5 keys as Forward, Reverse, Left, Right and Stop. The corresponding data associated with each key is as follows:

- Forward – 1
- Reverse – 2
- Left – 3
- Right – 4
- Stop – 5

When a key is pressed, the corresponding data is transmitted to the Bluetooth Module from the Phone over Bluetooth Communication.

In the Arduino code, the Arduino UNO receives any of this data from the Bluetooth Module (as per the key pressed) and performs a simple switch case operation, where each case associated with appropriate instructions to the Motor Driver Input Pins. For example, if 'Forward' key is pressed in the Android Phone, then '1' is transmitted. Arduino will then make IN1 and IN3 as HIGH and IN2 and IN4 as LOW to achieve a forward motion.

Similarly, other keys correspond to appropriate setting of IN1 – IN4 pins.

IV. LIMITATIONS

- As the range of the Bluetooth Communication is limited (a maximum of 10 meters for class 2 devices for example) the control range of Bluetooth Controlled Robot is also limited.

- Make sure that sufficient power is provided to all the modules especially the Bluetooth Module. If the power is not sufficient, even though the Bluetooth Module powers on, it cannot transmit data or cannot be paired with other Bluetooth devices.

V. APPLICATIONS

- Low range Mobile Surveillance Devices
- Military Applications (no human intervention)
- Assistive devices (like wheelchairs)
- Home automation

VI. CONCLUSION

The OS of smart phone is android which can develop effective remote control program. At the same time, this program uses blue-tooth connection to communicate with robot. It has proven to allow for meaningful two way communication between Android phone and the robot which allows a non-expert to interact with and adjust the functionality of system

Abstract - This document gives the Automatic Room Lights using Arduino and PIR Sensor, where the lights in the room will automatically turn ON and OFF by detecting the presence of a human. Such Automatic Room Lights can be implemented in your garages, staircases, bathrooms, etc. where we do not need continuous light but only when we are present. Also, with the help of an automatic room light control system, you need not worry about electricity as the lights get automatically off when there is no person. So, in this DIY project, we have implemented Automatic Room Lights using Arduino and PIR Sensor.

Keywords - Arduino UNO,PIR Sensor,Relay Module, LED and 1N4007 PN Junction Diode.

I. INTRODUCTION

Automatic Room Lights System using Arduino is a very useful project as you need not worry about turning on and off the switches every time you want to turn on the lights. The main components of the Automatic Room Lights project are Arduino, PIR Sensor and the Relay Module. Out of the three components, the PIR Sensor is the one in focus as it is the main device that helps in detecting humans and human motion. In fact, the Automatic Room Lights project can be considered as one major application of the PIR Sensor. A similar concept is being already implemented in automatic toilet flush valves, hand dryers, etc.

II. MATERIALS AND METHODS

Components Required for Automatic Room Lights using Arduino

- 5V Relay Module (Relay Board)
- LED
- 100Ω Resistor (1/4 Watt)
- Connecting Wires
- Breadboard
- Power Supply

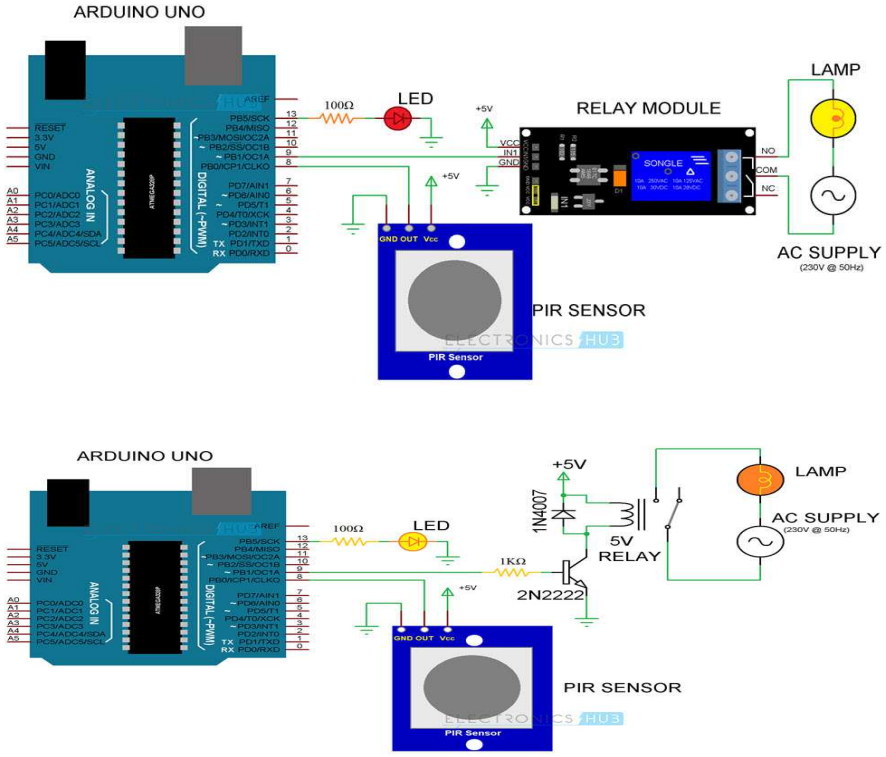
If you do not have a Relay Module, use the following components:

- 5V Relay
- 2N2222 (or BC547) NPN Transistor
- 1N4007 PN Junction Diode
- 1KΩ Resistor (1/4 Watt)

Component Description

PIR Sensor

We have already seen about PIR Sensor in the PIR Motion Sensor Tutorial and In order to control a single relay on the board, we need to use three pins of the relay module: VCC, GND and IN1.



Relay Module

A Relay Module is a very useful component as it allows Arduino, Raspberry Pi or other Microcontrollers to control big electrical loads. We have used a 2-channel Relay Module in this project but used only one relay in it. The relay module used in this project is shown below.

Circuit Diagram of Automatic Room Lights using Arduino

The following image shows the circuit diagram of the project implemented using Arduino UNO, PIR Sensor and a Relay Module. If you do not have a relay module, you can make one yourself using very simple hardware. The following circuit diagram shows the project being implemented with the help of discrete components for the Relay Module.

and Relay to mains supply. If you are unfamiliar with the connections, I strongly recommend having an adult supervision (or an expert supervision).

III. CIRCUIT DESIGN

PIR Sensor's Data OUT Pin is connected to Arduino's Digital I/O Pin 8. An LED is connected to pin 13 of Arduino to indicate whether the light is turned ON or OFF.

The IN1 pin of the Relay Module is connected to Pin 9 of Arduino. A bulb is connected to mains supply through relay. One terminal of the bulb is connected to one wire of the mains supply. The other terminal of the bulb is connected to the NO (Normally Open) contact of the Relay Module.

COM (Common) contact of the Relay is connected to the other wire of the mains supply. Be careful when connecting this part of the project.

IV. WORKING OF THE PROJECT

The Automatic Room Lights using Arduino and PIR Sensor is a simple project, where the lights in the room will automatically turn on upon detecting a human motion and stay turned on until the person has left or there is no motion.

Working of this project is very simple and is explained here.

Initially, when there is no human movement, the PIR Sensor doesn't detect any person and its OUT pin stays LOW. As the person enters the room, the change in infrared radiation in the room is detected by the PIR Sensor.

V. RESULTS AND DISCUSSION

As a result, the output of the PIR Sensor becomes HIGH. Since the Data OUT of the PIR Sensor is connected to Digital Pin 8 of Arduino, whenever it becomes HIGH, Arduino will activate the relay by making the relay pin LOW (as the relay module is an active LOW module).

This will turn the Light ON. The light stays turned ON as long as there is movement in front of the sensor. If the person takes a nap or leaves the room, the IR Radiation will become stable (there will be no change) and hence, the Data OUT of the PIR Sensor will become LOW. This in turn will make the Arduino to turn OFF the relay (make the relay pin HIGH) and the room light will be turned OFF.

Applications

I've already mentioned a few applications of the Automatic Room Lights concept. Some of them are:

- Garage Lights
- Bathroom Lights
- Hand Dryers
- Toilet Flushers
- Security Lights

VI. CONCLUSION

By using Automatic Room Lights using Arduino and PIR Sensor, where the lights in the room will automatically turn ON and OFF by detecting the presence of a human. Such Automatic Room Lights can be implemented in your staircases, bathrooms, etc.

ABSTRACT

Golomb coding is a loss-less data compression method using a family of data compression codes. Rice codes are a class of Golomb codes in which the divisor is valid only when it can be expressed as power of two. This work aims to increase compression by further encoding the unary part of the Golomb Rice (GR) code to decrease the numberof bits used. The algorithm was developed and coded in Verilog Hardware Description Language (VHDL) and simulated using Modelsim. The modifications carried out and reduction in bits used for a linearly distributed data set. Worst-case delays have been reduced acceptable level. Area reduction varies for different methods. An approximate 4% to 7% reduction in power consumption is observed. Modified Golomb Rice coding is used to compress multiple data types, which should ideally have a geometrical distribution.

Original Article

INTRODUCTION

S.W.Golombin the 1960s introduced the Golomb coding method. This algorithm is one of the lossless data compression methods and is using a family of data compression codes [1]. Golomb coding is highly suitable for situations in which the occurrence of small values in the input stream is significantly more likely than large values. In general, the images are classified in to two types First one is a Gray Scale image and second one a Colour Image. In analysis, compared with gray scale image, the colour image needs more attention and observation. In Image processing to reduce the memory size of the image and bandwidth, a high-performance lossless compression and decompression techniques is used [2-3]. Such cases, two algorithms are mainly used namely, Raster file and Golomb Rice Algorithm.

Embedded system applications and performance improvements the compressed memory schemes are used. Operating system-based and Discrete Cosine Transform based memory compressions are mainly focused areas in embedded system. Hadamard transform and Golomb-Rice coding are proposed for many researchers in hardware architecture-based Image compression [4]. Some demerits are in both Hadamard transform and Golomb-Rice encoding because of losses in data. So, overcome this difficulties and maintain the lossless data compression and decompression can be used to achieve low bit rate and improve imagequality [5].

Golomb Rice Coding

The sensor data and reduced data loss one of the efficient algorithms is Rice Golomb coding [5-7].

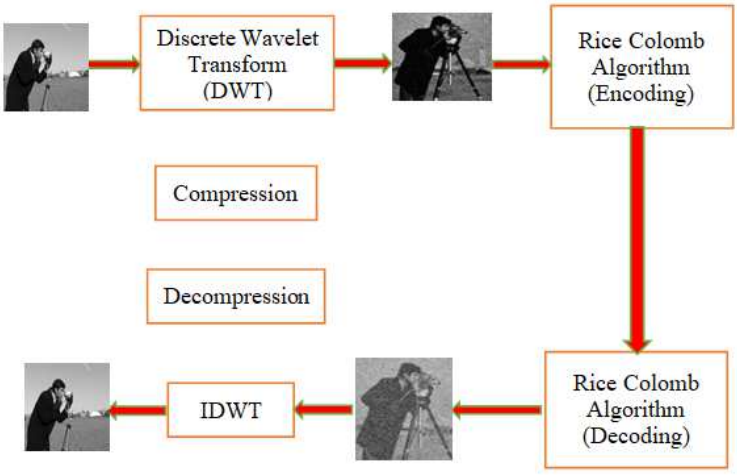

Figure 1: Block diagram of Image compression and Decompression.

In Figure 1, shows the discrete wavelet transform based compressed input image. The output of the 2-Dimensional discrete wavelet transform is in the form of sub-windows of m x n arrays. Then the image is converted into differential data by using raster file conversion. By using Golomb-Rice algorithm differential data has been encoded to produce length and code word of the input image. Based on the length and code word obtained the encoded image has been Decoded using Golomb-Rice algorithm. Thedecoded image has been decompressed using the inverse 2-D discrete wavelet transform. The output produced is similar to that of the input image.

OBJECTIVES

- To analyze and identify whether the proposed technique is a valid methods for image compression anddecompression.
- To compare the proposed method to exitingmethods.
- To prove, the proposed technique is efficientone.

METHODOLOGY

A simple procedure is adopted here for the easy implementation of Golomb, and it gives the pre ‘x’codes for the suboptimal. By a single parameter, the proposed method codes are distinguished from each other, in order to achieve dynamic update and accomplished for parameters estimations. Here, the methods are explained step by step procedure. From, countable alphabet the symbols are encoded by Golomb codes. All the encoded symbols are arranged in descending probability order. The Non negative integers beginning with ‘0’and the total number of encode integer is assigned value ‘n’. The ‘g’ is Golomb parameter. The ‘reset’ (rst) compute ‘hn=gc’ and output this integer using a unary code. Then we compute n mod m and output this value using a binary code, adjusted as described above so that we sometimes use ‘gc’bits and sometimes ‘ga’bits. Golomb coding and Rice coding are most probably same algorithm. Hence to encode integer n using the Rice code with parameter ‘z’ and ‘rst’ compute ‘hn=2kc’ and output this integer using a unarycode. Golomb-Rice

Encoder main task – as described before – is to generate code and length values. At each clock cycle, it receives the residual values of four pixels of one specific subtle (a1, a2, a3, and a4) of one component, and generates corresponding "code"and "header" values for each pixel. The Encoder block consists of three sub-blocks shown in Figure 2.

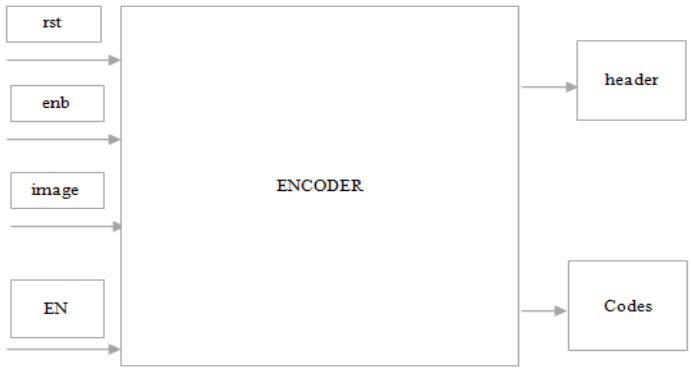

Figure 2: Encoder Block.

RESULTS AND DISCUSSIONS

The compressor and decompressor data path blocks are synthesized with the target clock frequency of 220MHz. The overall block size of the compressor is 9.20kgates. This size includes data path blocks; input-output data registers and address generators. 59.2 % of this block is combinational, and the rest is sequential logic size. In order to verify the functionality of the design, a verification framework has been designed. This framework consists of oneRAM blocks, a counter to generate the address for the memory, and a control block which is a finite state machine. There are three modes of operation during the functional verification. The input image to be compressed has already been converted to binary representation in MATLAB and stored in a text file as input file to the framework. This file has 32 columns which is equal to the 32-bit memory word-length. The number of lines in the file depends on the image size and therefore the memory size has to be adjusted accordingly. In the first mode, content of the input file is stored in the source memory, RAM. It takes 'n' clock cycle to perform this data transfer where 'n'is the number of lines in the input file. That is when the FSM issues "Execution" signal and the operation enters the next mode where the compressor/decompressor starts performing its task and sending the result to the destination memory, RAM. When it issues "Execution Complete" signal, FSM changes to the final mode where the content of RAM is written to the output text file. The functional verification blocks are shown in Figure3.

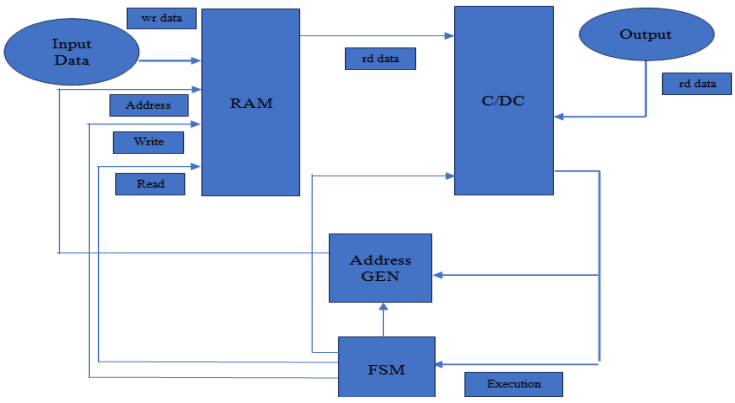

Figure 3: Functional Verification Frame.

The overall block includes 618 registers. The sub-block sizes inside the datapath are also of interest. Table 1

shows the hierarchical area distribution of the whole block.

Table 1: The Hierarchical Area Distribution Compressor

S.No.	Block Name	Area (kgates)
1.	Compressor	9.20
2.	Color Transform 1	0.23
3.	Color Transform 2	0.21
4.	Golomb- Rice Encoder	2.34
5.	Encoder 1	0.37
6.	Encoder 2	0.36
7.	Encoder 3	0.37
8.	Encoder 4	0.37
9.	GR Control	0.48
10.	GR Parameter Estimation	0.36
11.	Input Preparation	0.67
12.	Address generator 1	0.59
13.	Address generator 2	0.45
14.	Encoder register file control	1.87
15.	Prediction Register File control 1	0.65
16.	Prediction Register File control 2	0.66
17.	Prediction Register File control 3	0.72
18.	Prediction Register File control 4	0.73
19.	Predictor 1 -4	0.35

The overall block size of the decompressor is 9.23kgates. This size includes data path blocks; input-output data registers and address generators. 59.1 % of this block is combinational, and the rest is sequential logic size. The overall block includes 498 registers. The sub-block sizes inside the data path are also of interest. Table 2 shows the hierarchical area distribution of the whole block. An important result that can be extracted from synthesis is that functional blocks constitute relatively small portion of the overall cost. The more costly operations are the ones that are related with the traversal of the image. Also due to high throughput requirement (one pixel/clock in our case) the pipeline registers and temporary storage registers constitute a significant portion of overall size. In that sense, it would not be wrong to claim that fast implementations of such simpler algorithms are control dominated in terms of hardware cost. Another result is that the Ctrl block, which is added to improve compression ratio, only takes 470 gates to implement which corresponds to 3.9% of the overall compressor data path.

Table 2: The Hierarchical Area Distribution - Decompressor

S.No.	Block Name	Area (kgates)
1.	Decompressor	9.23
2.	Color Transform	0.29
3.	Golomb- Rice Encoder	0.27

10.	Construction register file control 3	0.58
11.	Construction register file control 4	0.58
12.	Constructor 1- 4	0.36
13.	Decoder register file control	1.61

CONCLUSIONS

The proposed work carried out in this paper investigated Modified Golomb Rice algorithms from hardware implementation point of view to be used in high throughput hardware. One such algorithm is aimed to be implemented in hardware in order to validate early cost estimations and gain more insight into problematic parts of the algorithms in terms of hardware implementation. A possible hardware realization for functional blocks of compression and decompression is proposed in this paper. Then, the work continued with introducing a compression algorithm based on proposed algorithm for in order to get a better compression performance. This proposed algorithm is chosen for hardware implementation in VHDL. In future various parameters will be considered for evaluation of the proposed algorithm and will be compared with different methods for optimum solution.

ABSTRACT

The conventional Unified Power Flow Controller (UPFC) exists two back 2 back inverters and more complex zigzag transformers for isolation and accomplishment high power & voltage ratings. To overcome these difficulties, two zigzag transformers are wholly eliminated in this place two cascaded multi-level inverters are presented. The single configuration and control of two CMIs as a power flow controller lead to the possible to separately control real and reactive power over a transmission line. The proposed configuration is exceptional features and several advantages over the traditional UPFC such as transformer less, high efficiency, light weight, low cost, high reliability and fast dynamic response. In this work, Fuzzy Logic Controller (FLC) is design to improve the system performance. In this work is done by MATLAB/Simulation model.

Key words: Multi level inverter, Transformer, CMI, UPFC, FLC

1. INTRODUCTION

The radial system are presented to transferring power with less reliability under uncertainty conditions, to avoid this problem have implemented the grid system. In recent days, power capability in grid system has to empower load ability of line, but additional control devices are used to get better performance operation and reliability. Hence, solution for power flow control in grid network, no limit for reactors, SSSC, UPFC and so forth. And also providing better solutions for power quality issues we are using custom power devices like STATCOM, DVR, and UPQC. Generally, the principle of FACTS has to enlarge capability and controllability of power transmitted in ac-system [1]. Comparing to past 20 years ago, this is drastically change came to our world. We need efficient and fast operating devices. Thus our electrical engineering mixed with combining mechanical & electronics engineering for providing fast and efficient equipment. These are sensitive and sophisticated devices manufacturing with mostly electronic components. In today life, large transformers are utilized in several appliances that are FACTS equipment are example to reach values in grid system. This requirement is provide to power flow controlled in transmission system. Generally, large transformers have following limitations are high priced, massively, energy wastage and collapse at few disturbances in system. Therefore system is not capable for sudden changing in power flow conditions. These problems are eradicated by introducing the power electronic devices. These devices are providing to large power and increasing power controls for utility applications.

2. MULTI-LEVEL INVERTERS

Multi-level inverter was brought into application by Dr. Nabae in 1981. This type inverters were classified with different strategies is: diode-clamped type, flying capacitor type and cascade multilevel type have developed [2]. So these inverters have following advantages are:

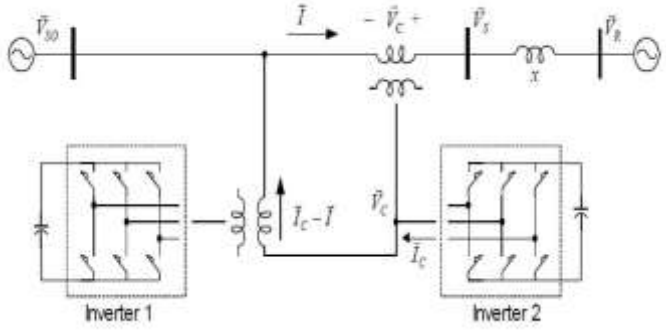
- Very low voltage dv/dt and low distortion in output-voltage waveforms.
- Small distortion in current at input waveforms.
- Low common node voltage.
- Facilitate the utilization of commercial low voltage devices in high/medium voltage applications.
- Minor switching losses because used short switching frequency.

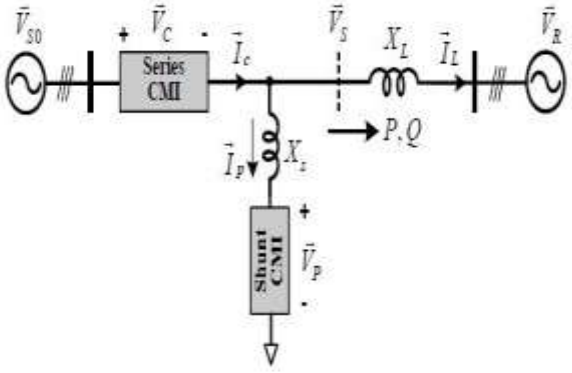
Meanwhile, dominance shared by multilevel arrangement, these obtained more benefits and limitations of different strategies. This diodes can raises the cost but also cause problems and presents parasitic inductances. The FCI require large capacitance, and its complicated control. Also, to maintain each capacitor voltage this needs the high-switching frequency. Comparatively, modular implementation of CMI is best suited and it's able to develop multi-step voltage waveform in form of staircase, when increasing the no. of levels while approaching nearer to sinusoidal output voltage. Moreover, there are no need additional circuits for voltage balancing at dc link. Therefore structure design and layout is simple, hence it builds more useful for high voltage and huge energy applications. Commonly, multilevel inverter is classified into two major types are Fundamental Frequency Modulation (FFM) and second one is Pulse Width Modulation (PWM) are utilized. Every device of FFM is simply switches to develop a voltage, the no. of levels is increasing while approaching a sinusoidal output-voltage [5].

3. APPLICATIONS OF MULTI-LEVEL INVERTER IN FACTS DEVICES

Above mentioned FACTS controllers, no substance in either transmission level or distribution level, have to response on heavy and difficulty of zig-zag transformers for output voltage and isolation requirement. Multi-level inverter is to build up technologies, particularly CMI has to utilize in FACTS application of multilevel design. The CMI based STATCOMs have been established in Europe and Asia (up to 200Mvar). Moreover, it can also demonstrate that CMI has based SSSC can coupled direct to transmission line without coupling transformer [3].

In despite of, the CMI could not couple directly to general UPFC, because it requires two inverters deal with real power ex-change. This problem can solved, a UPFC with CMI,s was introduced to eradicate of zig-zag transformers, Fig.1 shows at Circuit configuration of UPFC**,** that needed the normal multi-pulse inverter based UPFC and still required a isolation transformer [4-5] .





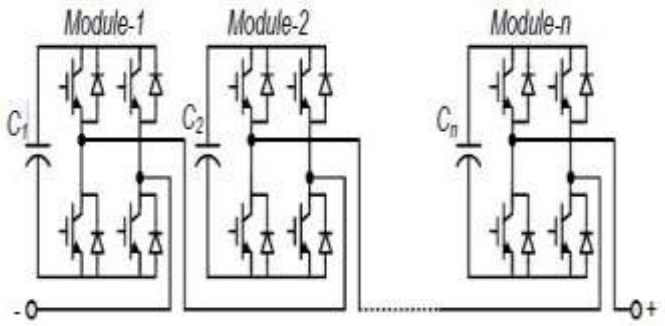


Figure 1 Circuit configuration of UPFC.

The transformer is eliminated totally, a new transformer-less UPFC has been proposed with novel configuration of two CMIs [6]. The system configuration is shown at Fig.2 (a). This arrangement UPFC exists two CMIs, one is series CMI, and it associated in series with line and the other shunt CMI, which parallel connected afterwards series CMI at sending end respectively. Each CMI has built of series cascade H bridge modules as shown Fig.2 (b) [7].

(a)

(b)

Figure 2 (a) Novel configuration of transformer-less UPFC (b) One phase of cascaded multilevel inverter.

4. CONTROL OF TRANSFORMERLESS UPFC

4.1. Dynamic Models of UPFC

In previous section, equations are restricted to steady-state analysis operation. A vector-oriented control is implement to perform dynamic conditions also for proposed transformer less UPFC, the dynamic modules is mandatory. And it based on synchronous reference (dq) outline. Voltage (V_{S0}) at actual sending end for the phase-angle is achieved from digital phase-locked loop (PLL), while *abc* to dq transformation used. In entire system, A dynamic models are illustrated at Fig.3 will classified into various parts, In dynamic models, voltages are from new sending end to user end bus is:

$$\begin{cases} V_{sd} = R_L i_{Ld} + L_L \dfrac{di_{Ld}}{dt} - \omega L_L i_{Lq} + V_{Rd} \\ V_{sq} = R_L i_{Lq} + L_L \dfrac{di_{Ld}}{dt} + \omega L_L i_{Ld} + V_{Rq}. \end{cases} \quad \text{.....} \quad (1)$$

Since, the series-CMI voltage Vc is subtracted from actual voltage Vs is equal to new voltage V_{S0} at sending end, are $\begin{cases} V_{cd} = V_{sod} - V_{sd} \\ V_{cq} = V_{soq} - V_{sq} \end{cases}$ (2)

Further model from new sending end to shunt CMI is

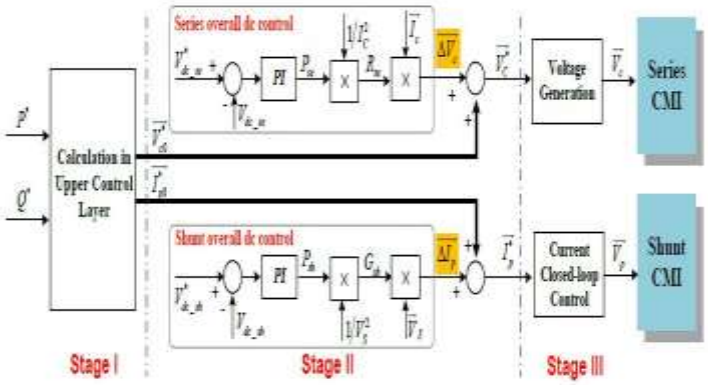
$$\begin{cases} V_{sd} = R_s i_{Pd} + L_s \dfrac{di_{Pd}}{dt} - \omega L_s i_{Pd} + V_{pd} \\ V_{sq} = R_s i_{Pd} + L_s \dfrac{di_{Pd}}{dt} + \omega L_s i_{Pd} + V_{pq}. \end{cases} \quad \text{.....} \quad (3)$$

4.2. Overall DC Voltage and Power Flow Control

It is desired to implement a control system, that stabilizes independently of P & Q over line, then similar as capacitor voltages of two CMIs has maintain at given values. While they are parted into three stages, that are stage-I, stage-II and stage-III.

Stage-I: The $\overrightarrow{V^*_{C0}}$ and $\overrightarrow{I^*_{p0}}$ are calculated from P^*/Q^*. As mentioned earlier, the $\overrightarrow{V^*_{C0}}$ is series-CMI voltage as reference, that developed according to transmitted power ordered is

specified, while $\overrightarrow{I^*_{p0}}$ is reference for shunt-CMI current, which keeps the zero active power for two CMIs are specified. Therefore, the $\overrightarrow{V^*_{C0}}$ is calculated alternative way instead of directly calculated. Reference line currents are I^*_{Ld}/I^*_{Lq} are computed with P^*/Q^* reference, then d- & q-axis components of series voltage V^*_{C0d}, V^*_{C0q} are determined. This includes the first dynamic model. Then current was controlled through a decoupling feed-forward control, so it achieved the better dynamic response for the line current [8].



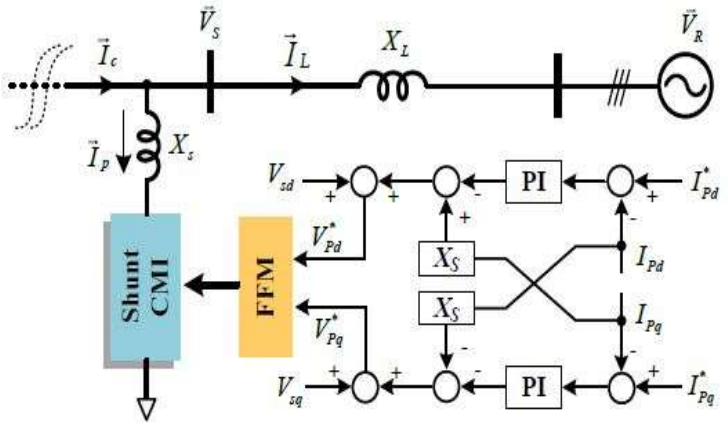


Figure 3 Overall DC voltage and power flow control

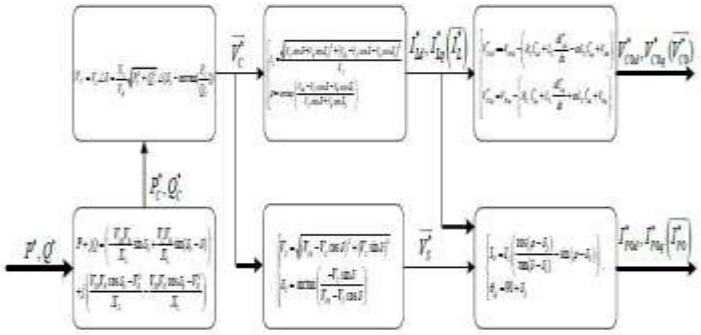

Stage-II: Overall dc-link voltage regulation. In previous stage a dc link voltage cannot sustained because followed three causes are, 1)the CMIs always have a power loss, 2) parameters deviations at error calculation and 3) error between actual and reference output. To maintain a dc link voltage with robust designs and variables of $\overrightarrow{\Delta V_C}$, $\overrightarrow{\Delta I_P}$ are presented for voltage regulation at dc link for series and shunt CMIs respectively, shown in Fig.3 Respectively $V^*_{dc_se}$ and $V^*_{dc_sh}$ is series and shunt CMIs references of dc voltages and V_{dc_se} and V_{dc_sh} are averaged for both CMIs of dc feedback [9].

For series-CMI, P_{se} is the output of overall dc-link voltage regulation loop, R_{se} is determined by ratio of P_{se} to I^2_{se}, finally $\overrightarrow{\Delta V_C}$ is produced with R_{se} and series-CMI current $\overrightarrow{I_C}$, which considered as active voltage component. When $P_{se} = P_{loss}$, resistance R_{se} are balanced for dc link and series CMI. For shunt-CMI, $\overrightarrow{\Delta I_P}$ is introduces for DC voltage control in same manner.

Stage-III: Generation of voltage for series and current for shunt CMIs respectively. For shunt CMI, output current can control by feedback signal of current with $\overrightarrow{I^*_P}$ as reference current, illustrated at Fig.4 (a,b) whereas, output of series CMI voltage can generated directly from $\overrightarrow{V^*_C}$ by FFM [10].

(a)

(b)

Figure 4 (a) Closed loop current for shunt CMI (b) P^*/Q^* to $\overrightarrow{V^*_{C0}}$ and $\overrightarrow{I^*_{p0}}$ calculation.

The given Fig.5 transformer less UPFC are proposed with desired control and modulation strategies, proposed system of 4160V are implemented in Matlab/simulink and the voltage $\vec{V}_R$ at sending eng is similar amplitude of actual voltage $\overrightarrow{V_{S0}}$ at sending end, hence a 30° phase lagging. A transformer2 are establishes that 30° phase lagging difference with Y/Δ arrangement. Basic functions of UPFC are implemented this system [11].

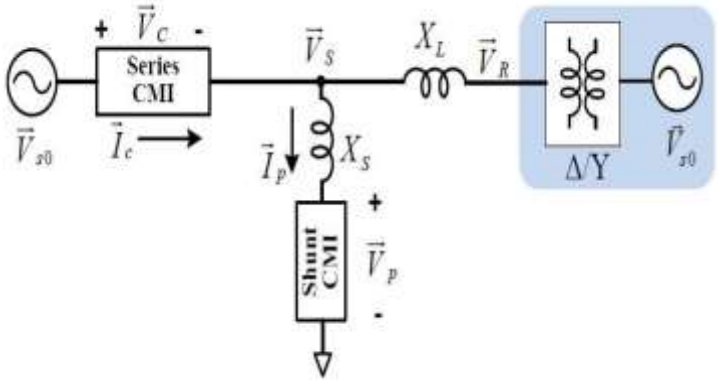

Figure 5 Equivalent circuit of transformer less UPFC.

5. FUZZY LOGIC CONTROL

5.1. Introduction to Fuzzy Logic

Fuzzy logic is another class of artificial intelligence, but its application in control theory has been developed in recent days. According to George Boole, humanoid thinking are based on yes/no or 1/0 logic. But the human thinking does not always follow the crisp logic yes/no, but this is qualitative, uncertain, and imprecise in nature. Based on the imprecise inputs, Lotfi Zadeh an Irish computer scientist developed fuzzy logic or fuzzy set theory. In the developing days it was highly criticized by the professionals, but in recently it is emerged as the new discipline of artificial intelligence.

The control architecture of process which is based on FL is defined as fuzzy control. A fuzzy control system specifically embeds experience and perception of a human plant operator. The design of normal control system is constructed on mathematical modeling of system. But this mathematical implementation is complex to design. On the other hand fuzzy control does not need any mathematical model and mainly on operator experience and heuristic. Fuzzy logic found in several applications specifically in power electronic controls at recent days. The generalized designing procedure for fuzzy control given as follows[12].

- At first, analyse the whether the system elements to warrant to FL applications.
- Collect all the information regarding the system parameters to be controlled.
- Identify the main elements where FL to be implemented.
- Identify input and output variables of each fuzzy system.
- Design the corresponding membership function (MF) for each variable.
- Formulate fuzzy rule table.
- Using defuzzification method to get required output.

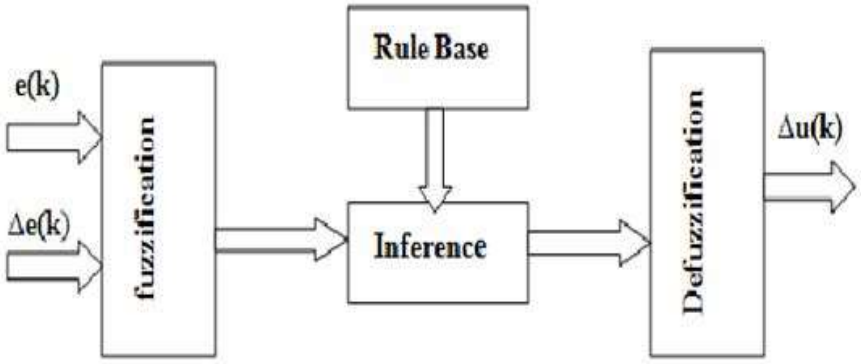

Figure 6 Block diagram of operation of FL.

Fuzzy logic execution of block diagram is presented in Fig.6, in which it contains mainly three basic blocks called as fuzzification, inference and defuzzification.

5.2. Fuzzification

Fuzzification is process where the numerical or any other format of input data is converted into fuzzy membership functions (MF). In FL there are so numerous types of membership functions like triangular membership function; trapezoidal membership function, Gaussian membership function etc. are available in fuzzy toolbox. Here the input variable is error and

change in error and output variable is change in duty cycle. The suitable membership functions are implemented for these variables.

5.3. Inference

The actual rules are given in this block. A suitable operator like AND, OR and NOT will be selected and IF-THEN rules are implemented. Select the appropriate operator between input variables. The rules are framed on knowledge base as human thinking.

5.4. De-fuzzification

Till now the result of implication and aggregation step is the fuzzy output, and union of all individual membership functions are validated. Conversion of this fuzzy output into crisp output is called defuzzification. Some of defuzzification methods like centre of area or centre of gravity, height method and mean of maxima methods are available. In this work centre of gravity (COG) method is utilized for de-fuzzification. Crisp output Z_0 of the Z variable is considered as geometric center of output fuzzy value $\mu_{out}(Z)$ area, where $\mu_{out}(Z)$ of is formed by taking union of all contributions of all rules. The general expression of COG defuzzification is

$$Z_0 = \frac{\int Z.\mu_{out}(Z)}{\int \mu_{out}(Z)dZ} \qquad (4)$$

With discretized universe of discourse, the expression is

$$Z_0 = \frac{\sum_{i=1}^{n} Z_i \mu_{out}(Z_i)}{\sum_{i=1}^{n} \mu_{out}(Z_i)} \qquad .... \qquad (5)$$

COG method of defuzzification is well known method in fuzzy systems as it is simple and fast.

Fuzzy logic for transformer less UPFC pulses is implemented using Matlab/Simulink fuzzy logic toolbox. The fuzzy logic toolbox is user friendly program developed in the Matlab environment. There are mainly five graphical tools used for building, editing, and witnessing of fuzzy inference system in fuzzy toolbox.

- Fuzzy inference system (FIS) editor
- Membership function editor
- Rule base editor

5.5. FIS Editor

After opening the fuzzy toolbox, FIS editor opens which displays general information about fuzzy system and this FIS editor is presented in Fig.7.

At left side of the top of editor consist of input variables and right side is output variables. MFs is shown in diagram is simple icons and there are not actual MFs. It is containing system name and inference method are indicated at below and right side the variable name for the associated MFs are given. All the viewer and editor boxes shows development of controlling the system.

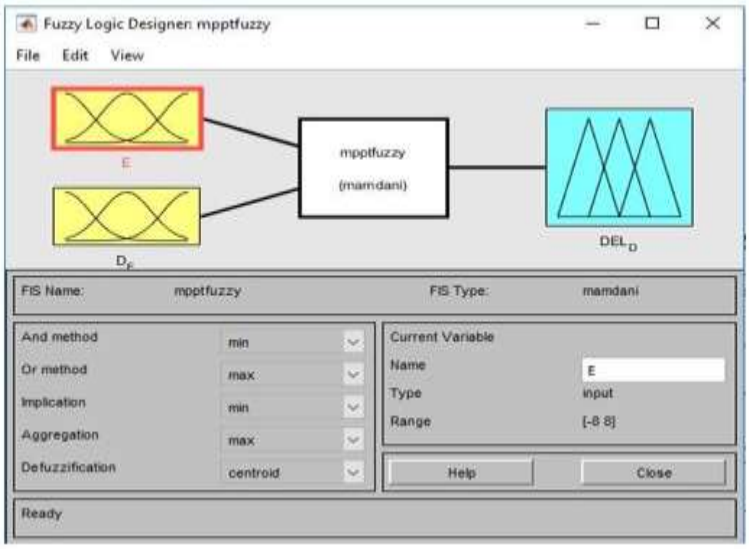

Figure 7 Fuzzy interfacing editor

5.6. Membership Function Editor

In proposed fuzzy system there are two input variables and single output variables are implemented. Input variables of fuzzy system are error (E), change in error (ΔE) and output variable is change in duty cycle (ΔD).

Error and change in error values are given as input to FIS editor and the MFs function for this input and out variables are given in fig.6. shows the MF of input variable error (E) and this work triangular based MF functions are considered.

6. SIMULINK DESIGN AND RESULTS

Simulation results are performed in Matlab/Simulink. In Simscape Power System toolbox is used for implementation of transformer less UPFC. Fig.8.4 (a,b) shows simulation model implemented in simulink and internal block diagram. Control structure is implemented as from proposed system and it helps for system stability and provides smooth variation at any changes in loadability as well as power commands in system.

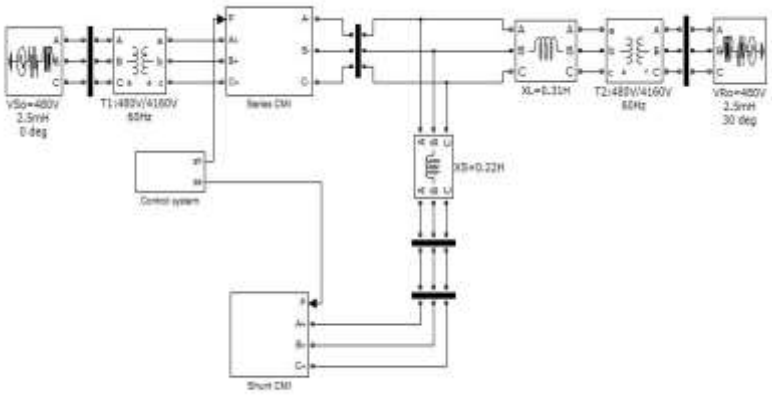

Figure 8 (a).Simulation model for proposed system

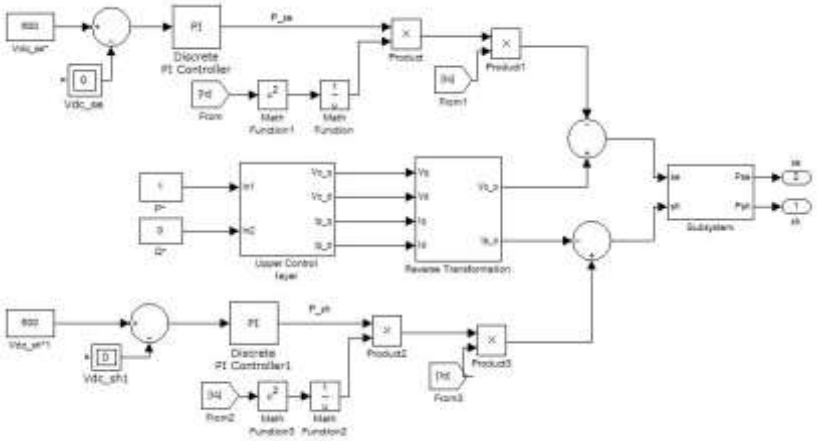

Figure 8 (b) Internal block diagram simulink block

6.1. Phase Shifting Control

Case1 to Case2:

From case1 to case2 (30° to 15° phase shift). In previous, there is 30° phase difference between voltages i.e., actual sending point $\vec{V}_{S0}$ and receiving terminal $\vec{V}_R$ voltages. For case1 $\vec{V}_S = \vec{V}_R$, the $\vec{V}_C$ is injected to shift $\vec{V}_{S0}$ by 30^0 lagging. Here, UPFC is compensating voltage difference caused by transformer 30° phase shift. Therefore, zero line current $\vec{I}_L$ has achieved.

While case2, new $\vec{V}_S$ is shifted from $\vec{V}_{S0}$ by 15°, therefore, 15° phase difference between $\vec{V}_S$ and $\vec{V}_R$ is 15^0. These results, 7.3A line current $\vec{I}_L$. Fig.(9) shows shunt-CMI line voltage V_{Pab} and line current $\vec{I}_L$. FFM have been generated with low THD of shunt-CMI phase voltage, even line-voltage has lesser THD because triplen harmonics in balanced system are absented and it is nearer to sinusoidal where doesn't usage extra filters. Here current easily and speedily raised from 0 to 7.3A, when operating point is changed from case1 to case2.

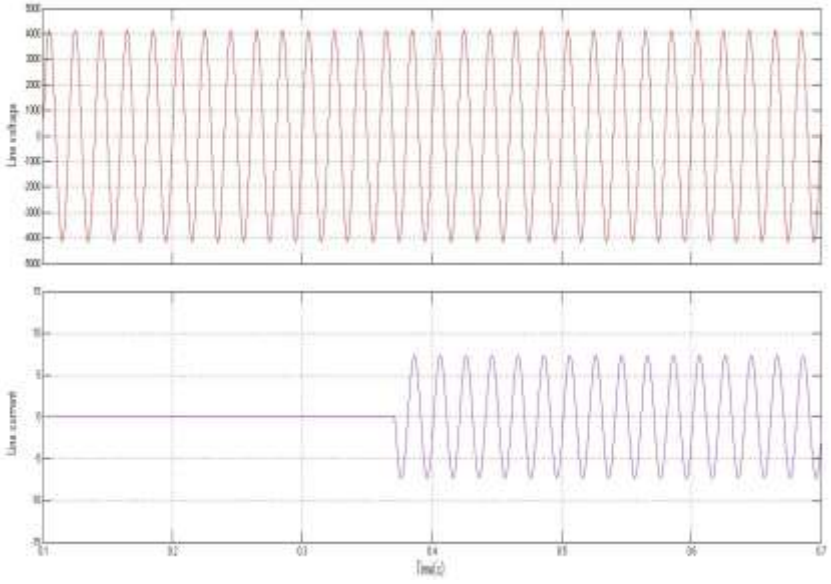

Figure 9 Shunt-CMI line voltage V_{Pab} and line current $\vec{I}_{La}$ in case1 to case2.

Case2 to Case3:

Like wise, case2 to case3 (15^0 to 0^0 phase shift). For case3 indicates a system has without compensation for 0^0 phase shift, then $\vec{V}_S = \vec{V}_{S0}$ and difference of $\vec{V}_S$ & $\overrightarrow{V_R}$ is 30^0. Hence, resulting current around 14.5A.

FFM has generated V_{Pa} and V_{Pb} with optimal firing angles, these are form in staircase. Then, shunt-CMI phase voltage V_{Pa} & V_{Pb} and line currents are I_{La}, I_{Lb} and I_{Lc} is illustrated at Fig.10 & 11.

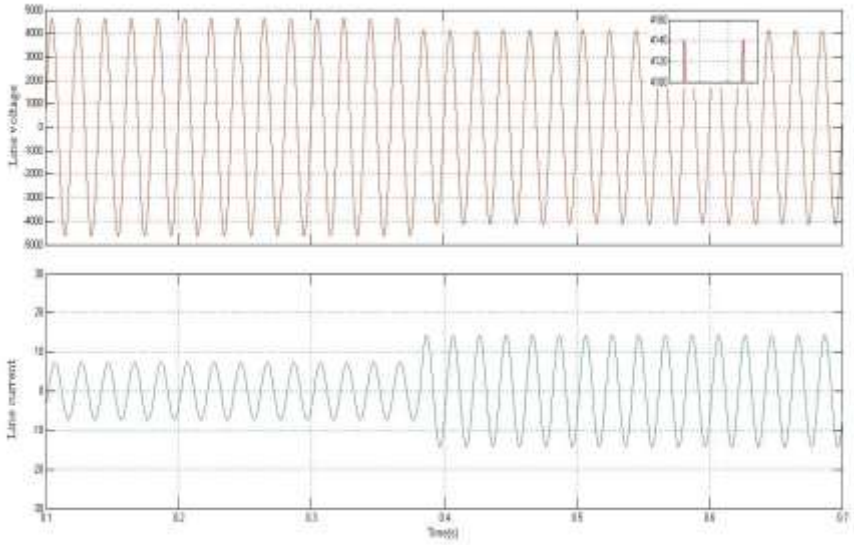

Figure 10 Shunt-CMI line voltage V_{Pab} and line current $\vec{I}_{La}$ in case2 to case3.

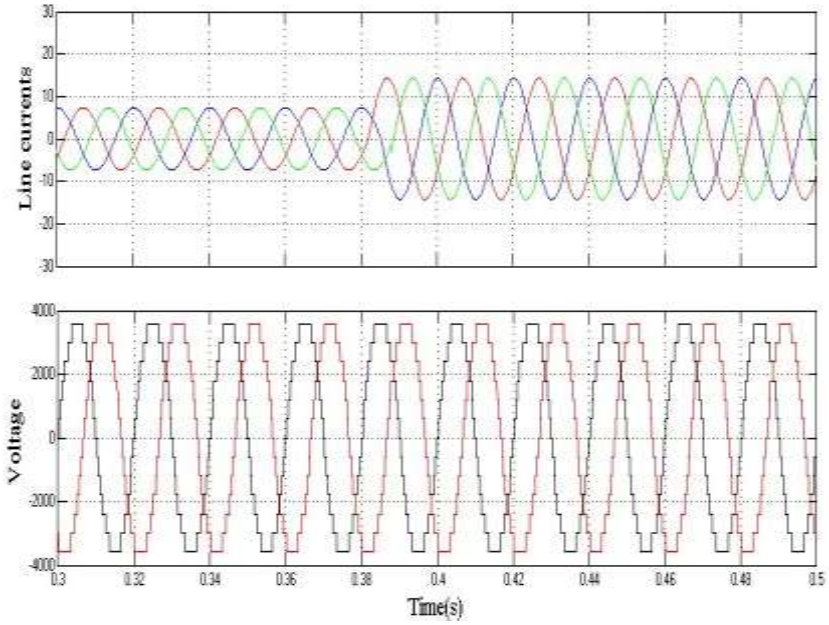

Figure 11 In mode1 to mode2, Line currents are I_{La}, I_{Lb} and I_{Lc} and shunt CMI phase voltages V_{Pa} & V_{Pb} .

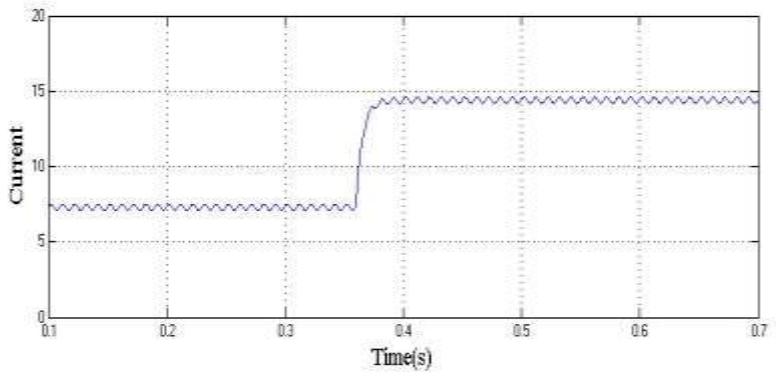

Figure 12 Dynamic response for changing case2 to case3.

The operating point changed from case2 to case3, then current is rapidly increases from 7.3A to 14.5A (amplitude) as shows Fig 12.

7. CONCLUSION

Hence, the cascaded multilevel inverter are used to eliminate the large transformers, generates output nearer to sinusoidal waveform and fast dynamic response. The controlling of new transformer less UPFC has successive improvements are extremely lower switching losses, greater efficiency of CMI by using FFM technique, all UPFC functions are achieved and quick dynamic response of the system. The operation and performance of new transformer less UPFC have been analyzed by using MATLAB/Simulink model. In proposed system FLC is improved the system performance and it gives better performance compared to conventional PI controller.

Power Transformer For Residual Life Assessment

P.Pooja[1], Y.Sudha[2]

Assistant Professor, Department of Electrical Electronics Engineering,

Malla Reddy Engineering College, Hyderabad, India[1,2]

Abstract: Power Transformers are the most vital components in a sub-station / Receiving station. Failure of a Transformer leads to loss of revenue besides affecting reliability of power supply to consumers. It can lead to non availability of the transformer for long durations. In this paper, an approach to evaluate transformer‘s aging condition is introduced based on multi-parameters. Firstly, the different types of insulations in transformers like solid insulation and liquid insulation have been discussed. Later, the ageing process of these insulations used in transformer has been illustrated in detail. Different condition monitoring techniques used for transformer are included to assess the life of insulating material. A program is developed in Visual Basic Software which is very user friendly software. Through the developed program, we can predict the remaining life of transformer. Moreover, a software system based on transformer’s electrical and thermal parameters is developed correspondingly, by using a multi- parameters analytic approach. This system is expected to help in planned maintenance of Transformer on fields. This can help the utilities in making optimum use of the transformers and also taking timely decisions regarding refurbishment / replacement of transformers. Various transformer insulation properties like electrical properties, oil quality and temperature are considered in assessment of remaining life of transformer.

Keywords: Transformer insulation, Insulation aging, Condition Monitoring, Dissolve gas analysis

I. INTRODUCTION

Power transformer is an electric device which is used to step up or step down the voltage level of the supply fed to its primary winding. The stepping up or down depends upon the number of turns of primary and secondary winding. If the number of turns on both the windings is same, and the losses of transformer are negligible, we may Conclude that the voltage across each of the winding is same. In this case the transformer is just utilized in isolating two electrical circuits. Generally power transformer is used in stepping up the voltage of the supply in order to decrease the transmission losses and then stepping.

These are mainly used in distribution side to interface step up and stepdown voltages. The life span of these type of transformers is around 30years.Based on ranges, the power transformers are classified into three types.

Small power transformers (500-7500KVA)
Medium power transformers (100MVA)
Large power transformers (100MVA and beyond)
These transformers transform the voltage and depend on the principal of faradays laws of induction. It holds a low voltage, high current circuit at one side of the transformer and on the other side of the transformer it holds the high voltage low current circuit.

II. POWER TRANSFORMER DESIGN

The skeleton of the power transformer is designed with metal which is laminated by sheets. It is fixed into either a core type or shell type. The skeletons of the transformer are wound and connected using conductors to make three 1-phase or one 3-phase transformer. Three 1-phase transformers requires each bank isolated from the additional and thus offer continuity of service when one bank flops. A single 3-phase transformer, whether the shell or core type, will not function even with one bank out of service.
The 3-phase transformer is inexpensive to make and it has a smaller footprint, and functions comparatively with higher efficiency.

Power Transformer (160 MVA 220/132/33 KV Auto Transformer)

III.EXIXTING SYSTEM

It plays a very significant role of the transformer insulation system and has the important functions of acting as an electrical insulation as well as coolant to dissipate heat losses. Another main function of transformer oil is it act as a diagnostic tool of the transformer.

The basic raw materials for the production of transformer oil is a law viscosity lube termed as transformer oil base stock (TOBS), which is normally obtained by fractional distillation and subsequent treatment of crude petroleum. TOBS is further refined by acid treatment process to yield transformer oil. Power transformers undergo prolonged drying processes, using electrical self-heating, the application of a vacuum, or both to ensure that the transformer is completely free of water vapor before the insulating oil is introduced. This helps prevent corona formation and subsequent electrical breakdown under load.

Chemical composition

Transformer oil consists of four major generic class of organic compounds namely paraffins, Naphthene Aromatics and olefins. All these are hydrocarbons and hence insulation oil is purely a hydrocarbon mineral oil. For good fresh insulating oil, it is desirable to have more of saturated paraffins, less of aromatic and\or naphthenic and none of olefins. Depending upon the predominance, oil is usually termed as of paraffinic base or naphthenic base. This is carried out to ensure that these are within guaranteed limits. The test comprises of following:

1.Routine tests
2.Type tests
3.Special tests

Routine tests:
Measurement of winding resistance
Measurement of voltage ratio and check for voltage vector relationship
Measurement of insulation resistance
Dielectric tests

Type tests:

All the tests listed as above and the temperature rise test and dielectric type tests.

Special tests:
Short circuit test

The key concept of life assessment is serviceability i.e., the ability to function as intended. Life assessment studies aim at comparing and ranking transformers with respect to their suitability for use in a relative evolution procedure of several transformer. The serviceability is determined by actions taken before the transformer was taken into the service and from the history and events occurring in service. The area evaluated for serviceability are: Technical Serviceability: - Detailed evaluation advanced of electrical, mechanical and auxiliaries. On-Technical Serviceability: - Strategies in particular to economy and environment. Screening Evaluation: en by the fans and oil pumps. It is a prime task to sort out the units, the efforts can be concentrated on doubtful units..Monitoring technique system for a transformer is an evolving process due to change in technologies, improving understanding..

Purpose of Monitoring Technique:
avoid forced outages
minimize failures
optimize maintenance costs
improve safety to personnel and environment.

IV. PROPOSED SYSTEM

The need for reliable and stable systems is being increasingly felt. Thus, emphasis is now being laid on 100% capacity utilization and the availability of equipment for reliable operation of the system. Fortunately, many tools are now available or underdevelopment, which can be used for condition monitoring of the transformer. With a view to cover detailed information about DGA and condition monitoring, wise residual life assessment, this chapter has been divided into two sectors: Dissolved Gas Analysis Interpretation.RLA And Refurbishment.Incipient faults in oil filled transformers are usually the result of electrical or thermal stresses in either the transformer oil or insulating materials. It is known that such excessive stresses produce a mixture of gases characteristics of which give an indication of the type of fault and location associated with the fault It is recommended that analysis of dissolved gases in transformer oil by gas chromatograph equipment's is made at the time of commissioning and then every six months for transformer s of 145 KV class and above.

Analysis method
Oil in transformers can be sampled through the drain or sampling valve near the bottom of the tank. Special care is to be taken not to introduce air, foreign matter, or dirty oil into the sampling container. For this purpose, first 0.5-1.0 litre of oil from the transformer is to be over-flown through the oil container. The oil sample must not be exposed to air before analysis Before taking total outage of transformer following preliminary physical inspection, tests should be carried out to establish the reason for the increasing trend of fault of fault gases.

Analysis of fault gases:
The gases to be analysed and the criteria for the gases found in the transformer oil are tabulated in below table.

Table: Analysis Method (S1)

S.no	Operating Condition	Gases to be analysed
1.	Normal	O2, N2, H2, CO, CO2, CH4.
2.	Abnormal	H2, CH4, C2H2, C2H4, C2H6.
3.	Deterioration	CO, CO2, CH4.

The generation of gases in oil by some typical faults in transformer active part models are shown in given below.
Table: Analysis Method (S2)

S.no	Type of faults	Decomposable gases in transformer oil
1.	Arcing in oil	H2, CH4, C2H4, (C2H6, C2H2, C3H6, C3H8)
2.	Overheating of solid insulating materials	CO, CO2, (C2H4, H2)
3.	Overheating of oil and paper combination	CO, CO2, CH4, C2H4, H2
4.	Arcing of oil and paper combination	H2, CO, CO2, CH4, (C2H4)

VI. CONCLUSIONS

This paper analyzes factors that affect transformer life and points out the uncertainty of factors. Considering the uncertainty factors, residual life evaluation model is set up based on Visual Basic Software which is very user friendly software and evaluates the residual life, which can provide support for transformer maintenance schedule and be benefit to the safe and economic operation of power system.

Modelling and Analysis of Microgrid by using Renewable Energy Sources

Y.Sudha[1], P.Pooja[2], P.Ganesh[3]

Electrical & Electronics Engineering, Malla Reddy Engineering College (Autonomous)

Abstract: This paper presents a control of a micro-grid at an isolated location fed from wind and solar based hybrid energy sources. The machine used for wind energy conversion is Doubly Fed Induction Generator (DFIG) and a battery bank is connected to a common DC bus of them. A solar Photovoltaic (PV) array is used to convert solar power, which is evacuated at the common DC bus of DFIG using a DC-DC boost converter in a cost-effective way. The voltage and frequency are controlled through an indirect vector control of the line side converter, which is incorporated with droop characteristics. It alters the frequency set point based on the energy level of the battery, which slows down over charging or discharging of the battery. The system is also able to work when wind power source is unavailable. Both wind and solar energy blocks, have Maximum Power Point Tracking (MPPT) in their control algorithm. The system is designed for complete automatic operation taking consideration of all the practical conditions. The system is also provided with a provision of external power support for the battery charging without any additional requirement. A simulation model of system is developed in Matlab environment and simulation results are presented for various conditions e.g. unviability of wind or solar energies, unbalanced and nonlinear loads, low state of charge of the battery. Finally, a prototype of the system is implemented using a 5-kW solar PV array simulator and a 3.7 kW wound rotor induction machine and experimental results are produced to reaffirm the theoretical model and design.

Keywords: Photovoltaic, Maximum Power Point Tracking (MPPT), MATLAB, Boost Converter.

I. INTRODUCTION

There are many remote locations in the world, which don't have access to electricity. There are also many places, which are connected to the grid, however, they don't receive electricity for up to 10-12 hours in the day and as a result of it, economic activities of inhabitants suffer. Many of such places are rich in Renewable Energy (RE) sources such as wind, solar and bio-mass. An autonomous generation system utilising locally available RE sources, can greatly reduce the dependency on the grid power, which is predominantly fossil power. Wind and solar energy sources, are more favorited than bio-mass based system as latter is susceptible to supply chain issue. However, wind and solar energies suffer from high level of power variability, low capacity utilization factor combined with unpredictable nature.

As a result of these factors, firm power cannot be guaranteed for autonomous system. While the Battery Energy Storage (BES) can be helpful of lowering power fluctuation and increasing predictability, utilisation factor can be increased by operating each energy source at optimum operating point. The optimum operating point also called as Maximum Power Point Tracking (MPPT), requires regulation of the operating point of wind energy generator and solar PV (Photovoltaic) array in term of speed and voltage to extract maximum electrical energy from input resource. The MPPT can be achieved by Power Electronics (PE) based frequency based on state of charge of the battery and slows down deep discharge and over-charge of the battery.

II. EXISTING SYSTEM

DFIG may operate variable speed operation with lower power rated converters. However, to work the system as a micro-grid, the generated voltage should be balanced and THD (Total Harmonics Distortion), must be within requirement of IEEE-519 standard at no-load, unbalanced load as well as nonlinear load. Moreover, both the wind and solar energies sources should operate at MPPT. All these are the issues. In the proposed system performance parameters e.g. power quality, system efficiency etc under the different operating conditions are not mentioned. Moreover, they also lack experimental verification

III. PROPOSED METHOD

This project presents a control of a micro-grid at an isolated location fed from wind and solar based hybrid energy sources. The machine used for wind energy conversion is Doubly Fed Induction Generator (DFIG) and a battery bank is connected to a common DC bus of them.

V. CONCLUSION

The proposed micro-grid system fed from REGS has been found suitable for meeting load requirement of a remote isolated location comprising few households. REGS comprises of wind and solar energy blocks, which are designed to extract the maximum power from the renewable energy sources and at the same time, it provides quality power to the consumers. The system has been designed for complete automated operation. This work also presents the sizing of the major components. The performance of the system has been presented for change in input conditions for different type of load profiles. Under all the conditions, the power quality at the load terminals, remains within acceptable limit. The effectiveness of the system is also presented with test results with prototype in the laboratory. The system has also envisaged the external battery charging by utilizing the rotor side converter and its sensors for achieving rectifier operation at unity power factor.

A T, Star-Delta and Zigzag Connected Transformer Connections of 5-Level and 7-Level VSC Based DSTATCOM for Power Quality Improvement

K.S.S. Naga Teja [1], P. Kamalakar[2]

Assistant Professor, EEE Department, Malla Reddy Engineering College (Autonomous), Secunderabad, India[1]

Associate Professor, EEE Department, Malla Reddy Engineering College (Autonomous), Secunderabad, India[2]

Abstract: In this paper, a new three-phase four-wire Distribution Static Compensator (DSTATCOM) based on a T-connected transformer and a three-leg Voltage Source Converter (VSC) is proposed for power quality improvement. The T-connected transformer connection mitigates the neutral current and the three-leg VSC compensates harmonic current, reactive power, and balances the load. Two single-phase transformers are connected in T-configuration for interfacing to a three-phase four-wire power distribution system and the required rating of the VSC is reduced. The Insulated Gate Bipolar Transistor (IGBT) based VSC is supported by a capacitor and is controlled for the required compensation of the load current. The DC bus voltage of the VSC is regulated during varying load conditions. The DSTATCOM is tested for power factor correction and voltage regulation along with neutral current compensation, harmonic elimination, and balancing of linear loads as well as nonlinear loads. The performance of the three-phase four-wire DSTATCOM is validated using MATLAB software with its Simulink and power system block set toolboxes.

Keywords: D-STATCOM, Harmonics, Inverter Transformer, Power Quality.

I. INTRODUCTION

D-STATCOM is a solid state, three phase inverter-based power controller which is connected in shunt to a distribution feeder through a coupling transfer that matches the inverter ac output voltage to the distribution system voltage [1]. Thus, D-STATCOM is used to protect the distribution system from power quality disturbances [2]. The main components of the D-STATCOM are the inverter using either GTO or IGBT, dc capacitor, coupling transformer and control system [3]. It can be regarded as an active energy exchanging device because it utilizes the passive energy storage component to realize the energy storing and exchanging and the switches to control the reactive power flow between different phases of a distribution system [4-6].The reactive power provided by the D-STATCOM is either capacitive or inductive depending on whether the magnitude of the D-STATCOM output voltage is larger or smaller than the magnitude of the system voltage [7]. In recent years, D-STATCOM has been extensively studied in which many papers in the literature have discussed its theory, modeling, control and applications (4,8-10). The conventional D-STATCOM is controlled at low switching fundamental frequency of the inverter based on the control of the phase angle of the fundamental switching pattern [11]. In recent years Electrical Power Quality had obtained more attention in power engineering. In present day's power distribution systems is suffering from severe power quality problems. These power quality problems include high reactive power burden, harmonics currents, load unbalance, excessive neutral current etc.

II. PROPOSED SYSTEM

Instantaneous real-power theory based cascaded multilevel inverter based DSTATCOM is connected in the distribution network at the PCC through filter inductances and operates in a closed loop. The DSTATCOM system contains a cascaded inverter, RL-filters, a compensation controller (instantaneous real-power theory) and switching signal generator (proposed triangular-sampling current modulator) as shown in the Figure 1. The three-phase supply source connected with non-linear load and these nonlinear loads currents contains fundamental and harmonic components. If the active power filter provides the total reactive and harmonic power, is (t) will be in phase with the utility voltage and would be sinusoidal. At this time, the active filter must provide the compensation current therefore; active power filter estimates the fundamental components and compensating the harmonic current and reactive power.

III. DESIGN OF THE T-CONNECTED TRANSFORMER

The figure shows the connection of two single-phase transformers in T-configuration for interfacing with three-phase four-wire system. The T- connected transformer not only provides a path for the zero-sequence fundamental current and harmonic current when connected in shunt at Point of Common Coupling (PCC).

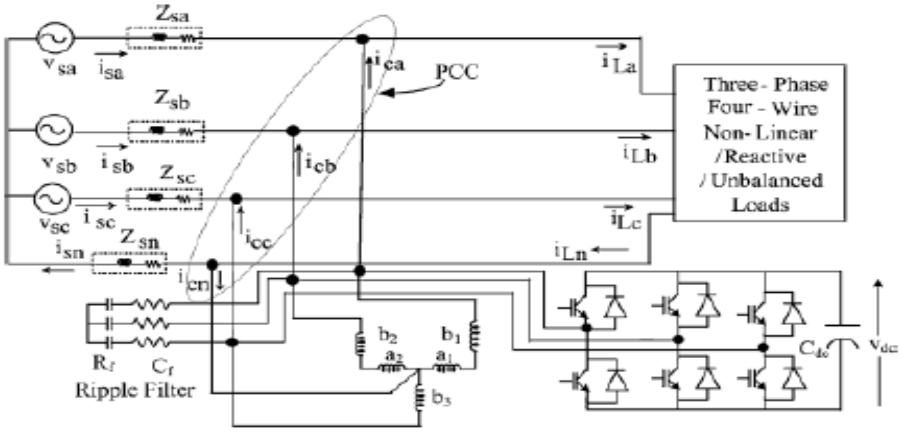

Fig 2.Schematics of the proposed three-leg VSC with T-connected transformer-based DSTATCOM connected in distribution system.

The T-connected transformer is used in the three-phase distribution system for different applications [6]–[8].But the application of T-connected transformer for neutral current compensation is demonstrated for the first time. Moreover, the T-connected transformer is suitably designed for Magneto Motive Force (mmf) balance. The T-connected transformer mitigates the neutral current and the three-leg VSC compensates the harmonic current and reactive power, and balances the load. The IGBT based VSC is self-supported with a dc bus capacitor and is controlled for the required compensation of the load current. The DSTATCOM is designed and simulated using MATLAB software with its Simulink and Power System Block set (PSB) toolboxes for power factor correction and voltage regulation along with neutral current compensation, harmonic reduction, and load balancing with nonlinear loads.

IV. DISTRIBUTION STATIC COMPENSATOR (D-STATCOM)

A D-STATCOM (Distribution Static Compensator), which is schematically depicted in Fig. 1 and consists of Voltage Source Converter (VSC), a DC energy storage device, a coupling transformer connected in parallel to the distribution network through a coupling transformer. Necessary adjustment of the phase and magnitude of the D-STATCOM output voltages allows effective control of active and reactive power which transfers between the D-STATCOM and the AC system. Such configuration allows the device to absorb or generate controllable active and reactive power flows. [7].

Vol. 8, Issue 5, May 2020

The D-STATCOM commonly utilized mainly for regulation of voltage, correction of power factor and elimination of current harmonics. Such a device may be employed to provide continuous voltage regulation using an indirectly controlled converter. In this paper, the D-STATCOM is used to regulate the voltage at the point of common connection. The control technique is based on sinusoidal PWM and requires the measurement of the rms voltage at the load variation.

The shunt injected current I_{SH} can be written as,

$$I_{SH} = I_L - I_S$$

Where $I_S = \frac{V_{TH} - V_L}{Z_{TH}}$

Therefore

$$I_{SH} = I_L - I_S = I_L - \frac{V_{TH} - V_L}{Z_{TH}}$$

Or

$$I_{SH}\angle\eta = I_L\angle -\theta - \frac{V_{TH}}{Z_{TH}}\angle(\delta - \beta) + \frac{V_L}{Z_{TH}}\angle -\beta$$

The complex power injection of the D-STATCOM can be expressed as,

$$S_{SH} = V_L\, I_{SH}$$

It may be mentioned that the effectiveness of the D-STATCOM in correcting voltage variations depends on the value of ZTH or fault level of the load bus. When the shunt injected current ISH is kept in quadrature with VL, the desired voltage correction can be achieved without injecting any active power into the system. On the other hand, when the value of ISH is minimized, the same voltage correction can be achieved with minimum apparent power injection into the system.

V. REFERENCE CURRENT CONTROL STRATEGY

The control scheme of the shunt active power filter must calculate the current reference signals from each phase of the inverter using instantaneous real-power compensator. The block diagram as shown in Figure.3, that control scheme generates the reference current required to compensate the load current harmonics and reactive power. The PI controller is tried to maintain the dc-bus voltage across the capacitor constant of the cascaded inverter. This instantaneous real-power compensator with PI-controller is used to extracts reference value of current to be compensated. To enhance the performance of distribution system, D-STATCOM was connected to the distribution system. D-STATCOM to be designed using MATLAB - SIMULINK R2010a 7.10 version [6].

Simulation model and results:

DSTATCOM for mitigating power quality problems like voltage variations with load balancing in 3-phase 4-wire distribution network. Four leg inverter is used for the compensation purpose and .synchronous reference frame theory based controller is used with the control of DSTATCOM.

Here the simulation is carried out by Seven cases:

1. Non-linear load Without DSTATCOM and APF
2. Non-linear load with APF
3 Non-linear load with DTSATCOM and APF
4. Non-linear load with DSTATCOM, PI Controller and five-level cascaded multilevel.
5. Non-linear load with DSTATCOM, PI Controller and seven-level cascaded multilevel.
6. Non-linear load with DSTATCOM, PI Controller and five-level cascaded multilevel, with T and PI connections.
7. Non-linear load with DSTATCOM, PI Controller & seven-level cascaded multilevel, with T and PI connections.

Three-phase Transformer Line Voltage and Current

Configuration	Line Voltage	Current
Delta – Delta	$V_L \Rightarrow nV_L$	$I_L \Rightarrow \frac{I_L}{n}$
Delta – Star	$V_L \Rightarrow \sqrt{3}.nV_L$	$I_L \Rightarrow \frac{I_L}{\sqrt{3}.n}$
Star – Delta	$V_L \Rightarrow \frac{nV_L}{\sqrt{3}}$	$I_L \Rightarrow \sqrt{3}.\frac{I_L}{n}$
Star – Star	$V_L \Rightarrow nV_L$	$I_L \Rightarrow \frac{I_L}{n}$

Where: n equals the transformers "turns ratio" (T.R.) of the number of secondary windings N_S, divided by the number of primary windings N_P. (N_S/N_P) and V_L is the line-to-line voltage with V_P being the phase-to-neutral voltage.

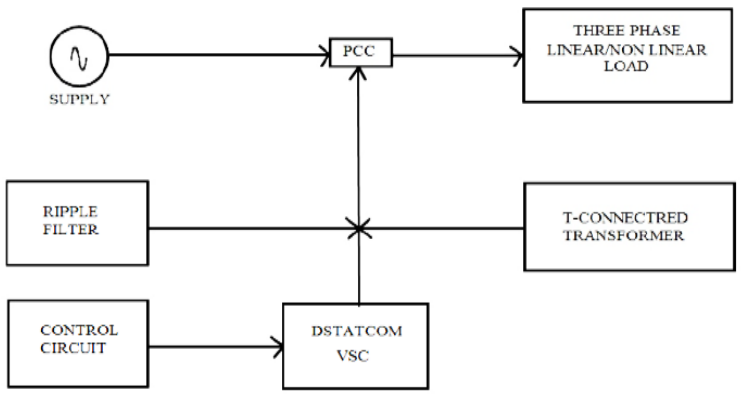

Fig 4. Block Diagram of T-connected VSC DSTATCOM

The block diagram representation of the proposed Three-Phase Four-Wire DSTATCOM and T-connected Transformer based distribution System is as shown in fig 2.1. It consists of three phase linear/nonlinear load block, ripple filter block, control circuit block and shunt active filter block. The T-connected Transformer block is used for neutral current compensation and it reduces the rating of three leg voltage source converter. The control circuit consists of DSATATCOM with Three leg Voltage Source Converter. This block is used to compensate the harmonic current and reactive power and load balancing. Also The DSTATCOM is tested for power factor correction and voltage regulation. The three leg VSC is used as an active shunt compensator along with a T-connected transformer. The ripple filter block is used to reduce the high frequency ripple voltage in the voltage at **Point of Common Coupling (PCC)**. High frequency ripple is due to switching current of the VSC of the DSTATCOM. All the blocks should be connected at PCC.

5	Inverter parameters	DC Link voltage=14kv

VI. CONCLUSION

A seven level cascaded multilevel voltage source inverter based DSTATCOM using instantaneous real power controller is found to be an effective solution for power line conditioning. A new three phase four wire DSTATCOM using T-connected transformer has been proposed for Three-Phase Four-wire DSTATCOM system to improve the power quality. The performance of three-phase four-wire distribution system with and without controller circuits for Non-linear load was discussed in the above section and following observation is obtained. Two single phase transformers are used for the T-configuration of the transformer to interface with a three-phase four-wire system. The total kilovolt amperes rating of the T-connected transformer is lower than a star/delta transformer for a given neutral current compensation. From the above discussion, the proposed technique is very efficient one for power quality improvement of Three-phase Four-wire distribution system compared to other techniques (Using star-delta and etc).

ABSTRACT

Human tracking is implemented on a video sequence, which involves the analysis of the presence, size, shape and position of human beings. Human tracking is generally used in applications like video surveillance, crowd monitoring. Videos are series of images, called frames, which are displayed in faster frequency, such that human eyes will not be able to percept the continuous contents. Usually, the information of the contents present in two consecutive frames will be closely related. This paper presents a new approach for recognition of human use Histogram Specification with Kalman filtering approach. The main aim of this work is provide accurate recognition of human and view of their location from an unknown scene, Finally Kalman filter approach is apply the different positions of humans are identified based on the computation of Euclidian distance by using correlation matrix method. In this work results are drawn by using MATLAB tool by in view of the input video dataset taken from different sources and extract the frames from the input video for the detection and the efficiency of the proposed techniques will be calculated.

I. INTRODUCTION

Image Processing is the field where various number of research work has been taken up and implemented successfully. With increasing concerns for public safety and security nowadays, the need for automatic surveillance systems based on real time videos of public places is realized. The highly crowded and sensitive places like markets, shopping space, famous restaurants, railway stations etc. Must be equipped with these surveillance systems, without constraining their application to security under public spaces, they are also most demanded for the purposes of traffic control and examination, activity recognition and tracking, fault detection in industrial applications and semantic video indexing. In order to achieve the high level tasks of classification or tracking a target from video stream, the strategy used is to detect the target of interest in individual frames in the first place.

The technique used in many of the works for surveillance is the background subtraction method. This technique performs extraction of the foreground object i.e. the target under motion by separating the background and foreground pixels in the frame under processing. The advantages of this method namely the performance in the presence of a non-mobile video camera and illumination invariance are well exploited by many researchers. The building of a background model of the captured video frame is a key point to be considered.

II. HISTOGRAM SPECIFICATION WITH THE KALMAN FILTERING

The histogram specification is mainly applied for multiple human identification, the blob detections carried out using background modelling. The blob detection is mainly used to carry out the filing operation which is mainly

ISSN- 2394-5125 VOL 7, ISSUE 6, 2020

needed to identify the connected components in the video frames. These connected components are defined as the blobs which are identified by using the adjacency of the neighbour frame pixels that are similar in nature. The present location of the identification stage is predicted by the features of the human being. These types of features are mainly obtained using the centroid of the blobs for the each blob that should be tracked [1-2].

The common plan of background segmentation is to involuntarily produce a binary mask that splits the cluster of pixels into 2 sets, foreground and background pixels. A stationary background frame are often matched to current frame uncomplicated cases. Pixels with high pixels area unit known as foreground. This straightforward technique may add few specialised situations. Each constituent is characterised by its intensity within the RGB house.

Next is Kalman Filtering Kalman filter may be a region primarily based technique to seek out the regions of the article in forthcoming frame. Centre of object is set 1st then Kalman filtering is formed use for predicting position of a similar within the next frame. Kalman filtering is most popular to cipher the state of a linear system. Kalman filtering consists of 2 steps, prediction and correction [3-5].

III.ALGORITHM FOR HISTOGRAM PATTERN WITH THE KALMAN FILTERING

It provides optimum estimate to come up with the position for the motion model for a moving object though the video contains some quantity of dynamic noise and uproarious observations concerning the position at on every occasion step. For Gaussian noises, Kalman filtering can give an optimum resolution. The filter reduces the mean sq. Errors of the parameters like position, velocity, etc [9].The Kalman filter is essentially an internet method, which implies the new observations are going to be processed as and once they arrive. A distinct time dynamic linear system having AN additive racket that may model surprising disturbances are going to be needed to formulate a Kalman filter is the problem [10].

Step1: Firstly, reading the input video data; a continuous signal to extract the individual frames it is comprised of is performed.
Step2: The input video is usually color image in RGB color space. It is easy to apply image processing techniques.

Step3: Thus, next step is to convert each RGB video frame into its gray scale form.

Step4: Blob analysis technique can be applied involves Thresholding and morphological operations.
Step 5: In the next step sing Kalman filtering technique can be applied to remove noise inherent in the frames so that final output is refined well.
Step 6: The task of background subtraction is a challenge as it is subject to variations in the lighting conditions or occlusions in the scene.
Step 7: Morphological processing is carried out on the target detected frames where a number of operations perform noise removal.
Step 8: As a last step, Fourier transform is applied on the morphologically processed frame to extract the lost frequencies of the target video frame in the noise signal so that no data is compromised.

IV.FLOWCHART FOR PROPOSED SYSTEM

This diagram presents in theform of bubble graphs can be defined as dfds. Data flow diagram is one of the easiest graphical representations describes in Figure 1 [11].

performing outside the framework will be referred as performing artists. The main objective of this design diagram is to describe how the communication between each module is done, that's helps in the implementation of the work [14-15].

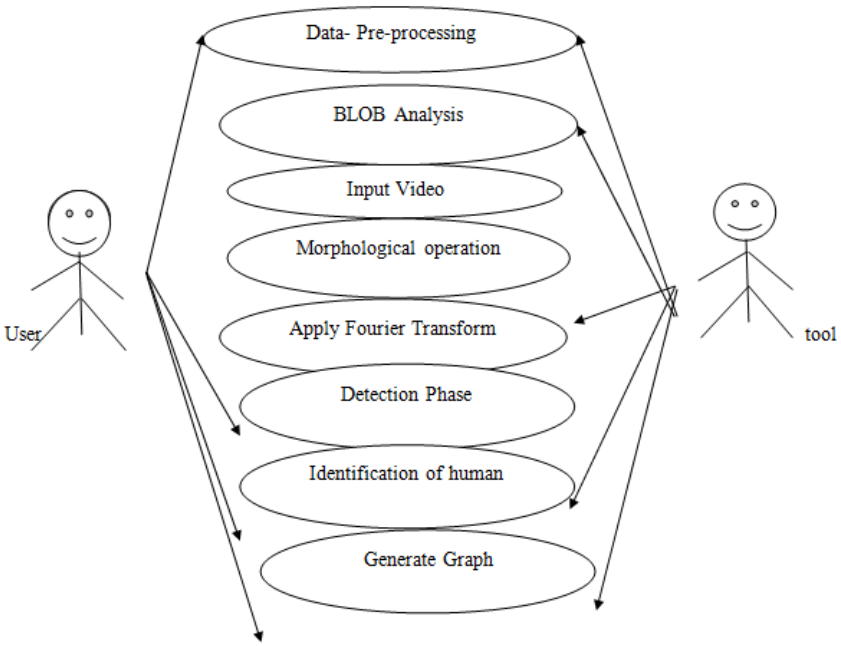

Figure 3: The Use Case Diagram for Proposed Technique

V. SIMULATION RESULTS AND DISCUSSION

The results of the proposed approach are drawn in the MATLAB tool which provides us the effective solution for Multiple Human detection in the video. Even though there are various works has been carried out so far the proposed research work strands unique with its desire to provide an excellent results for the different kinds of the videos considered [6-8]. In this research work first the BLOB analysis is applied then applied the Kalman filtering along with Euclidean distance provides more effective results with minute number of false detections. The main advantages of this proposed work is provide an efficient algorithm which is easy to implement and contains less complexity in detecting the human presents in the video [12-13].

The first input video under the consideration is a good quality video of the duration 15 seconds and the memory size is 25MB. The video taken is from jewelry shop which consists of 3 persons with sitting in the shop watching the jewels. The identification of human result its grey scale image representation of a video frame is as shown in below Figure.4 with the background subtraction. The figure.4 describes the identification of persons based on the hand movements. Figure.5 describes the human identification based on the face and the leg movements of the person [16-18].

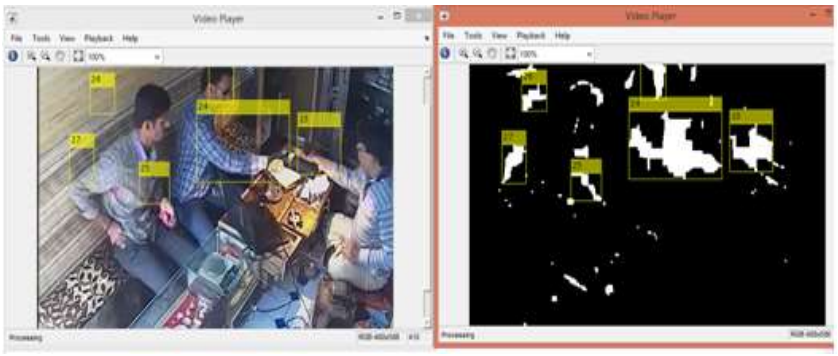

Figure 4: Human identification based on Hand Movements

ISSN- 2394-5125 VOL 7, ISSUE 6, 2020

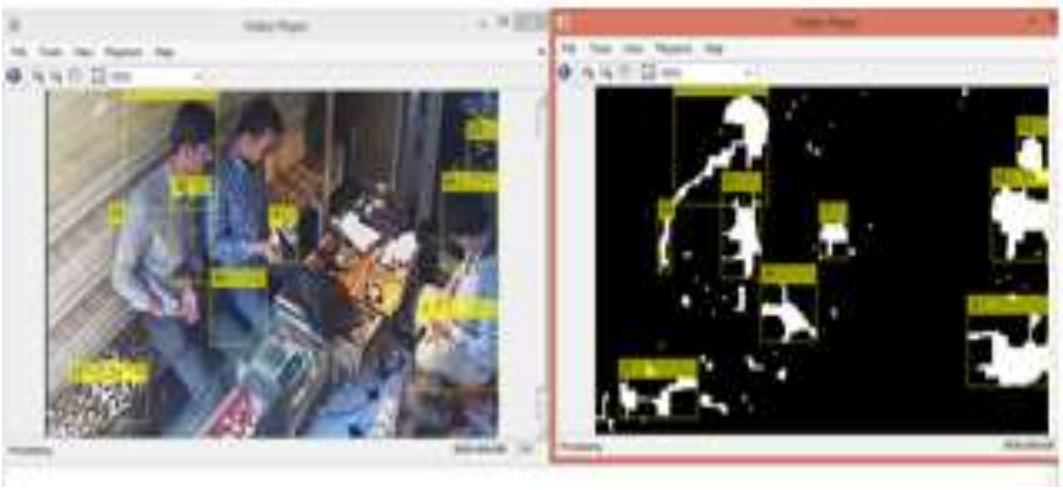

Figure 5: Human Identification based on Face and the Legs of the Human

The accuracy of the proposed technique described in Figure.6. This accuracy of this proposed work is represented in the output graph which is plotted against number of frames identified with human and total number of frames and drawn with the help of five different input video from different sources by varying the size of the video along with different background. An average accuracy of 90.5% has been achieved, where each of the video frames varies from 150 to 1500 and for each of the video accuracy varies from 82% to 95% in identifying the human [19-21].

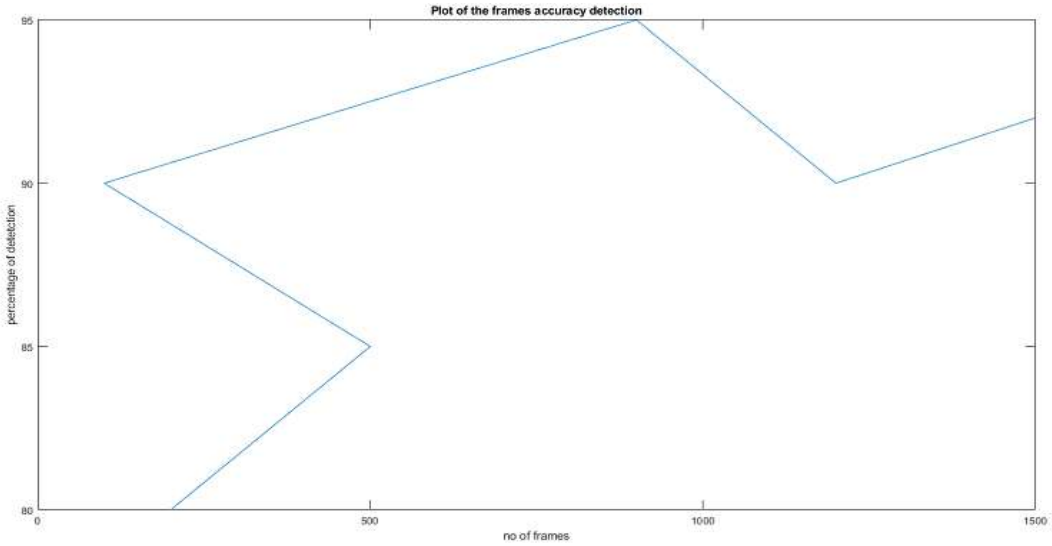

Figure 6: Accuracy of the Proposed Number of Frames vs. Percentage of Detection

The graph is plotted by considering the axis (X, Y) generates a 2-Dimentional plot for the line for the data obtained from Y vs. The values presents in X.

- If both the considered variables are vectors, then the length between both the variables will be equal. Then plot the graph againstY versus X.
- If both the considered variables are matrices, then the size between both the variables will be equal. Then plot the graph against function of variable Y versus function of variable X.
- If anyone the considered variables are defined as vector and the other is defined as matrix, then the defined matrix must contain all the dimensions in such way that they should be in equal length. If the row of a matrix contains equal length then graph must be plotted for each of the matrix against each of the vector.
- The total number of identified in the matrix considered for blob analysis and the filtering processing provides the number of frames percentage against the blob detected.

VI. CONCLUSION

This section concludes the human identification with Histogram Specification and Kalman filtering with Euclidian distance techniques can be presented. During this human identification process the input video frame pixels are applied with various pre-processing methods. The subtraction of background method is applied to remove background unmatched objects. All the moving objects will be detected in background subtraction method by keeping the background of the video frame stable and constant. Then the Histogram Specification with the kalman filtering approach is applied, where Blob Analysis technique for modelling then followed by kalman-filter technique is applied where different positions of humans are identified based on the Calculation of Euclidian distance calculation using the correlation matrix. In the future the scope is to implement the Human identification based of his theft actions using multiple cameras, when the person's activities found doubtful the he is identified as the theft and alarm must be generated to identify the theft, this provides accuracy in tracking results in an efficient manner by considering the videos captured with different position and fields using the Raspberry Pi hardware.

Abstract

Currently the electrical energy demand is rising faster way in developing countries like India. As a result, more distribution losses and low voltage profiles in the large and complex electrical distribution systems (EDS). Studies observed that nearly 10-15% of the total generated electrical power is fed on as I2R losses at the stage of distribution level. The consumers voltages have reduced when moved away from the substation and such consumers contribution in distribution losses is more based on associated connected load of consumers. In addition to that voltage stability decreases and maximum loadability margin also reduced in the distribution lines. Subsequently, it will be imperative to improve the capacity of power transmission in EDS. The planning and optimization of compensating device and Distributed Generation (DG) are estimated to improve the reduction of energy losses and beautify the consumer voltage profile in the EDS. The recommended approaches introduce with planning and optimization using simple and fast load flow solution for optimal placements and optimal sizes of the Distribution Static Synchronous Compensator (DSTATCOM) with different optimization methods.

Keywords: *EDS, D-STATCOM, ITLBO.*

1. Introduction

Generally, the radial distribution networks have high R/X ratio, which causes high line losses in the system and it leads to affect the system stability. So many researchers approximated that the distribution system power loss is high compared to transmission system. From the consumer point of view, the power loss reduction is one of the important issues to improve the overall efficiency of the power delivery [1]. Reactive power compensation is one of the best ways to reduce the losses in the distribution system. The shunt capacitors and serious voltage regulators are traditionally used for reactive power compensation in the distribution system. But these devices cannot able to provide the reactive power continuously and they have very slow response. In addition to that the shunt capacitors produce oscillation in the distribution system when it combines with inductive circuits [2].

Now a days the application of FACTS concept such as DSTATCOM has been applied for distribution system for line loss reduction, voltage profile enhancement, power quality improvement and load balancing etc., Compare with other reactive power compensation devices, DSTATCOM has many features, such as low power losses, less harmonic production, high regulatory capability, low cost and compact size. The primary function of DSTATCOM is to supply reactive power in the distribution system in order to reduce the line losses, power factor correction and voltage profile enhancement.

Copyright © 2019 SERSC

DSTATCOM is predicted to play significant role in the radial distribution systems due to the increasing power system load.

Optimum allocation of DSTATCOM maximizes the load ability, power loss minimization, stability enhancement, reactive power compensation and power quality enhancement [8]. To determine the optimal location and sizing of DSTATCOM has a considerable impact in radial distribution system. In appropriate placement in some situations can reduce the benefits and even endanger the entire system operation. Only a few research works were done in the area of DSTATCOM allocation [3].

No work done in the literature to focus on the power loss reduction along with system voltage stability improvement reduces the voltage deviation, improve the LLM and decrease the loss allocation to consumer [4]. This work proposed various indices based on the power losses, voltage deviation, voltage stability, LLM and consumer loss allocation. Proposed a generalized multi objective function which can use in any of the planning optimization to improve the EDS performance [5].

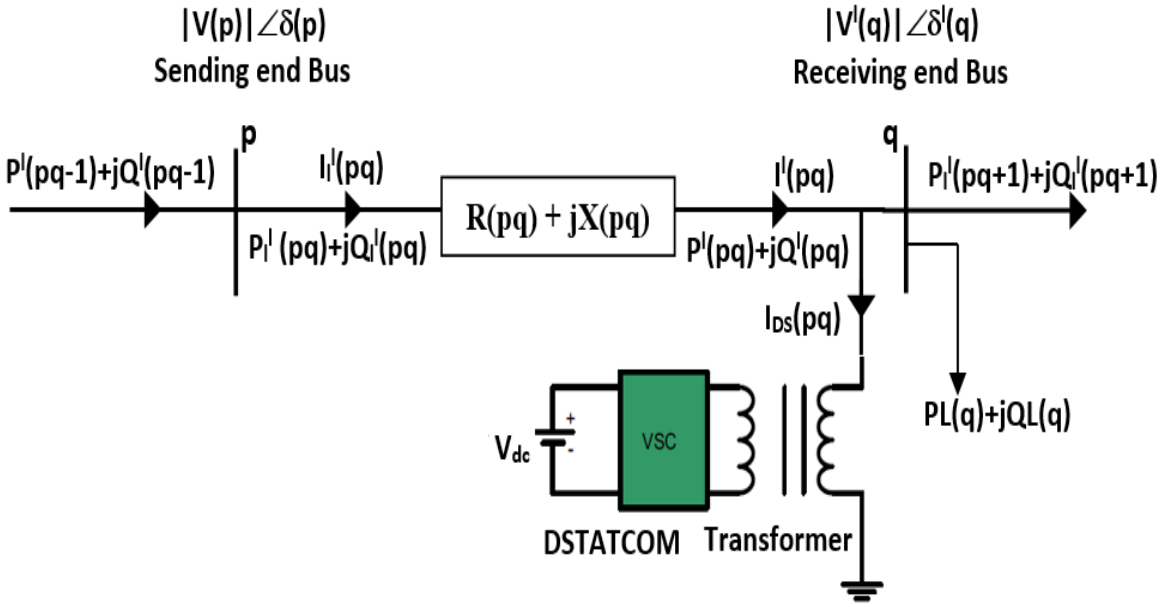

Figure.1: Equivalent circuit model of EDS of a typical branch pq with DSTATCOM

A new approach is investigated to find the optimal location and sizing of DSTATCOM with an objective function of minimizing the total system power losses by including the voltage stability, voltage deviation, LLM and loss allocation to consumer. Improved Teaching Learning Based Optimization algorithm is used to find the optimal location and sizing of single and multiple DSTATCOM. The proposed work is tested on 33-node and 69-node EDS. The obtained result shows that optimal placement and sizing of DSTATCOM in the EDS effectively reduces the total power losses of the system and also improve the performance of the EDS.

2. Various Impact Indices for the Multi-objective Problem

For the planning and optimization of EDS, the multi-objective formation includes six individual objectives that are transformed to related impact indices in or to make the analyze all objective simultaneously with simple analysis. Following are the indices proposed to handle the planning and optimization EDS problem effectively.

2.1 Index for Power losses based on available load (IAPL and IRPL)

Copyright © 2019 SERSC

The system operates at maximum performance represent as reduces the losses. In this case, the real and reactive power loss indices are defined as follows respectively [6].

$$IAPL = \left(\sum_{pq=1}^{br} P_{loss}(pq) / \sum_{q=1}^{nd} PL(q)\right) \quad (1)$$

$$IRPL = \left(\sum_{pq=1}^{br} Q_{loss}(pq) / \sum_{q=1}^{nd} QL(q)\right) \quad (2)$$

where

$\sum_{pq=1}^{br} P_{loss}(pq)$ is total APL in kW

$\sum_{pq=1}^{br} Q_{loss}(pq)$ is total RPL in KVAr

$\sum_{q=1}^{nd} PL(q)$ is total active load in kW

$\sum_{q=1}^{nd} QL(q)$ is total reactive load in kVAr

Planning and optimization of EDS will decrease the total network losses, which means near zero values of IAPL and IRPL.

2.2 Index for Deviation of bus voltages (IVDI)

The system voltage deviation index (VDI) is defined with respect to eqn. above equations for EDS. The index for the voltage deviation is the system voltage deviation index only as shown below

IVDI= VDI (3)

The decreasing value of IVDI refers to the improvement of voltage profile as well as voltage regulation at the nodes. Any planning and optimization of EDS will decrease the system voltage deviation index and make it zero value of IVDI.

2.3 Index for consumer loss allocation based on total APL (ICPL)

The loss allocation to consumer far away from the substation is high with the proposed PLAM . It is needed to observe the consumers with high loss allocation burden and any allocation method should always give the best to reduce their loss allocation. The index is developed to observe the maximum loss allocation consumer based on the total system APL.

$$ICPL = \max_{q=1\ to\ nd}\left(CP_{loss}(q) / \sum_{pq=1}^{br} P_{loss}(pq)\right) \quad (4)$$

Where

$CP_{loss}(q)$ is the loss allocation of q^{th} consumer

Copyright © 2019 SERSC

For any planning and optimization, it is accepted to reduce the burden of high loss allocation to the customer and ICPL should reach near to zero and loss allocation to most of the consumers will decrease.

2.4 Index for VSI (IVSI)

The VSI gives a significant detail about the voltage stability of the radial distribution systems. In this approach, VSI is taken as the decisive factor which variation of VSI value indicating the system voltage stability during of any planning and optimization in EDS. The index of VSI is defined as

$$IVSI = \min_{q=1\ to\ nd}\left(VSI(q)\right) \quad (5)$$

The intensity of stability can measure the distribution system using the IVSI and thereby necessary action, possibly taken if the index indicates the instability condition of the system. The system operates at secure and stable condition the evaluated VSI values are greater than zero, otherwise instability occurs.

2.5 Index for LLM (ILLM)

With planning and optimization of EDS significantly changes the power flow in various sections of the EDS. The maximum loading allowed with the addition of branch LLM is the acceptable limit of branch to avoid the system instability. The ILLM index gives in details of minimum loading of LLM from all branches of LLMs in EDS.

$$ILLM = \min_{pq=1\ to\ br}\left(\frac{LLM(pq)}{LML(pq)}\right) \quad (6)$$

It is needed to increase the ILLM value increase to operate the EDS system with high LLM values and utilize the existing lines for handling the future load growths.

3. Flow Chart for DSTATCOM Placement and Sizing using ITLBO Algorithm

To solve the optimal location and size of the single and multiple DSTATCOM problem in EDS, ITLBO is applied to minimize the MOPI function eqn. (7) [7]. Initially, ITLBO algorithm parameters (such as number of generations, population size (i.e. number of learners), number of teachers and number of subjects), the number of DSTATCOMs locations and according to that sizes, constraints and the system specifications, including the bus and line data, should be considered as inputs of the ITLBO. The ITLBO algorithm based MOPI is given by

$$MOPI = w_1.IAPL + w_2.IRPL + w_3.IVDI + w_4.ICPL + w_5.\left(\frac{1}{IVSI}\right) + w_6.\left(\frac{1}{ILLM}\right) \quad (7)$$

The location of DSTATCOMs can be chosen as any integer number between 2 and the maximum number of system nodes (as 1 is the substation) and size of corresponding location DSTATCOM changes from 5 kVAr to less than or equal to total reactive load of EDS. The variables for optimization are the location of the DSTATCOMs and sizes of imaginary DSTATCOMs powers.

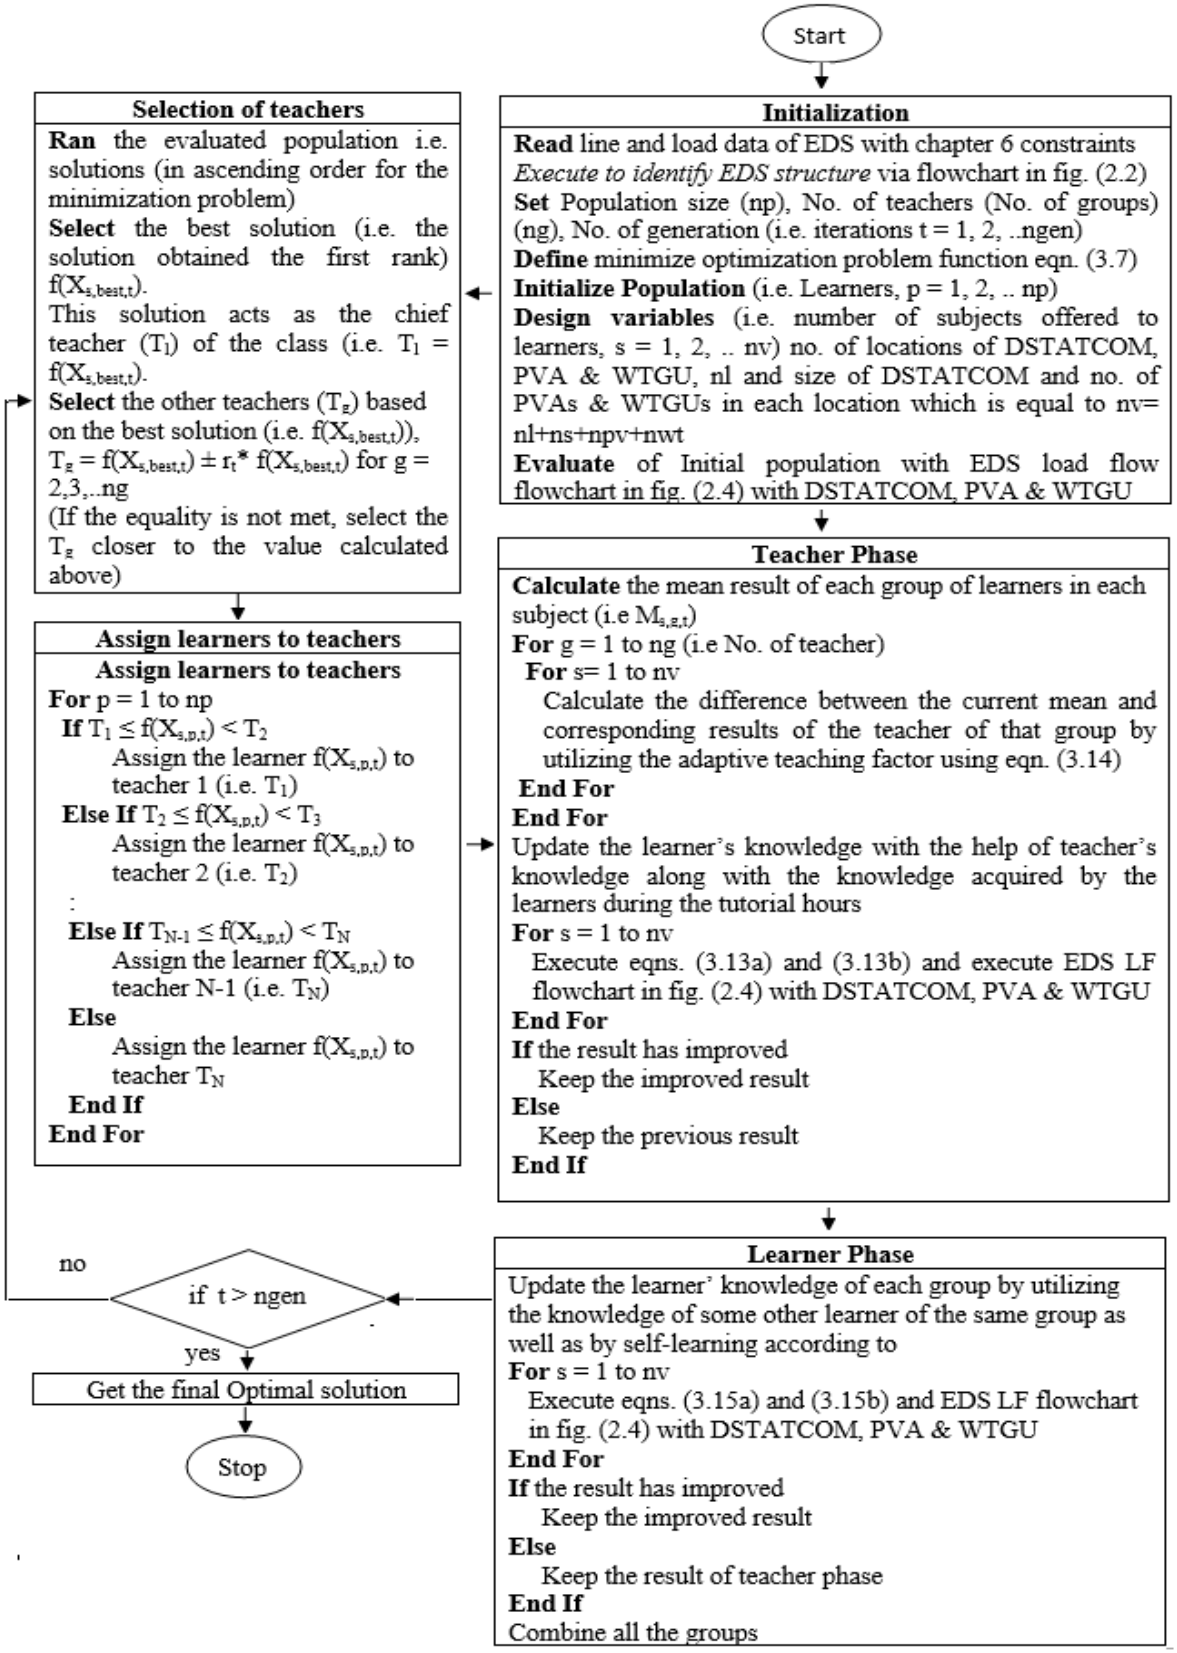

Figure.2: Flow chart for DSTATCOM, PVA and WTGU Placement and Sizing using ITLBO

Copyright © 2019 SERSC

4. Conclusion:

In this work, the utilization of the ITLBO procedure for solving the DSTATCOM location sizing problem for minimizing the system MOPI function with different number of DSTATSOMs has been considered. In this proposed method a generalized MOPI function developed and which is used to search the optimal location and size of DSTATCOM. DSTATCOM location and sizes can be found by using ITLBO among a large number of combinations by optimizing the objective function. The present approach reduces the power loss and improves the bus voltage accurately and effectively in the EDS to enhance the minimum LLM and reducing the consumer loss allocation.

ABSTRACT

A bus bar in an electrical power distribution refers to bulky segments of copper or aluminum that carry out electricity within a switchboard, distribution panel and substation. In this task, bus bar can be protected from the over current condition. Mechanical instruments disappointments have numerous causes and one of the primary causes is over burden. The crucial of the distribution transformer is anticipated to work at assured particular current, if that current passing through that feeder is more than the rated then instantaneously the feeder may damaged because of over load, through this projected work we are departing to defend the bus bar from heavy load condition. In this work, more loads are applied to the circuit to produce high current. So that the current will be increased. At whatever point the over current happened the circuit will be tripped. Here, one relay is utilized which will control through our microcontroller to trip the circuit. Whenever over load is occurred relay will trip the whole circuit and buzzer will on control through our microcontroller to indicate over load. Whenever over load occurs micro controller automatically triggers the load to OFF and data will alert through IoT.

Index Terms *–IoT, Buzzer, Fault, Feeder Protection, Fuse, Microcontroller, Over Load, Relay and Smart Grid.*

1.INTRODUCTION

In electric power distribution, a programmed protection of over burdenof distribution network is an electrical circuit breaker equipped with an instrument that can naturally close the breaker subsequent to that it has been opened owing to a fault. Programmed over-burden securitysystems are used in coordinated protection schemes for overhead line power distribution networks. These circuits are horizontal to momentary faults such asoverload and short circuit faults. A transient fault roots open the breaker contacts or gust the fusewith conservative circuit breaker or fuse, disabling the line awaiting a technical person could physically close the breaker or substitute the blown fuse. But a programmed overload protection system will make quite a few pre-automatic attempts to or bring back to healthy or strengthen the line.

In order to reduce the problem many design techniques can be found in literature [I],[II],[VII],[IX]. One of them is commonly used feeder protection &relay converters [III],[VII]. The power of a proposed design is very effective and reliable manner.

The upheaval has bring in the present world by Internet of Things (IoT) supported technology behind its innovatory in the pasture of PC and web. In this manner we can utilize the derivation of IoT innovation inside the grid. In distribution network, a modified programmable over-burden

safeguard system which is an electrical switch secured with a component that can lacking human intercession shuts the breaker after it has been unlocked owing to a fault. These networks are mostly laying face down to the transitory faults such as overload or short circuit faults. With mainstream fuse or breaker switch, a fault will open the breaker or blow the fuse. Thus immobilizes the line turn over a specialist can physically replace the gusted fuse or shuts the electrical switch i.e., breaker on. Be that as it may, the overload protection system can create numerous preprogrammed attempts consecutively to boost the line or recover the original network. The preliminary protection of feeders with fault clearing time as described is drawn in Fig. 1.

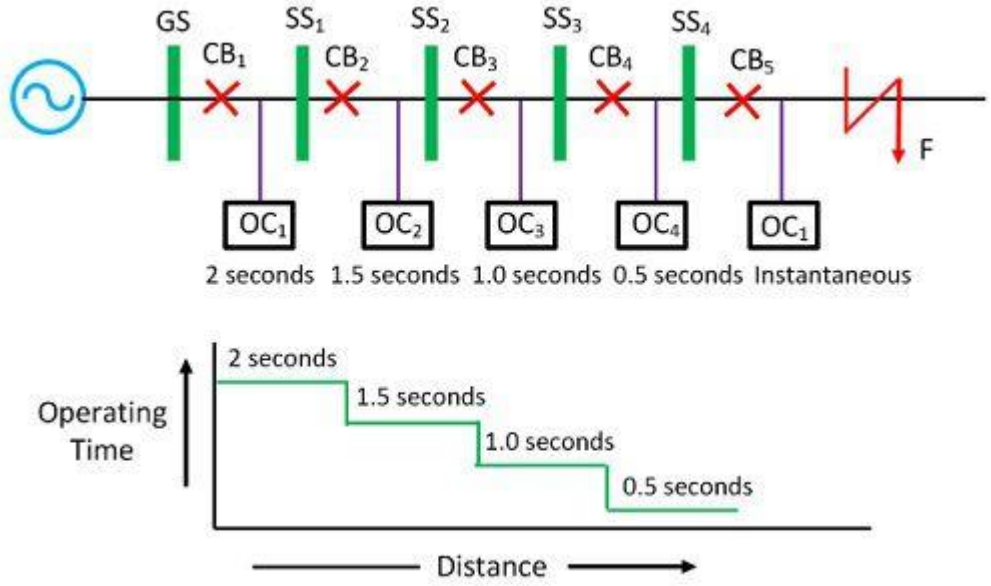

Fig. 1 General Representation of protection of Feeders

If the fault has been cleared then breaker circuit of the computerized over-load security system will keep on secured and power supply continues working. Today the world is moving quickly towards the more equipped and efficiently organized smart grid structure by subbing the present overworked proficiency with the smart grid technology which is illustrated in Fig. 2. So we can utilize both the information so as to make the near power system more functional and efficient. Smart grid and IoT is a portrait wonderful mixture of two, which will bring about upgrade of the current network configuration with feeders.

An embedded scheme is a combination of programming and equipment to play out to perform a devoted task. A portion of the fundamental devices utilized in embedded items are Micro-controllers and Micro-processors. Microprocessors are frequently referred to as general purpose processors as they merely recognize the efforts, process it and give the output. Interestingly, a microcontroller acknowledges the data as inputs as well as controls it, interfaces the data with a variety of devices to control the data and thus finally gives the output.

2. TRADITIONAL SYSTEM

In existing power feeder network, load current is escalating in environment so it will directly pressure to the customers equipments and end user side end users. The protection of total system of Parallel Feeders as shown in Fig. 3.

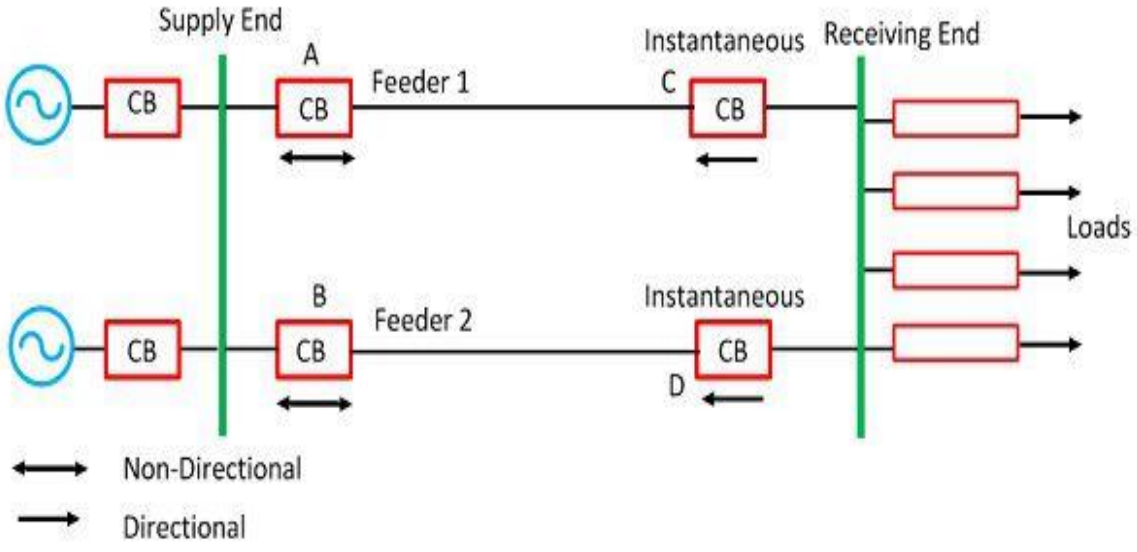

Fig. 3 Protection of Parallel Feeders

The equipment is associated in end user side will be collapse due to flow of over currents in the feeder streams. There is no precise controller is mounted on power lines for fault identification. The existing network will not be able to identify the faults like feeder overloading which reasons the load balancing problem of feeders for the reasons that of chances of failing the equipment owing to huge heavy load current.

3. IMPLEMENTATION OF PROPOSED SYSTEM

Here, Arduino used as a controller. If current sensor is sensed on the buzzer which will be displayed on LCD. Web server updated using IOT module and trip the relay bulb is OFF. POT is used if Voltage increased that time load will off. In order to implement, the system code is shown in Fig. 4. After sensing the fault, the microcontroller will sent signal to overload entity to trip the relay immediately. Also sends SMS through IOT module.

```
#include <LiquidCrystal.h>
#include <stdio.h>
LiquidCrystallcd(6, 7, 5, 4, 3, 2);
int buzzer = 13;
int relay  = 8;
int FS =A0
int POT   = A2;
void beep()
{
digitalWrite(buzzer, LOW);
delay(1500);
digitalWrite(buzzer, HIGH);
}
void setup()
{
Serial.begin(9600);//serialEvent();
pinMode(POT, INPUT);
pinMode(FS, INPUT);
pinMode(buzzer, OUTPUT);
pinMode(relay, OUTPUT);
digitalWrite(buzzer, HIGH);
digitalWrite(relay, LOW);
lcd.begin(16, 2);
lcd.print("iot feeder over load alert");
lcd.setCursor(0, 1);   //column,row
lcd.print("F:");         //3,1
```

The microcontroller ARDUINO UNO is heart of our working model. Feeder protection from overload is the prototype modules which consist of ARDUINO UNO microcontrollers, current sensor, ADC 0808, relay module, 16*2 LCD module, IOT module, Buzzer, Bulb, feeder supply and power supply. The automatic overload protection System circuit has a current sensing unit to detect the over current through the power line through potentiometers POT. A schematic diagram of conventional D-flip flop is illustrated in Fig.9.

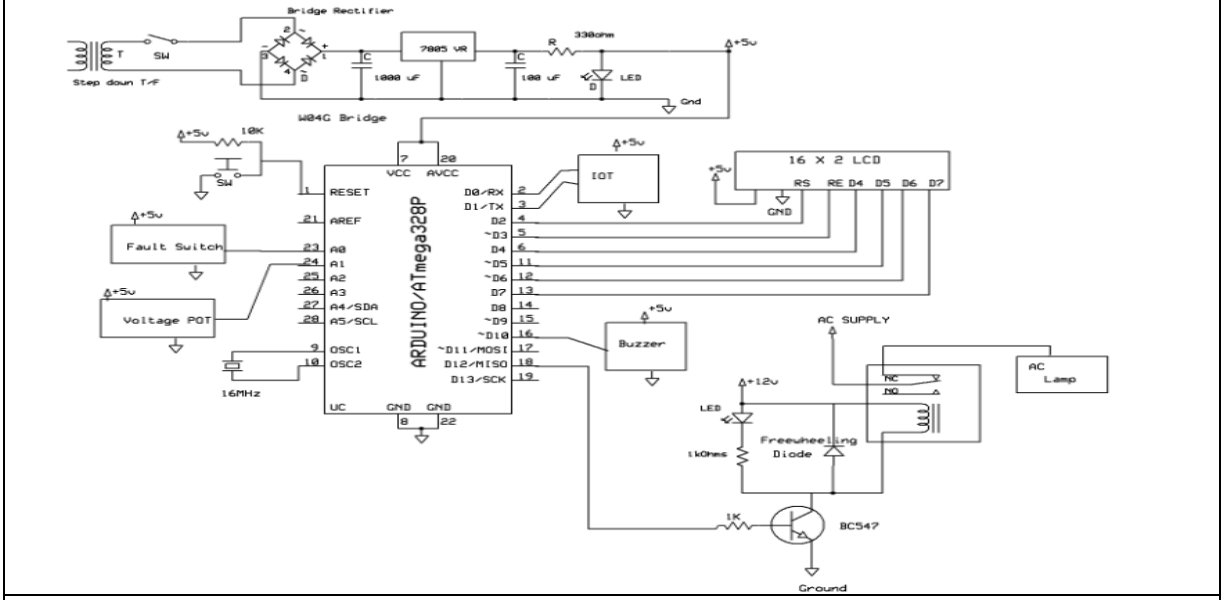

Fig. 9 Architecture of proposed model

The basic two reasons for the over current in a power line are overload and short circuit. So, when these faults occur the gives a signal to the line controller circuit. In this work, to produce high currents, more loads are relating to the network which will increases current. The current sensor in the system is associated in series with the power line and sense the current flow through the power line is to be tripped. To trip the circuit. Here, one relay is used to control through our microcontroller for tripping.

4. WORKING PRINCIPLE

In this section we are going to describe Block Diagram with Arduino for protection which is drawn in Fig. 10. The schematic of working model as shown in Fig. 11.

5. CONCLUSION

In this work, learned about plan to accomplish sort out and scrutinizing of overload state of feeder lines by estimating the voltage of each line. In this projected work, a system is designed in such a way that, it will supervise and manage the load continuously and that information is send to user mobile number using IoT technology. Today the world is stirring rapid towards the more active and efficient smart grid technology by exchanging the current time worn technologies. The object of this work is to develop the allocation of power, where hitches resembling burden shedding a typical circumstance.

ABSTRACT

An electrical vehicle charging hub is a charging power gracefully for electrical vehicles. This paper proposes the structure model for a PV based mechanical electrical vehicle which goes about as a wellspring of electric source to charge Electric vehicles (EV). EVs are viewed as the upcoming methods of transportation by 2030. The key drivers for EVs are their high effectiveness and zero carbon discharges. However, EVs are just reasonable if the power used to charge them originates from inexhaustible sources and not from petroleum product based force plants. It is here that the UV light based charging of EV has picked up enthusiasm for late occasions, as it gives a suitable strategy to charge EVs. The objective of this task is to "Develop a profoundly proficient, automated EV charging station which empowers brilliant charging framework for electric vehicles at working environments that is fueled by Solar Energy".

Index Terms *– Electric Vehicles, Photo Voltaic Cells, Sun, UV light, Solar*

1.0 INTRODUCTION

The growth of Electric Vehicles (EVs) is causing a profound transformation in the automotive industry. The differences in the manufacturing process, additional safety concerns, different requirements for the materials involved, and so on have changed the way the car industry operates. These changes are also reflected in different disciplines, such as energy conversion, because power electronics has a fundamental role in both EV traction and battery recharging processes. Several studies on traction have been con- ducted in order to provide lighter and smaller converters, smoother dynamic response, improve the efficiency and reliability of the equipment, which are not excessively distant from the conventional requirements in most motor drive applications. The fast charging process of the batteries, however, implies fundamental changes with conventional high- power applications because, aside from the vehicle, this process also involves the utility grid. In addition, the low-voltage levels of the battery packs increases the complexity, as typically these applications require medium voltage (MV) levels, hence impose a trade- off between the current stress of the switching devices[3].

Solar Power is effectively bridled in the tropic locales in light of the more drawn out daylight encounters contrasted with non-tropic areas. India is fortunately inside the tropics, this means a preferred position to its populace. Indeed, even with all the luck, the principle issue comes in the crew and preservation of these inexhaustible sources in addition to the high and disallowing introductory expenses of funding to set even a little scope sun based station.

This model of structuring a sun based controlled automated electric vehicle charging hub that uses UV light based force as a vitality source is intended to address various issues that standard interior ignition motor vehicles don't. An electric vehicle with a UV light powered charger will be simpler to utilize. It will minimize those unnecessary trips to the gas station for fill-ups. Simply plug the vehicle into the charging station when not being used and it will be powered and prepared for your drive. Above all, it eliminates interior ignition vehicle which are for the most part answerable for ecological contamination

and causes the green house gases believed to be responsible for the global warming.

2. EV TECHNOLOGY DEFINITIONS

The term EV is often used to designate different vehicle technologies, even though they have some substantial differences. To clarify the concepts used in this proposal the main types of EVs available today are defined as follows [1]:

Hybrid Electric Vehicles (HEV): This technology uses the electric power of batteries to improve the fuel efficiency of their internal combustion engine. The electric power to charge their batteries does not come from any external source.

Electric Vehicle (EV): These vehicles run on a purely electric motor which is powered by batteries. Refueling is done by plugging in the vehicle to the grid. The term battery EV is also used in the literature for this type.

Plug-in HEV (PHEV): As their name suggests, these vehicles can run on gas- line, similar to the HEVs, and recharge their batteries by plugging in the vehicle to the grid, similar to EVs. The result is increased driving range and reduced fuel usage and emissions.

This dissertation is mainly concerned with EV technology, although the same principles apply to PHEVs. For this reason, the remainder of this study exclusively considers the EV family as in Fig. 1.

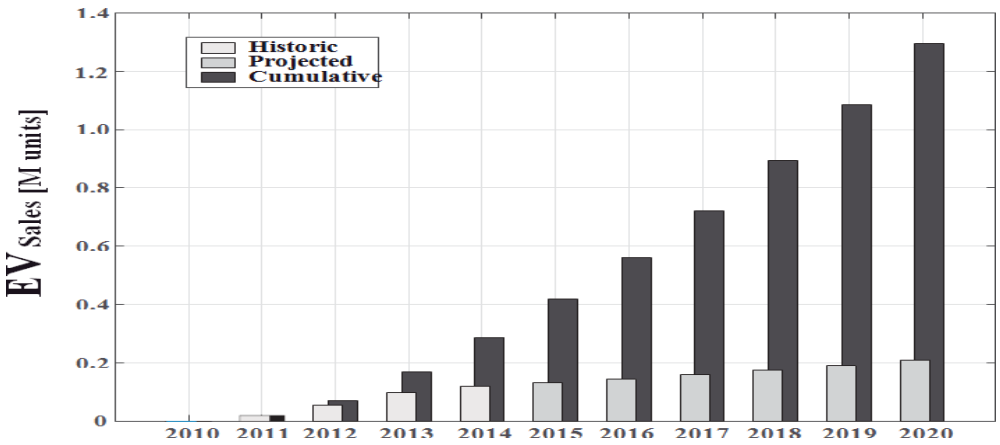

Figure 1 Cumulative and annual historical-projected EV sales across the globe

3. EVS BATTER PACK CHARGING

A significant piece of the activity of the EVs is the reviving of their battery pack. This procedure can be completed in two unique manners: conductively or inductively. The first charging technique utilizes electrical

The subsequent technique utilizes remote power through electromagnetic field coupling, taking out the module rope [2, 3]. This kind of charger has been investigated for Level I and II devices and still a work in progress and would not be talked about in detail here.

On the other hand, conductive charging has just been received by the EV Start-up, including standard EV makers. Contingent upon the rate at which the EV battery is charged, conductive chargers can be commonly ordered into moderate chargers and quick chargers. The customary chargers can revive the battery in 8 hours, while the quick chargers can do this procedure in 30 minutes. More particulars on the power levels, charging times for the accessible charging strategies can be found in some of the existing charging standards.

To control and normalize the conductive chargers a few associations, for example, the Institute of Electrical and Electronics Engineers (IEEE), the Society of Automotive Engineers (SAE), the International Electro technical Commission (IEC), are preparing to manage the utility/client interface.

4. ELECTRIC VEHICLE

Both, EVs and PHEVs have risen as the most probable replacement to ordinary inward ignition motor vehicles. From the ages, sales of these vehicles have been continually hiking, as appeared in Figure 1 and this expanding pattern is relied upon to proceed in future. The inadequacies of these vehicles must be tackled before they can turn into a genuine option in contrast to transportation.

Figure 2 Proposed PV base Robotic Charging Station Model

The paper intends to create a machine which would diminish individuals from a normal undertaking of charging electric vehicles. An electrical vehicle charging station is a charging power flexibly for electrical vehicles. This paper proposes structure of a model for a Photovoltaic (PV) based electrical vehicle that estimates complete force yield under specific conditions. The connection to MV AC grids of EV RCS it is not a straightforward task because of the particularities involved. Unlike conventional multilevel converter applications, the loads in the system are volatile and present a stochastic behavior, therefore, the control scheme and the balancing techniques need careful designing. To develop a robotic charging station using PV through common bipolar dc bus fast charging architecture that allows the grid integration of several high- power fast charging units. To provide simulation results those verify the proposed architecture and control schemes. To complete the validation of the topics, the implementation of a low-voltage prototype of PV based RCS will for the experimental validation shown in figure 2.

These reasons justify using the concept of the charging station as an enabling alternative for EV fast charging. These stations are similar to petrol stations, meaning that are commercial facilities composed by several off-board high-power chargers located in public places throughout the city (e.g., parking lots, shopping locations or rest stops along highway). In this way, the load is concentrated in strategic points, which can be coordinated with the utility operator (i.e., retrofit distribution and transmission equipment, discourage the demand in congested nodes, medium voltage (MV) connection, and so on). This concept allows the driver to choose its preferred charging method for his vehicle. An additional charging possibility alleviates range anxiety, maximizes the use of EV batteries, and most importantly, provides the EV user a regimen equivalent to that of conventional cars.

5. PROPOSED SYSTEM

This proposed model of designing solar robotic electric charge vehicle for generating energy and charge electric vehicle as portable mode by using Arduino microcontroller we execute this design [2].
It is extrapolated from existing innovation this segment looks at the structure of charging foundation for an electric vehicle with the assistance of PV boards. The proposed framework can be adjusted for neighborhoods and working environments to charge electric vehicles according to the accommodation of the EV client. The significant goal here is to expand the utilization of PV vitality for EV charging by using vitality stockpiling frameworks and limit the vitality trade with the matrix[8].

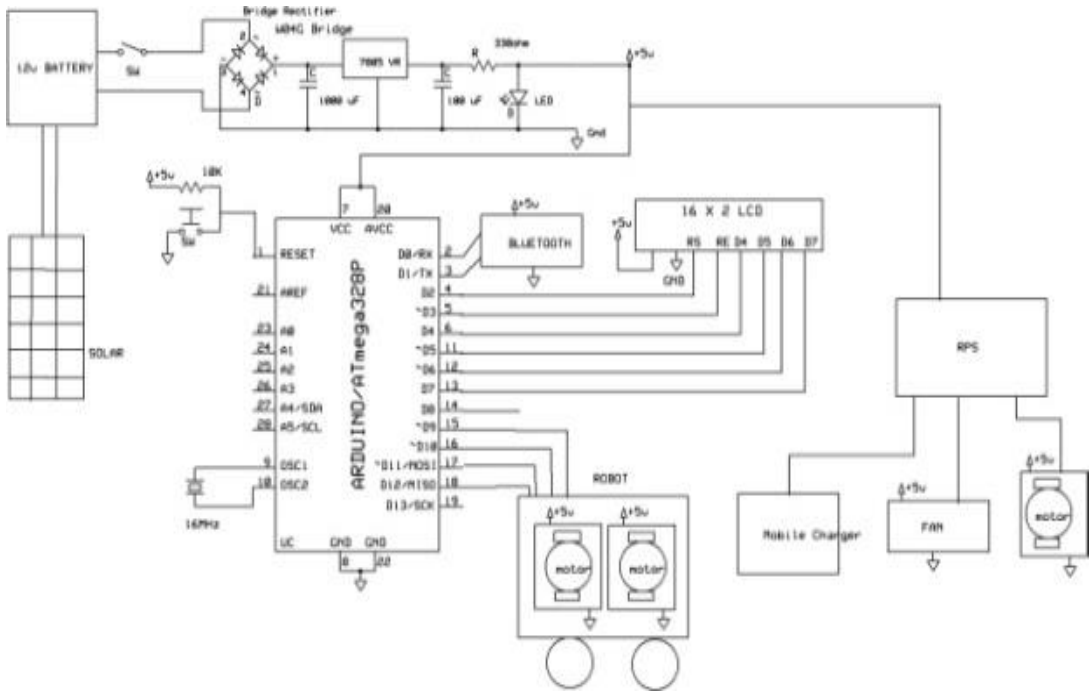

Figure 3 Block Diagram of propose system.

Sun based controlled vehicles have been made accessible to the overall population for more than 30 years; its far reaching or open use then again has been constrained fundamentally because of the current expenses of such gadgets. As sustainable power source is the fate of intensity age, it is essential that it is considered for electric vehicle charging also. PV board based EV charging station is being set up in numerous nations. For understanding the sun based controlled EV charging foundation [4], it is important to understand the current EV−PV framework, which is being used as of now by the businesses or are in the improvement stage by an alternate scholastic establishment. The proposed framework can be adjusted for neighborhoods and working environments to charge electric vehicles according to the accommodation of the EV client. The significant target here is to expand the utilization of PV vitality for EV charging by using vitality stockpiling frameworks and limit the vitality trade with the lattice.

7. CONCLUSION

As a result of limited oil unique assets, sustainable power sources got basic for our everyday life vitality request. In this viewpoint this venture is proposed to give a productive, appropriate and savvy model of PV based EV charging station. This investigation demonstrates that it is conceivable to execute and advertise Solar PV based EV charging station without framework association in Mode-1. In understanding accessible irradiance and temperature esteems, it can create adequate vitality while battery utilized as reinforcement. Rather than utilizing the matrix power as reinforcement source, vitality stockpiling framework (ESS) batteries are picked so that at whatever point sun oriented force is lacking to gracefully control for charging of EV, ESS takes the control and infuses the important vitality to the charging framework. The introduced model of sunlight based force vitality can be a decent activity for the future apparatuses and usage to be completed around there.

There are a few applications for keen charging like charging from renewable, diminishing charging costs or postponing conveyance organizes redesign. The focal point of existing exploration in this area is to discover better and effective calculations for every one of these applications thinking about them as discrete improvement issues. Decrease in the net expense of EV charging from PV utilizing charging calculations that consolidate sun powered figure, vitality costs, guideline administrations are suggested as expansion of the work conveyed in this proposal.

Abstract

The article describes the current control scheme for Shunt Active Power Filter (SAPF) meant for setting up on a power system. There is also a supplementary function in the active power filter for eliminating harmonics, correct power factor, and asymmetrical balance load studied in this paper. A brief explanation of the execution of the classical current detection algorithms for active power filters provided. After understanding various severe power excellence problems and a range of commission needs a current control scheme put forth. The system gives shortest time delay when compared with other methodologies. A range of commissioning current references, thus, is precisely and efficiently attained by following the suggested current control approach.The proposed system can assured that to achieve a variety of compensation purposes. The simulation outcomes we arrived with MATLAB / Simulink are proof that our method gives outstanding performance apart from being more effective compared to the existing methods.

1. Introduction

Increased deployment linked with those power distributing frames to DC supply/inverter and converter dependent applications, lead to downgrading in power supply networks concerning voltage/current harmonics, power factor besides resonance issues. Modest and cheap passive filters are highly efficient. But, the source impedance decides their performance thereby causing unnecessary problems with the electrical power network [1,2,3]. Moreover, they are also heavy and not suitable for N-LL applications. When there are N-LL current source loads, the best option for downsizing the current harmonics in both low and high power applications is the SAPF [4,5]. Either in series or in combinations of both (unified power quality Conditioners) and hybrid configurations, the Active power filter can be connected [6,7]. Since the current harmonics compensation is the widely preferred one for industrial applications, the SAPF is considered the most popular choice compared to the [8,9] series active filters as they are tiny, versatile, come with more choice and robust. Studies have been conducted on SAPF and thereby leading to new developments and innovations [10].

Figure. 1 shows the primary commission motto for a plant with an N-LL using a SAPF. The SAPF consists of a three phase Voltage Source Inverter (VSI) containing just a dc link capacitor. Where the former one is linked to the load at the Point of Common Coupling (PCC) via the input

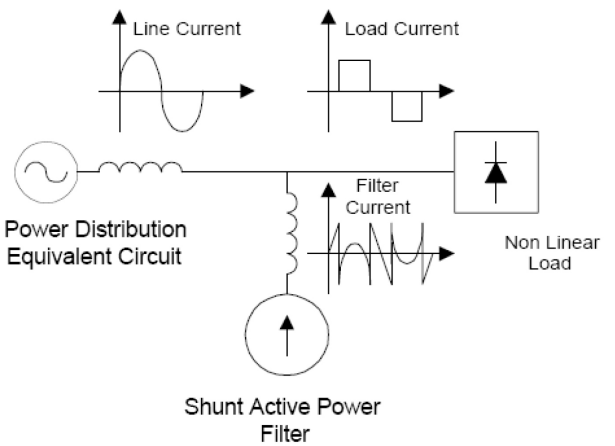

Figure 1

Principle of Shunt Compensation

inductor. Like a controlled current source, the SAPF works, thereby the load harmonic current. A sinusoidal current is obtained from the mains at the PCC. The SAPF will require an active fundamental current part to keep its DC connection capacitor activated at a voltage more significant than the threshold to line voltage. The reference current is not sinusoidal, so receiving a 0 - steady-state error is severe.

2. Principle of Shunt Compensation System

We keep the SAPF in link with the supply grid at Point of Common Coupling (PCC) via filter inductance. While switching the power inverter, harmonics are created, which is suppressed by the filter. We achieve the current harmonic commission by inoculating equivalent yet reverse present harmonic parts at PCC so that the previous alteration is canceled and power quality is also improved [11,12].

The immediate source current is shown in Figure 1.

$$I_S(t) = I_L(t) - I_C(t) \tag{1}$$

The immediate source voltage is

$$V_S(t) = V_m \operatorname{Sin} \omega t \tag{2}$$

The load current has the basic components and current harmonic parts, shown as [3]

$$\begin{aligned} I_L(t) &= \sum_{n=1}^{\infty} I_n \sin(n\omega t + \phi_n) \\ &= I_1 \sin(\omega t + \phi_1) + \left[\sum_{n=2}^{\infty} I_n \sin(n\omega t + \phi_n) \right] \end{aligned} \tag{3}$$

The immediate load power (P_L) can be calculated from the source voltage and load current, and the computation is given as

$$\begin{aligned} P_L(t) &= I_S(t) * V_S(t) = \begin{array}{l} V_m Sin^2 \omega t * Cos\phi_1 + V_m I_1 Sin\omega t * \\ Cos\omega t * Sin\phi_1 + V_m Sin\omega t * \left(\sum_{n=2}^{\infty} I_n Sin(n\omega t + \phi_n) \right) \end{array} \\ &= P_F(t) + P_R(t) + P_H(t) \end{aligned} \tag{4}$$

The given load power has basic active power, reactive power, and harmonic power. From Eq. (4), we arrive the real basic power obtained from the load as

$$P_F(t) = V_m I_1 Sin^2 \omega t * Cos\phi_1 \tag{5}$$

In case the active power filter offers the total reactive and harmonic power, the source current $i_s(t)$ would be in line with the utility voltage and sinusoidal. The triple phase source currents post-commission is given as

$$I_A^* = I_m \text{Sin } \omega t \tag{6}$$

$$I_B^* = I_m \text{Sin } (\omega t - 120^\circ) \tag{7}$$

$$I_C^* = I_m \text{Sin } (\omega t + 120^\circ) \tag{8}$$

We derive the maximum value of the reference current Iref with the regulation of the DC-bus capacitor voltage of the inverter.

3. Reference Current Estimation

In the 3-phase 3 wire scheme, the direct load currents of phase "*a*" "*b*", "*c*" (i_a, i_b, and i_c) can be taken apart into +ve sequence and -ve sequence parts in accordance to the proportioned weigh laws stated by Fortes cue discretely.

$$i_x(n) = \sum_{k=1}^{\infty}\left[I_{1k} Sin\left(\frac{2\pi nk}{N} + \phi_{1k} - \frac{2l\pi}{3} \right) + I_{2k} Sin\left(\frac{2\pi nk}{N} + \phi_{2k} + \frac{2l\pi}{3} \right) \right] \tag{9}$$

It is just the +ve sequence, -ve sequence, active power, and reactive power of the basic current are monitored, and decomposing of the hormonic is unnecessary. Thereby, the current fundamental part is expressed as:

$$i_{x1}(n) = I_{11} Sin\left(\frac{2\pi}{N} n + \phi_{11} - \frac{2l\pi}{3} \right) + I_{21} Sin\left(\frac{2\pi}{N} n + \phi_{21} + \frac{2l\pi}{3} \right) \tag{10}$$

Here, the former component of (2) is directed to the +ve sequence part line with the phase voltage, called as the active power component of the +ve sequence necessary current; the second part of (2) is directed to the +ve sequence component orthogonal to the line voltage, called as the reactive power part of the +ve-sequence fundamental current; the third component of (2) is directed to the -ve sequence part in line with the line voltage, called as the active power component of the -ve sequence necessary current; the final segment of (2) is directed to the -ve sequence component orthogonal to the line voltage, called as the reactive power part of the -ve sequence fundamental

$$
\begin{aligned}
i_{x1}(n) &= I_{11}Sin\left(\frac{2\pi}{N}n-\frac{2l\pi}{3}\right)Cos\phi_{11} \\
&+I_{11}Cos\left(\frac{2\pi}{N}n-\frac{2l\pi}{3}\right)Sin\phi_{11} \\
&+I_{21}Sin\left(\frac{2\pi}{N}n-\frac{2l\pi}{3}\right)Cos\left(\phi_{21}-\frac{2l\pi}{3}\right) \\
&+I_{21}Cos\left(\frac{2\pi}{N}n-\frac{2l\pi}{3}\right)Sin\left(\phi_{21}-\frac{2l\pi}{3}\right)
\end{aligned} \tag{11}
$$

Current.

Where '$Sin\frac{2\pi}{N}n$' is in line with the +ve sequence necessary voltage of phase "a" which finds the exact computing of active and reactive power parts. The system performance is regulated by the low-pass filter [13]. For a range of commission reasons, the separator conveniently gets various constituents that are greater to the algorithm according to the immediate reactive power theory. We created a Phase Locked Loop (PLL) system that is apt for time-domain analysis in an inaccurate utility circumstances. This was adjusted to the regulator effects like gain deterioration, line harmonics, and frequency turbulences. We did the entire incorporation of the PLL in software with no aid from hardware filters at all, as shown in Figure 2.

As mentioned above, we did a complete installation of the PLL in software devoid of hardware filters. If the reference Ude*is 0, the θ^* derived is in sync with the +ve sequence part of first voltage [14,15]. When $u_{de}^*$is not set to zero, there is a fixed phase difference amid the θ^* and the +ve sequence part of necessary voltage, thereby rendering the management of the displacement factor efficiently. Further, this phase variance not going

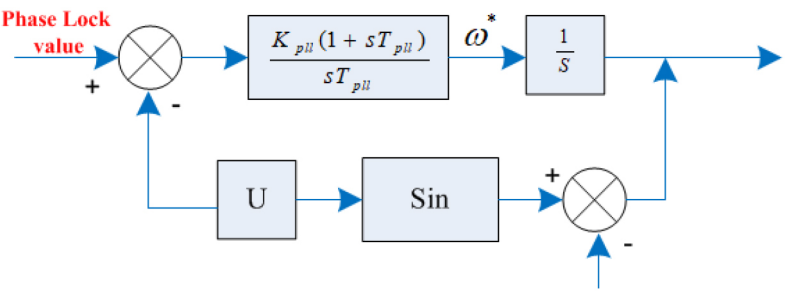

Figure 2

Proposed PLL System

to influence the strength of the chosen harmonics detection [16,17,18]. We gained the phase voltages U_{as}, U_{bs}, U_{cs} from sampled line-to-line voltages. The transformation of the obtained stationary reference frame voltages into voltages U_{de}, U_{qe} (in a frame of reference synchronized to the utility frequency) with the help of the 3/2 and e / s alterations. The angle θ* employed in the above conversions is gained by assimilating a frequency command ω^*. In case of frequency command ω^* is equal to the utility frequency, the voltages U_{de} and U_{qe}, look like dc values relying on the angle θ*.

In our proposed system, we have deployed a PI regulator forgetting that value of θ*(or ω^*) that carries the feedback voltage U_{de} to a commanded value U_{de}^*. Alternatively, the regulator ends up in a rotating frame of reference with respect to which the transformed voltage U_{de} has the desired dc value U_{de}^*. The rotating frame's incidence is similar to the rate of the utility voltage. The Extent of the controlled quantity U_{de} governs the phase difference between the utility voltages and sin (θ*) or cos (θ*).This approach leads to not just the utility frequency ω^* but also lets one to lock at an arbitrary phase angle θ* corresponding to the utility angle θ. The angle Δθ is controlled by the commanded values U_{de}^*.

The phase voltage is stated by per-unit; the base numbers for per-unit value are the peak value of +ve sequence fundamental phase voltage. Then, three-phase voltages can be expressed as $Sin\left(\frac{2\pi}{N}n-\frac{2l\pi}{3}\right)$, respectively. The immediate power of the significant current can be attained by multiplying current $i_{x1}(n)$ by phase voltage. Likewise, the instantaneous power of harmonics can be accomplished by increasing flow. $i_{xk}(n)$ $i_{xk}(n)$ $Sin\left(\frac{2\pi}{N}n-\frac{2l\pi}{3}\right)$ We could observe that the -ve sequence or +ve sequence component has alone part out of which the three-phase sum up to zero. Without any energy storage, we can compensate for this using a compensator. The least frequency constituent is two times the primary frequency; the dc component can be attained by a low pass filter with a limit frequency smaller than two times the basic rate or by a sliding window with *N/2* samples.

$$X_{x1} = I_{11}Cos\phi_{11}+I_{21}Cos\left(\phi_{21}+4l\pi/3\right) \tag{12}$$

with a similar methodology, the below equations can also be obtained

$$Y_{x1} = I_{11}Sin\phi_{11}+I_{21}Sin\left(\phi_{21}+4l\pi/3\right) \tag{13}$$

From equations (6) and (7),

$$\begin{pmatrix} X_{11} & Y_{11} \\ X_{21} & Y_{21} \end{pmatrix} = \begin{pmatrix} I_{11}Sin\phi_{11} & I_{11}Cos\phi_{11} \\ I_{21}Sin\phi_{21} & I_{21}Cos\phi_{21} \end{pmatrix} \quad (14)$$

Where X_{11} and Y_{11} denote the highest values of the reactive power part and active power part of +ve sequence underlying current. X_{11} and Y_{11} are the highest values of the active power part and active power part of —ve sequence primary flow of phase **"a."** Therefore,

$$i_{x11} = X_{11}Cos\left(\frac{2\pi}{N}n - \frac{2l\pi}{3}\right) + Y_{11}Sin\left(\frac{2\pi}{N}n - \frac{2l\pi}{3}\right) \quad (15)$$

$$i_{x21} = X_{21}Cos\left(\frac{2\pi}{N}n + \frac{2l\pi}{3}\right) + Y_{21}Sin\left(\frac{2\pi}{N}n + \frac{2l\pi}{3}\right) \quad (16)$$

$$i_{x1} = X_{x1}Cos\left(\frac{2\pi}{N}n - \frac{2l\pi}{3}\right) + Y_{x1}Sin\left(\frac{2\pi}{N}n - \frac{2l\pi}{3}\right) \quad (17)$$

$$i_{xk} = X_{x1}Cos\left(\frac{2\pi}{N}n - \frac{2l\pi}{3}\right) + Y_{xk}Sink\left(\frac{2\pi}{N}n - \frac{2l\pi}{3}\right) \quad (18)$$

The segregation of different results is composed by Equations (14)–(16). This is achieved based on various compensation purposes generating a range of effects. In case SAPF is deployed to recompense harmonics and the —ve sequence part of the primary current, the +ve sequence constituent of the underlying present i_{x11} can be taken from (9), and the current reference can be given as $i^*_{cx}(n) = i^*_x(n) - i_{x11}(n)$ by deducting i_{x11} from the load current. Post the compensation when the line current is predicted as a regular three-phase necessary current, and the power factor is 1, the active power component of the +ve sequence fundamental current i_{px11} can be drawn by considering $X_{11} = 0$ in (9), and the current reference can be gained as $i^*_{cx}(n) = i_x(n) - i_{px11}(n)$ by deducting i_{px11} from the load current. Likewise, when we set Y_{11} to 0, the reactive power part of the +ve sequence underlying current is derived. The -ve sequence part of the fundamental present is derived from (15). If APF is utilized for compensating the selected order harmonics, we can calculate the by (17). The "active power" part and "reactive power" part of harmonics does not require a division, hence the factors $Cosk\left(\frac{2\pi}{N}n - \frac{2l\pi}{3}\right)$ and $Sink\left(\frac{2\pi}{N}n - \frac{2l\pi}{3}\right)$ can be substituted with $Sin\left(\frac{2nk\pi}{N}\right)$ and $Cos\left(\frac{2nk\pi}{N}\right)$, separately. Followed by

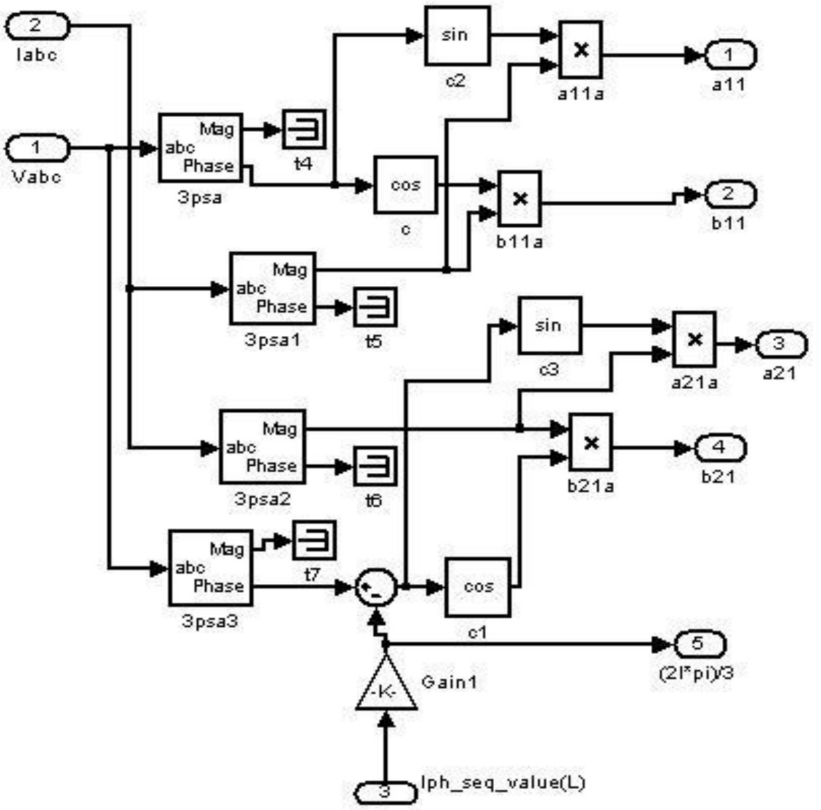

Figure 3

Proposed current control scheme

the simplification of programming. According to the detection methods, various compensation goals could be attained with specific combinations.

4. Proposed Control Scheme

A Phase Loop Lock, a sine wave generator and the separator form the principal constituents of our control scheme. We applied the current control scheme based on the strategy arrived by us for finding the reference recreating current. Figure. 3 shows current control scheme.

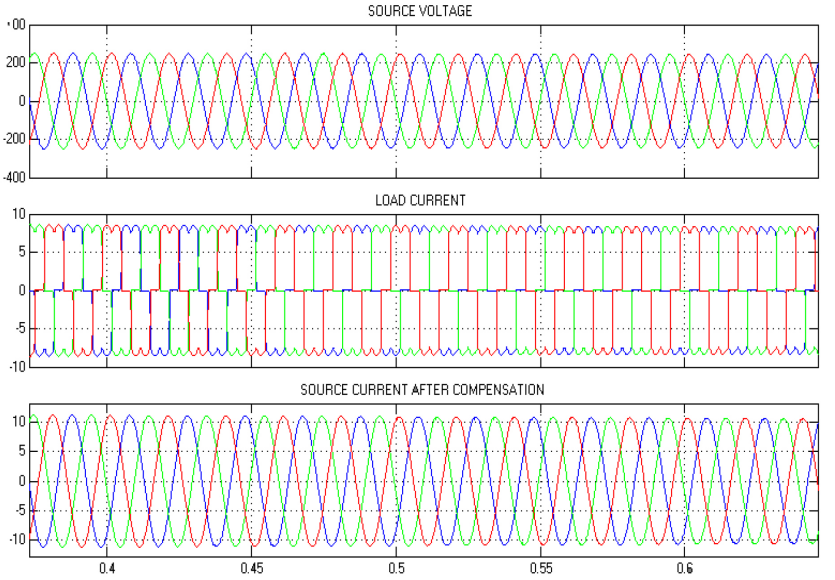

Figure 4

Source voltage, load current and source current after compensation

5. Simulation setup for Sinusoidal, Balanced Source Voltages

The main aim of the recreation is for showcasing the benefits of the SAPF control strategy suggested here. The source voltages are sinusoidal and stable, having a magnitude of 230 V, frequency of $\omega=100\pi$ and the source offers an unnecessary nonlinear load.

The stable and sinusoidal three-phase voltages measured are,

$$V_a = 230 \sin(\omega t)$$

$$V_b = 230 \sin(\omega t - 120^o)$$

$$V_c = 250 \sin(\omega t + 120^o)$$

The bridge rectifier load we incorporated here also dons the role of a nonlinear unbalanced load. To have clarity, we have plotted the simulation results separately. The source voltage, load current, and the source current after compensation depicted in Figure 4 and figure 5 depicts the outcomes recreated using the filter current created by the controller.

With Harmonic Compensation

Table 1

THD Comparison

CASE	THD %
With no Harmonic Compensation	28.37
Harmonic Compensation	0.84

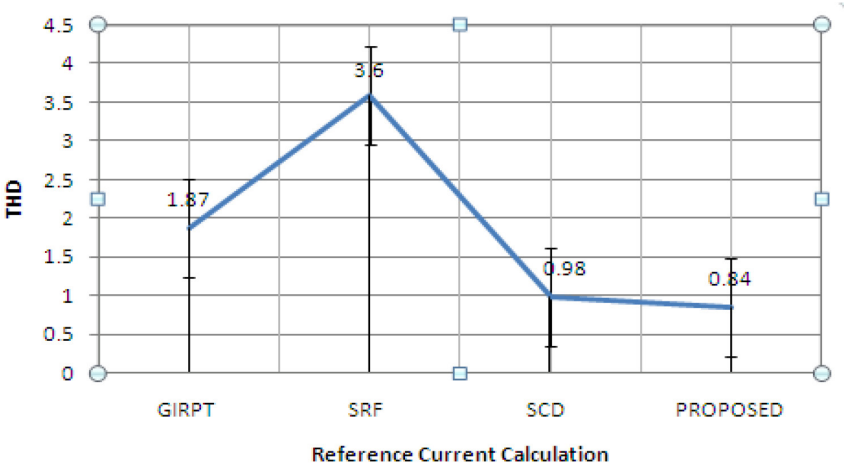

Figure 11

Comparison of % THD

6. Analysis of Simulation Results

The outcomes recreated obtained for a stable state is taken into account. From figure. 8 and figure. 10, we understand that harmonic currents are injected by SAPF into the line so that the input supply is made sinusoidal.

Figure 11 depicts the comparison of THD for the three studied and accessible approaches viz. Generalized Instantaneous Reactive Power Theory-based methods, Synchronous Reference Frame method, and the Synchronous Current Detection methods. Based on the outcomes (Fig. 10 and Fig. 16), we conclude that for stable source voltages, the THD for our approach is considerably lower than of the above-discussed methods. Even the setback as the result of the suggested plan is shy of 50% of the prime cycle; this is subsequently is shy of 50%of DFT and similar to the proposed method in accordance to the IRPT.

7. Conclusion

The outcomes recreated by using our proposed methodology are analyzed against the above-discussed methods. From the comparison we understand that the proposed method has a delay which is just shy of 50% of the prime cycle, this is subsequently is shy of 50% of DFT and also the algorithm created using IRPT. Based on the simulation and comparison studies, we find that the current control scheme proposed here is much superior in terms of affability, fidelity, and ease in operation. Also, as the reference commission currents are calculated in the 'a-b-c' reference setting, reference setting conversion is not needed. Hence, there is reduced complication in understanding the SAPF control circuit. In spite of that, it keeps an excellent filter performance. Post injection of compensation currents by SAPF, we infer that the source currents turn perfect and stay at par with the +ve sequence fundamental source voltages. Hence, the anticipated utility source power factor at the definite sequence fundamental frequency is obtained, and the harmonic currents kept under control. The Total Harmonic Distortion (THD) analysis divulges that our methodology has a source current THD lower than the previous methods. The commission methodology of SAPF put forth is verified via MATLAB/Simulink generating better understanding with the anticipated SAPF targets.

Abstract:

This work presents a low-cost approach to power factor correction (PFC) of single-phase diode rectifiers using a series active filter. Comparing with the traditional PFC, the proposed PFC has lower requirements of power device ratings, which leads to lower cost, higher efficiency, and lower electromagnetic interference. It also can eliminate the bulky inductor needed in the traditional PFC. The topology, operation principle, and application issues of the proposed PFC are analyzed in this paper. The control strategy is discussed in detail and simulation results are provided.

Keywords: Adjustable-speed drive, heating, ventilating, and air conditioning (HVAC), power factor correction (PFC), series active filter.

I. Introduction

IN the recent years, more and more variable speed motor drives fed by single-phase utility power are used in residential heating, ventilating, and air-conditioning (HVAC) systems. Most of them are using diode rectifiers with smoothing dc capacitors as the front-end. The diode rectifier draws

pulsed current from the utility line, which leads to low power factor, low efficiency, and high rating requirements to the switching devices. As a result, some standards such as IEC 1000-3-2 have been brought forward to limit the harmonic current of the utility line. To comply with these standards, power factor correction (PFC) is needed. So far, a variety of passive and active PFC techniques have been proposed [1]–[5]. While the passive PFC may be the simplest way in the low power applications, the active PFC are used in the majority of applications for their high performance, compact size, and light weight[6].

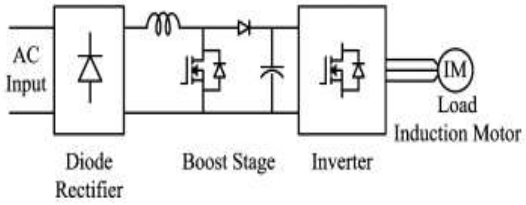

Fig 1: Traditional power factor correction

Fig. 1 shows the most common approach to signal-phase active PFC, where a boost circuit with an additional filter inductor is used to shape the line current[7]. The boost stage forces the dc bus current to follow the line voltage, which results in a nearly sinusoidal line current without phase difference. However, it brings in high dc bus stress, high switching device ratings, high switching losses, and high electromagnetic interference (EMI). In this paper, a new compact, low-weight, low-cost PFC using a series active filter is proposed. Comparing with the traditional PFC, it has lower device ratings, lower cost, lower EMI, and higher efficiency. The inductor needed in the proposed series PFC is also much smaller than those in the traditional PFC, and in the most cases, the line impedance of the utility line is enough for its normal operation[8]-[9]. A hysteresis control strategy, which is simple and easy to implement, is presented to eliminate line harmonics[10]. Simulation and experimental results are given to verify the analysis and demonstrate the control performance.

II. PROPOSED CONVERTERTOPOLOGY

The diode rectifier with proposed PFC for typical residential HVAC is shown in Fig. 2. Because the ac

line is 100 V and low, a voltage doubler is used for rectification, i.e., two capacitors are charged alternatively over one cycle. The output voltage is doubled, resulting in an approximate 250 V dc link voltage (V). The PFC circuit, implemented by a full bridge inverter with an optional inductor, connected in series with the diode rectifier. Since the diode rectifier and the full bridge inverter behave like voltage sources, the line current is determined by the difference among these three voltage sources and the loop inductance, which includes the line impedances and the inductance of the optional inductor.

Although four switching devices are used in this topology, each power device only needs to sustain a low capacitor voltage, , which is limited below 50 V. Thus low-cost, high-efficiency 60-V metal-oxide semiconductor field effect transistors (MOSFETs) can be employed. The voltage rating of each device is only 20% of the voltage rating of the switching device that are used in the boost stage of the traditional PFC. Therefore, even though four MOSFETs are used in the proposed topology, its total cost of switching devices is still less than the cost of the high voltage device in the traditional topology. In addition, the gate drive circuit of the proposed topology can draw power directly from the dc capacitor of the inverter without isolation. A simple charge-pump gate drive circuit powered by the inverter dc capacitor can be easily implemented for each MOSFET. Compared with the high transfer ratio and isolated power supply needed in the gate drive circuit of the traditional boost PFC, the proposed topology can also reduce the complexity and cost of the gate drive signal tremendously.

The EMI problem due to the while switching is also a big concern of the PFC system. In the proposed PFC, the voltage stress on the switching devices is only , which is less than 50 V, while the switching device in the traditional boost PFC needs to switch on and off the whole dc bus voltage, 250 V. Therefore, the EMI interference during switching will be reduced significantly. The voltage distortion brought into the acgrid by the proposed circuit also can be neglected because 1) the inverter dc voltage is relatively low (V) and 2) the line impedance, with the inductance of the optional inductor, are normally far greater than the source impedance, . The simplified equivalent circuit is shown in Fig. 3, where is the total line impedance, . The relationship between the output voltage of the inverter and the state of each switch can be summarized by

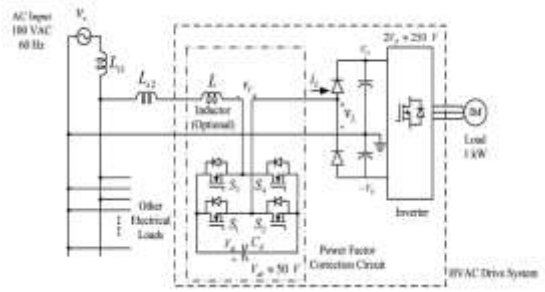

Fig2: Proposed power factor correction converter (PFC).

$$v_C = kV_{\mathrm{dc}} \quad \text{--→(1)}$$

where k is defined as

$$k = \begin{cases} +1, & \text{for } S_1 \text{ is ON and } S_3 \text{ is OFF} \\ 0, & \text{for both } S_1, S_3 \text{ are ON or OFF simultaneously} \\ -1, & \text{for } S_1 \text{ is OFF and } S_3 \text{ is ON.} \end{cases}$$

--→(2)

III. CONTROL STRATEGY

The easiest way to control the proposed topology is to use the hysteresis control, as shown in Fig. 4(a). In this control, the harmonic component of the line current, is extracted by a notch

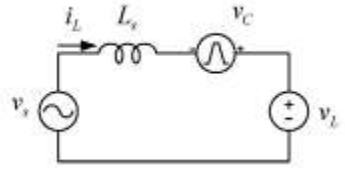

Fig. 3. Equivalent circuit of proposed PFC.

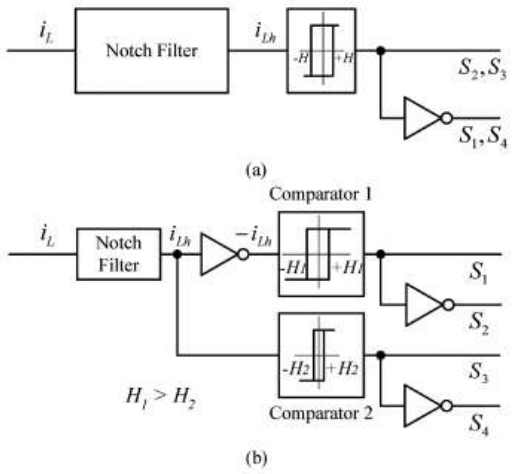

Fig. 4. Hysteresis control.

filter, and fed into a hysteresis comparator. The output of the inverter will switch between and to limit the harmonic current within the hysteresis band. In this control strategy, the zero voltage of the inverter is not utilized, which results in higherswitching frequency and higher switching ripples. In order to reduce the switching frequency and the voltage ripple, the zero voltage has to be utilized.

Fig. 4(b) shows the proposed double hysteresis control, which utilizes the zero voltage output of the inverter. In this control strategy, two hysteresis comparators with different hysteresis widths, H1 and H2, are used. Since the two-phase legs of the full-bridge inverter are symmetrical, we can assume that H1 is greater than .H2

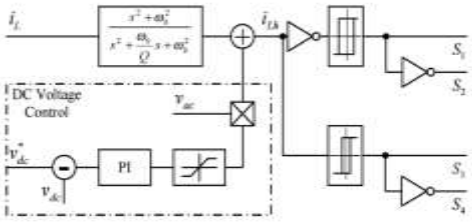

Fig 5: Block diagram of Hysteresis control with PI control

In this control strategy, switches S1 and S2 only switch three times per fundamental cycle. The switching frequency of switches S3 and S4 is approximately half that of the single hysteresis control with the same hysteresis width. Therefore, the double hysteresis control strategy tremendously reduces the switching frequency.

Since the hysteresis control is used to control the switching devices, the switching frequency is not constant. However, it is desirable to estimate the average switching frequency for design purposes

In this circuit, the actual dc capacitor voltage is detected and compared with the reference value, and the error is fed into a PI controller. A sinusoidal signal in phase with the line voltage is added to the harmonic currents extracted by the notch filter. The amplitude of the sinusoidal signal is controlled by the PI controller. By adding the sinusoidal offset to the input of the hysteresis comparator, active power flowing into the capacitor will be changed, thus the dc capacitor voltage can be controlled.

IV. COMPARITVE ANALYSIS OF PFC OF WITH SERIES FILTER AND WITHOUT SERIES ACTIVE POWER FILTER

V. CONCLUSION

A new PFC with double hysteresis control has been presented. The operation principle has been discussed in detail.. It shows that a high power factor has been obtained. Compared with the traditional PFC, the proposed PFC has the following advantages: 1) lower devices rating, which reduces cost, EMI, and switching losses, 2) no additional inductor is required, the line impedance is enough for most cases, and 3) the proposed double hysteresis control reduces the switching frequency significantly, which leads to higher efficiency

***Abstract*—These works present a structure of DC system base wind power generating system. The proposed of a system is permits adaptable activity of different equal associated wind generators by taking out the requirement for voltage and frequency synchronization. The model prescient control calculation that offers enhanced transient reaction as for the adjustments in the working conditions is proposed for the control of the inverters. The structure idea is checked through different test situations to exhibit the operational capacity of the proposed micro-grid when it works associated with and islanded from the distribution grid, and the results acquire are examined**

***Keywords*—Wind energy, PI Controller, DC/AC.**

1. INTRODUCTION

Wind turbines to diminish the homesteads' interest on the lattice. The Malaysia government is effectively advancing this new idea of collecting wind type energy from electric airing fans in poultry ranches which has been executed in numerous nations around the globe [4]. The significant contrast between the circumstance in poultry ranches and normal wind ranches is wind speed inconstancy. The conversion ability of wind speed in wind cultivates legitimately relies upon the natural and climate circumstances though awind speed in fowl ranches is commonly steady all things considered created by steady speed ventilation fans. In this way, the generation irregularity gives that influence the unwavering quality of power gracefully and power base balance is not predominant in farm ranch wind base energy systems. As of late, the exploration consideration on dc matrices has been resurging because of mechanical progressions in power hardware and energy base storagedevices, and increment in the assortment of dc type loads and the infiltration of dc Distributed energy-resources (DER,) for example, sunlight based photo-voltaic and energy units. Many examination takes a shot at dc micro-grids have been directed to encourage the reconciliation of different DERs and energy storagesystems.

In [5], [6], a dc micro-grid type based wind ranch design in which each of a wind energy transformation unit comprising of a system converter, at high level frequency transformer and a solitary phase ac/dc converter is proposed. Be that as it may, the proposed design expands the system unpredictability as three phases of conversion are essential. In [7], a dc type micro-grid based on wind ranch design in which WTs are bunched into gatherings of four with each gathering associated with a converter is proposed. In any case, with the proposed design, the disappointment of one converter will result in each of the four WTs of a similar gathering to be unavailable.

2. Introduction to Wind Energy

Low voltage DC small scale lattices have been generally utilized for providing basic burdens, for example, server farms and remote correspondence stations. Therefore, it is imperative to guarantee excess and enough energy limit so as to help potential additions in load utilization. This is accomplished by methods for development of the energy storagesystem by including extra distribute.Remaining on head of the structure, he can feel the extraordinary speed up contrasted with being on the ground. Wind power stations are regularly found in a similar spot as huge radio broadcast reception apparatuses. Similarly as the high rise encourages the radio signs to travel farther, the expansion heigh above ocean level speeds up and causes the station to create more power.

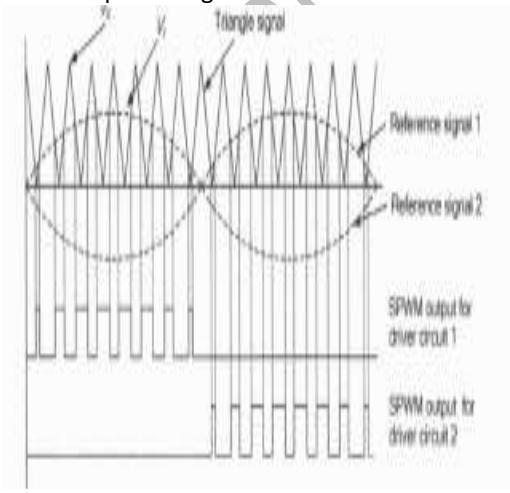
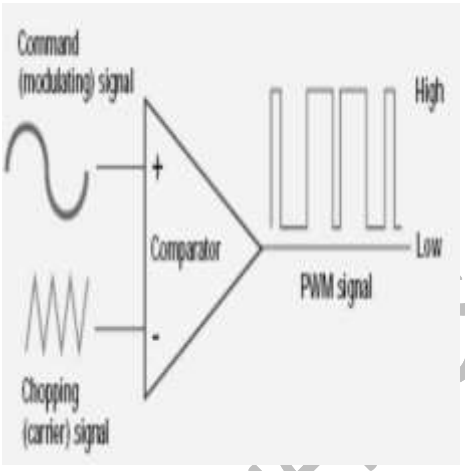
3. Sinusoidal Pulse Width Modulation

The Sinusoidal Pulse Width Modulation (SPWM) is a notable wave forming strategy in power devices for acknowledgment, a high frequency triangular bearer signal, V1, is contrasted and a sinusoidal reference signal, V, of the ideal frequency. The hybrid focuses are utilized to decide the exchanging moments. The extent proportion of the reference signal (Vr,) to that of triangular sign (Vc) is known as the balance record. The magnitude of fundamental component of output voltage is proportional to modulation index (MI).The amplitude Vr, of the. Triangular signal is generally kept constant. By varying the modulation index output voltage is controlled.





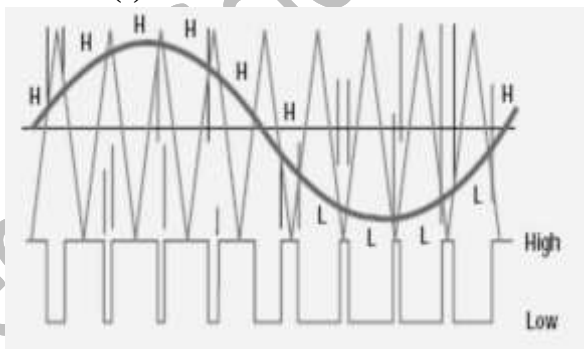


Fig.2: Signals of PWM

The pulse width modulation technique is applied to control the output voltage of the inverter which is also known as variable duty cycle regulation.

(a)

(b)

Fig.4.: Generation of Signals in PWM

The greatness of crucial segment of output voltage is relative to MI.The adequacy Vr, of the. Triangular sign is commonly kept steady. By fluctuating the adjustment file output voltage is controlled. The pulse width balance procedure is applied to control the output voltage of the inverter which is otherwise called variable obligation cycle guideline. Generation of the ideal output voltage is accomplished by looking at the ideal reference waveform (adjusting signal) with a high-frequency triangular 'bearer' wave as delineated schematically. Contingent upon whether the sign voltage is bigger or littler than the transporter waveform, either the positive or negative dc transport voltage is applied at the output. Note that over the time of one triangle wave, the normal voltage applied to the heap is relative to the sufficiency of the sign (accepted steady) during this period. The subsequent cleaved square waveform contains a copy of the ideal waveform in its low frequency segments, with the higher frequency segments being at frequencies of a near the bearer

frequency. Notice that the root mean square estimation of the air conditioner voltage waveform is as yet equivalent to the dc transport voltage, and consequently the absolute consonant mutilation isn't influenced by the PWM procedure.

Conclusion

In these work, the plan of a dc micro grid based wind power generation system in a micro-grid that empowers equal activity of a few WGs in a poultry ranch have been introduced. When contrasted with regular wind base power generation system, the proposed micro-grid engineering disposes of the requirement for voltage and recurrence synchronization, in this manner permitting the WGs to be turned on or off with insignificant aggravations to the micro-grid activity. The plan idea has been checked through different test situations to exhibit the operational ability of the proposed micro-grid and the simulink results has indicated that the proposed technique idea can offer expanded adaptability and unwavering quality to the activity of the micro-grid. Be that as it may, the proposed control configuration despite everything requires further trial approval since estimation problems because of problems of the voltage and current sensors, and demonstrating blunders because of varieties in genuine system boundaries, for example, conveyance line and transformer impedances will influence the exhibition of the controller in down to earth usage.The recreation

results got and the examination acted in this paper fill in as a reason for the structure of a dc system based wind power generation system in a micro-grid.

Speed Control of AC Motor

Y Sudha, P Pooja, K Rama, P Shweta

Abstract*: An enormous number of motors have been using in our daily life ranging from home appliances to industrial machinery. During the last decade, there has been tremendous change industry automation and home automation. Electric motor is always the essential part in home appliances as well as industrial applications in the automation. There is always a need to control the speed of the motor to run the appliances smoothly. Other important part of the appliances is the microcontroller. Microcontroller is always the essential part in all the embedded system applications because of its economical price and easy to customize to any specific need. Electronic devices like thyristors, diodes have been widely used in industrial applications to control the speed of the motor The Objective of this paper is to control the induction motor speed by using triac and zero crossing detector. Usually in many industrial applications speed varying is important to run the process in different stages, this paper demonstrates the mechanism of varying the speed of the AC Motor. The circuit is equipped with microcontroller and the induction motor. Induction motor is controlled by using triac and zero crossing detector by controlling the pulses of input AC signal. Microcontroller input is connected with two input modules that is one increment switch and one decrement switch. Increment switch is used to increase the speed of motor by varying in steps that is already dumped the code in microcontroller and also same for decrement switch. An LCS screen has been used to display the speed of the motor. Touch screen is used to operate the motor.

***Keywords:** Microcontroller, LCD screen, Rectifier, PWM, Embedded systems, AC Motor, Triac, Zero Crossing detector.*

I. INTRODUCTION

The Objective of this paper is, controlling the AC Motor speed by using Microcontroller interfaces with touch screen and the speed displayed on LCD. By using a Pulse Width Modulation method, the motor speed will be controlled from 0% - 100%. If the motor crosses predefined threshold level, system alerts the user with a buzzer alarm. Automation is the widely used term in the electronics field. The research on automation has fetched many developments in the prevailing technologies. Touch screen sensor is one among those technologies, which had tremendous developments. Touch screen haven been using in almost all the embedded applications due to its user-friendly interface. Devices with Touch screen functionality can operate very easily by anyone without much technical knowledge and any assistance from a technician. The contact-less speed measurement method is used to measure the motor. PWM method is used to control the motor speed. By operating the touch screen, user can control the motor speed. The direction of the motor can also be controlled by operating the touch screen. Microcontroller is the control device for the total system. The Microcontroller receives input from touch screen sensor and operates consequently on the motor speed. IR module sends the speed of motor to Microcontroller, which displays it on LCD screen. Whenever the speed crosses the set threshold level, the controller takes the accountability of alarming the buzzer to alert the user. The Microcontroller used in the paper has been programmed using Embedded C language.

II. OVERVIEW

Embedded system, an amalgamation of software and hardware to accomplish a committed task. Some of the main components used in embedded systems are Microprocessors or Microcontrollers. Microprocessors called as general-purpose processors, as they solely receive the inputs, process it and deliver the output. In difference, a microcontroller not only receives the data as input but also handles it, communicates the data with multiple interface devices, controls processed data and thus finally provides result. This paper “Speed monitoring of AC induction motor” using PIC16F876, PIC16F72 microcontroller is an exclusive paper which has object such that home appliances can be controlled by using a touch screen sensor interface. Objective of this paper can also use, to control home appliances like fans, lights, auto washing machines, many more electrical devices and day-to-day life, by interfacing the touch screen sensor hence manual switching mechanism has been eliminated and we can operate any home appliance just by a gentle touch on touch screen sensor.

III. PROPOSED SYSTEM

This paper endeavors a new speed control procedure of single phase AC induction motor. It is available at economical cost; with high efficiency, this drive is proficient of supplying a single-phase induction motor with PWM modulated sinusoidal voltage output. An ARDUINO family Microcontroller is used to control the circuit operation .The device is a substitute for frequently used TRIAC phase angle, control drives. The circuit is capable of supplying single-phase induction motor with inductive or resistive load and with variable AC voltages. It is comparable to TRIAC control, the voltage applied to the load can be changed from minimum to maximum value. Furthermore, a PWM technique has been used and it can be compared with phase angle control, which will be used for TRIAC, which produces considerably low higher order harmonics.

P. Shweta, Department of Electrical Engineering, Zeal College of engineering & Research, Pune, India. Email: shwetabhade@gmail.com

Since the circuit, aimed at economical cost, medium powered applications, to get the output voltage waveform; it may not need any conservative converter topology . It can modulate mains AC voltage. As related with expensive converter, it needs low in number of active and passive power components. The device endeavored here takes advantage of, economical cost of the phase angle control and the low harmonic content with higher efficiency, which have standard converter topology. The drive accompanies MOSFET with PWM control and load in series with bridge rectifier. This control drive based on this recommended control procedure can be used in consumer as well as industrial products like fans, blowers, and washing machines etc.

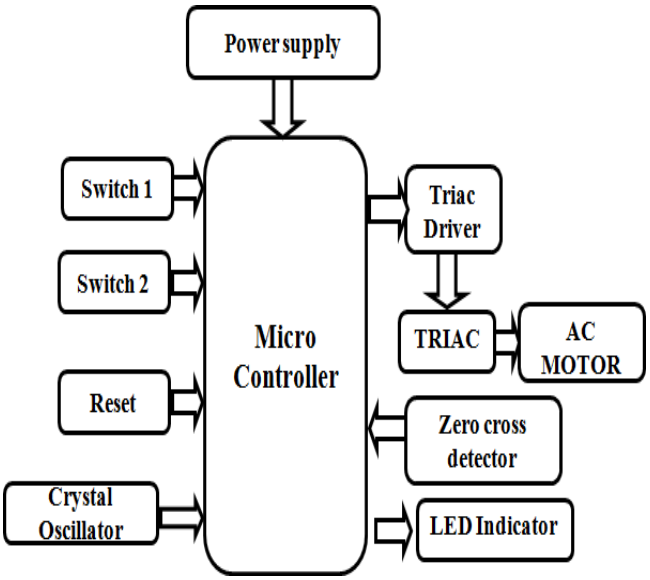

Fig 1 :Microcontroller

IV. CIRCUIT DIAGRAM

The schematic diagram and interfacing of PIC16F876, PIC16F72 microcontroller.

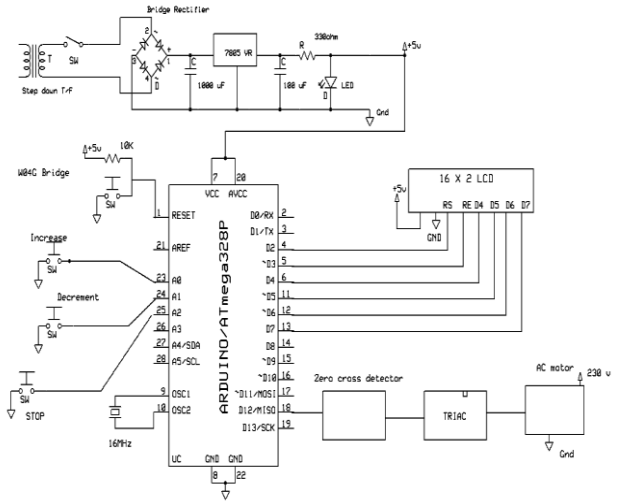

Fig 2 : Interfacing Diagram

The circuit works on the principle of pwm technique for speed control of an induction motor. When we want to increase or decrease the motor this project will be more useful. First to increase the motor increment switch is turned on and it can vary in steps and also when the user want to decrement the speed of motor, decrement switch will be turned on. Both these switches are provided on left of the microcontroller through pins. These speeds are controlled by using TRIAC and Zero Crossing detector connected to the circuit between the microcontroller and the induction motor. Ie The triac will control the pulses of the Ac supply input by using the microcontroller input signal and also zero crossing detector. Advantages And Disadvantages

A. Advantages:

1. This system eliminates electrical shocks when manual switching mechanism Is used.
2. The electrical appliances can be switched ON/OFF just by a gentle touch.
3. Visual and audible alerts using LCD and buzzer
4. Efficient and economical design.
5. Consume less power.
6. Quick response.
7. High voltage devices can also be operated.

B. B. Disadvantages:

1.Touch screen need to be handled carefully.
2.Interfacing Touch screen to Microcontroller is difficult
"Float over text" should *not* be selected.

V. RESULTS

The project " Speed monitoring of AC induction motor" was designed such that controlling the AC Motor speed by using Microcontroller interfaces with touch screen and the speed displayed on LCD

VI. CONCLUSION

Speed control of the induction motors is one of the most trending topics nowadays, through this paper we found a new method controlling the speed by frequency variation of the induction motor by using Arduino Uno, this method shows a smooth control of the speed through control the output frequency by setting a code wrote in Arduino Uno coding language. This code will control the whole operation by changing the Arduino output voltage and this will change the output frequency and voltage of the inverter and as a result the speed of the induction motor will be changed, setting a specific time for each speed, the code can be modified easily to get the desired speeds for different applications, it's an efficient method through the following facts, its consume less power as Arduino can operate by connecting 9V battery only,

the scheme can be upgraded to connect Ethernet shield to control the operation from distant area.

FUTURE SCOPE

Our project "Speed monitoring of AC induction motor" is mainly intended controlling the AC Motor speed by using Microcontroller interfaces with touch screen and the speed displayed on LCD. The input is given by the user using touch screen to micro controller which in turn operates the AC motor speed. The input value from the touch screen to the micro controller will be checked and respective operation of that press will be performed like increasing or decreasing the speed of the AC motor. system can be extended by using wireless Zigbee technology to operate the devices from longer distances.

ABSTRACT

The high voltage transmission over long distance is mainly focused on safety and economic. If necessary, to transmit certain amount of power through long area should care about power regulation, efficiency and losses. Any time fault may occur if any deviation in voltage and current reaches above normal range. The faults in power system causes over current, under voltage, unbalance of the phases, reversed power and high voltage surges. Three-phase symmetrical faults are known to be the most severe in a power system due to large fault currents. However, single phase, phase to ground faults are more common faults that occur. If not checked in due time, these faults may grow to symmetrical fault which is uncommon but most severe. Trial and error method is usually practices for detecting the fault location on transmission line. In this method, the supply feeds at the single end at a time by dividing that transmission line into two parts and detect the fault up to that limit. This paper provides a modern approach for detecting a fault and diagnosing overhead transmission lines through the implementation of DWT and ANN controllers. Voltage signals are found from the sending end for each phase, the decomposition using DWT to obtain a detail coefficient of up to 2 stages.

Original Article

INTRODUCTION

In power transmission lines if any deviation of voltages and currents from nominal values or states are normally called electrical faults. At any circumstance, if the operating conditions are normal, the power system equipment or lines carry normal voltages and currents which results in safer operation of the system. Whenever the fault occurs in transmission lines, it may cause excessive flow of currents and make severe damages to the electrical equipments and devices. So, avoiding such kind of damages and protection of switchgear equipment, electromechanical relays circuit breakers, and other protection devices it is necessary to select or design suitable fault detection and diagnosis method.

Fault condition in the Phasor measurement unit is calculated measured input voltages comprises of 2 steps:

- First step authors in have matched degree measurement utilized to classify defective location, as defective buses have low matching degree value systems.
- A mathematical generator was used in second step to evaluate the accurate location of the fault. This method is taken to transmission lines on networks.

ANN provides to detect and diagnose errors. This is a natural or artificial method which these are upon this

design and real functions of the neurons in the brain biological systems. This could receive all the functions: failure identification, error diagnosis and fault position. It's also proposed in a feed forward propagation network for detecting faults. Neural network training is provided with inputs and targets. Hence it is identified that the technique based on ANN can solve the problems that are common in the design of conventional distance relays. Through this method, a final stage of voltage and current being utilized to detect faults using ANN with feed forward neural scheme as the primary approach. Efficiently this approach identifies and classifies electrical power failures. This scheme can therefore easily solve the problems as opposed to non-linear loads. The sample rate for each period is 1KHZ for training ANN results. The method involves two steps in detecting and classifying faults. For the detection of faults, human beings are using six input data of ANN technique and analyze these value systems with pre-fault values obtain sample set. Output of the artificial neural network system is 1 and 0 that both detects presence and shortage of fault. For fault classification, a certain approach selected and 4 inputs of the ANN method, that are A, B, C and G have been utilized. Results of the model are dependent on reliability of the artificial neural network design to identify and recognize faults.

TYPES OF FAULTS

Symmetrical Faults

Attention need for these faults because it makes more damage and interruption on the power transmission.

But it occurs in frequently in the power lines. Another name of this fault is balanced faults (IX, X).

In Figure 1, these faults are classified in to two types

- Line to line to ground (L-L-L-G) and
- Line to line (L-L-L).

Total faults in power line the symmetrical faults estimate only 2-5 percent of system. But these faults occur, the system remains balanced but results in severe damage to the electrical power system equipment also.

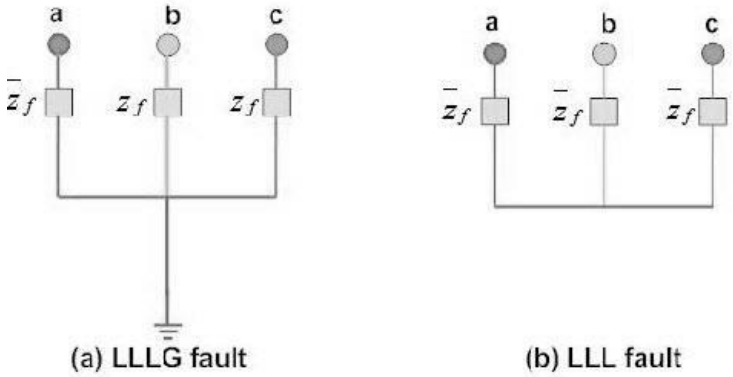

Figure 1: Symmetrical Faults

Asymmetrical Faults

In Figure 2, Asymmetrical faults are common faults occurs in transmission lines and less severe.

The followings are main type of asymmetrical faults

- Line to Ground (L-G),
- Line to Line (L-L), and
- Double Line to Ground (LL-G) faults.

All the above line to ground fault (L-G) is the most common fault and 65-70 percent of faults are of this type.

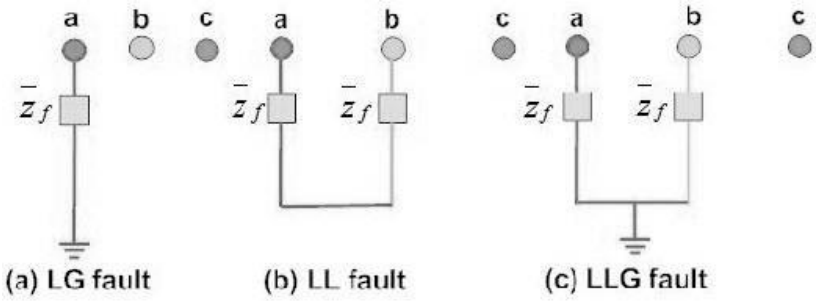

Figure 2: Asymmetrical Faults

MATERIALS AND METHODS

The electrical faults occur because of following weather conditions, equipment failures, human errors and smoke of fires. Once fault occurs it may create over current flow, danger to operating personnel, loss of equipment, electrical fires and Disturbs interconnected active circuits.

Discrete Wavelet Transform

In Figure 3, wavelet transformation, the high-pass filter is being used to evaluate high frequency information of signal and low frequency. Low-pass filter content analyzed. It performs two stages of decomposition. The signal during the first stage was decomposed into cA1 and cD1 with this kind of frequency band among 0-fs/4 and fs/4-fs/2 during which fs is called sampling frequency. cA1 is broken down to give rise to cA2 and cD2 discretely, in the second stage decomposition. The cD2 part band frequency is fs/8-fs/4, and 0-fs/8 for cA2. Upon decomposition the energy can be calculated from the detailed coefficients expressed in mathematical equations as below:

$$E(t_a, t_b) = \int_{t_a}^{t_b} (|y(t)|)^2 dt \quad \ldots\ldots \quad (1)$$

Where,

y(t) represents the signal,

E = Time interval of energy (ta, tb)

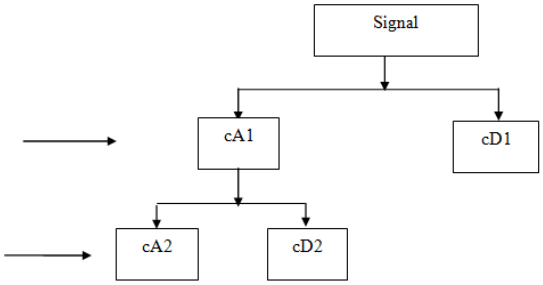

Figure 3: Discrete Wavelet Transform

ARTIFICIAL NEURAL NETWORKS

The Figure 4, network generally comprises of 3 layers, such as input, output, intermediate layer or the hidden layer shown in Fig.4. Each of these layers is made up of artificial neurons form wide network of neurons. Weights assigned the interconnection indicate strength of signal. Depending on the back - propagation algorithm, those weight values are modified.

Voltage and current values for the corresponding 3 stages are dissimilar and remain controlled through the fault category. Fault classification thus necessary a neural network that enables to identify type of fault from trends of voltages and currents produced from principles are calculated after a single terminal, electrical power system's three-phase transmission system. The neural network is calculated by sum 3 input quantities, i.e. the three-phase current etc. Using such six inputs, the neural network remains equipped. The number of total neural network output are in three stages A, B, C and four are grounded on three stage transmission networks. As we discussed protection and prevention of transmission line is most important work in order to safeguard electric the power systems. Hence, detection of faults in transmission lines, classified, and located accurately. Immediate action should be taken in very short duration whenever fault occurs. The proposed methods are based on the use of neural network and implementation of digital signal processing concepts.

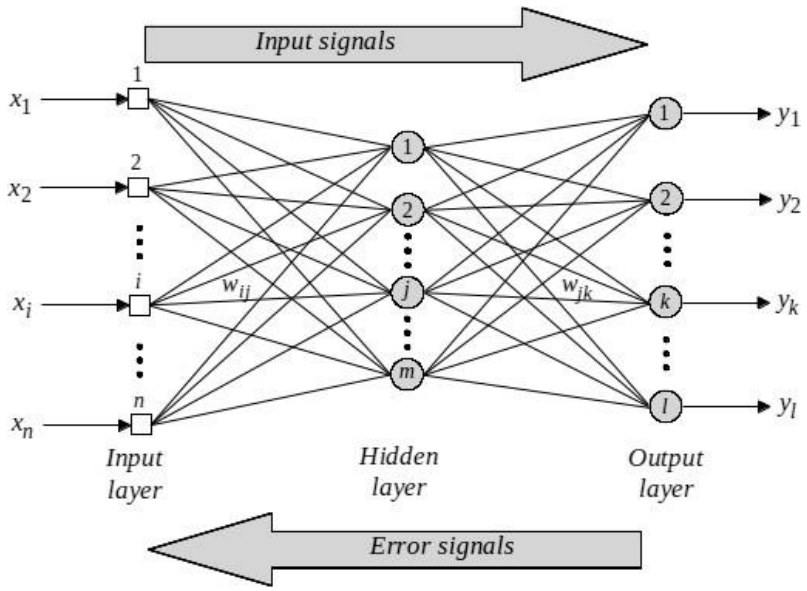

Figure 4: The Structure of BPN

SIMULATION RESULTS AND ANALYSIS

Over long distance power transmission normally high voltages are used. In our country standard voltages are used for power transmission over long distance. Moreover, cost is the main constraint for those transmission in terms of power lines, circuit breakers, insulators and transformers etc. In high voltage transmission those equipments cost are very high in the range above 230 KV. Using low power voltages, it is worth to check whether the required power can be transmitted. The different countries are following some standard voltage rating like 11 kV, 22 kV, and 33 kV for short lines, 66 kV and 110 kV for medium lines and 132 kV, 166 kV, 230 kV and above for long lines. Test data was obtained from MATLAB/ Simulink modeling, using 70-percent sample data and 30- percent testing dataset. Throughout comparison with WT, ANN has contributed to finding solutions with the power system, including such load estimation, error detection, fault diagnosis and structure. WT is also used for this method by converting the currents and voltage signals to find fault, artificial neural network identifies fault depending on the dissolved wavelet transform input signal. The normalized Voltage (v) and Current (i) are used as signals for the fault detection module and those signals samples are used for a fault location classification module. The results are shown in Figures 6 to 13.

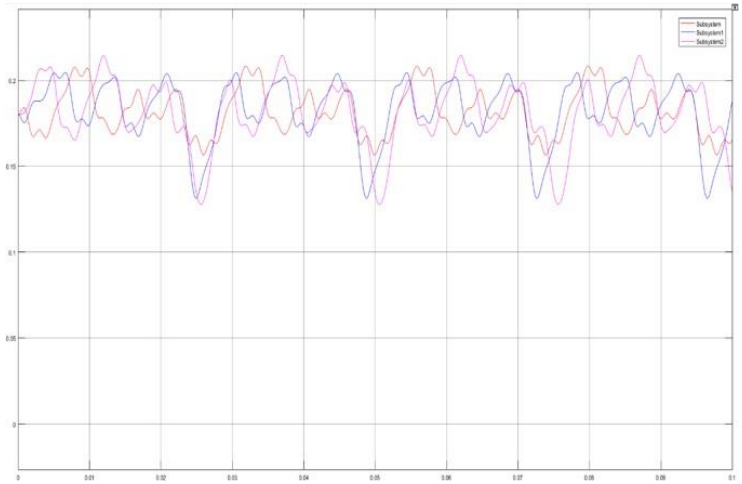

Figure 6: NO Fault

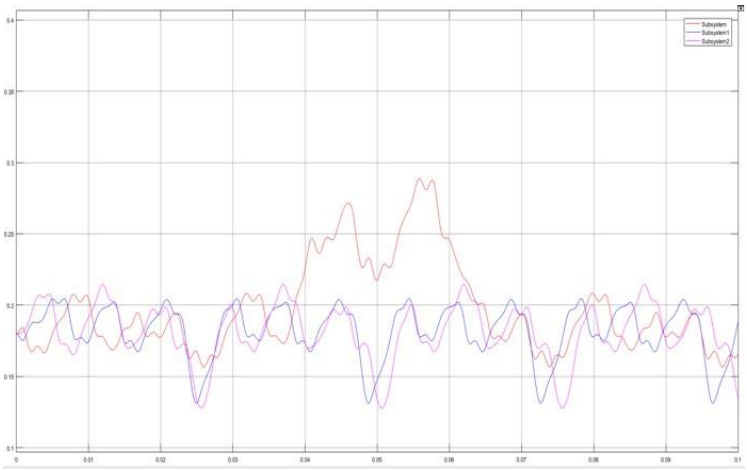

Figure 7: AG Fault

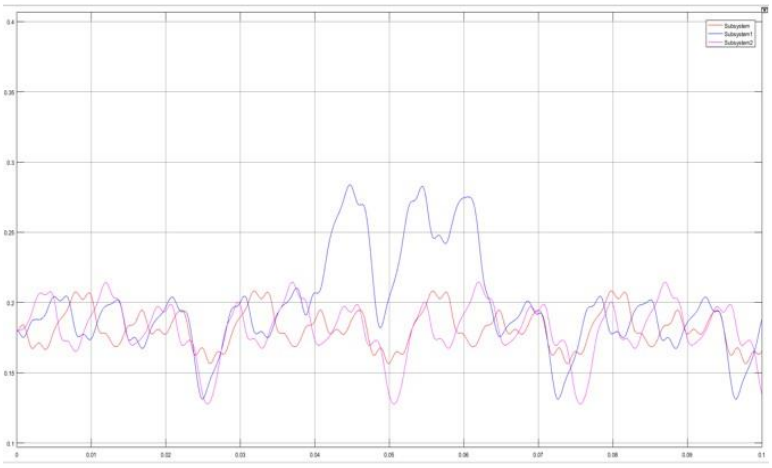

Figure 8: BG Fault

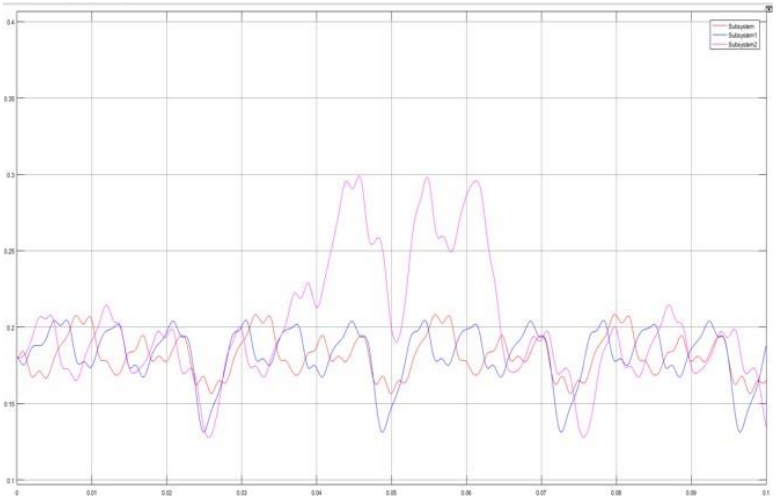

Figure 9: CG Fault

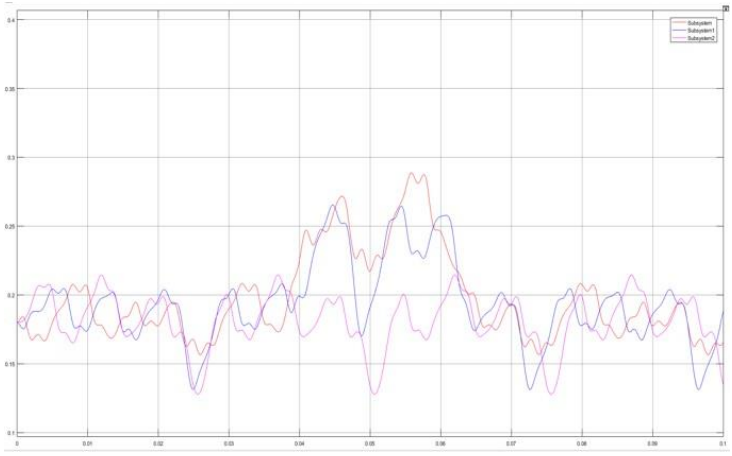

Figure 10: AB Fault

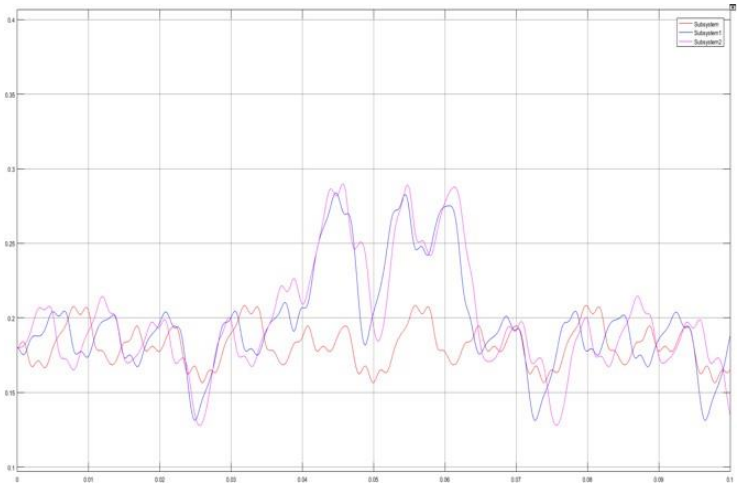

Figure 11: BC Fault

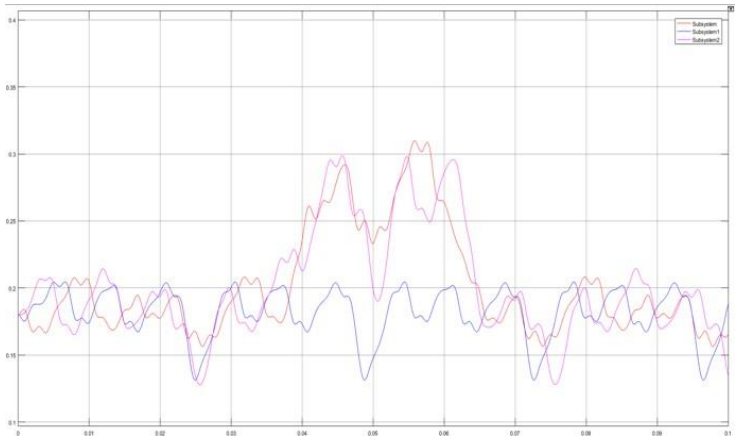

Figure 12: AC Fault

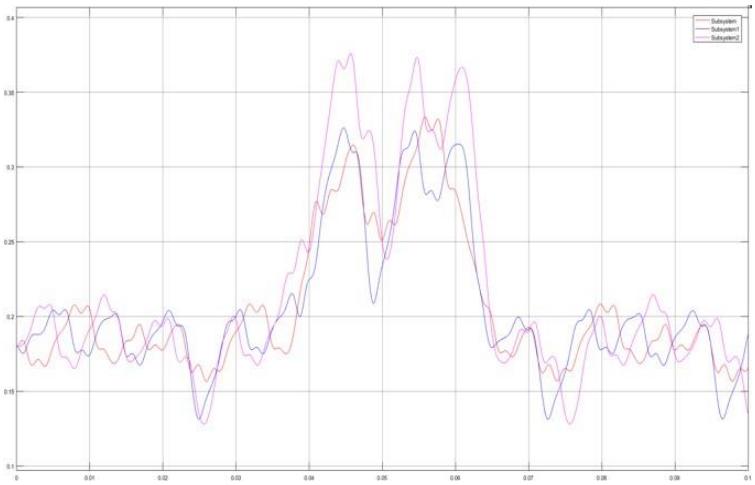

Figure.13: ABC Fault

It is observed from the above results during the fault voltages and currents more oscillations and it takes more time for settled. By using DWT with neural network based BPN technique is used to mitigate the voltage and current harmonics.

CONCLUSIONS

Different Faults are in the transmission lines and are affected by one of the elements that the reliability of the system. If the faults are increased it may reduce the reliable the system. Also it may disturb the service. The result of the experiment illustrates which all have proposed neural networks have achieved the satisfactory performance and are practically implementable. In this work, importance has been placed on the necessity of selecting the correct ANN model to get the maximum network output.

Abstract: *The Internet of Things (IOT) fills the gap between the real world and cyber world. This technology enables the world to achieve connectivity between objects by combining physical and digital world; through various objects such as; actuators, processors, sensors which communicate over the internet. It is one of the flourishing technologies in the world. A Distribution Static compensator (DSTATCOM) which is installed in a remote village of Warangal district is interfaced with IOT. In this paper we combine IOT with a DSTATCOM, to keep a check on the power factor and other transmission line parameters remotely. IOT technology is used to monitor the health conditions of the DSTATCOM, with the swift and apt notification feature using Gmail.*

Index Term **- Internet of Things (IOT), DSTATCOM, JAVA Programming, MATLAB.**

1. INTRODUCTION

Internet of Things (IOT) was first invented by Kevin Ashton in 1999. Internet of things is an integrated platform of devices or objects, interconnected to each other through wired/wireless mode and they share information to develop an application. The internet of things dwells in two parts; the first comprises of physical objects i.e. devices, vehicles, buildings and other items. The second part is the electronics, software sensors and network connectivity which are embedded to the first part. These enable the objects to collect and exchange data. The internet of things is an emerging topic of global technological advancements. Consumer products, household appliances and large industrial equipments are connected using this technology [1-2]. It provides connectivity and powerful data analytic capabilities that promise to transform the way we work, live, and play [3]. In the days IOT will become an imperative part of our daily life.

There are the major advantages and characteristics of IOT which can be utilized for the benefit of mankind. IOT is characterized such that everything can be connected to the global information and communication infrastructure [4]. It can be utilized to provide services within the constraints of things, such as privacy and consistency between physical and virtual things. The devices within IOT have different hardware and use different networks but they can still interact with other devices through different networks. It can be used to change the state of a device dynamically. Devices powered by IOT have a unique identity and unique identifier. They have the capability to dynamically adapt with the changing contexts and take actions based on their operating condition. These devices will be integrated with information network for communication purpose.

The IOT is cinch, elementary and uncomplicated, thus many modern day systems utilize this platform for the amelioration of their products. In an IOT based atmospheric environmental

monitoring system, the quality of air in terms of air pollution index can be measured using this system; without the restriction of place and space. The atmospheric environmental measurement device is linked to the environmental analyzer through LTE networks. The analysis is based on C# and DBMS, whereas the user application is implemented in C# Windows Presentation Foundation (WPF). This system is known to measure fine dust, ultra-fine dust and also ozone characteristics [5]. Among many prominent applications of IOT is wireless home automation using MQTT protocol. This system uses multiple sensors which notify the users in several ways for diverse devices [6]. The Application of IOT have also reached the agricultural field, where the concept of IOT based system is utilized to measure the temperature, humidity and water level moisture values of the field; resulting in the improved quality and quantity of the farm yield [7-8]. It is evident that the use of IOT technology in association with the other aspects of science and technology is trending as many embryonic technologies [9].

In this paper DSTATCOM is interfaced with IOT technology to improve power factor and real time monitoring of the distribution line. The calling mechanism of the JAVA program in MATLAB gives accurate results. The use of IOT technology for sending timely notifications in the case of a low power factor; is an efficient system for the monitoring of the health of the DSTATCOM.

2. WORKING OF INTERNET OF THINGS

A device powered by this technology can sense the environment and collect information related to it and transmit it to a different device of same or different networks. The users are entitled to set conditions for the working of the devices and these can be programmed into the device. The device can be actuated to other devices in correlation to the conditions set by the users. The device is designated to receive information from the network and to provide information between two devices of the same or different networks.

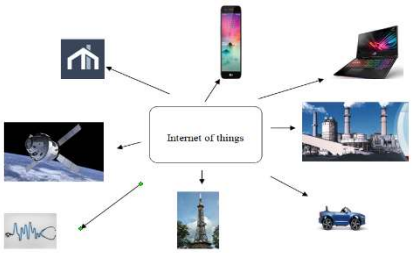

Fig 1 – Architecture of Internet of Things

The basic architecture of IOT is apparent and effortlessly simple. It consists of different layers which are interconnected to give the user the simplest working [10]. The precipitation layer consists of sensor devices. This layer covers and adjusts everything needed in the physical worlds to gain the necessary insights for further analysis. Next in line is the network layer, this layer is a connecting link between the upper and the lower layers. It forwards information from lower layers to the upper layer. This layer works through Wi-Fi, wired LANs and transmits the information between layers. The Middle layer is concerned with service management and storing the lower layer information into the database. This layer enables for follow-up revision and feedback for the lower layers. The application layer is known to manage the IOT applications. It is the frontend layer visible to costumers and used in daily lives. The top most layers is the business layer, it covers the entire IOT applications and service management [11]. It is a sophisticated integration of the architecture of IOT. The layered architecture of IOT provides stability and flexibility to the IOT devices and systems.

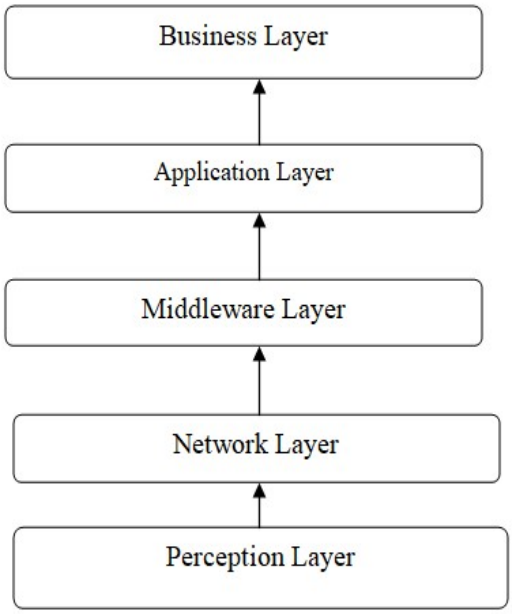

Fig 2- Layered Architecture

3. APPLICATIONS OF IOT TECHNOLOGY ON AN ELECTRICAL DEVICE – DSTATCOM

3.1 DSTATCOM

DSTATCOM is a shunt connected device crafted for power factor improvement, toning source currents and harmonic mitigation in distribution lines. It is meritoriously used in load compensation for balancing unbalanced load currents for various source voltage conditions [12]. In recent years Distribution Static Compensator (DSTATCOM) is the most active device used in distribution lines for easing of power quality hitches like high reactive power compensation, unbalanced loading conditions and low power factor. It be made up of of Voltage Source Inverter (VSI) [13]; controller to stimulate firing pulses for IGBT's in VSI, dc link capacitor and coupled at Point of Common Coupling (PCC) through an interfacing inductor to reduce ripple content in distribution line.

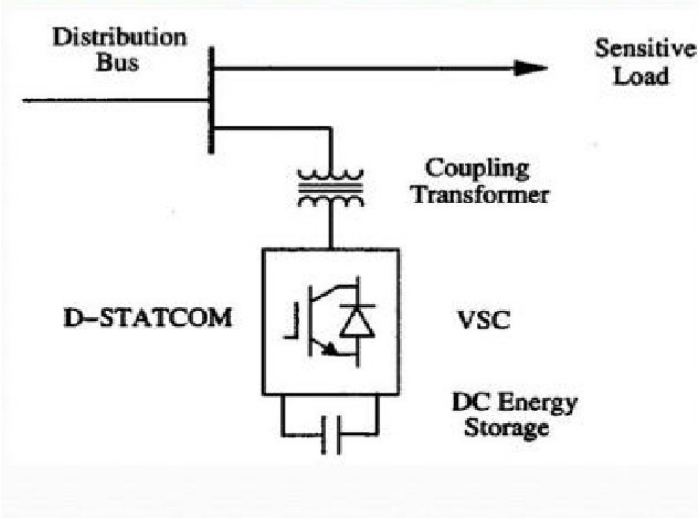

Fig 3 – DSTATCOM Block Diagram

3.2 APPLICATION OF DSTATCOM AND IOT

In this paper IOT technology is implemented to monitor the characteristics, performance and health of the DSTATCOM. A DSTATCOM has been installed in the rural village of state of Telangana, India called, Chandrayangutta. This village is situated in Warangal district, where

heavy motors are a cause of low power factor in the lines. Various power factor problems are analyzed in the considered village. A major issue for the villagers is the monitoring of the device. We aim at merging the two emerging technologies of IOT and DSTATCOM to improve the power factor and real time monitoring of the distribution line. The software is designed to identify low power factor conditions and communicate the same to the user. The communication module uses JAVA programming which is integrated in MATLAB through calling procedure. The interface of IOT with DSTATCOM is studied in terms of performance using MATLAB/SIMULINK, with the help of simulation results. The information of low power factor in the distribution line is collected by the IOT module and an email notification is to be sent to the users Gmail account.

The software is designed to process the low power factor in the DSTATCOM. JAVA Programming is used by the system in integration with MATLAB as a calling procedure.

3.3 THE LOW POWER FACTOR DISCRIMINATION ALGORITHM AS FOLLOWS:

1)Created java project with class DSTATCOM IOT.

2) Created class for Complex Number which holds the real and imaginary values in the form of data type double.

3) Created a utility class to handle arithmetic operations (add, subtract, multiply, square root, inverse, divide) between complex numbers and real numbers which are stored in the form of Complex Number object.

4) Created the static method called calculate Power Factor in DstatcomIot class which takes the Va, Vb, Vc, Ia, Ib, Ic, time, logflag as input in the forms of real and imaginary numbers to calculate Power Factor and returns the p,q,and pf values.

5) Created a map for getter and setter method to store variables like mailsSent, positivePFCount, negativePFCount, prevPF, switchoffTime .

6) MailsSent value prevents sending mails more than
Configured count (ex: send one mail per shut down of system)

7) PositivePFCount, negativePFCount, prevPF, switchoffTime values to prevents sending mails only when power factor reached lessthan desired value.

8) Additionally added a flag to print the input, output values.

9) Used a method called printData to print logs for any additional information required.

10) Created the jar file called DstatcomIot.jar file.

11) Created the javaclasspath.txt file in MATLAB BIN DIR ($MATLABHOME\BIN\) by adding jar classpath as content.

12) Created Matlab function which takes input Va, Vb, Vc and Ia, Ib, Ic.

13) Created statements to call java from Matlab [e.g.: code Extrinsic (“java method”)] and called calculatePowerFactor java method from matalab function by passing Va, Vb, Vc and Ia, Ib, Ic, time, logflag and capture the powerfactor.

14) Using the setValue, getValue method store and retrived the mailsSent, positivePFCount, negativePFCount, prevPF, switchoffTime variables to prevents unnecessary mails.

15) Developed logic for sending a mail when power factor level gets decreased.

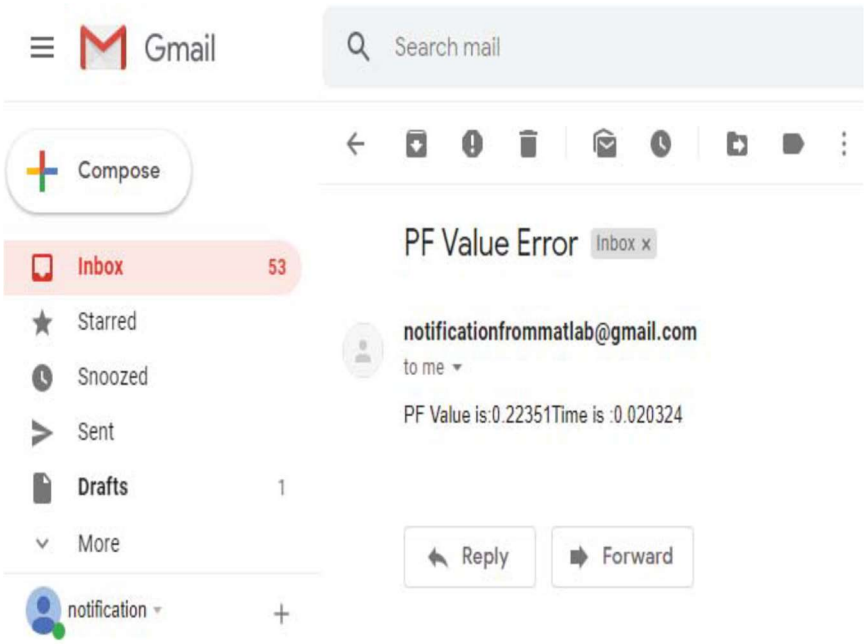

Fig 4 – Low power factor notification 1.

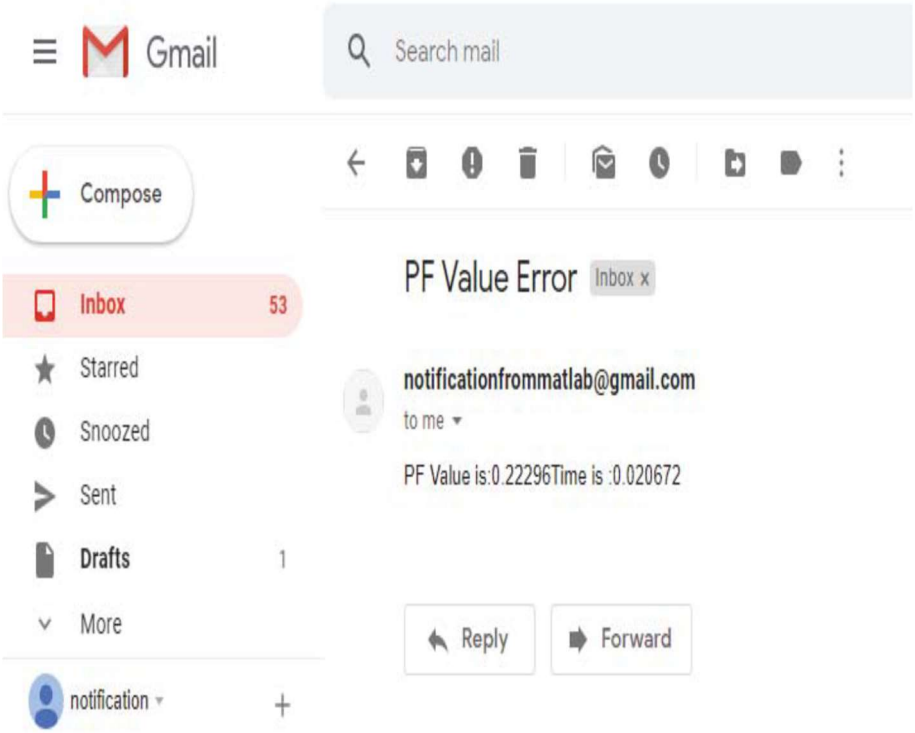

Fig – 5 Low power factor notifications 2.

It is observed that here a metering technology based on IOT is being used to solve this problem. Internet of things provides the connectivity between objects timelessly, seamlessly combining physical and digital world. The IOT based module is helpful in monitoring the results very precisely and it leads to taking necessary actions astutely and on time. Even the minute and very small variations can also be monitored remotely using this IOT technology. The monitoring of

the distribution line is metaphorical to one to one care using this system. The Internet of Things (IOT) represents a step beyond the utilization of conventional technology by increasing the use of wireless technology and provides real-time data acquisition. This system is evident to function without human presence at the site of fault, thus making it tranquil and efficient.

4. CONCLUSION

In this paper the use of IOT for the monitoring and control of an electrical device – DSTATCOM is proposed. This technology can be utilized for the real time monitoring of the distribution lines distantly. The IOT module is supported by the low power factor discrimination and communication module developed using JAVA Programming in MATLAB/SIMULINK. The results have proved that the use of IOT technology leads to monitoring of low power factor conditions. The data acquisition using IOT is very powerful and accurate. The mail sent to the registered user during the condition of low power factor is the most crucial part of the system, as this is responsible for the in-time action of switching on of the DSTATCOM. As, part of our future research we intend to develop a real time prototype; for the evaluation and on ground implementation of this technology. It is evident that the real time monitoring and timely action of the distribution system will increase the efficiency of the whole distribution system. Apparently, it has come to light that IOT is an emerging technology and a powerful tool which has its applications in various fields of work. It can flawlessly be known as a multidimensional technology useful in all works of life.

Abstract

In recent years the biometric system lacks in security due to fraudulent access. Old systems relayed on Multi-Spectral Imaging (MSI) for security which is found to be ineffective. The advanced technology in the biometric system to improve security is Image Quality Assessments (IAQ). In the previous system, the Multi-Spectral Imaging (MSI) was implemented in which the usual digital protection mechanisms and enhanced security systems are not effective. A novel software based biometric detection system is proposed here to detect the fraudulent biometric access attempts. It is used to enhance the security of biometric recognition systems. In this system from the original image, 30 image quality features are extracted, the same acquired for authentication purposes. Among various biometric recognition, finger recognition, iris recognition and face recognition are presented by using image quality assessment technique.

Keywords : Biometric, Finger Print, Multiplexer, Image Quality Assessment (IAQ) and Multi Spectral Imaging (MSI)

I. Introduction

Biometric advancements have developed as devices to help ID in a worldwide and versatile society (V). In Fig.1, the term biometrics in the data innovation field alludes to the particular utilization of identifiers or anatomical and social qualities for verification or acknowledgment purposes.

Numerous recognizable proof systems fathom three components:

1) Trait identifiers like Social Security Number, driver's permit number, account number,

2) True to life identifiers like location, calling, training, conjugal status, and

3) Biometric identifiers like a unique mark, voice, iris, face, and walk. Biometric systems, as different uses of example acknowledgment and AI, are influenced by the nature of information (VII).

Thusly, it is essential to quantitatively assess the nature of an example that is demonstrative of its capacity to work as a biometric.

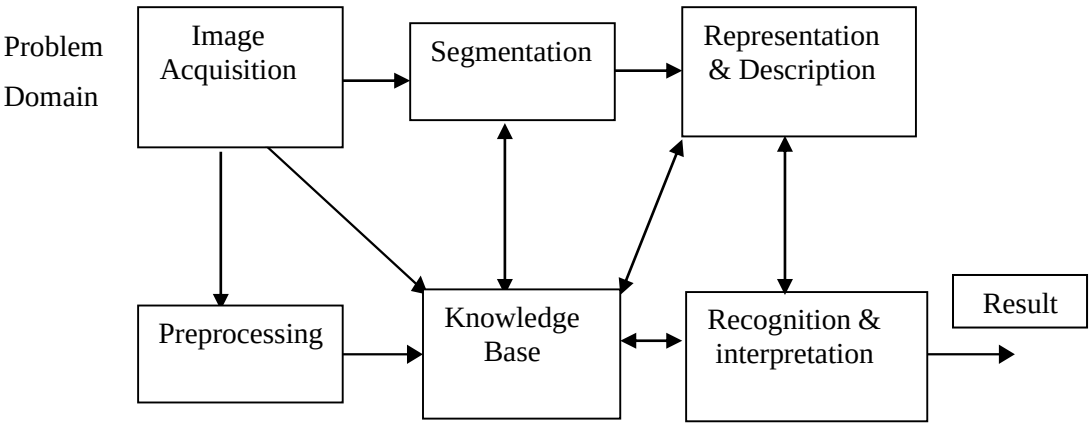

Fig. 1: Basic process of Biometric system

II. Methods

The basic role of a security system is used to present non-repudiable confirmation. Verification suggests that just genuine or authenticated users will access to the physical or sensible assets secured by the biometric system and (ii) impostors are kept from getting to the ensured assets (VIII). While a system can be undermined in various manners, one of the possibly harming assaults is the spillage of biometric layout data. The spillage of this format data to unapproved people comprises a genuine security and protection danger (IX).

Along these lines a model of making a joined details layout is proposed. By utilizing the joined details layout, the total particulars highlight of a solitary unique mark won't be undermined when the database is taken.

In Existing systems of fingerprint recognitions are need the protected datasets (VI). These systems showing the templates of two fingerprint structures, it's easily identified from hackers. The overcome of this drawback the proposed system has dot line templates, so the hackers are not easily identified that. Previous fingerprints output source is a template only. It's not possible for any other usable source. Existing

fingerprint system processes are direction and image wise template creation method. This system is not suitable for twins, some relationship members (III).

Mixing of Finger Prints

This work investigates the chance of blending two distinct fingerprints at the picture level to produce another fingerprint (I). To blend two fingerprints, each unique mark is disintegrated into two distinct parts, viz., the ceaseless and winding segments. After pre-adjusting the segments of each unique mark, the ceaseless part of one unique finger impression is joined with the winding segment of the other unique mark picture.

Direction Map β (X, Y)

The course is particularly characterized in the range 0◦ to 360◦ (modulo 2π). Interestingly, the unique mark edge direction is indistinct from that of a 180◦ pivoted edge (modulo π). Along these lines, the unique finger impression's direction map, signified by θ (x, y), ought to be opened up to a bearing guide, β (x, y). Stage opening up is a procedure used to address a 2π stage hop in the direction map. The opening up process includes or takes away a balance of 2π to progressive pixels at whatever point a stage hop is identified. This procedure continues by beginning at any pixel inside the direction picture and utilizing the nearby direction data to navigate the picture pixel-by-pixel, and doling out a course (i.e., the crossed bearing) to every pixel with the condition that there are no discontinuities of 2π between neighboring pixels. Notwithstanding, the nearness of stream singularities implies that there will be pixels in the direction picture with brokenness of±2π the crossed way and, accordingly, the above opening up procedure will come up short.

Helmholtz Decomposition

The Helmholtz Decomposition Theorem is utilized to deteriorate the decided stage Ψ(x, y) of a unique finger impression picture into two stages. The principal stage, ψc is a consistent one, which can be opened up, and the second is a winding stage, ψs, which can't be opened up yet can be characterized as a stage that displays winding conduct at a lot of discrete focuses in the picture. The Bone's buildup indicator is first used to decide the winding stage ψs(x, y) from the demodulated stage Ψ(x, y). Next the consistent stage, is figured as ψc(x, y)=ψ(x,y)−ψs(x, y). At long last, the separated branch cuts from the past advance are utilized again to open up the nonstop stage. This method needs two separate databases to cooperate. It prompts a decrease in coordinating precision. The client personality may likewise be undermined when both the key and the ensured diminished unique mark are taken.

III. Proposed System

An epic system for securing unique mark protection by consolidating two distinct fingerprints into another personality is proposed. We extract the target positions from unique finger impression, the direction from the other unique mark, and the reference focuses from the two fingerprints. In light of this removed data and our proposed coding methodologies, consolidated details layout is created and put away in a database. In the verification, the system requires two question fingerprints

from a similar two fingers which are utilized in the enlistment. A two-phase unique mark coordinating procedure is proposed for coordinating the two question fingerprints against a consolidated details layout. By putting away the joined details layout, the total particulars highlight of a solitary unique finger impression won't be undermined when the database is taken.

In Existing systems of fingerprint recognitions are need the protected datasets. These systems showing the templates of two fingerprint structures, it's easily identified from hackers. The overcome of this drawback the proposed system has dot line templates, so the hackers are not easily identified that. The previous fingerprints output source is a template only. It's not possible for any other use source. Existing fingerprint system processes are direction and image wise template creation method. This system is not suitable for twins, some relationship members.

Reference Points Detection

In Fig.2, The reference point's location procedure is performed by utilizing complex channels for particular point recognition. Given a unique mark, the principle steps of the reference point's identification are summed up as follows:

1. Compute the direction from the unique finger impression utilizing the direction estimation calculation. The direction is gotten in complex space.
2. Calculate an assurance guide of reference focuses utilizing a convolution administrator, which is the portion for reference focuses identification.
3. Calculate an improved assurance map.
4. Identify a measuring target fulfilling the 2 measures
5. Sufficiency of the matter is a nearby greatest
6. The nearby most extreme ought to be over a fixed limit.
7. Repeat advance (4) till all found.
8. If no target is detected to the unique finger impression in 4 and 5 (e.g., a curve unique mark), find a reference point with the greatest sureness esteem in the entire unique finger impression picture.

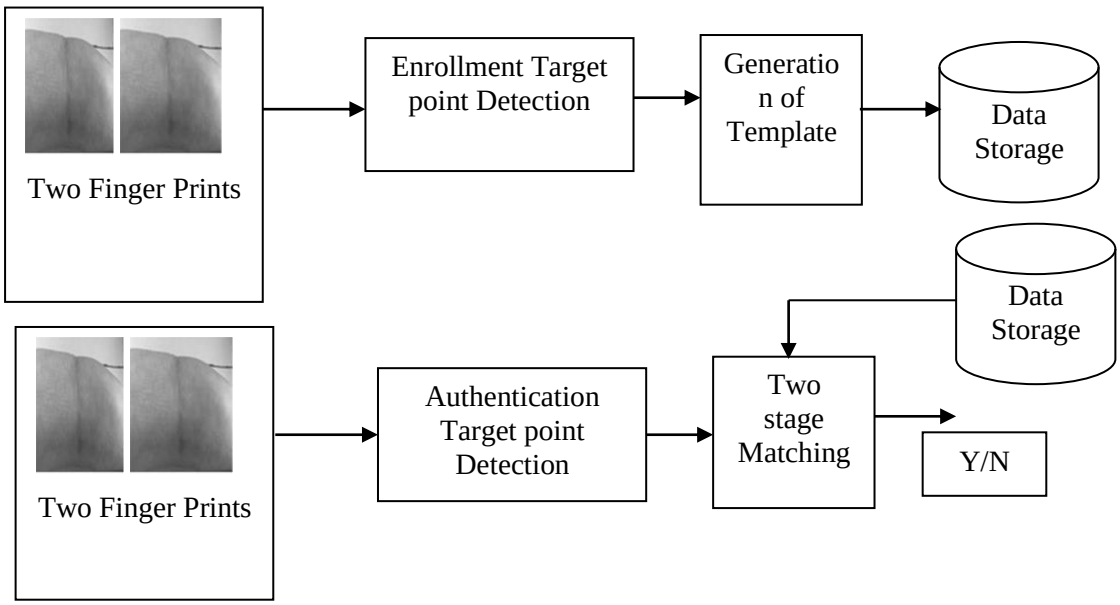

Fig. 2: Proposed system

IV. Results and Discussion

For each unique mark, we characterize the reference point closest to the checked top most circle as the closest reference point for effortlessness. The reference focuses are viewed as really distinguished if the Euclidian separation between the checked top most loop and the closest reference point is under 35 pixels. Something else, the reference focuses are considered to be erroneously identified. Table .1 shows the presentation of the reference focuses identification at various settings of edge, where "No." alludes to the all-out number of reference focuses distinguished among the 250 fingerprints. It tends to be seen that setting T = 7 will accomplish a decent harmony between the exactness and proficiency. By setting 0.5 and T = 7 the normal Euclidian separation between the checked highest circle and the closest reference point is 6.50 pixels.

Table 1: Detection of reference points

	3	**4**	**5**	**6**
Number	1100	610	271	195
True Detection Rate (%)	99.9	99.9	99.9	99.0
False Detection Rate (%)	0.1	0.1	0.1	1.0

Fig. 3: Detection of Target Points in Finger prints

Fingerprint with only one reference point in Fig.3a and the corresponding certainty value map in Fig.3b; fingerprint with two reference points in Fig.3c and the corresponding certainty value map in Fig.3d as shown in Figure 3.Furthermore, by adopting such settings, will only detect one reference point for the majority of fingerprints, which is the loop as shown in Fig. 3a and 3b. In Fig. 3c and 3d illustrate an example with two reference points detected. The reliability of the angle of the nearest reference point (by setting σ=1.7 and T = 7) for each of the 250 fingerprints is measured as follows:

Rotate the imaginative fingerprint from -30 to 30 degrees with 2 degrees per step base on the highest loop distinct before.

Achieve the reference point's recognition for the creative fingerprint and its rotated version. The angle of the nearby reference point of the creative fingerprint is denoted as α0, and the matching angle for each of the rotated versions as αq, where q = -30,-29,...-2,2,4,...30 refers to the degree of rotation.

approximate the degree of rotation for every rotated version by,

$$\bar{q} = \alpha q - \alpha 0$$

calculate the supreme estimation error for each rotated version by,

$$e = \bar{q} - q$$

Calculate the mean and standard deviation of all the rotated versions, which are denoted as ***emean*** and ***estd,*** respectively. Among all the 250 fingerprints, the average ***emean*** and ***estd*** are 1.90 degrees and 2.10 degrees, respectively.

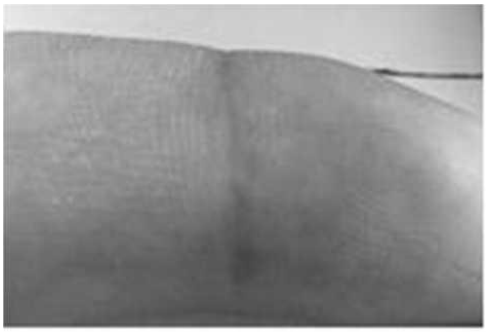

Fig. 4: Original fingerprint

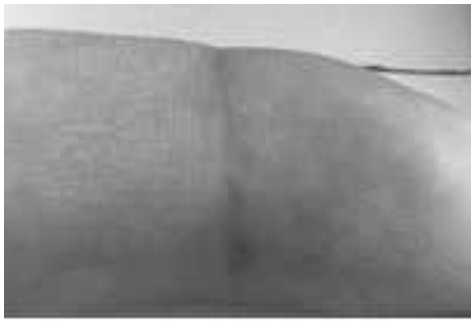

Fig. 5: Trained fingerprint

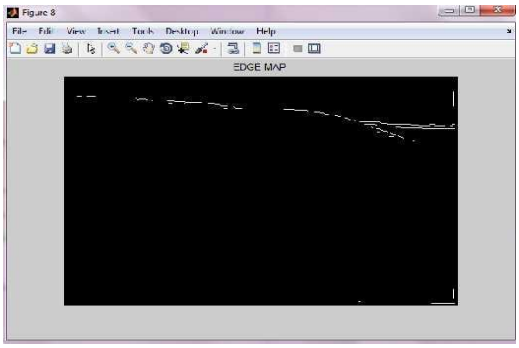

Fig. 6: Edge map of original image

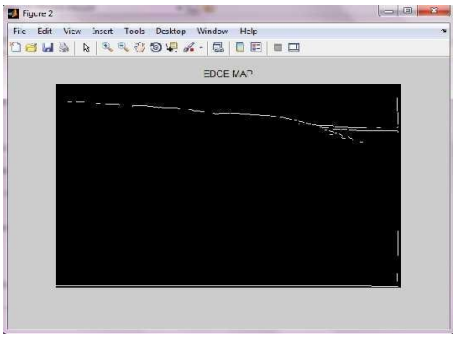

Fig. 7: Edge map of trained image

The original and trained finger prints are shown in Figs 4 and 5. The implementation of an edge map of the original image and trained images are presented in Figs 6 and 7. For over a century, a criminal agent has utilized fingerprints to recognize associates on the premise with proof left at the wrongdoing scene (VIII) (IX). Though unique finger impression was once thought about outwardly, today PCs accelerate the procedure: the computerized fingerprints ID system, presently utilized in most western nations, analyzes follows found at a wrongdoing scene with a large number of putting away unique mark pictures in only a couple of moments. As of late, the police in different German urban communities presented portable, empowering correlation with be made quickly over versatile correspondence systems. Be that as it may, it isn't just criminal agent who utilize such innovation; numerous business gets to control system use distinguishing proof system dependent on biometrics the computerized acknowledgment of people by utilizing conduct or natural qualities. Notwithstanding fingerprints, biometric advancements can utilize a rich assortment of anatomical attributes, for example, pictures of the face, iris or retina, the portrayal of the geometry of the hand.

V. Conclusion & Future Scope

The investigation of the vulnerabilities of biometric systems against various sorts of assaults has been a functioning field of exploration as of late. This intrigue has led to large advances in the field of security-upgrading advances for biometric-based applications. In any case, despite this observable improvement, the advancement of productive security techniques against realized dangers has demonstrated to be a difficult errand. Basic visual investigation of a picture of a genuine biometric attribute and a phony example of a similar characteristic shows that the two pictures can be fundamentally the same as and even the natural eye may think that it's hard to make a qualification between them after a short assessment. However, a few inconsistencies between the genuine and phony pictures may become clear once the pictures are converted into an appropriate component space. These distinctions originate from the way that biometric attributes, as 3D objects, have their optical characteristics (assimilation, reflection, dissipating, refraction), which different materials (paper, gelatin, electronic showcase) or artificially delivered tests don't have. Moreover, biometric sensors are intended to give great quality examples when they interface, in a typical activity condition, with a genuine 3D attribute. On the off chance that this situation is changed, or if the attribute introduced to the scanner is a surprising phony curio (2D, diverse material, etc.), the qualities of the caught picture may essentially fluctuate. These systems additionally use conduct or physiological qualities, for example, a composed mark, voice or the composing design on the console. Such capacity makes an individual sign that can be estimated by biometric innovation.

***Abstract*— Energy storage technology (EST) is an important way to boost the power output of renewable energy production (such as solar and wind energy), but it is difficult for a single energy storage device (ESS) to satisfy the demand for secure grid service. A battery / super-capacitor HESS is proposed according to the configuration and operating characteristics of the current battery / super-capacitor hybrid energy storage system (HESS). The HESS work theory and three working modes (the super-capacitor pre-loading cold stand-by mode, boost mode and buck mode) are studied in detail. The boost mode and buck mode state equations are extracted. To create the small signal equivalent model under the buck / boost mode, the state space average method is used. In addition, the HESS charge and discharge control technique is obtained via the combination of the closed-loop voltage control. In Matlab / Simulink, the simulation model is designed to verify the efficacy of the suggested HESS and its control strategy. The results show that the HESS and its control strategy can ensure good stability and superior anti-interference of the DC bus voltage, and can simultaneously produce large current, increase battery life and improve the technological economy of storage of energy.**

***Index Terms*— Battery, bi-directional DC/DCconverter, HESS, super-capacitor, voltage closed Loop.**

I. INTRODUCTION

With the large amount of renewable energy utilized in the grid, renewable energy power generation (such as solar energy and wind energy) is going to play an indispensable role in the future development of the power system [1]. However, the output power of distributed generation (DG) units are intermittent and random, which brings new challenges to the safe and stable operation of the power system [2, 3]. space, size, weight, changes in transmission, control strategy management etc. Existing on-board Energy storage technology (EST) with the function of "peakcutting and valley filling" is an effective way to solve the power quality of renewable energy generation, and it is also the key technology to ensure the safe and stable operation of the grid [4].The hybrid energy storage system (HESS) has been becoming a hot research topic because it can overcome the limitations of the single energy storage system (ESS) (low power density, low energy density, slow effect speed and short life, etc.) and combine the advantages of both [5]. The ESS is mainly composed of two parts: an energy storage unit and a bi-directional DC/DC converter [6]. A battery ESS can reduce the fluctuation of wind energy output in wind power generation, but the power density of the battery is low [7]. A super-capacitor ESS can realize the storage of regenerative braking energy in urban rail transit, but the low energy density of the super-capacitor may affect the safe and stable operation of the train [8]. An isolated bi-directional DC/DC converter can achieve high power density and current isolation, but when the isolation transformer exists, the leakage inductance and control of the transformer should be considered [9]. Authors of [10] have proposed a high ratio DC/DC converter, which can effectively reduce the voltage stress of the switch. A high-power bi-directional DC/DC converter for distributed photovoltaic power generation has been suggested by [11], which can maximize the solar energy collection capacity.An HESS of a battery and super-capacitor has been presented [12], which effectively combines the advantages of both and reduces the impact of wind energy fluctuation.

However, the HESS is a parallel two independent branches with complex control and poor economy. The application of the HESS in the grid is investigated [13–15]. The results show that the HESS can effectively combine the advantages of a battery and super-capacitor, stabilize the stable operation of the grid and improve the battery life.Based on the study of energy storage requirements for safe and stable operation of a DC microgrid, this paper proposes a battery/super-capacitor HESS, which adopts voltage closed-loop control to improve the voltage stability of a DC bus and the anti-interference performance of the HESS. This paper compares the recovery effect of the HESS and battery ESS on the DC bus voltage to illustrate the advantages of the HESS.

The specific arrangement of the paper is as follows: Section 2 exhibits the topological structure and working principle of the proposed HESS, while section 3 displays the control strategy of the HESS. Section 4 introduces the simulation results and analysis of the system. Finally, section 5 summarizes the article and shows the next work.

II. SYSTEM CONFIGURATION AND WORKING PRINCIPLE

2.1. System configuration

The HESS shares a set of a DC/DC converter, adds a diode D with the function of selective switch, and adds a separate pre-charging circuit as cold stand-by to ensure the normal operation of the super-capacitor. The specific topology is shown in Fig. 1. Among them, UE and UC are the battery and super-capacitor terminal voltages, respectively, and U_d is the DC bus terminal voltage.

2.2. Working modes of the system

The HESS has three working modes: the super-capacitor pre-charging cold stand-by mode, the boost mode and buck mode.

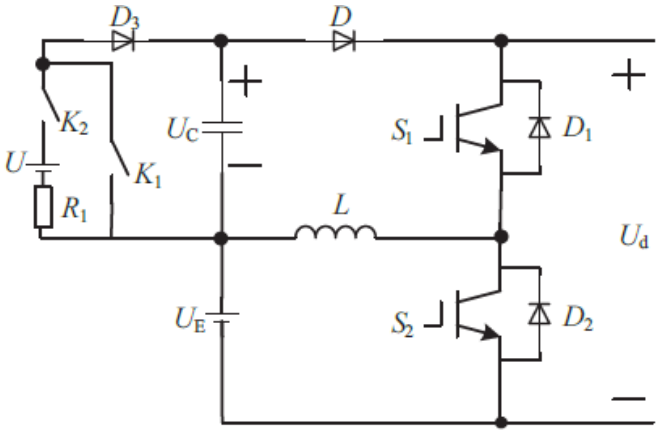

Fig. 1. Structure of battery-super-capacitor HESS

Case 1: the super-capacitor pre-charging cold stand-by mode

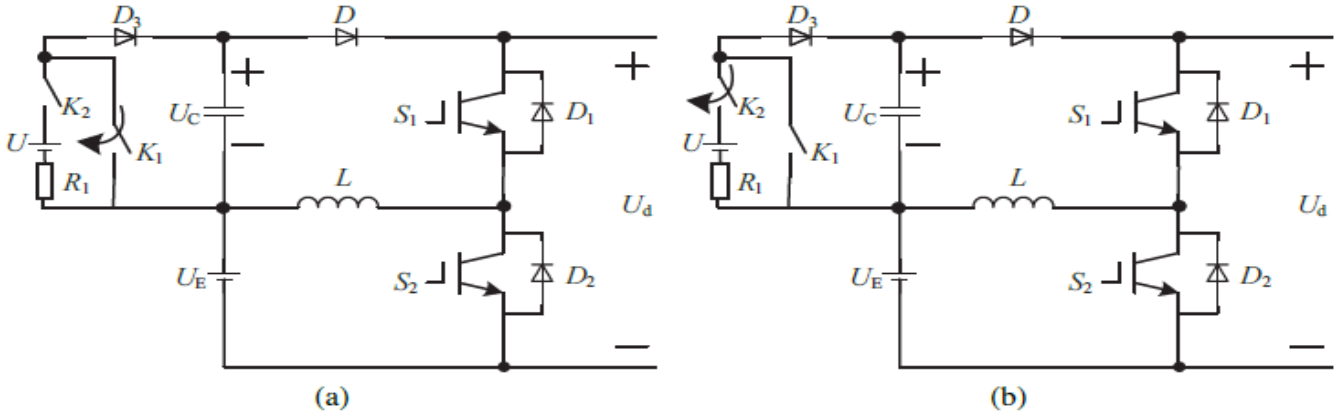

Fig. 2. Equivalent circuit diagram in supercapacitor pre-charging mode:
Working state 1 (a); working state 2 (b)

When the system is in the stand-by state, provided that UC is detected to be in safe working voltage, K1 is closed and K2 is opened. The equivalent circuit diagram is shown in Fig. 2(a). As can be seen from Fig. 2(a), D3 is cut off due to reverse voltage UC, and the super-capacitor pre-charge circuit will not work [16]. Provided that UC is detected to be lower than the cut-off voltage, K1 is opened and K2 is closed. The equivalent circuit diagram is shown in Fig. 2(b). As can be seen from Fig. 2(b), D is cut off due to reverse voltage, and the super-capacitor is in the pre-charge mode.

The super-capacitor pre-charging mode is actually a first-order RC circuit. Power supply U (power supply U is actually introduced from the DC bus voltage to improve the economy of ESS) charges the super-capacitor through discharge resistance R1. Meanwhile, the pre-charge circuit of the proposed topology has been applying the pre-charge of capacitor voltage in the sub-module of the modular multilevel converter.

Case 2: the buck mode

When the DC bus voltage rises, the system operates in the buck mode. Its equivalent circuit diagram is shown in Fig. 3. In buck mode, the anti-parallel diode D2 of switch S2 and switch S1 works alternately.

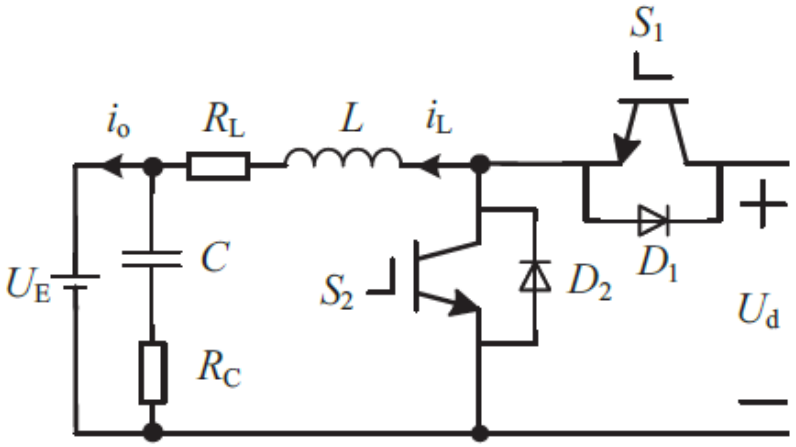

Fig. 3. Equivalent circuit diagram of buck mode

Define switch function *S*:

$$S = \begin{cases} 1 & \text{the } S_1 \text{ or } S_2 \text{ is turned on} \\ 0 & \text{the } S_1 \text{ or } S_2 \text{ is turned off} \end{cases}. \tag{1}$$

According to Fig. 3, the corresponding equation of the state can be obtained as follows:

$$\begin{pmatrix} \frac{di_L}{dt} \\ \frac{du_C}{dt} \end{pmatrix} = \begin{pmatrix} \frac{1}{L} & -\frac{R_L}{L} \\ 0 & \frac{1}{C} \end{pmatrix} \begin{pmatrix} S U_d \\ i_L \end{pmatrix} + \begin{pmatrix} -\frac{1}{L} & 0 \\ 0 & -\frac{1}{C} \end{pmatrix} \begin{pmatrix} U_E \\ i_o \end{pmatrix}. \tag{2}$$

According to Equation (2) and the state space average method [17], the corresponding average equation can be obtained:

$$\begin{pmatrix} \frac{\mathrm{d}i_{\mathrm{L}}}{\mathrm{d}t} \\ \frac{\mathrm{d}u_{\mathrm{C}}}{\mathrm{d}t} \end{pmatrix} = \begin{pmatrix} \frac{D}{L} & -\frac{R_{\mathrm{L}}}{L} \\ 0 & \frac{1}{C} \end{pmatrix} \begin{pmatrix} U_{\mathrm{d}} \\ i_{\mathrm{L}} \end{pmatrix} + \begin{pmatrix} -\frac{1}{L} & 0 \\ 0 & -\frac{1}{C} \end{pmatrix} \begin{pmatrix} U_{\mathrm{E}} \\ i_{\mathrm{o}} \end{pmatrix}, \tag{3}$$

Where:

$D = t_{\mathrm{on}}/(t_{\mathrm{on}} + t_{\mathrm{off}})$, is the duty cycle of S_1.

Added disturbance:

$$\begin{cases} d = D + \hat{d} \\ i_{\mathrm{L}} = I_{\mathrm{L}} + \hat{i}_{\mathrm{L}} \\ u_{\mathrm{d}} = U_{\mathrm{d}} + \hat{u}_{\mathrm{d}} \\ u_{\mathrm{E}} = U_{\mathrm{E}} + \hat{u}_{\mathrm{E}} \\ u_{\mathrm{C}} = U_{\mathrm{C}} + \hat{u}_{\mathrm{C}} \end{cases} . \tag{4}$$

By substituting Formula (3), the small signal transfer function of control-voltage can be obtained through the Laplace transformation:

$$G_{v\mathrm{d}1} = \left. \frac{\hat{u}_{\mathrm{E}}(s)}{\hat{d}(s)} \right|_{\hat{u}_{\mathrm{d}}(s)=0} = \frac{U_{\mathrm{d}}(s)}{LCs^2 + R_{\mathrm{L}}Cs + 1} . \tag{5}$$

Case 3: the boost mode

When the DC bus voltage decreases, the system operates in the boost mode. Its equivalent circuit diagram is shown in Fig. 4. In the boost mode, the anti-parallel diode D1 of switch S1 and switch S2 works alternately.

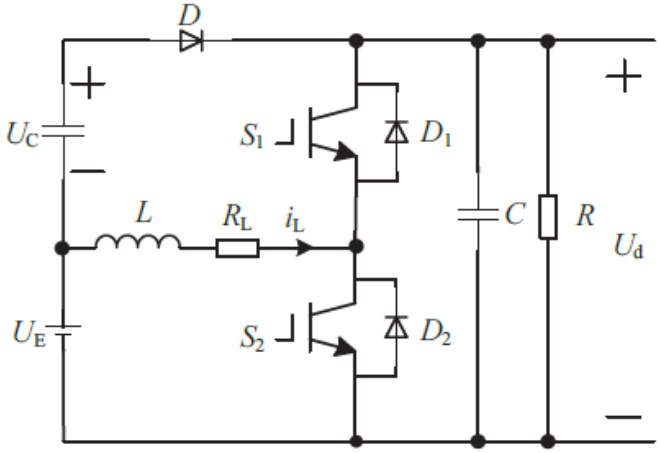

Fig. 4. Equivalent circuit diagram of boost mode

According to Fig. 4, the corresponding equation of the state can be obtained as follows:

$$\begin{pmatrix} \frac{\mathrm{d}i_{\mathrm{L}}}{\mathrm{d}t} \\ \frac{\mathrm{d}u_{\mathrm{d}}}{\mathrm{d}t} \end{pmatrix} = \begin{pmatrix} -\frac{(1-S)}{L} & -\frac{R_{\mathrm{L}}}{L} \\ \frac{1}{RC} & \frac{(1-S)}{C} \end{pmatrix} \begin{pmatrix} U_{\mathrm{d}} \\ i_{\mathrm{L}} \end{pmatrix} + \begin{pmatrix} \frac{1}{L} \\ 0 \end{pmatrix} U_{\mathrm{E}}. \tag{6}$$

According to Equation (6) and the state space average method, the corresponding average equation can be obtained:

$$\begin{pmatrix} \frac{\mathrm{d}i_{\mathrm{L}}}{\mathrm{d}t} \\ \frac{\mathrm{d}u_{\mathrm{d}}}{\mathrm{d}t} \end{pmatrix} = \begin{pmatrix} -\frac{(1-D)}{L} & -\frac{R_{\mathrm{L}}}{L} \\ \frac{1}{RC} & \frac{(1-D)}{C} \end{pmatrix} \begin{pmatrix} U_{\mathrm{d}} \\ i_{\mathrm{L}} \end{pmatrix} + \begin{pmatrix} \frac{1}{L} \\ 0 \end{pmatrix} U_{\mathrm{E}}, \tag{7}$$

Where:

$D = t_{\mathrm{on}}/(t_{\mathrm{on}} + t_{\mathrm{off}})$, is the duty cycle of S_2.

By substituting Formula (4) into Formula (7), the small signal transfer function of control- voltage can be obtained through the Laplace transformation.

$$G_{\mathrm{vd2}} = \left.\frac{\hat{u}_{\mathrm{d}}(s)}{\hat{d}(s)}\right|_{\hat{u}_{\mathrm{d}}(s)=0} = \frac{U_{\mathrm{d}}(s)\left(D' - \frac{R_{\mathrm{L}} + sL}{RD'}\right)}{LCs^2 + \left(R_{\mathrm{L}}C + \frac{L}{R}\right)s + \frac{R_{\mathrm{L}}}{R} + D'}, \tag{8}$$

where: D`= 1-D

3. CONTROL STRATEGY

The energy management of the HESS mainly depends on the control strategy of a bi-directional DC/DC converter, that is, the charge and discharge of a battery and super-capacitor bank are realized by controlling the bi-directional DC/DC converter. It is the core of control to keep the voltage of the DC bus constant. In this paper, the voltage closed-loop control is used to make the DC bus voltage stable at the rated voltage quickly. The way to generate the control pulse of the bi-directional DC/DC converter is mainly composed of complementary pulse width modulation (PWM) and independent PWM. The difference between them is whether the driving signals of S1 and S2 are complementary. In order to improve the stability of the system, the independent PWM mode is used.

The bi-directional DC/DC converter control strategy of the HESS consists of two parts: a logic judgment unit and a voltage closed-loop control unit. The specific control block diagram is shown in Fig. 5. When the voltage U_d suddenly rises (such as locomotive braking process), the difference ΔUd1 between the reference voltage U^*_d at the DC bus and the actual value Ud, then the theoretical duty cycle d'_1 is obtained through PI and the limiting link, and then the current actual duty ratio d1 is obtained by combining the independent PWM mode. At this time, the HESS works in the buck mode, S2 is off, S1 is in PWM. When the voltage U_d suddenly drops (such as the starting process of the locomotive), the difference ΔUd_2 between the reference voltage U^*_d at the DC bus and the actual value U_d, then the theoretical duty cycle d'_2 is obtained through the proportional-integral (PI) and limiting link, and then the current actual duty ratio d_2 is obtained by combining the independent PWM mode. At this time, the HESS works in the boost mode, S1 is off, S2 is in the PWM. The PI is used to realize the tracking control of U_d at the DC bus to U_d ref.

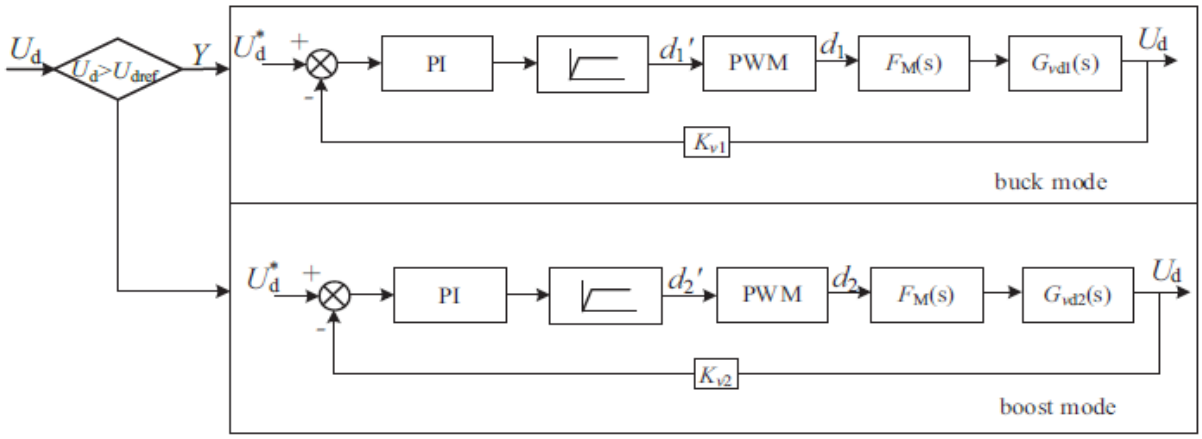

Fig. 5. Control strategy block diagram of bi-directional DC/DC converter for HESS

3.1. Simulation results and discussion

In order to verify the effectiveness of the HESS and its control strategy, Matlab/Simulink scientific computing environment was used to simulate, and the main simulation parameters of the system are shown in Table 1. Fig. 6 shows the pre-charge waveform of the super-capacitor when the discharge depth of the super-capacitor is 50%. From Fig. 6, it can be seen that when the super-capacitor voltage is detected to be reduced to 24 V or below, the super-capacitor pre-charging circuit is activated to Charge the super-capacitor. At 600 ms, the super-capacitor voltage reaches 47.2 V, and the power supply will be restored to the normal working voltage. Meanwhile, the pre-charge time of the super-capacitor is within a reasonable range [18].

Table 1. Main simulation parameters of the system

Parameter name	Symbol	Value	Unit
Battery voltage	U_E	48	V
Super-capacitor voltage	U_C	48	V
DC bus voltage	U_d	120	V
Inductance	L	8.2×10^{-5}	H
Discharge resistance	R_1	6.94×10^{-5}	Ω
Output capacitance	C	3.76	mF

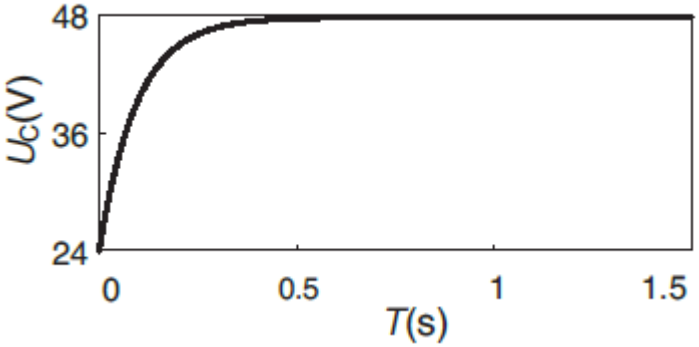

Fig. 6. Pre-charging waveform of super-capacitor

Case 1: no load disturbance

When the DC bus voltage suddenly decreases (such as the moment of motor start, etc.), the system works in the boost mode. Fig. 7 shows the waveform of the DC bus voltage *U*d of the HESS and the battery ESS in the boost mode when the DC bus voltage is reduced to 90 V. It can be seen from Fig. 7 that under the HESS, the maximum voltage *U*d at the DC bus is 134.1 V, and the *U*d stability value is 120 V; the system overshoot is about 11.6%; the system regulation time is 0.95 ms; the voltage ripple is about 0.73%, less than 2%. Under the battery ESS, the stable value of the DC bus voltage *U*d is 123.9 V, the stable value of *U*d is 119.8 V; the system overshoot is about 3.5%; the system regulation time is 1.45 ms. The regulation time of the battery ESS is 34.5% longer than that of the HESS. Therefore, the DC bus voltage recovery effect and dynamic
Performance of the HESS in the boost mode are better than that of the battery ESS.
When the DC bus voltage suddenly increases (such as locomotive braking process, etc.), the system works in the buck mode. Fig. 8 shows the waveform of the DC bus voltage Ud in the buck= mode when the DC bus voltage increases by 150 V. It can be seen from Fig. 8 that under this condition, the stable value of the DC bus voltage Ud is 118.55 V; the system overshoot is about 11.25%; the system regulation time is 0.8 ms; the voltage ripple is about 0.75%, less than 2%.

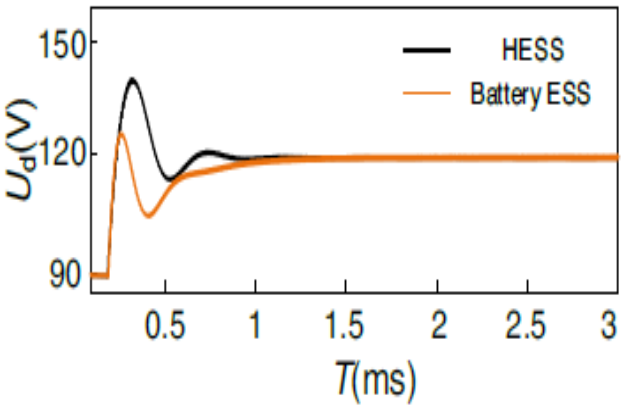

Fig. 7. Waveform of boost mode

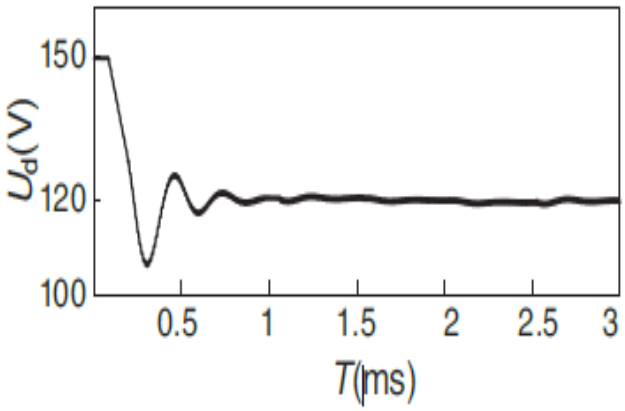

Fig. 8. Waveform of buck mode

Case 2: adding load disturbance

When the DC bus voltage suddenly decreases (such as the moment of motor start, etc.), the system works in the boost mode. A periodic load disturbance is added at 1 ms to decrease the DC bus voltage, and a periodic load disturbance is added at 2 ms to increase the DC bus voltage. Fig. 9 shows the waveform of the voltage Ud at the DC bus of the proposed HESS in the boost Mode when the load disturbance is added. It can be seen from Fig. 9 that the voltage at the DC bus drops to 111.8 V in 1 ms and recovers to 120 V after 0.305 ms; the voltage at the DC bus rises to 129.5 V in 2 ms and recovers to 120 V after 0.385 ms. When the DC bus voltage suddenly increases (such as locomotive braking process, etc.), the system works in buck mode. A periodic load disturbance is added at 1 ms to decrease the DC bus voltage, and a periodic load disturbance is added at 2 ms to increase the DC bus voltage. Fig. 10 shows the waveform of the DC bus voltage Ud in buck mode of the proposed HESS when the load disturbance is added. It can be seen from Fig. 10 that the voltage at the DC bus drops to 114.3 V in 1 ms and recovers to 119.8 V after 0.41 ms; the voltage at the DC bus side rises to 126.3 V in 2 ms and recovers to 119.8 V after 0.39 ms.

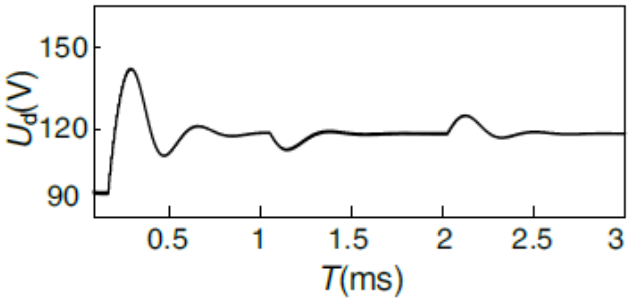

Fig. 9. Waveform of boost mode with load disturbance

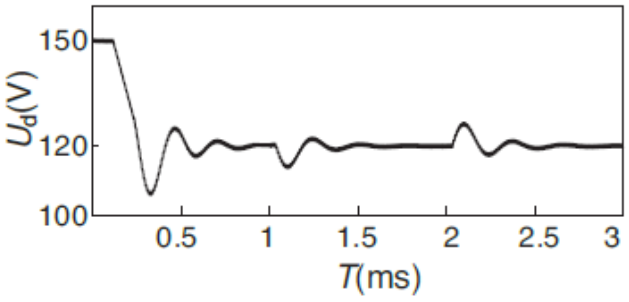

Fig. 10. Waveform of buck mode with load disturbance

4. CONCLUSION

Maintaining a constant DC bus voltage is the first prerequisite for the safe and stable operation of the DC micro grid. In this paper, the HESS and its control strategy are analysed in theory and simulation. The results demonstrate that the HESS and its control strategy can increase the service life of the battery, reduce the size of the battery, and improve the economy of the ESS. Simultaneously, the super-capacitor pre-charge cold standby state and the boost, buck mode work
Independently. The diode D with the function of a selective switch can charge the main power battery, and the super-capacitor pre-charge circuit, as the cold standby, effectively guarantees the performance of the super-capacitor. In addition, the voltage ripple of the HESS and its control strategy is small, while the voltage stabilizing effect and the anti-interference performance is superior.
Finally, the next step is to verify the proposed HESS in practical engineering, and further discuss and analyze the coordinated control strategy of the HESS for a micro grid.

ABSTRACT: Artificial Intelligence methods are the latest developments in power quality enhancement. Fuzzy logic and neural networks also include Artificial Intelligence. This paper deals with the artificial neural network application to power quality improvement. This paper presents a study designed to enhance Total Harmonic Distortion (THD) caused by improper utilization of electronic control (PE) devices as well as nonlinear loads. Shunt Active Power Filter is also one of controller which is used to suppress source currents harmonic currents and to offset the reactive power as it has ability to minimize the harmonic problems that nonlinear loads cause. The P-Q Instant Reactive Power Theory (IRP) is used for the removal of the harmonic component. In DC-link controller and for current error adjustments Artificial Neural Network (ANN) were employed. The hysteresis current controller scheme can be used to generate trigger pulses and to controlling voltage source inverter swapping. Artificial intelligence gives better results when compared to the conventional methods. Continuous and effective electricity supply is required for the operation of modern and advanced society today. Simulations are performed in MATLAB environments using toolbox power system.

KEYWORDS: Artificial Neural Networks (ANN), Total Harmonic Distortion (THD), Shunt Active Power Filter (SAPF), Power Quality (PQ).

I. INTRODUCTION

"These days power electronic converters have wide spread application due to the advanced technology. Such power electronic converters have deeply recognized residential and commercial uses Profoundly, but because of power electronic converters we have come across the power quality issue" [1-2]. The truth that the power electronic converters operates as highly non-linear loads tends to cause this problem. Such highly nonlinear loads interrupt the waveform of power supply that passes device axes, resulting of highly harmonic supply currents and thus reduces input power factor. The major causes of nonlinear systems are un regulated bridge rectifiers and phase regulated converters. consequently, Advanced power electronics appliances used mostly in speed-controlled motor drives, thyristors, grinders, un interruptible power supplies (UPSs) and personal desktops are major cause of voltage distortion at point of common coupling (PCC) as well as power flow in transmission lines [3-4]. They result in Total Harmonic Distortion (THD) from voltage supply far higher than the allowable limit set by IEEE 519 standard of 5 percent.

The easier and cheaper technique for eliminating these harmonics currents is the using of passive filters, but they eliminate specific harmonics and require adjusting to reduce others. The issue is related to the characteristics of resonance compensation for the fixed capacitance, inductance and their huge size. Also used were hybrid filters included both passive and active filters, but these are too costly to implement for harmonic discharge [5]. Therefore, Shunt Active Power Filters (SAPF) will built to solve these issues. The Shunt Active Power Filter aim should be delivering current with same magnitude but in reverse direction, which negates the harmonic currents in the network. In general, SAPF provides harmonious mitigation, reactive power compensation and

ISSN- 2394-5125 VOL 7, ISSUE 15, 2020

compensation for unbalances, voltage harmonics, current harmonics by improve the power factor. As a harmonic current source, SAPF helps to reduce the harmonic components produced by PE-based non - linear loads.

Recently, due to its accuracy and efficiency, Recent methods like the Artificial Intelligence (AI) are becoming highly widespread. Neurons interconnected show the response depending on the stimulation of the input. The input neurons convert the stimulus to decision as network output. In order to make a decision, data samples are used in an iterative training section, and weights are changed until the expected results are obtained. For efficient service, artificial neural network (ANN) uses algorithms such as recurrent network and Hopfield. ANN adaptability is quicker compared to conventional high-pass filter (HP) control systems and PI controllers. ANN can implement with different approaches based on artificial neural intelligence, where the minimum loss control technique is applied to permanent magnet synchronous motors (PMSM s) which increase motor efficiency and reduce losses. A three-phase SAPF with ANN controller is proposed in this paper, using conventional hysteresis to address the quality of electricity. Using IRP p-q theory, reference signals are calculated. ANN is used to allow the extraction of compensating currents, and its implementation into SAPF's control system makes it stronger and more complex.

II. SAPF PRINCIPLE OF FUNDAMENTAL COMPENSIS

The fundamental principle of compensation for Shunt Active Power Filter that can be seen in Figure 1.

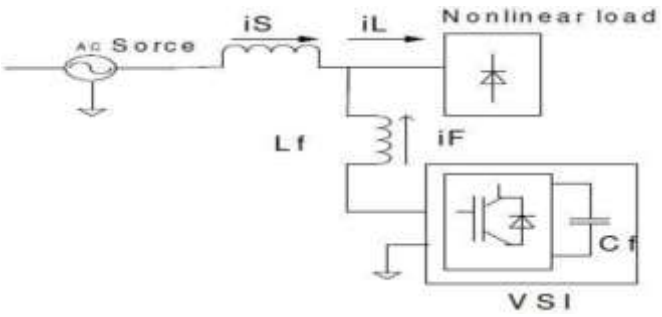

Figure 1: Basic SAPF Principle

Shunt Active Power Filter depending on voltage source inverter is an attractive and efficient way of solve the current emission issues with harmonics and to improve electrical system's power efficiency. The Shunt Active Power Filter by a self-controlled DC bus is directly attached to the distribution systems to minimize harmonic substance, enhance the power factor and keep the network healthy. Figure 1 illustrates the schematic diagram of Nonlinear SAPF Load. The basic concept of SAPF is to inject the harmonic currents produced by a 180degree phase angle load.

For the following reasons Dc link capacitor is being used:

a) To keep a DC voltage at a steady state with a small ripple.
b) To act as an energy-storage function throughout the transient duration to provide real power differential between loads and source.

III.INSTANTANEOUS ACTIVE REACTIVE POWER (PQ) APPROACH

In addition to manage the instantaneous voltages in a three-phase power circuit numerically, this is appropriate to describe such substances with in instantaneous space vectors but rather to optimize the evaluation, The components of the zero-phase series in the three-phase power voltage in this method are better for reducing and recognizing the currents. The basic control algorithm of SAPF was seen in Figure 2.

ISSN- 2394-5125 VOL 7, ISSUE 15, 2020

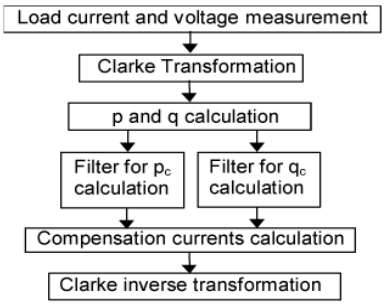

Figure 2: Fundamental Control Algorithm of SAPF based on P-Q Theory

Consider some scheme of A-B-C coordinates where axes A, B and C were also placed along the same plane, and there are $2\pi/3$ rad apart from each other, The A-axis of the instantaneous space vectors, e_A and i_A Their (positive, negative) magnitude and direction change over time. Similarly e_C and i_C are positioned on C-axis e_B and i_B similarly on B-axis. Such space vectors are quickly translated to co-ordinates of α -β as follows:

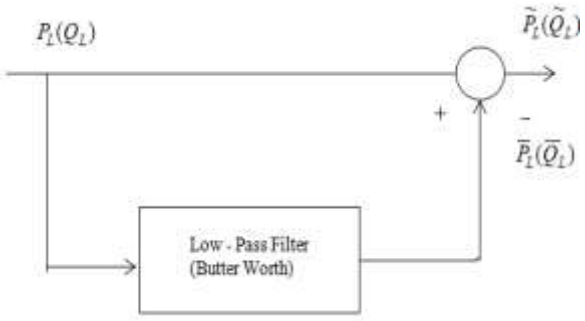
$$\begin{bmatrix} e_\alpha \\ e_\beta \end{bmatrix} = \sqrt{2/3}\begin{bmatrix} 1 & -1/2 & -1/2 \\ 0 & \sqrt{3}/2 & -\sqrt{3}/2 \end{bmatrix}\begin{bmatrix} e_A \\ e_B \\ e_C \end{bmatrix} \quad (1)$$

$$\begin{bmatrix} i_\alpha \\ i_\beta \end{bmatrix} = \sqrt{2/3}\begin{bmatrix} 1 & -1/2 & -1/2 \\ 0 & \sqrt{3}/2 & -\sqrt{3}/2 \end{bmatrix}\begin{bmatrix} i_{LA} \\ i_{LB} \\ i_{LC} \end{bmatrix} \quad (2)$$

Both e_α and i_α are both on α -plane, e_β and i_β are both on β - axis and the position of each of their amplitude (negative, positive) varies over time.

A. Instantaneous space variables along α -β coordinates:

On 3-phase circuit, the conventional instantaneous power can be described as:



$$P_L = e_\alpha i_\alpha + e_\beta i_\beta \quad (3)$$

Where p refers to the traditional equations:

$$P_L = e_\alpha i_{LA} + e_b i_{LB} + e_c i_{LC} \quad (4)$$

To measure the active instantaneous power and the reactive power, may assume that instantaneous reactive space vector has been defined.

$$Q_L = -e_\alpha i_\beta + e_\beta i_\alpha \quad (5)$$

ISSN- 2394-5125 VOL 7, ISSUE 15, 2020

Figure 3: Diagram of Dynamic Computation

As shown in Figure 2 that space vector becomes position of the imaginary axis and right angles to both the real plane on coordinates α -β, to be in line with the law of the right. Considering that e_β is analogous to i_α and e_α is analogous to i_α and also e_α is right angles to i_β and e_β towards i_α traditional instantaneous power, P_L imaginary instantaneous power Q_L.

Let the ac and dc part of P_L have $\tilde{P}_L$ and $\overline{P}_L$. In similar way let $\tilde{Q}_L$ and $\overline{Q}_L$, excude the corresponding relation respectively

$$P_L = \overline{P}_L + \tilde{P}_L \qquad (6)$$
$$Q_L = \overline{Q}_L + \tilde{Q}_L$$

B. Calculating the currents of compensation

The following expression results throughout the circuit measurement P_L and Q_L, circuit measurement of compensation of reference currents.

$$\begin{bmatrix} i^*_{CA} \\ i^*_{CB} \\ i^*_{CC} \end{bmatrix} = \sqrt{2/3} \begin{bmatrix} 1 & 0 \\ -1/2 & \sqrt{3}/2 \\ -1/2 & \sqrt{3}/2 \end{bmatrix} \begin{bmatrix} e_\alpha & e_\beta \\ -e_\beta & e_\alpha \end{bmatrix}^{-1} \begin{bmatrix} P^* + P_{av} \\ Q^* \end{bmatrix} \qquad (7)$$

Where P_{av} is True instant power equal to loss of active filter, P^* and Q^* are determined by

$$P^* = -\tilde{P}_L \quad Q^* = -\tilde{Q}_L \qquad (8)$$

To determine P* values then We want a high pass filtering setup with a low pass butter worth filter but also that system provides a quantities $\tilde{P}_L$ From P_L and $\tilde{Q}_L$ from Q_L Inside the control circuit design considerations of a low pass filter play a significant function because, as shown in experimental results, different Compensation properties are measured in conjunction With cutoff frequency and filter low pass order. All measuring circuits are multipliers, dividers, and op-amps analogues.

IV.HYSTERESIS CURRENT CONTROLLER

The hysteresis band current control scheme shown in Figure 4 has been shown to be more suitable for all appliance in active power filters of current controlled voltage source inverters. The regulation of the hysteresis band current is characterized by unconditional stability, very quick response and good precision [13].

ISSN- 2394-5125 VOL 7, ISSUE 15, 2020

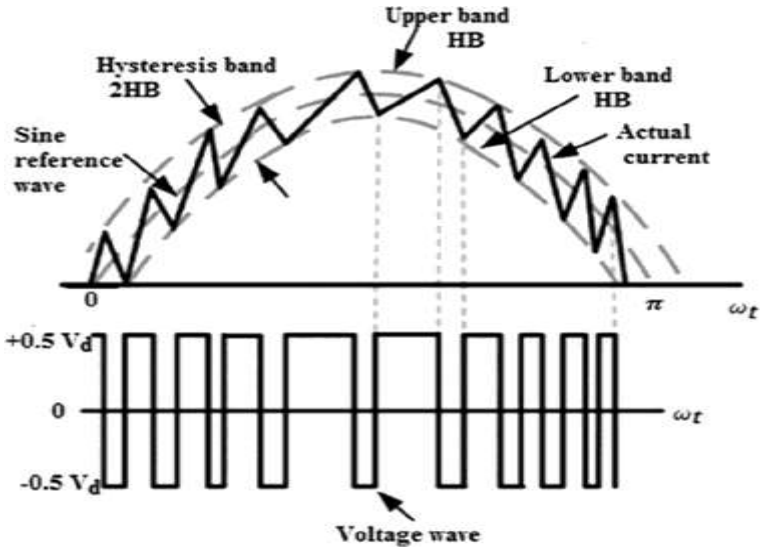


Figure 4: Hysteresis Controller

A. Calculation of the reference signals

Taking into consideration a balanced three-wire system, the p-q IRP method was used for the reference current generation. Currents are determined in IRP p-q theory using the instantaneous time domain factors. Such currents can be further transformed by Clark transformation into three-phase space vectors and two co-ordinates network [10]. We may describe the three-phase quantities for the balanced three-wire network.

B. PWM Signal calculation

The hysteresis band (HB) of the HBCC calculator varies according to Present waveform slope to DC-link voltage (Vdc) And voltage supply (Vs).If the injected current attempts to escape the HB limit, a suitable switch must operate to state ON and OFF, so that the current stays within the HB limit. HBCC thus self-adjusts the HB to fit the designed device. SAPF output is improved by keeping the frequency of the modulation to constant. Control pattern to move the inverter to different check points. The three band phases show the same profile with the variation in phase between them [9].

The corresponding operating switches state the following:

The intial turn is 1 (ON) and the second turn is 0 (OFF)

$HB \geq$ When (iref−imeas)

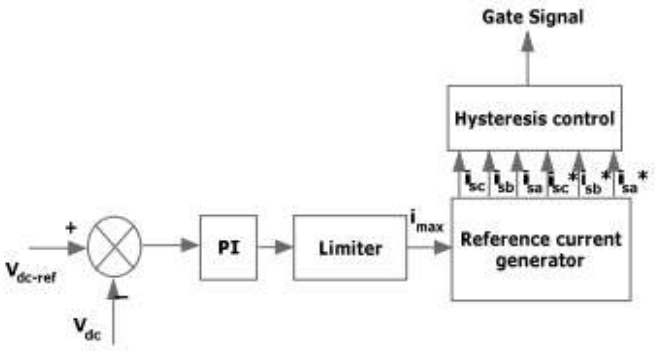
The initial turn is 0 (OFF) and second turn is 1 (ON)

$HB \leq$ When (iref−imeas)

V. PROPORTIONATE INTEGRAL (PI) CONTROLLER

Inner PI Controller management circuit layout shown in Figure.5. The control method composed some kind of limiter, PI controller but also three-phase sinusoidal waveform generator both for development of reference current and switching signal development. By control of DC connection voltage, maximum quantity of reference currents was measured. That real voltage of capacitor in comparison with a given reference value.

ISSN- 2394-5125 VOL 7, ISSUE 15, 2020



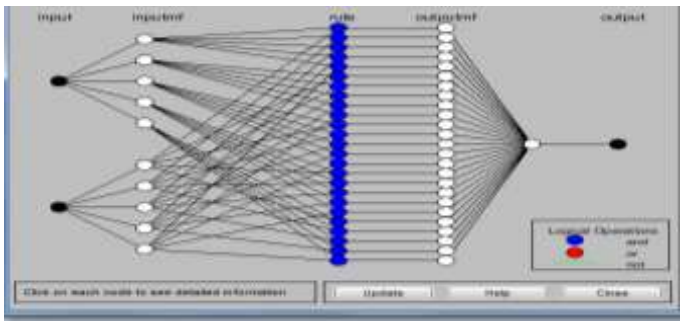


Figure 5: Functional PI Controller

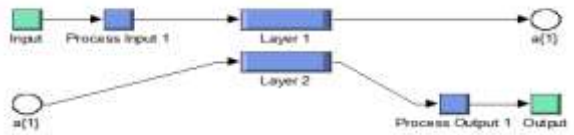

That error value becomes analyzed using such a PI controller that results in the detection of a current reference signal at zero steady loss. That PI controller output signal also known as its source current maximum value ($i_{\max}$), which consists of two layers: (i) The basic real power part of a load current (ii) SAPF reduction element; to maintain a constant mean voltage level for the system. The resulting maximal threshold value ($i_{\max}$) is multiplied by a sinusoidal vectors of the device in step only with corresponding supply voltage which achieve its current relation offsetting. Such predicted reference currents ($i_{SA}^{*}, i_{SB}^{*}, i_{SC}^{*}$) but also actual observed currents (i_{SA}, i_{SB}, i_{SC}) are evaluated by comparing them in hysteresis controller that offers a fault warning modulation method. The whole error signal helps determine a switching action. The supplier / supply current was chosen during the whole entire structure of a control scheme circuit to obey the sinusoidal reference current i_{ABC} within just a fixed hysteretic range. The length of such a hysteresis windows specifies the configuration of source current, the harmonic spectrum and equipment for switching frequency. DC link capacitor voltage is maintained steady and throughout operating period of a converter. Every stage of a converter is inspected in this system Regardless. The lowest switch associated with specific phase is turned further to maximize the current of such a specific section whereas the upper switch of a corresponding converter phase is triggered to decrease the current.

VI. ARTIFICIAL NEURAL NETWORK

Abbreviated as ANN, the Artificial Neuron Network is a programming technique that can easily solve non-linear problems. The algorithm (back propagation) effectively separates its input from each power of relation. Here, the Artificial Neuron Network is the feedforward back-propagation network improving the quality of power. Getting familiar, the network consists of three different levels namely output layers, hidden layers, intermediate layer or input layers. Each one of these layers is made up of interconnected neurons that form a large network of neurons. Depending on the back-propagation algorithm, certain weight values are changed.

The structure of the neural network employed is the following:

Input signal: $x = x_1, x_2, x_3 \ldots X_i$.
Output signal: $y = y_1, y_2, y_3 \ldots Y_n$.
Neuron weights: W= wi1, wi2, wi3..... win.

ANN are divided into three sections, that is structure, training methods and activation function. Every neuron layer is linked to the other and activated only via activation function [11]. Multilayer perceptron (MLP) is also used for harmonic reduction, and as shown in Figure 4 the model consists of three main inputs. ANN has the benefit of easily calculating the harmonic-equivalent Fourier variables [12]. Transfer functions are logsig for layer 1, and tansig for layer 2 or hidden layer. During the first layer number of hidden neurons is 3, as well as 18 in second layer. The output layer depends on the type of data to be analyzed for optimal / desirable results.

VII. SIMULATION DIAGRAM

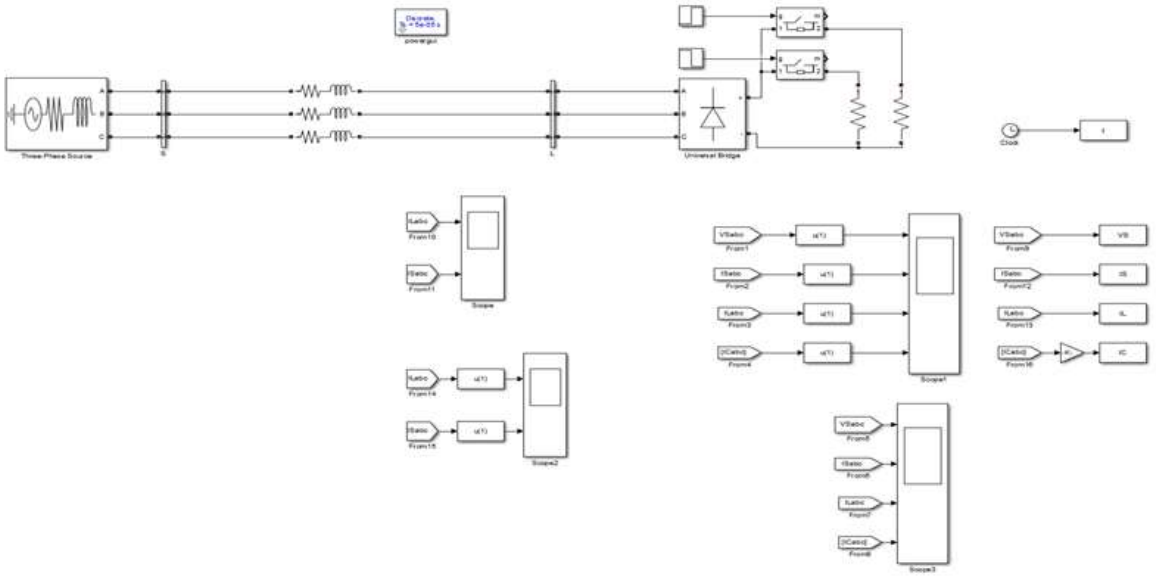

Figure 7: Simulation of System with Non-Linear Load without SAPF

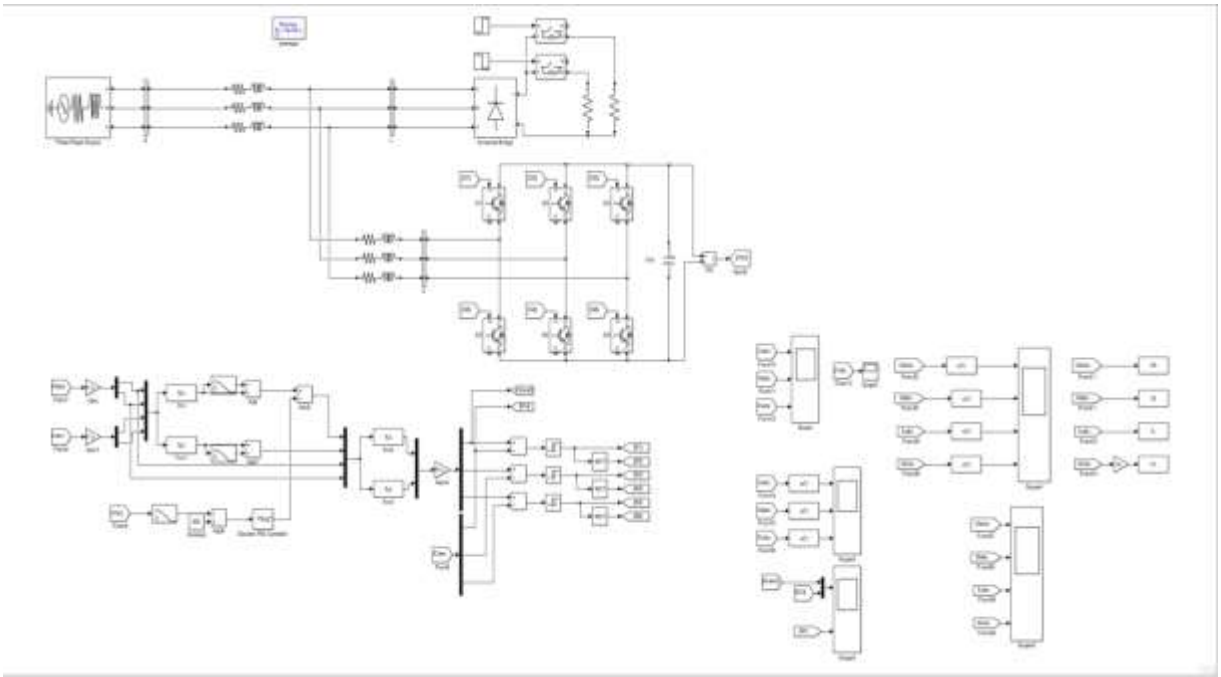

Figure 8: Simulation Diagram of SAPF with PI Controller

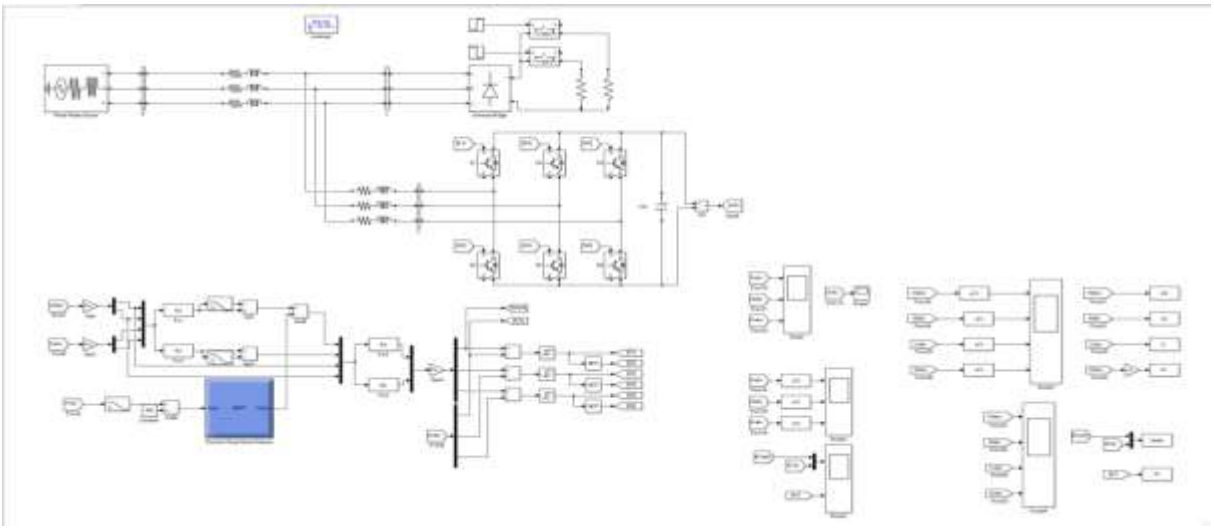

Figure 9: Simulation diagram of SAPF with Artificial Neural Network (ANN)

VIII. RESULTS AND DISCUSSIONS

Table 1: Simulation Parameters

Parameters	Values
Source Voltage (rms)	230V
Frequency	50HZ
Resistance (R)	0.1 ohm
Inductance (L)	1mH
Source Resistance	0.01 Ohm
Source Inductance	1mH
DC Capacitance	1200MF
Intial Load	10 KW
Load increased to	15 KW

The proposed ANN based SAPF is designed but also simulated with MATLAB/ Simulink Tool. Simulation of SAPF is performed with PI Controller and Artificial Neural Networks under dynamic load conditions and the results obtained were compared and checked with IEEE 519 Harmonic standard.

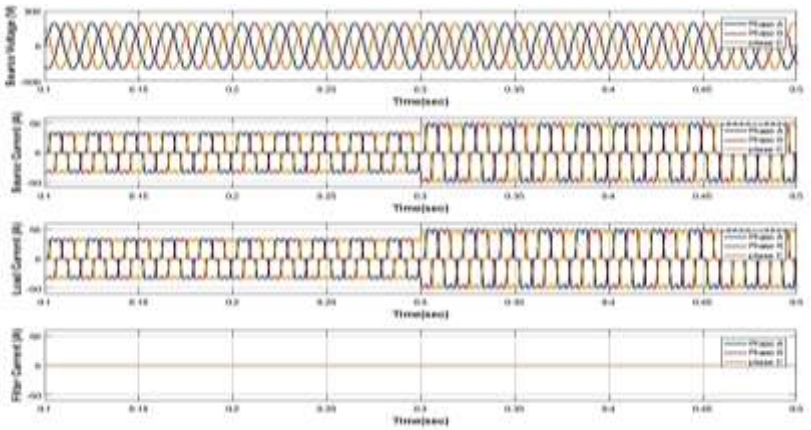

Figure 10: Output waveforms under dynamic load condition without SAPF (a) Source Voltage (b) Source Current (c) Load Current (d) Filter Current

The performance of system without SAPF will be evaluated under dynamic load condition is shown in Figure 10. The Simulation results obtained shows that before load change (up to 0.3 seconds) the current magnitude is less

and at the instant of 0.3 seconds a new load of 5 KW is added to the existing load of 10 KW which increases the magnitude of current.

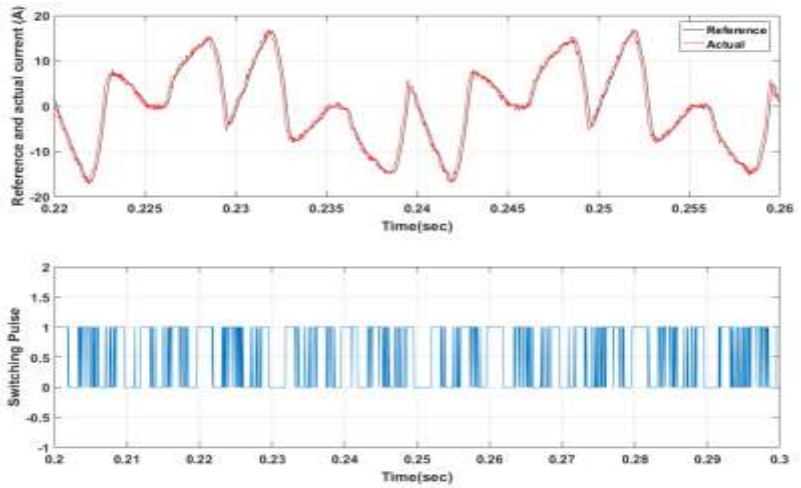

Figure 11: Switching Pulses: (a) Reference and Actual Current (b) Switching Pulses

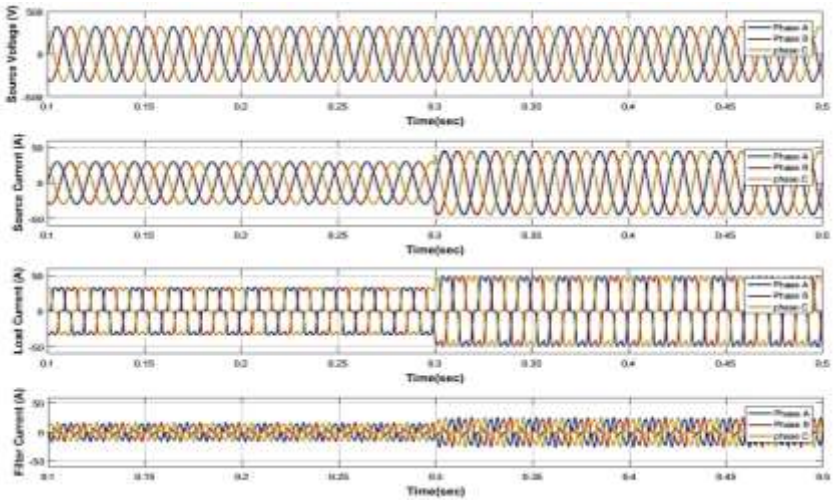

Figure 12: Output Waveforms of SAPF Under Dynamic Load Condition with PI Controller (a) Source Voltage (b) Source Current (c) Load Current (d) Filter Current

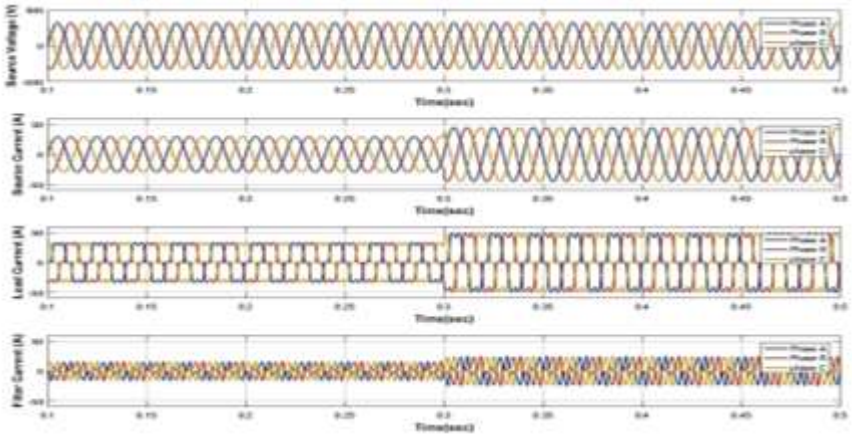

Figure 13: Output Waveforms of SAPF with ANN Control Under Dynamic load Condition (a) Source Voltage (b) Source Current (c) Load Current (d) Filter Current

ISSN- 2394-5125 VOL 7, ISSUE 15, 2020

The performance of system with SAPF will be evaluated under dynamic load condition with PI and ANN is shown in Figure 12 and 13 respectively. The Simulation results obtained shows that before load change (up to 0.3 seconds) the current magnitude is less and at the instant of 0.3 seconds a new load of 5 KW is added to the existing load of 10 KW which increases the magnitude of current. It is observed the SAPF with ANN control responds quickly to the load change and alters the magnitude of filter current at a faster rate.

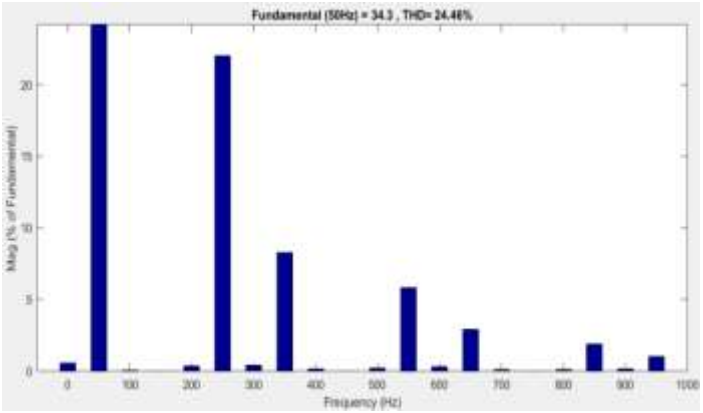

Figure 14: FFT Load Current Analysis without SAPF

The above Figure 14 shows harmonic spectrum evaluation of the load current without SAPF. The % THD is measured as 24.46%.

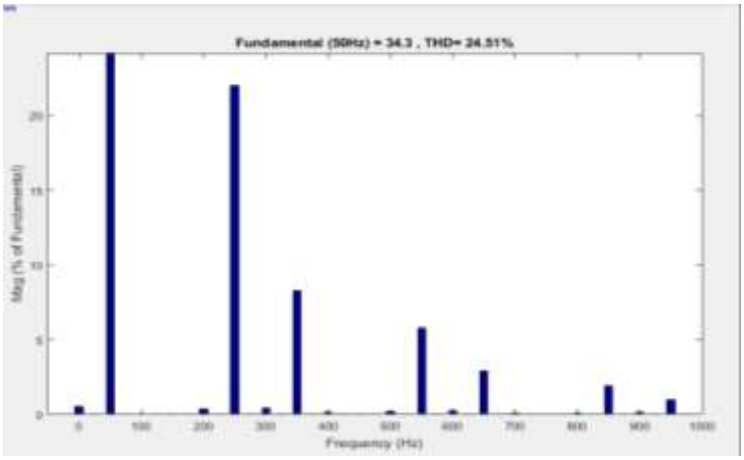

Figure 15: FFT Load Current Analysis with SAPF PI Controller Before Change of Load

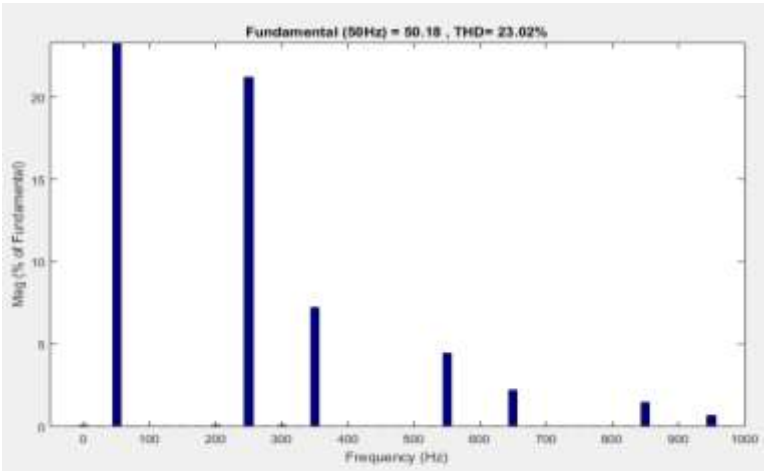

Figure 16: FFT Load current Analysis with SAPF PI Controller after Change of Load

ISSN- 2394-5125 VOL 7, ISSUE 15, 2020

The above Figure 15 and Figure 16 shows harmonic spectrum evaluation of the load current with SAPF PI Controller during dynamic load conditions. The % THD before and after load change is measured as 24.51% and 23.02% respectively.

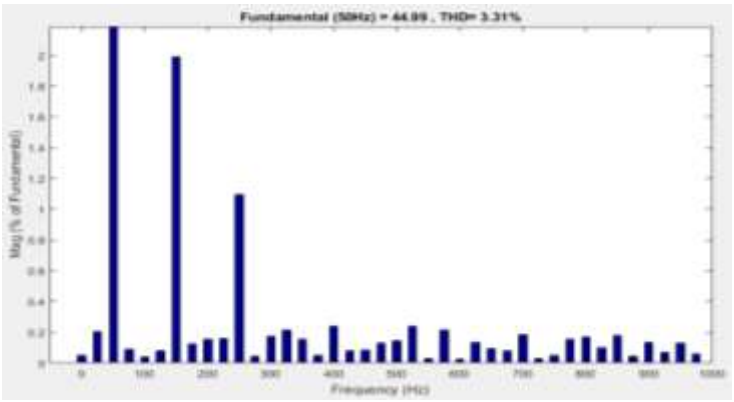

Figure 17: FFT Source Current Analysis with SAPF PI Controller after Change of Load

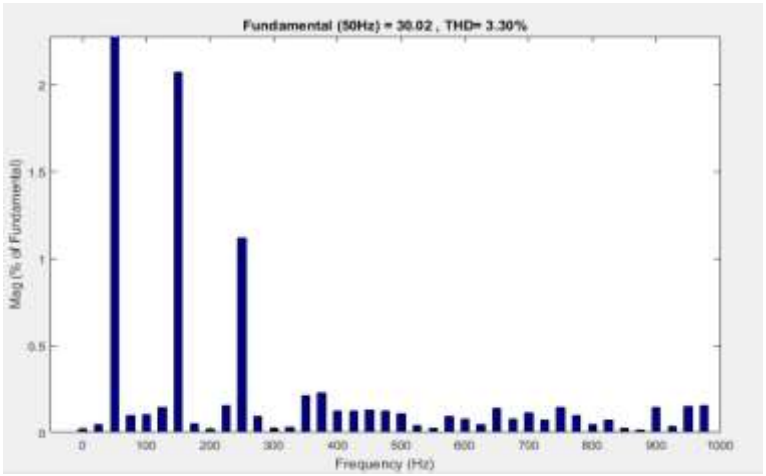

Figure 18: FFT Source Current Analysis with SAPF PI Controller Before Change of Load

The above Figure 17 and Figure 18 shows harmonic spectrum evaluation of the source current with SAPF PI Controller during dynamic load conditions. The % THD before and after load change is measured as 3.31% and 3.30% respectively.

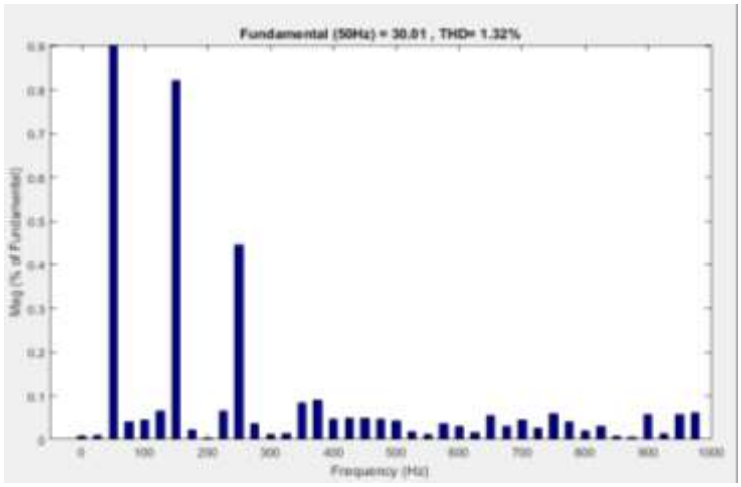

Figure 19: FFT Source Current Analysis with SAPF Artificial Neural network Before Change of Load

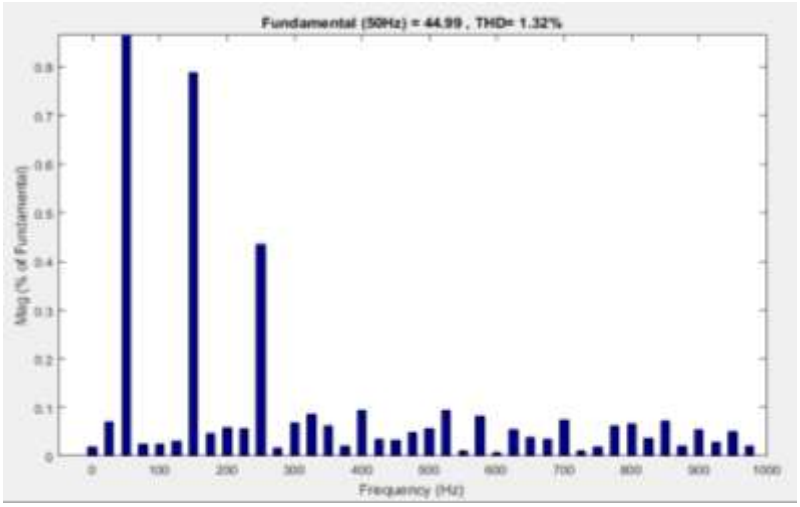

Figure 20: FFT Source Current Analysis with SAPF Artificial Neural Network after Change of Load

The above Figure 19 and Figure 20 shows harmonic spectrum evaluation of the source current with SAPF ANN during dynamic load conditions. The % THD before and after load change is measured as 1.32%.

It is evident from the above results that the Artificial Neural Network get better results when compared to PI controller and Total Harmonic Distortion (THD) level is reduced to 1.32% .

Table 2: Simulation Results

Parameter	Without SAPF	With SAPF			
		Source Current before Load change		Source Current after Load change	
		PI	ANN	PI	ANN
THD (%)	24.46	3.30	1.32	3.31	1.32

IX. CONCLUSION

This paper modifies the SAPF control structure and employs Artificial neural networks. The p-q technique is used to extract reference signals. Artificial neural network the effect is a reducing of THD to sufficient levels. However, the simulation results indicate an outstanding compensation by ANN and are similar to improve harmonic compensation. THD becomes mitigated to that very minimum value, meaning that reactive power but also harmonics produced by a nonlinear load are removed completely.

ABSTRACT: Solar PV system is one of the best substitute in renewable energy at sizable. This paper proposes the long term field performance analysis of 100kWp grid-connected rooftop solar PV power plant installed at B.V.Raju Institute of Technology (BVRIT) at Narsapur, Telangana. The monitored data of the system from five years of continuous operation is used to evaluate the performance. In this paper, the solar PV plant generated energy, performance ratio, capacity utilization factor and efficiency are measured and also compared with the simulation values obtained from pvsyst 6.8.7 software. Performance analysis of the grid connected plant will be helpful in operating, designing and effective maintenance of new grid connected systems. The average estimated energy for five years is 192334.2 kWh, average energy generated is 146616 kWh, average performance ratio is 76.22% and average capacity utilization factor is 16.74%. Here five 20 kW inverters are used for operating the plant whose output is deviated in few months of operation due to maintenance.

KEYWORDS: Capacity utilization factor, Generated energy, Normalized energy, PV plant, Performance ratio, PVSYST, System efficiency.

I. INTRODUCTION

To meet the energy demands in India sun is one of the substitutes for energy production. The light energy produced from the sun is directly converted to electrical energy by photovoltaic energy conversion principle. The performance of the solar photovoltaic plant is dependent on type of panel technology, environmental conditions such as temperature and humidity, location of the site, seasonal fluctuations, solar insolation, air pollution and module maintenance.

In India the installed solar power capacity is 28464.17 MW as of 31 March 2019. In solar power generation capacity Karnataka stands first with the capacity of 6095.56 MW and Telangana stands second with the capacity of 3592.09 MW.

K. Padmavathi at el., (2013) [1], the performance evaluation of grid connected solar photovoltaic power plant of capacity 3 MWp located in Karnataka. The performance ratio is evaluated for two years; in 2010 it was less than 0.6 from August to November due to high inverter failure losses. The next year, 2011 PR values improved of an annual average value of 0.7 and inverter failure losses were reduced.

Vikas Pratap Singh at el., [2], the data quality check on global horizontal irradiation and tilted global horizontal irradiation to obtain the estimated performance ratio (PR) of the PV plant. The performance ratio is inversely proportional to module temperature which depends on climatic parameters. Plant under standard condition provides maximum power generation with higher performance ratio. Performance ratio is higher in winter season compared to summer or rainy season; the variation is due to thermal losses.

B. Shiva Kumar at el., (2015) [3], simulation values obtained from PV syst and PV-GIS software values are compared, plant is operating nearer to the predicted generation of energy modelling software. Utmost total

energy generation of 10 MWp grid connected solar photovoltaic power plant is in the month of January and nethermost in the month of July (2014-2015). The plant is operating with good amount of PR and CUF.

Robins Anto at el., (2014) [4], the photovoltaic systems integrate power build up units generate harmonics that rely up on operating conditions of structure which impact the quality of power supply, reliable operation, life span of the system components. The efficiency of 100KWp plant is shrinking during the evening time as irradiance diminishes. Capture losses and system losses are high during the low radiation levels due to the variation of solar radiation.

Lana S. PANTIC at el., [5] Practical field study of performances of three identical monocrystalline solar modules, single power of 60 W, with different inclinations (horizontal, optimally inclined oriented toward South and vertically oriented toward South) in real meteorological conditions, in Nis, Serbia are presented. The efficiency, performance ratio and fill factors are measured and compared.

Cristina Cornaro at el., [6], the results of a two years outdoor monitoring campaign that has been carried out on the same polycrystalline photovoltaic module at two different locations in Europe: the SUPSI-ISAAC outdoor facility in Lugano, Switzerland, from April 2006 till May 2007, and the outdoor ESTER facility in Rome, from April 2008 till May 2009. The monthly PR appears higher for Lugano than for Rome apart from the April 07-09 case where the performance in Rome has been higher. A 3% maximum PR deviation between the two sites has been registered during the autumn months.

Pablo Ferrada at el., [7], the paper has reported on the performance of photovoltaic systems in the coastal zone of Antofagasta, northern Chile. It analyzed how the performance ratio is influenced by the dust accumulation and the ambient temperature associated to this place. It came out that the difference of energy yield between the technologies became larger for summer and smaller for winter, and that the performance ratio decreased due to the dust accumulation.

Lana S. PANTIC at el., [8], the performance of PV modules under actual outdoor conditions is found to be quite different from that determined under controlled laboratory conditions. Performance of PV modules will not be the same for a given PV module if it is located in places with different climate type e.g. wet tropical, dry desert or continental climate.

Gay, Rumberg and Wilson at el., [9] thirty years ago, researchers in the PV field acknowledged the need to go beyond STC, suggesting that module performance be characterized by categories of weather conditions (hot sunny, cold sunny, hot cloudy, cold cloudy, and nice).

Seung-Ho Yoo at el., [10] presented the influence of tilt angle of PV panel, building azimuth and shading effects on power generation of SPV modules were considered to optimize the performance of a Building Integrated Photovoltaic (BIPV) system located in Korea. The efficiency of this BIPV system during different months was compared. According to this study, the power generation is more influenced by the above factors in summer than in winter.

M. Shravanth Vasisht at el., [11] study showed a 20 kWp Solar Photovoltaic (SPV) system was set up on the library roof-top in Indian Institute of Science, Bangalore, India. This Roof-top photovoltaic (RTPV) system partly powers the Central Office of IISc. The main objective of setting up this SPV system was to study the performance of solar plants under different seasons and climatic conditions of Bangalore.

In this paper five operation years performance of the grid connected rooftop solar PV plant is figured out by using the parameters efficiency, performance ratio, capacity utilization factor, generated energy. System operation from 2014 to 2018 is considered for estimation of the plant. To valuate the performance ratio and to calculate theoretically generated energy values are collected from NASA.

II. EXPLICATION OF SYSTEM

The 100 KWp solar photovoltaic system installed at roof top of Aryabhatta block of B.V.Raju Institute of technology (BVRIT), Narsapur, and Hyderabad. This plant is located in South India with latitude of 17.30^{o} N, longitude of 78.90^{o} E, altitude of 590 m and azimuth angle of 0^{o}. The aim of installation of solar PV plant is to extend the green technology into the institute and also to overcome the energy calamity.

Fig. 1 replicates the rooftop solar PV plant installed at BVRIT, Plant consists of 20 strings, each string is equipped with 20 modules and each module consists of 60 cells i.e. 400 PV modules of poly crystalline silicon technology with rated power 250 Wp. The module efficiency at STC is 14.3%, open circuit voltage (V_{oc}) is 37.56

ISSN- 2394-5125 VOL 7, ISSUE 15, 2020

V, short circuit current (I_{SC}) is 8.53 A, rated voltage (V_{MPP}) is 31.18 V, rated current (I_{MPP}) is 8.02 A, power tolerance is ±3%.

Fig. 1: Rooftop Solar PV Plant Installed at BVRIT

Five REFUsol string inverters of 20 kW_p are connected to the panel strings as shown in Fig. 2. The inverter specifications are as mentioned in table. 1.

Fig. 2: REFUsol Inverter of 20kw_p Capacity

Table 1: Inverter Specifications Used in 100 kW_p solar PV Plant

DC Specifications		**AC Specifications**	
Max. Input voltage	1000 V	Nominal operating voltage	3ϕ 400 V + N
MPP range	480-850 V	Nominal operating frequency	50/60 Hz
Max. input current total	41.0 A	Rated power	19.2kVA
Max. Input current per input pair/-triplet	25 A	Max. Active power@ cosϕ=1	19.2 kW
Operating temperature range	-25 to +55° C	Max. Output current	3*29 A= 87 A

III.INSTANCED COMPUTATIONS

Estimated energy

Estimated energy is defined as the product of peak sun hours, plant capacity and number of days in month/year.

ISSN- 2394-5125 VOL 7, ISSUE 15, 2020

$$Estimated\ energy = peak\ sun\ hours * plant\ capacity * no.of\ days\ in\ month/year \quad (1)$$

Peak sun hours data is collected from NASA. Estimated energy is measured in terms of kWh.

Normalized energy (P_{norm})

Normalized energy is defined as the ratio of generated energy to the product of plant capacity and number of days [15].

$$P_{norm} = \frac{generated\ energy}{plant\ capacity * no.of\ days}\ W_p/kWh \quad (2)$$

Performance ratio (PR)

Performance ratio is defined as the ratio of generated energy to the estimated energy [2], [15],[16].

$$PR = \frac{generated\ energy}{estimated\ energy}\ \% \quad (3)$$

Capacity utilization factor (CUF)

Capacity utilization factor is defined as the ratio of generated energy to the product of number of days, number of hours per day and installed plant capacity [2],[3],[12],[16].

$$CUF = \frac{generated\ energy}{no.of\ days * 24 * installed\ plant\ capacity}\ \% \quad (4)$$

Efficiency

$$system\ efficiency(\%) = \frac{practical\ energy\ generated}{solar\ irradiation\ value * no.of\ days * plant\ area}\ \% \quad (5)$$

IV. PERFORMANCE ANALYSIS

To evaluate the performance of 100 kWp solar PV plant, the data is tracked for five operational years is considered. The parameters considered in this study are

Table 2: Estimated Energy, Generated Energy, Normalized Energy, Performance Ratio and Capacity Utilization Factor for Five Years.

Year	Estimated Energy (kWh)	Generated Energy(kWh)	Normalized Energy(Wp/kWh)	PR(%)	CUF(%)
2014	193258	152687	4.19	79	17.45
2015	195176	151534	4.16	77.63	17.30
2016	188538	145914	3.99	77.39	16.62
2017	192962	147211	4.04	76.29	16.82
2018	191737	135733	3.73	70.79	15.51

Table 2 consists the values of generated energy, performance ratio and capacity utilization factor for five years. Fig.3 shows the generated energy of 100kwp solar PV plant from 2014 to 2018. The generated energy is getting decreased every year but in between 2016-2017 the generation has been increased. At intervals the generation difference from 2014 to 2015 is -0.7%, 2015 to 2016 is -3.7%, 2016 to 2017 is 0.88% incremented, 2017 to 2018 is -7.79%. The decrease in generation can be due to losses, repairs, temperature, shadow, maintenance, degradation and weather conditions.

ISSN- 2394-5125 VOL 7, ISSUE 15, 2020

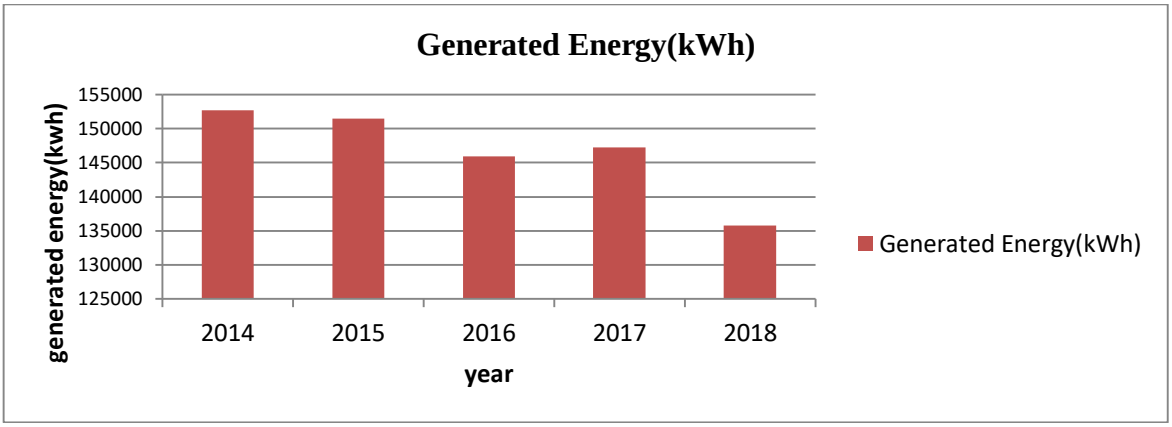

Fig. 3: Energy Generated in Five Years

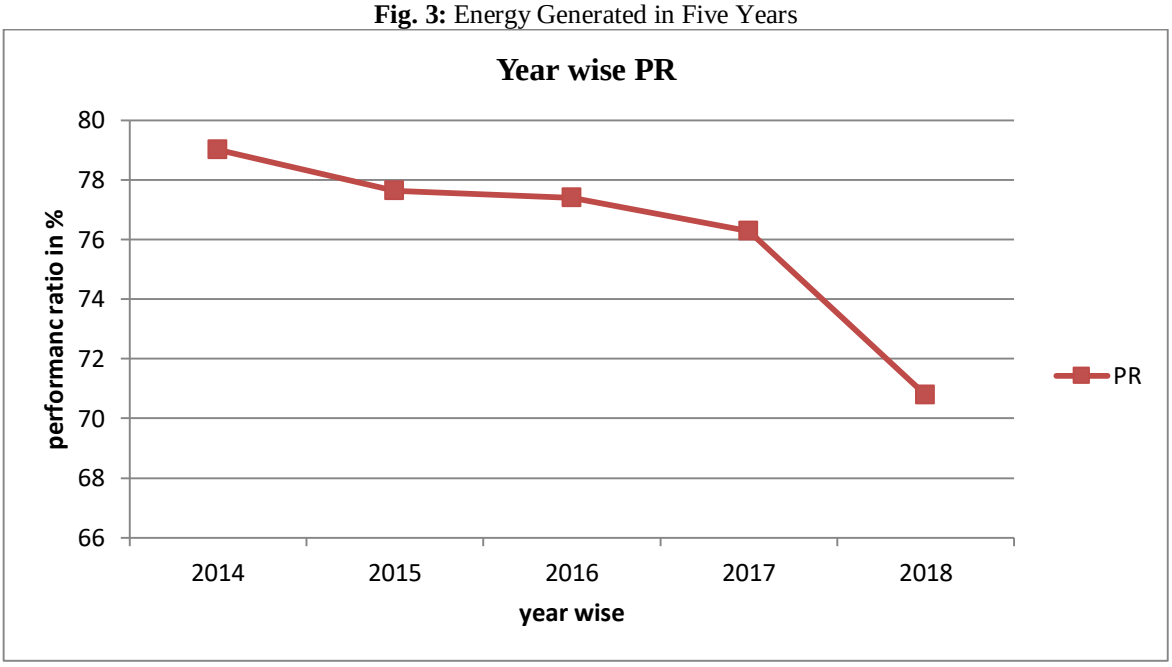

Fig.4: Year Wise Performance Ratio for Five Years

ISSN- 2394-5125 VOL 7, ISSUE 15, 2020

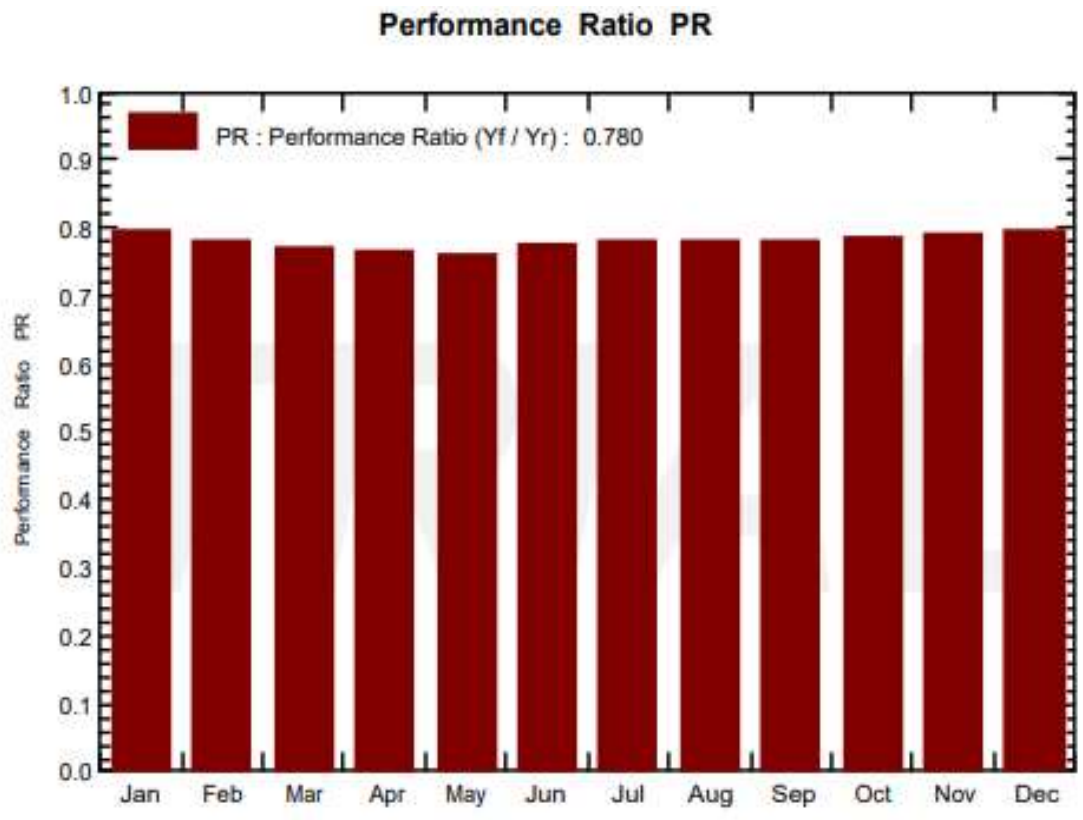

Fig.5: Performance Ratio for Year by PVSYST Software Simulation

The year wise performance ratio of plant from 2014-2018 show in fig 4. In 2014, the performance ratio is 79%, in 2015 it is 77.63%, in 2016 it is 77.39%, in 2017 it is 76.9%, and in 2018 it is 70.79%. From 2014-2018, performance ratio is gradually decreasing, from 2014-2015 performance ratio is decreased to 2%, in 2015 and 2016 it is equal, from 2016-2017 performance ratio is decreased to 1%, from 2017-2018 performance ratio is decreased to 6%. The fig 5. Shows that the annual performance ration of the solar PV plant given by the the pvsyst simulation and also seen that the performance ratio is 78% from this we can observe that the actual performance ratio is almost nearer to the pvsyst simulation report but it changed 7% in year 2018.

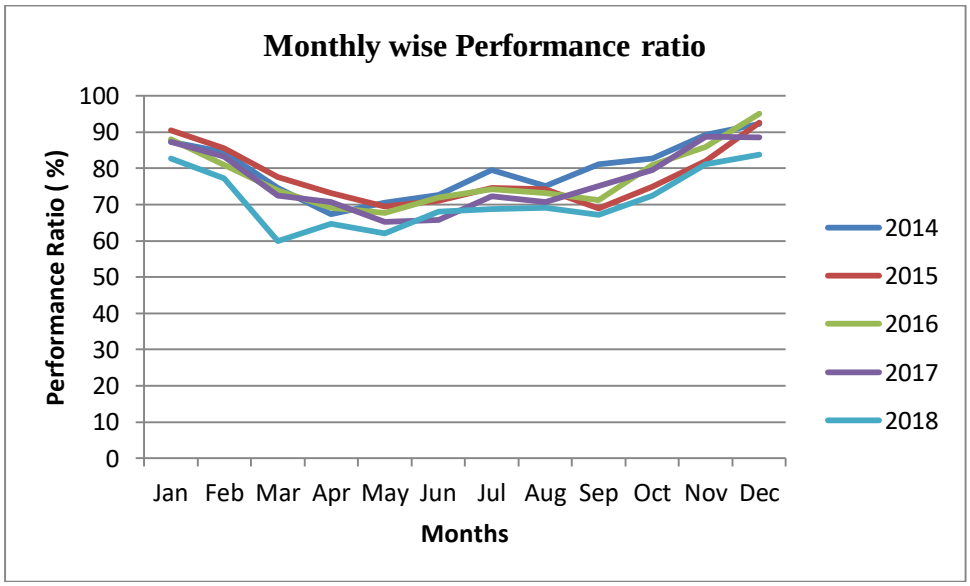

Fig.6: Monthly Wise Performance Ratio

Fig.6 shows the monthly wise performance ratio of plant for five years i.e., from 2014-2018. Generally in India the performance ratio of solar plant is about 80%. The performance ratio is higher in the months of January and

ISSN- 2394-5125 VOL 7, ISSUE 15, 2020

December i.e., in winter season as the temperature is low, solar irradiance will be more. In summer season i.e., in the months of April and May performance ratio is less due to more temperature and less irradiance.

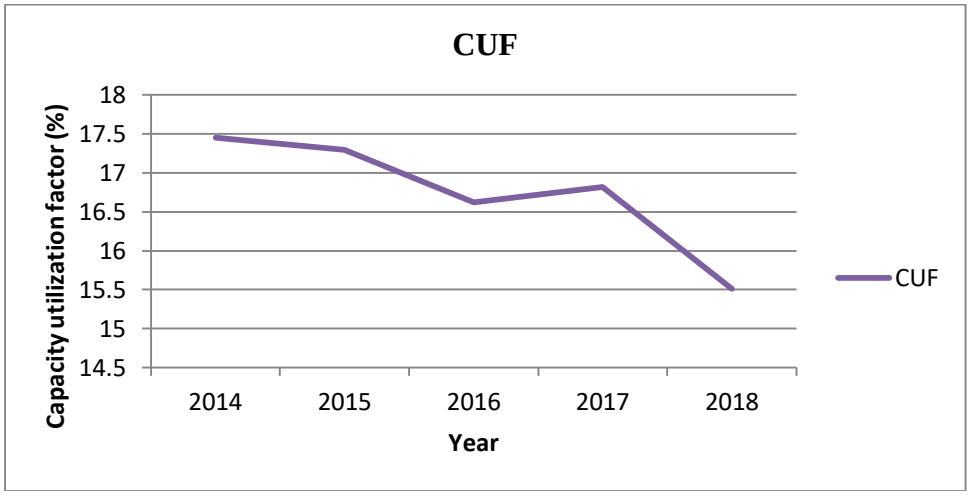

Fig.7: Capacity Utilization Factor for Five Years

Fig.7 depicts the capacity utilization factor (CUF) for different operation years. Generally in India, capacity utilization factor of solar PV plant must be about 16-17%. In 2014, 2015, 2017 the capacity utilization factor is 17% and in 2016 and 2018 it is 16%.

Table 3: All Five Inverters Energy Output in Five Years

Inverter	2014	2015	2016	2017	2018
Inverter 1	30448.7	30664.1	29368.7	29965.2	27406.3
Inverter 2	30489.2	30599.1	29345.8	29308.9	28081
Inverter 3	30653.3	29551.1	29979.8	30347.5	26607.2
Inverter 4	29979.9	29987.5	28243.7	27923.4	25694.1
Inverter 5	31115.7	30732.4	28976.5	29666.1	27944.8

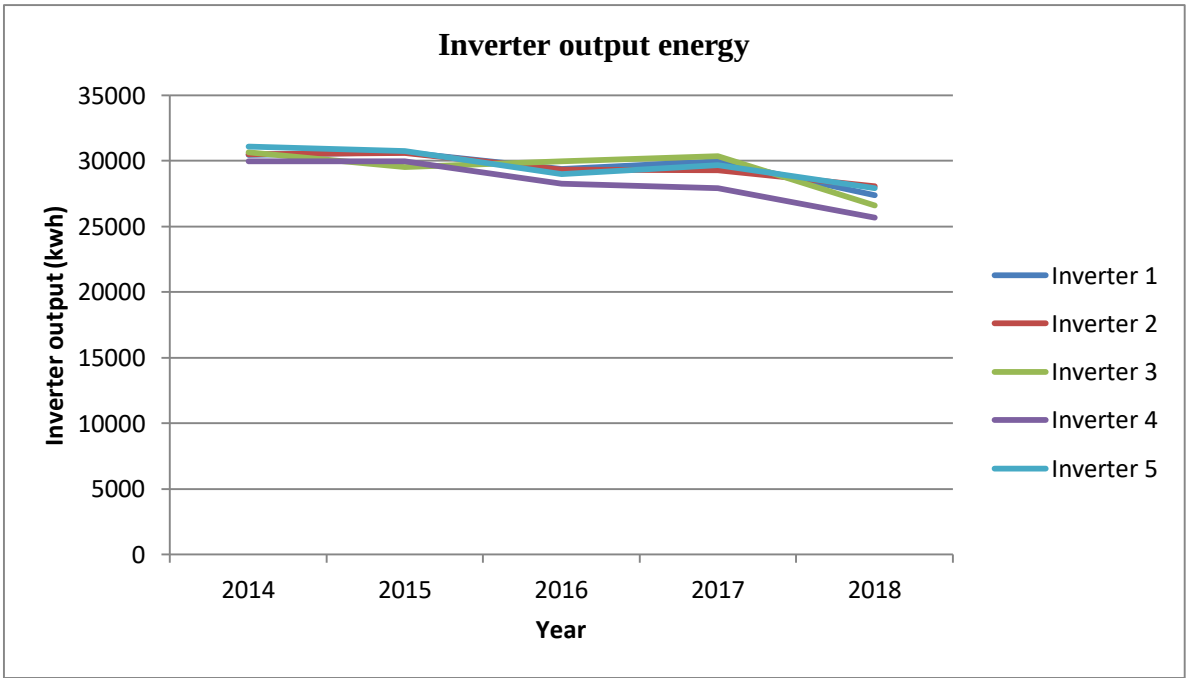

Fig.8: Inverters Output Energy in Five Years

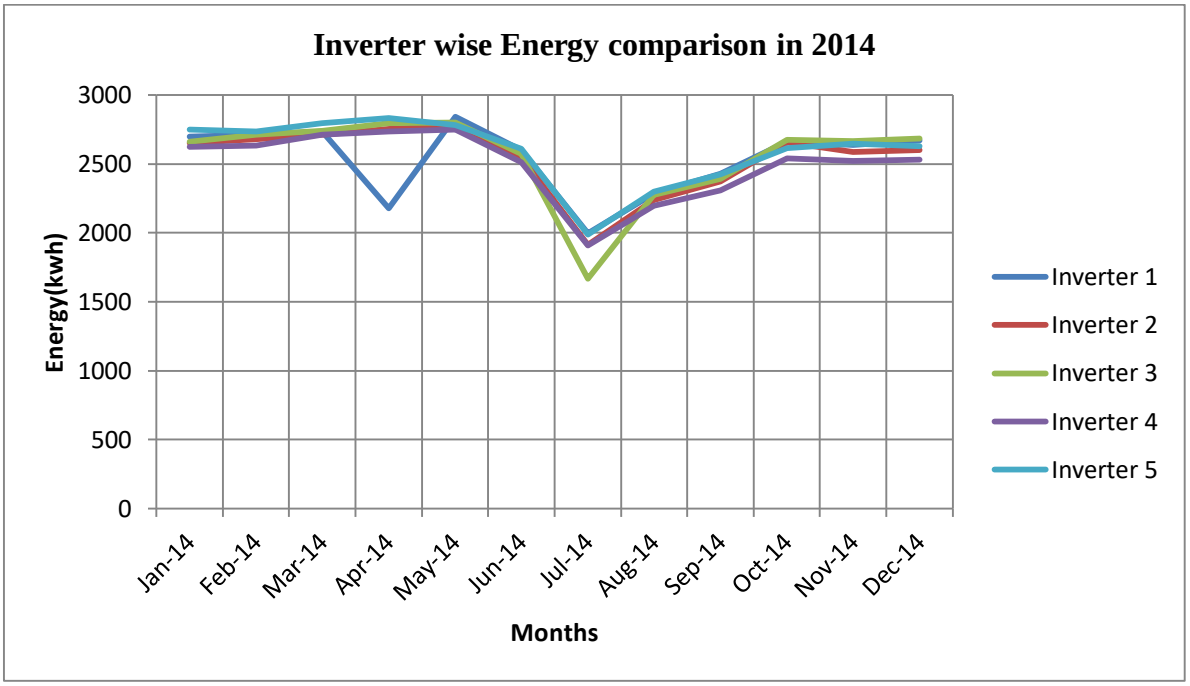
ISSN- 2394-5125 VOL 7, ISSUE 15, 2020

The table.3 and fig.8 shows the year wise inverter output energy from 2014-2018. For 100kwp solar PV plant, we have five inverters of capacity 20kw each. The output of each inverter used must be equal but the inverter output energy is approximately equal for all five inverters used, from 2016 the output has been gradually decreasing for inverter 4.



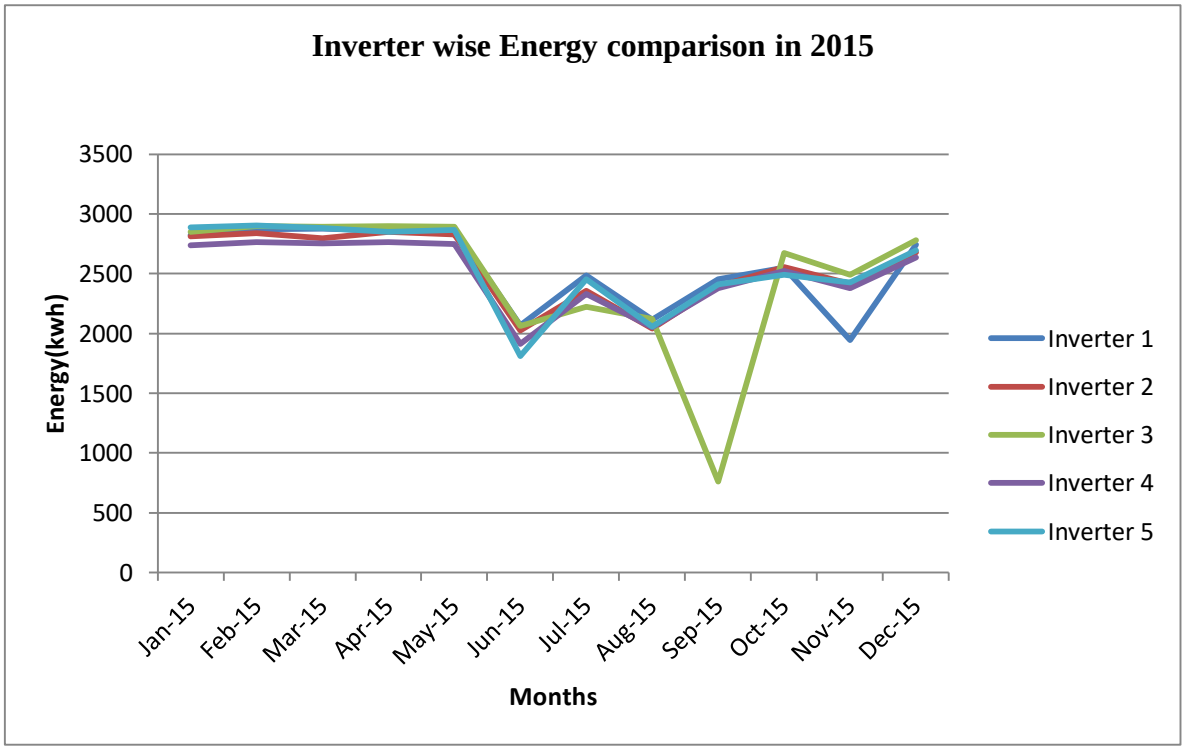


Fig.9: Inverter Wise Energy Comparison in 2014

Fig.9 shows the inverter wise energy comparison in the year 2014. In 2014, all five inverters output is almost equal in the months of January, February, March, May, June, August, September, October, November, December and in the April month the output of inverter 1 has decreased and in the month of July the output of inverter 3 has decreased.

ISSN- 2394-5125 VOL 7, ISSUE 15, 2020

Fig.10: Inverter Wise Energy Comparison in 2015

In 2015, the output of all inverters is almost equal in all months except in September and November. In the month of September inverter 3 output decreased and in the month of November inverter 1 output decreased are shown in fig.10.

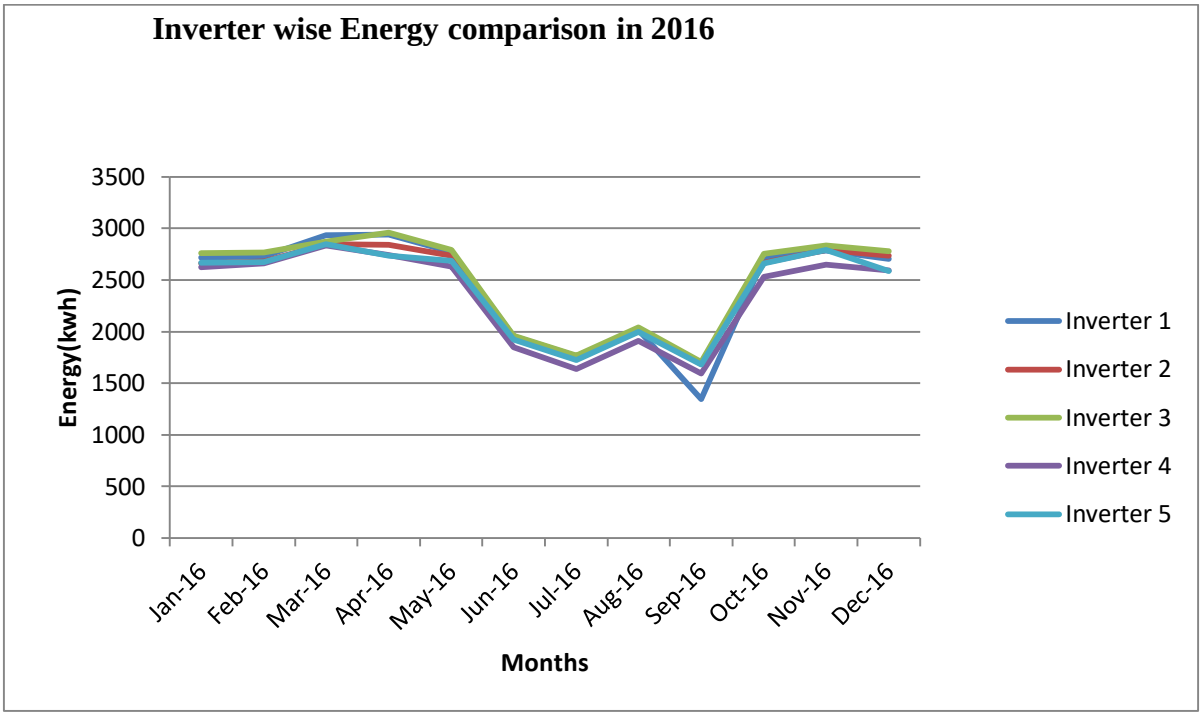

Fig.11: Inverter Wise Energy Comparison in 2016

In 2016, almost equal energy output is observed for all inverters in all months as shows in fig.11 but in the month of September inverter 1 output is less. Later the energy output is almost equal for all the inverters from the month of October.

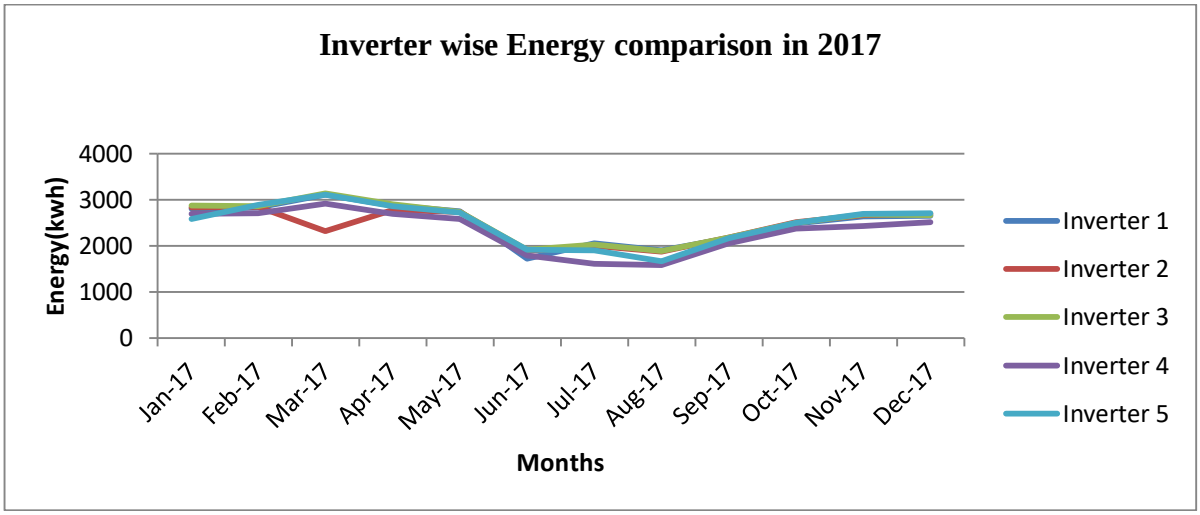

Fig.12: Inverter Wise Energy Comparison in 2017

Fig.12 shows Inverter wise energy comparison in 2017, inverter energy output is deviated in the month of March in inverter 2 and in the months of June, July, August output is decreased in inverter 4 and in July, August inverter 5 output is decreased.

ISSN- 2394-5125 VOL 7, ISSUE 15, 2020

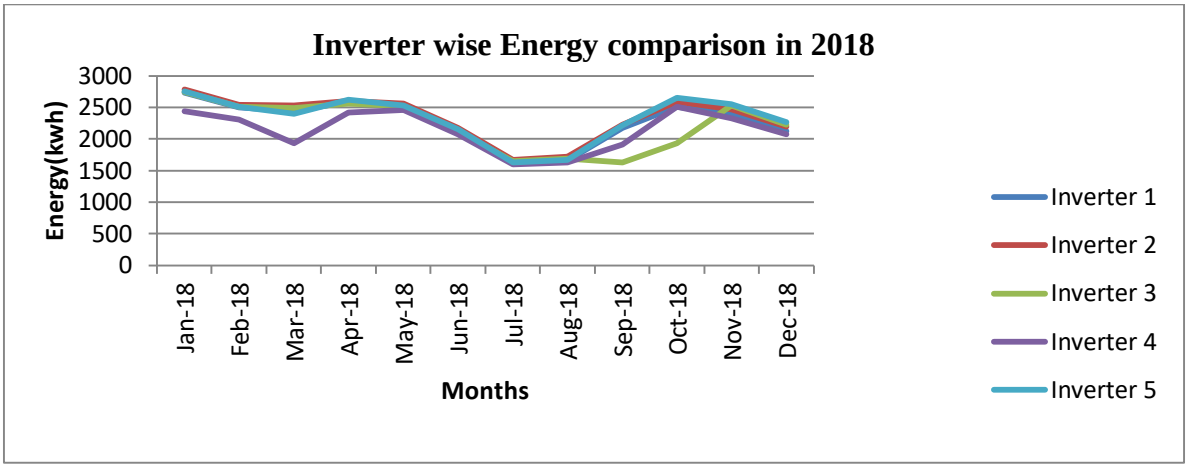

Fig.13: Inverter Wise Energy Comparison in 2018

Fig.13 shows Inverter wise energy comparison in 2018, the inverter 4 output has been decreased in January, February, March and inverter 3 output is decreased in months of September, October, November and in the months of September and October the inverter 4 is decreased.

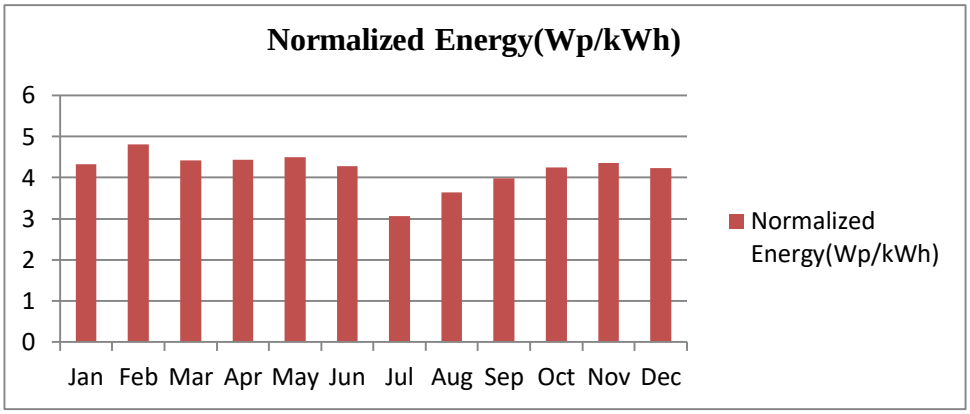

Fig.14: Normalized Energy

ISSN- 2394-5125 VOL 7, ISSUE 15, 2020

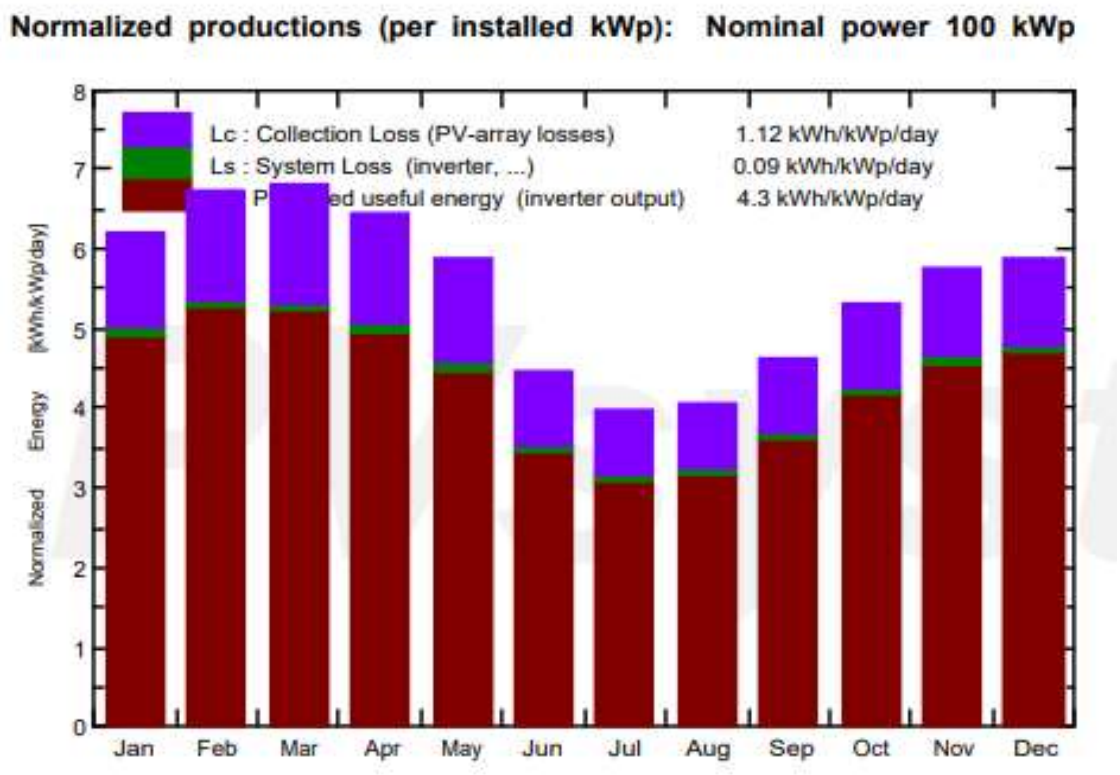

Fig.15: Normalized Energy by PVSYST Software

The fig 14 shows that the normalized energy calculated by the real time data of one year. Fig 15 shows the normalized energy produced by the pvsyst software simulation for year. From the normalized energy graphs we can observe that the normalized energy produced by the plant is 4.19 kwh/kwp/day and the normalized energy produced by the pvsyst simulation report is 4.3 kwh/kwp/day. For Five years normalized energy are like this 2014 it is 4.19kwh/kwp/day, 2015 it is 4.16 kwh/kwp/day, 2016 it is 3.99 kwh/kwp/day, 2017 it is 4.04 kwh/kwp/day and in 2018 Normalized energy is 3.73 kwh/kwp/day. Comparing with the pvsyst simulation report the normalized energy production is less it dependence on the generated energy pvsyst gives the simulation without considering the failures and losses of the plant like module cleaning, weather condition, module failures, junction box damages and due to other problems the energy production may varies from the pvsyst simulation report to real time PV plant output.

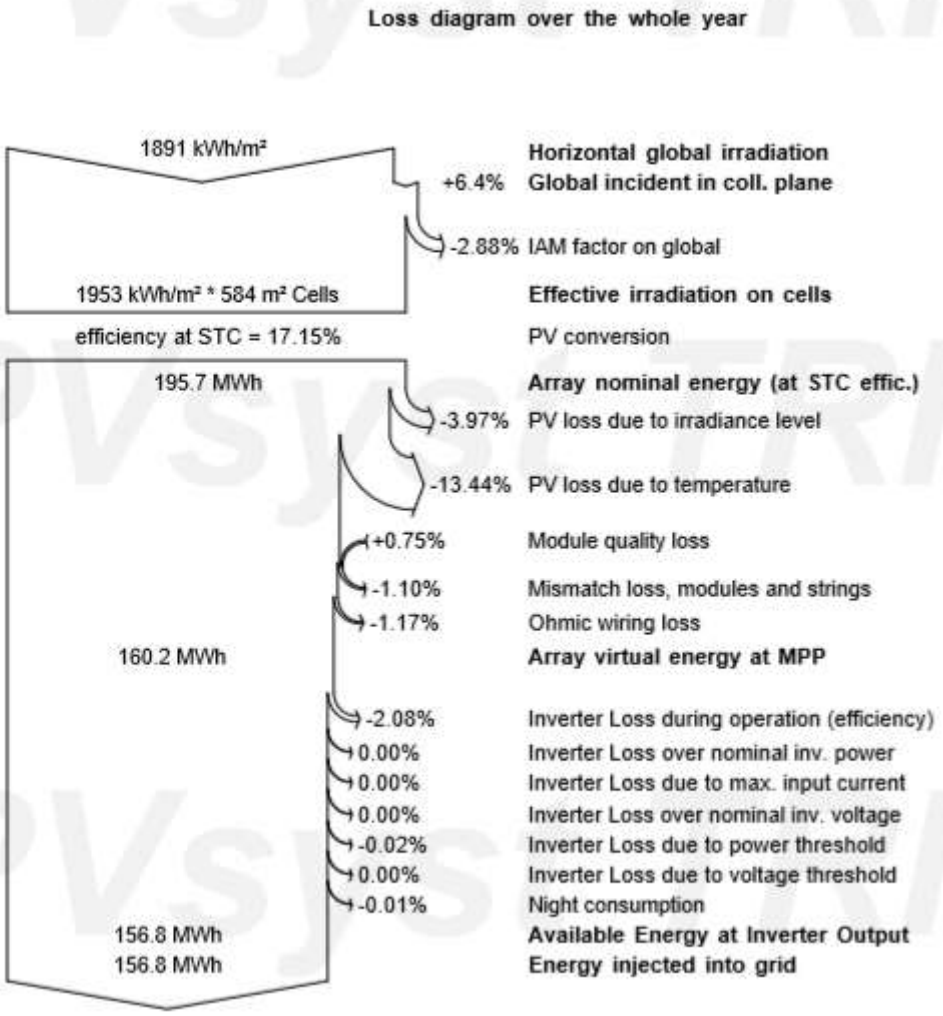

Fig.16: Loss Diagram Over the Whole Year by PVSYST Software

The PV system efficiencies for five years monthly wise are listed in the table 4 and also the system efficiency at standard test condition given by the pvsyst simulation is shown in the loss diagram fig 16.Efficiency at standard test condition is 17.15% for whole year from the table 4 we can see that the PV system efficiency for the year 2014 is 10.10%, 2015 is 9.87%, 2016 is 9.81%, 2017 is 9.70% and 2018 is 9.05%.comparing with the pvsyst report 100kwp solar PV system get the 58.89% efficiency in the year 2014, 57.55% in 2015, 57.20% in 2016, 56.58% in 2017 and 52.76% of efficiency in the 2018 year [13],[14].

V. CONCLUSION

Long term field performance analysis of 100KWp grid-connected rooftop solar PV power plant installed at BVRIT was studied and the following observations are drawn.

The generated energy is getting decreased every year but in between 2016-2017 the generation has been increased. The year wise performance ratio of plant from 2014-2018 is getting decreased progressively, in winter season the performance ratio is more compared to summer season. Performance ratio of the 100kwp solar PV plant is nearer to the pvsyst simulation Performance ratio. Capacity utilization factor of plant is varying between 16-17%. The output of all five inverters in five operation years is almost equal except in some months. Mainly the output of inverter 4 is comparatively less as the panel strings connected to this inverter are under shaded region. The PV system efficiency compared to the pvsyst simulation report getting 58.89% to 52.76% of standard test condition.

ABSTRACT

The usage of Electric Vehicles is increasing rapidly, we need to decrease the time required for charging. Therefore there is a demand to built High rated Charging Stations (CS) to reduce drivers Range Anxiety. Neutral Point Clamped (NPC) Converter containing Charging Station have benefits, but this converter has problem of unbalanced power. To overcome this problem, Comprehensive DC Power Balance Management (PBM) in coordination of Fast Chargers based on High Power Converter is used. Active DC PBM (APBM) is used to support balancing power of NPC converter so that an extra circuit for balancing is abolished. Where as Passive DC PBM (PPBM) is used to remove fluctuating currents in the neutral terminals and enable consistent operation of fast chargers. In these paper the DC-DC Converter is controlled using both proportional plus Integral(PI) and Artificial Intelligence(AI) controllers. The performance of PI controller is compared with AI controller to evaluate the system performance. Simulation results are validated using MATLAB/SIMULINK software.

I. INTRODUCTION

A feasible alternative to traditional internal combustion engine vehicles (ICEVs), Electric vehicles (EVs) are slowly rising their shares in the automobile industry due to low consumption of fuels and carbon emission gases [1], [2]. The price, time for charging and charging facilities are consumer's key importance, they are affecting their choice of EVs [3], [4]. So in order to increase the purchase of electric vehicles, need to implement the quick charging stations. If fast chargers minimize replenishment of EVs at reasonable rates than the normal replenishment of ICEVs and the fast charging stations scattered across the cities, then purchase of EVs would be increased [1], [5].

Not only the charging station circuit, the DC-DC converter used for fast chargers also plays an important role in terms of system efficiency and time required for charging battery. Usually Level I and Level II chargers are used for slow charging with low power rating so, they are mounted on board. The voltage and power rating are very high (DC Level III) for fast charging to reduce charging time. The DC voltage ranges from 200V to 600V and power from 50kW to 240kW, so it is mandatory to be off board charging station.

The bipolar dc bus circuit is studied in [6] and NPC converter used in centralized grid converter to convert AC-DC as shown in Fig 1. The bipolar bus gives more power capacity and flexibility for loads connected to it. The NPC converter's switching frequency is twice the switching frequency of device. Therefore results in low dv/dt, filter circuts and good performance in current. To solve problems arrived due to configuration in [6], comprehensive dc PBM is used. DC-DC converter used in high power fast charging stations does not need electrical isolation. So these convereters are more economical.

ISSN- 2394-5125 VOL 7, ISSUE 6, 2020

The social optimality of the proposed policies is established when each station is equipped with multiple charging slots[7]. The characteristics of EV charging, charging and discharging periods of loads for energy storage systems for whole day are studied in [8]. To support V2G and reactive power compensation the charging station was designed[9]. The performance of converters like classical buck converter, QZS and QZSC are studied in [10]. Measurements of EV fast charging process ABB Terra 52 charging stations installed in Aleksandro Lodzki(Poland) in [11]. The intelligent decision making system based on ANN is presented in [12]. The impact of EV charging stations on grid and distribution network in countries like Bangladesh is analysed in [13]. The step up DC-DC converter topologies in terms of start up currents and passive components are analysed in [14].

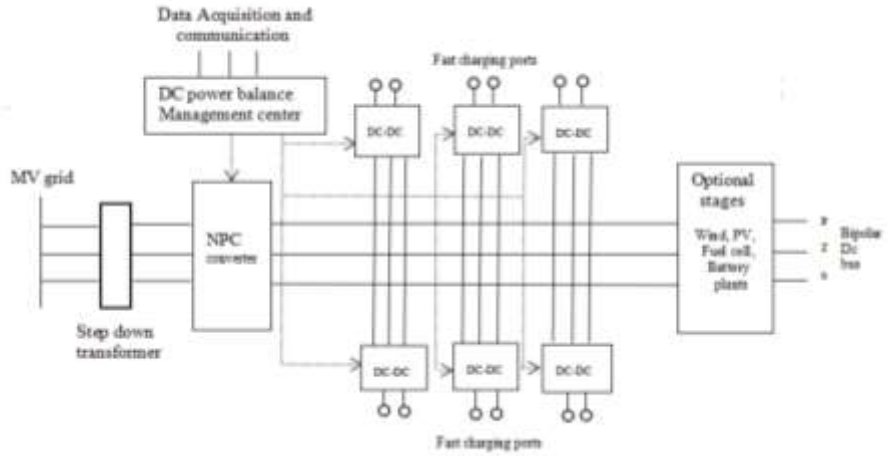

Fig. 1: Block Diagram of Controlling DC-DC Converters through DC Power Balance Management

These paper proposes the controlling of DC-DC converters with AI controllers. The high power dc-dc converter are used in fast chargers for high rated fast charging stations. The existing system has fast chargers with DC PBM capability which helps to remove additional balancing circuit and transformers. The NPC converter used as centralized grid converter will control the grid side currents leads to high power quality. The comprehensive DC PBM is used to solve the unbalanced power problems among positive and negative DC bus.

The PI controllers used in fast chargers have high steady state error. To reduce this AI controllers in the fast chargers are proposed which can reduce the error and leads to stable operation. The performance of proposed fast chargers with AI controllers are verified through simulation results.

II. PI CONTROLLER

A PI controller is a feedback controller which produces error by taking difference between two variables. The rise time decreases and overshoot and settling time decreases by using PI controller.

When proportional gain increases, it effects on control signal proportionally to error. Closed loop system will act fast because controller pushing harder for a given level of error. The erroer will not removed completely but reduced by incresing K_p.

When integral gain (K_i) added to the controller, it will reduce the error. If the error is constant, the integrator increases their gain, so control signal increases there by reduces the error. The only effect of integral term is it can make the system slow, because it will takes time to unwind when the sign of the error signal changes.

The output of PI controller y(t) can be written as,

$$y(t) = K_p e(t) + K_i \int e(t)dt \quad (1)$$

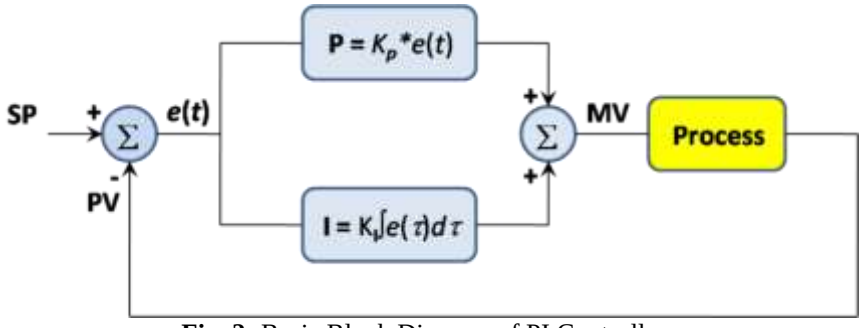

Fig. 2: Basic Block Diagram of PI Controller

III. AI CONTROLLER

An Artificial intelligence is an information processing model inspired by the way how biological neural system like brain process information. The central aspect of this paradigm is the new framework of the Model Application development system. It consists of a large number of fully integrated processing components, which work together to solve particular problems.

An ANN is set for a particular applications, such as pattern Recognition or evaluation of data, by way of learning. Genetic learning involves the modifications of Synaptic linkages between the neurons. That's it Also true Ann. It offers very extensive capabilities for Modelling of complex systems, predictions, controls and Achievement.

IV. DC-DC CONVERTER

A. Toplogy

The circuit of high power converter for fast chargers can be shown on Fig.4, it is composed of two 3 level DC-DC converters connected in parallel for handling high currents. Each converter unit consists of four switches with Free-wheeling diodes and two output inductors.

B. Modulation and principle

In the case where the circuit in balanced condition and the two convereter units are working in in-phase mode (as no phase difference between their gating signals.

To analyze the converter 2 operating modes are presented when Dx1=Dx4=D≤0.5, the waveforms of converter is shown in simulation results and also displays the waveforms when Dx1=Dx4=D≥0.5. where dx1 and dx4 are duty cycles obtained from controller and x indicates 1or 2 equivalent to unit 1 or 2. As modulation signals Dx1 and Dx4 are compared to two interleaved signals at 180^0 carrier signals c1, c4 to produce outer switches sx1 and sx4 gate signals. While sx2, sx3 will operate complimentarily to switches sx1 and sx4 respectively.

V. COMPREHENSIVE DC PBM

If the unbalanced power here between buses is not in the limits of central NPC converter's predefined control zone, the APBM is triggered for balancing the power so that there is no need of extra circuits for balancing. Where the unbalanced power is inside the balanced region, then the passive PBM is triggered to enhance the operation of the fast chargers in balanced region and to reduce fluctuation of the neutral currents. The comprehensive DC PBM will benefit the combination of APBM and PPBM in achieving the far more better cooperation for the charging station's total power balance. Therefore, it is proposed to cause the switching between APBM and PPBM by the power difference between Pp and Pn. The APBM is selected if ΔP is outside the pre-determined zone; If ΔPis within the zone, the PPBM is selected. For this the transition rule is as follows:

$$PBM = \begin{cases} APBM, & if \Delta P \notin [-P_{be}, P_{be}] \\ PPBM, & if \Delta P \in [-P_{be}, P_{be}], \end{cases} \quad (2)$$

ISSN- 2394-5125 VOL 7, ISSUE 6, 2020

Where P_{be} is selected on the basis of the NPC converter balance limits[6] and the sharing of balance tasks between the converter and the converter fast chargers.

The PBMC commands the reference power P_b^* for balance, which is calculated by collecting voltage and current values from loads which are connected to bipolar dc bus and getting the information of number of fast chargers 'n' which are in operation.

$$P_b^* = \Delta P / n = (P_n - P_b) / n \quad (3)$$

We can calculate the power to be balancedP_{bx}obtained from the each converter by,

$$P_{bx} = (D_{x1} - D_{x4}) v_i i_{ox} \quad (4)$$

By generating the control signals $\Delta\overline{D}_x$, the power can be controlled. And the control signals $\Delta\overline{D}_x$ have limits in the boundary[- $\Delta\hat{D}_x$, $\Delta\hat{D}_x$], and $\Delta\hat{D}_x$ is defined as:

$$\Delta\hat{D}_x = \begin{cases} \min\{\overline{D}_{x1}, \overline{D}_{x4}\}, & \overline{D}_{x1,x4} \le 0.5 \\ 1 - \max\{\overline{D}_{x1}, \overline{D}_{x4}\}, & \overline{D}_{x1,x4} \le 0.5 \end{cases} \quad (5)$$

The control signals$\Delta D_x$is obtained by multiplying $\Delta\overline{D}_x$ bysign of Output current i_o:

$$\Delta D_x = \Delta\overline{D}_x \operatorname{sgn}(i_0) \quad (6)$$

The final modulation signals D_{x1}, $D_{x4}$are obtained by above calculated$\Delta D_x$and original modulation signals $\overline{D}_{x1}$ $\overline{D}_{x4}$

$$D_{x1} = \overline{D}_{x1} + \Delta D_x \quad (7)$$

$$D_{x4} = \overline{D}_{x4} - \Delta D_x \quad (8)$$

VI. SIMULATION AND RESULTS

Fast charger is simulated by MATLAB / Simulink with comprehensive DC PBM with both PI controller and AI controller. A 240 kW rating converter is intended for verification, and the parameter values of the system model are given in below table I.

Table I: Simulation Parameter

PARAMETER	Sym.	SIMULATED VALUES
TOTAL DC VOLTAGE	2Vi	3.3 PU
INPUT CAPACITANCE	Ci	0.56 PU
OUTPUT INDUCTANCE	Lf	1.25 PU
OUTPUT CAPACITANCE	Cf	0.6 PU
SWITCHING FREQUENCY	Fs	72 PU
BASE FREQUENCY	Fb	60 HZ

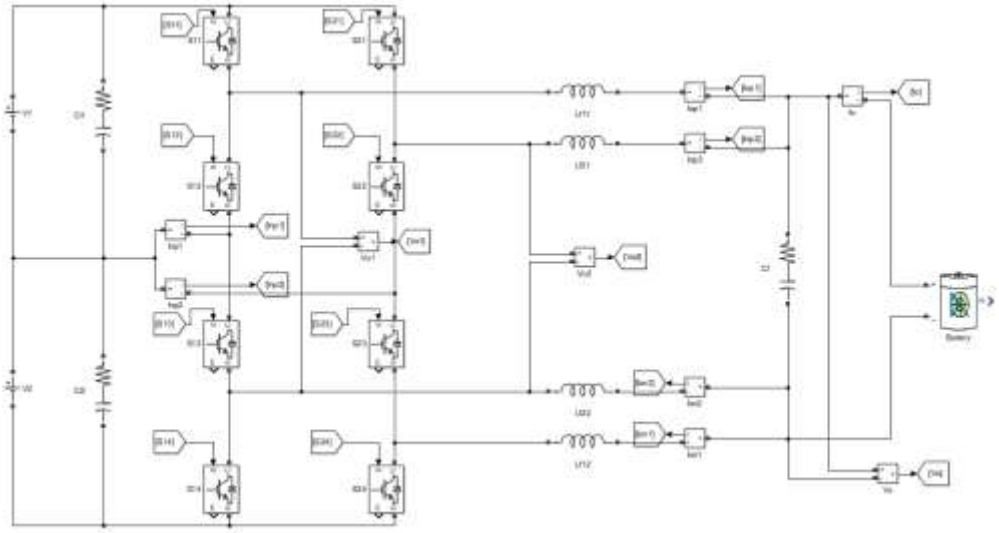

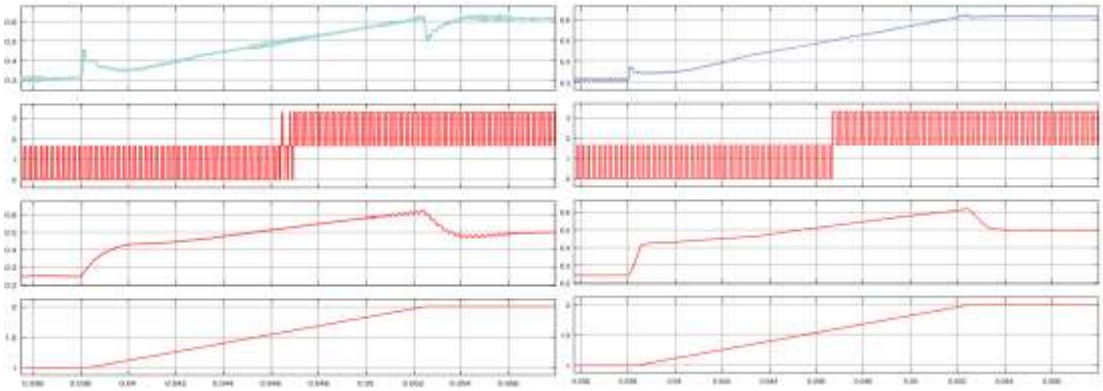

Fig. 4: Simulated Circuit for dc-dc Converter

(b) Simulated Results and discussion

The simulation results for changing from constant current to constant voltage condition for both PI and AI contollers are given in Fig 5. Modulation signals, output voltage across converters first unit, total output current and output voltage are compared using both PI and AI controllers.

Fig 5. shows that the modulation signals D11 and D14 using PI and AI controllers. The signals obtained AI controller have smooth signal compared to PI controller. The steady state error is less in case of AI controller and balanced operation can be achieved. In the same way the voltage and current signals have less error and steady state operation can be seen.

With PI Controller With AI Controller

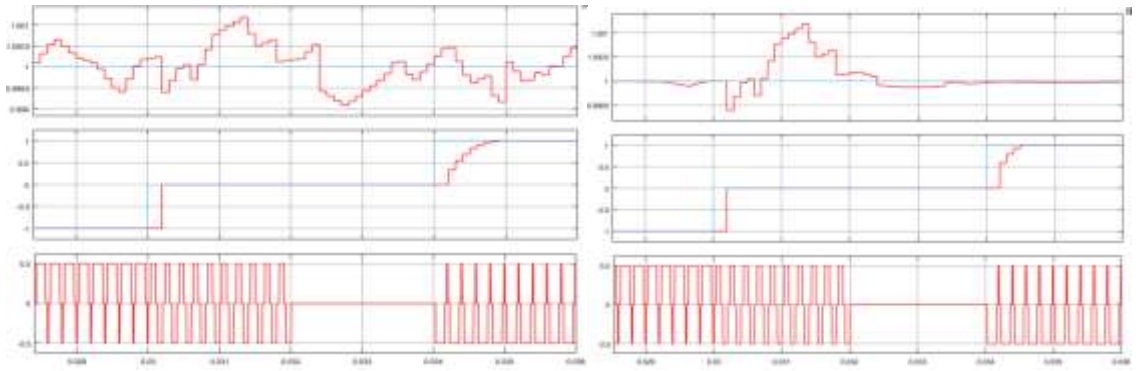

Fig. 5: Simulation Performance for Changing from Constant Current to Constant Voltage Condition. (a) Modulation Signals D11 and D14. (b) Output Voltage of First Unit V_{01}. (c) Output Current I_0. (d) Voltage Across Output V_0

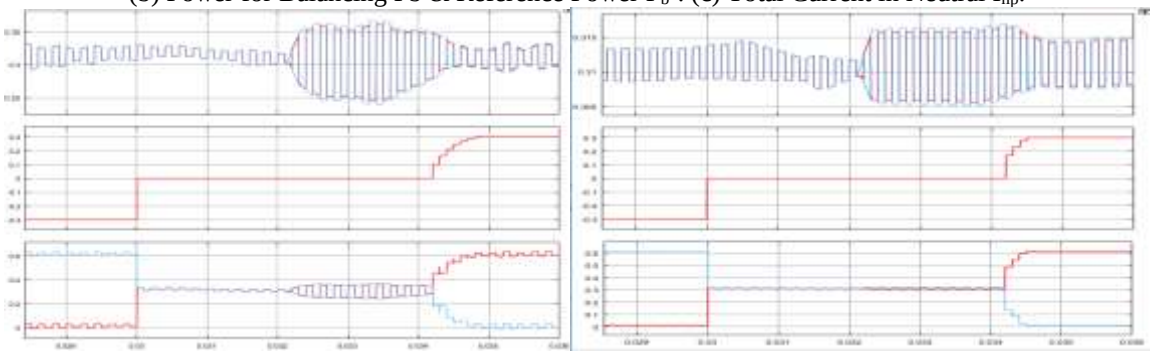
Fig 6. shows the conduction of PBM in constant current condition for D≤0.5. Here current, balance power & neutral point currents are compared. The output current signal had more dampings using PI controller which can be drastically reduced by using AI controller.

The Fig 7. and Fig 8. shows the simulated outputs of Modulation signals and output currents at constant current condition when D≤0.5. Modulation signals and current signals are compared using both PI and AI controllers.



ISSN- 2394-5125 VOL 7, ISSUE 6, 2020

The modulation signals D11 and D14 shown in Fig 7 can observe the changes clearly obatined using both controllers. As well as the current signals as shown in fig.8, are continuous and uniform by using AI controller.

VII. CONCLUSION

The DC-DC converter used in Fast chargers is controlled using PI and AI controllers. The fast chargers used in this project has a capacity of DC power balancing and results in removing extra circuit for power control and high rating transformers. And there by increasing overall system performance. The performance of PI and AI controllers used in DC-DC converters are analyzed. The simulated results shows the AI controller gives high speed response and study state error compared to PI controller. The study state error in using AI controller is low and stabilization is best compared to PI controller. The computation time for AI controller is less than PI controller.

ABSTRACT:

Optimization technique plays very important part in frequent issues. During this optimization techniques like Advanced Honey Bee algorithmic program are tested in an IEEE-14 Bus installation. As a result of reducing the power losses, the voltage profile improvement and voltage stability improvement can be maintained throughout the power system. In addition, these views show the enhanced optimization technique that ensemble the power system to take care of voltage stability by reducing power losses in transmission line. Among a variation of FACTS controllers, Unified Power Flow Controller (UPFC) is the main powerful and versatile device in facts controller. To boost system bus voltage and to reduce the reactive power and active power losses within the lines as well as steady state model of UPFC in Newton-Raphson (NR) power flow algorithmic program. To see the steady state performance of the UPFC within the load Flow studies an IEEE-14 bus system has taken. Also, this paper shows the higher optimization performance that suit in the ability of power system to retain the voltage stability by reducing losses in the transmission system. These results are tabulated to improve the power quantity losses and reduced from the actual losses in the power system.

KEYWORD: *Unified Power Flow Controller (UPFC), Advanced Honey Bee algorithmic*

INTRODUCTION

Power Generation and Transmission could be a composite process, everywhere power is to be resettled, and therefore the 2 main parts are active and reactive power. During a three-phase ac power structure reactive power and real power flows at the generating station toward the load through various transmission lines and networks buses. The true power and reactive power flow line is termed as the power flow or load flow in transmission system.

In this paper, a singular optimization method primarily based on the mixing of the normal honey-bee mating optimization algorithm with a plant boom model for this set of rules are carried out. Initially, then Honey-bee mating optimization algorithm became most commonly mimic the mate and breeding of the queen of a hive. Its calculation begins with a mate flight procedure with the aid of the usage of an annealing characteristic to pick out correct solutions and save in the sperm theca.The plant growth simulation set of rules was technologically advanced based on the categorization of the plant growth process and plant phototropism, only sure solutions pleasurable the limitations in conjunction by their health are superior to one of the basis version and are stored in the following search. The effects can be compared with numerous strategies toward analyze of robustness and working out efficiency of this technique.

As a consequence, the optimization of control strategies and development in the performance of ac strength systems, we require the various exceptional kinds' compensators. These devices represent an emerging technology known as FACTS (bendy alternating contemporary transmission structures).The FACTS generation open up new opportunity for calculating the each kind of real and reactive power and enhancing the existing transmission structure.

The power through a transmission line may be prohibited for increasing the capacity of strains. This prospect will rise thru the capacity of FACTS controllers to regulate the electrical parameters along with series impedances and shunt impedances connected in power system

HONEY-BEE MATING OPTIMIZATION TECHNIQUES:

A colony of honey bees be inclusive of a queen, numerous hundred drones, 30,000 to 80,000 people and brood at some stage in the energetic season. The queen and handiest has capable of laying eggs upto 1,500 throughout a one day processing time period. Drones' position is to mate with the queen.

The obligations of an employee bee are consisting of rearing brood, nurture of the queen and drones, clean-up, regulating temperature, grouping of nectar, pollen, water, and so forth. The HBMO technique Algorithm is the aggregate of numerous

techniques correspond to exclusive section of mating procedure of the queen.

The primary points of HBMO set of guidelines Based on their mating process are given beneath:

Initially the mating process is done which queen select drones to form the sperm theca (list of drones) probabilistically. Subsequently, a drone is chosen from the mention list at random process for the era of the broods. Making a new broods through crossover of genotypes, by their drone's and their queens.

Before starting of mating technique, the queen's length of sperm theca huge range equals to certain level of the quantity with mating of the queen and unmarried mating escape is determined. When the queen pals efficaciously, the genotype drone is saved.

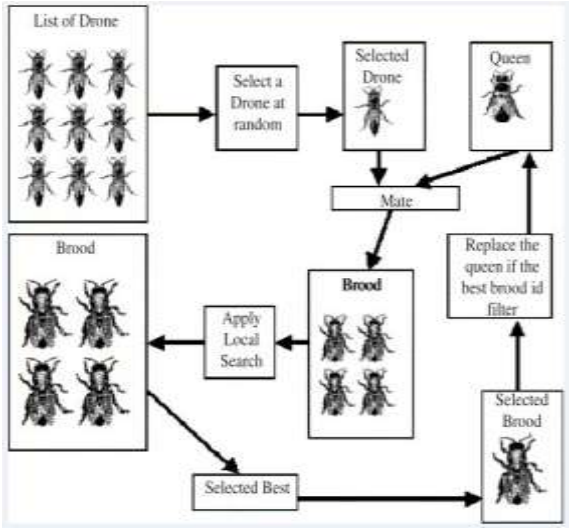

Figure 1. The HBMO algorithm

Two distinctive parameters need to be described, the wide sort of queen and the quantity broods as a manner to be borne by means of queens. In this performance advanced HBMO set of rules, then variety of queens is same to be one, and the quantity of broods is situate equal to the amount of the queens sperm theca period. Drone buddies with queen probabilistically the usage of an annealing that means as follow:

$$\text{Prob}(D) = \exp(-\Delta(f)/S(t))$$

When the queen is at high-speed quantity or health of drone is same as the queens, then possibility of mating is extreme. After seeing each process, the velocity of queens and energy level is decreases by keeping this equation:

$$S(t+1) = \alpha \times S(t)$$

$$\text{Energy}(t+1) = \alpha \times \text{Energy}(t)$$

Let α is speed and strength reduction issue in each step. Initially, fee and the energy of each queen are generating at different process. Since the speed and strength are equal impact on their mating procedure, in this paper, speed of queen and strength has been determined. This brood may be stepped forward, inside the next degree, via using people to use local search.

The people put into effect the limited search techniques to improve broods produced with mating process. This technique is implemented by using the number of local seek heuristics (NWorker1) and combining with them (Nworker2). Therefore, wide varieties of workers are calculated with the aid of sum that number.

CALCULATION OF THE ADVANCED HONEY-BEE MATING OPTIMIZATION TECHNIQUE:

The certain range of optimization solution in honey-bee mating technique with set of rules and qualification lies in the variant of control parameters. As a result of combining both the merits and demerits of omission with outside parameter and reduction of infeasible answers which exhibit in plant growth reproduction technique, then most advanced HBMO algorithm with set of rules to improve the result

Step 1. Input places in the shielding gadgets

The calculation process starts with the evolved records and retrieval of relay & Circuit breakers from SCADA method. Then this parameter contains of colony range, and wide variety of queen and brood.

Step 2. Structure the hive

Using colony N bees are shaped at this stage, in which all bees consist of M gene. An environment shape H= [H1 H2 H3….Hi…..HN] T is used to symbolize this type of colony, wherein Hi =xi,1 xi,2…xi,j…..Xi,M], and xi. Then Honey-bee colony usually includes of queen, drones, workers, and broods. Only the queen bees are capable to lay the eggs. The drones inside the honey-bee colony are haploid and act as their moms' genome by changing its genetic symphony. Then fitness standards (Hi) of its every bee in the colony is evaluated and differentiate between the queens and drones, where

$$F(H) = 1 / (1 + \text{job } j).$$

Step 3. Mating of the queens, breed & broods

Based on their mating possibility compute are suggested, and then threat sperm maintenance within the queen's spermatheca. A lay down of N broad answers (broods) Hbroad be subsequently generated in the crossover process. In this line to line fault are estimated and trouble shouted, by this mating a solution will be modified chances of line fault happening at a positive section in an energy storage device.

Step 4. Advanced Bee fitness with broods

In this process, fitness of each bee generated answer f (Hbroad) is calculated. These solutions are most important fitness serves as compared to foundation version R0. Then R0 may be a fundamental view to look N answer, such that the trunks locate T is fashioned. If the fitness of d^{th} node f (Td) be greater than (R0) then there is deemed the

viable answer; in any other case, Td is abandoned. Until the answer determined within the new brood gives the preceding queen, then comes with an anticipated solution.

Step 5. Preventive circumstance

The complete procedure is terminated to end process when the computation fallout converges. To improve the facilitate and visualization process, a picture with user interface design is essential to expose the location of faulted phase.

THE PLANT GROWTH SIMULATION TECHNIQUES:

Here PGS technique based on the power system in which plant increase, where as stem grow beginning from the roots and the plants; some of the branches develop from nodes at trunk; at this time a few sparkling branches develop from the nodes on the branches. Inspired by the matching with the plant development technique, an optimization set of rules may be defined. The gadget that is to be optimized initial then `grows' begin at the bases of a plant stem and keep `growing' subsequences branches is located.

The Plant Growth simulation law procedure:

The following records were proved through the organic experiments approximately the increase laws of plant,

(i)There is a morphactin concentration in the node and it's far above the ground, the chance of developing a brand new buds and branch at the node.

(ii)Here morphactin awareness in any node to be analysis in the plant simulation. The ecological information to plant growth with node is depending on the digital role. Here morphactin concentrations of nodes are assigning to the new atmosphere records to a certain node which is new branch.

Probability of plant growth Model:

A possibility model which is famous for simulate the boom process in plant phototropism. During this structure, the feature g(Y) is defined for illustrating the surrounding process of node Y in a plant. The much less significant cost of g(Y) is higher for surroundings condition of the node Y for developing a fresh branch. The most important comic strip of this form can be explained as shown: At first, Plant growth simulation trunk M at its origin B0. but we imagine that there is k nodes B_{M1}; B_{M2};: : : ; B_{Mk} are better environment than the root node B_0, and the trunk M, significance in that job g(Y) of its nodes B_{M1}; B_{M2}; : : : ; B_{Mk}, and B_0 suit $g(B_{M\,i}) < g(B_0)$ (i = 1; 2; 3; : : : ; k), next morphactin concentration C_{M1}; C_{M2}; : : : ; C_{Mk} of its nodes B_{M1}; B_{M2}; : : ; B_{Mk} are obtain from the subsequent steps.

$$C_{Mi}=\frac{g(B0)-g(Bmi)}{\Delta 1} \text{ Where (i = 1, 2, :: : k)}$$

$$\Delta 1 = \sum_{i=1}^{k} g(B0) - g(BMi)$$

The following Equation are the morphactin concentration at any node is dependent to their relative magnitude with the gap of the environmental function between the root nodes and the corresponding node in the nodes, in which it's essential, to give the relationship between the Morphactin concentration and location.

$\sum_{i=1}^{k} Cmi = 1$, that means there is morphactin concentration C_{M1}, C_{M2},….M_k of the nodes.

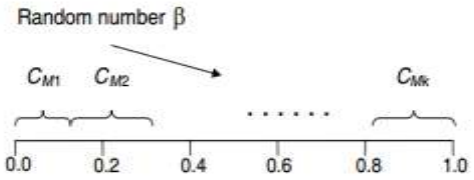

Figure 2. Morphactin concentration state space.

New superior plant growth nodes will grow a new branch in next step which can gain a similar way as that of B_{M2}. This procedure is repeated till here is no new fresh branch are grown, which means that plant are produced.

UPFC Injection Model for Load Flow Studies:

The UPFC is the most controlling and versatile FACTS-equipment used to manage the power system over the power flow and stability of the system. UPFC can be performing static as well as dynamic condition. Static is an analysis at the steady state condition and dynamic state analysis at the transient condition such as faults occur in power system.

Operation of UPFC:

The UPFC is a device that can manipulate simultaneously all three parameters of line strength float (line impedance, voltage and segment perspective).UPFC is one of the FACTS households that used to lessen strength float in transmission. The UPFC is mixture of both STATCOM and SSSC. Converters are operating from common dc system with a dc storage capacitor. The controller provide the gating alerts to the converter valves to provide the favored collection voltages and concurrently drawing the vital shunt currents, In order to provide the desired collection injected voltage, the inverter calls for a dc supply with regenerative skills. The viable solution is to use shunt inverter with help of dc bus voltages.

Advantages of UPFC:

The UPFC can make a feature of STATCOM and SSSC and phase perspective regulator. The Unified Power Flow Controller (UPFC) is includes two switching converter, which

can be consider as voltage source inverter the use of gate thyristor valves, as illustrated. These inverters, named as "VSC1" and "VSC2" can be determined and its operated with a common place dc hyperlink supplied by way of a dc storage capacitor.

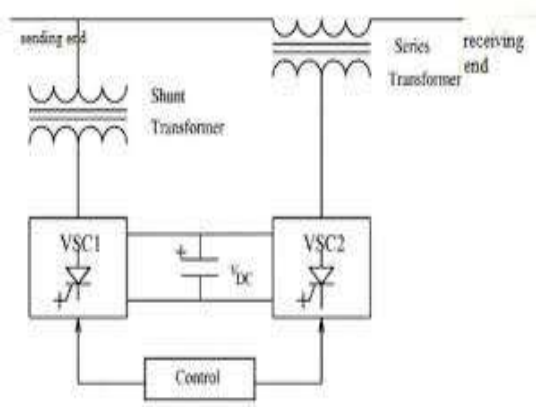

Figure 3. The Schematic diagram of UPFC

While the collection converter of the UPFC can inject a voltage with choppy importance and segment angle it is able to alternate actual power with the transmission line with the assist out of series transformer. However, a UPFC as a whole (each converter) can't deliver or soak up real electricity in regular state (besides for the electricity interested in atone for the losses).

The characteristic of voltage source converter to be generate or take into the account of real and reactive power by converter 2 on common place dc hyperlink. Inverter 2 gives the foremost feature of UPFC is to inject a voltage with controllable converter significance (zero= V= V) and its section attitude ρ (zero = ρ = 360°), on the electricity frequency is delivered with line thru an insertion transformer.

Then modern transmission line flows through voltage supply which will resultant an actual or true power and reactive power trade between them. So, that Inverter may be operates at a unity power factor or manage to have a reactive power flow in transmission system and its alternate with reactive power which is exchange between the two Inverter.

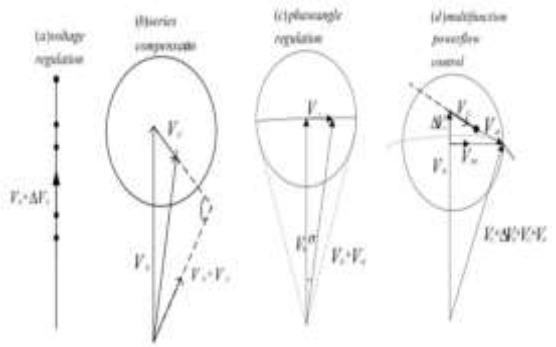

Figure 4. Basic diagram for UPFC control function.

The Unified Power Flow Controller are standard and conventional devices in power system which based on its real and reactive series compensation, shunt compensation, then UPFC is the only device which can complete all the role in transmission line.

In this representation, conventional series compensators are needed for phase shifting. An UPFC can control both the magnitude and angular position of injected voltage in the real system, and also to improve the real and reactive power flow in the transmission line.

RESULT AND DISCUSSION

In this research advanced Honey bee mating technique and advanced plant growth simulation process are based on hybrid algorithm for the voltage stability and to enhance the system. This was performed on MATLAB and output was evaluated in IEEE-14 bus system.

First of all, Newton-Raphson load flow analysis is used to analyze the system performances. Contingency analysis for the systems were performed and based on that performance indices were calculated at normal load and were ranked accordingly. Thus, the optimal solution for UPFC is determined based on its contingency analysis. Then the location of UPFC is determined by PGS which depend on the value. Bus 1,2,3,6 and 8 are the generator buses excepted whereas UPFC is connected at all other buses. The standard IEEE 14 bus system was shown in figure.

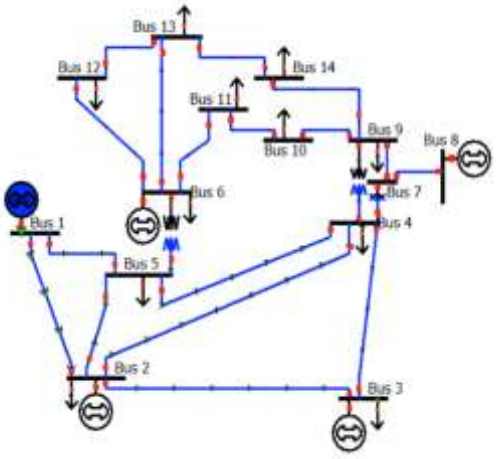

Figure 5. Systematic diagram to an IEEE-14 Bus System.

An IEEE-14 bus system was important for voltages, active and reactive powers at each bus. A MATLAB plan is used for IEEE-14 bus system with standard IEEE-14 bus system data input file.

12	1.055	-15.096	6.100	1.600	0.000	0.000	0.000
13	1.050	-15.174	13.500	5.800	0.000	0.000	0.000
14	1.034	-16.041	14.900	5.000	0.000	0.000	0.000
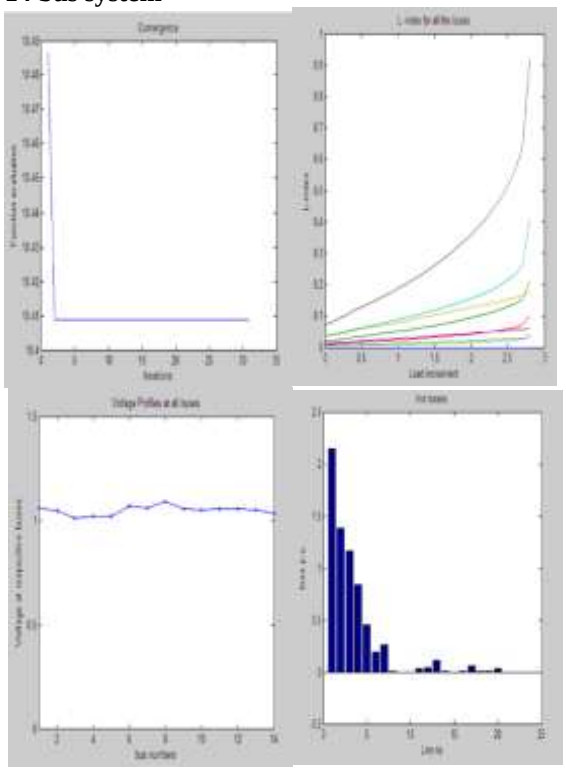
Total			259.000	73.500	272.344	80.779	19.000

Load voltage deviation is 0.673299
Real power loss is 13.393541 MW
L-index is 0.858395
Voltage stability index is 3.000000
The weak bus is 14
Location of UPFC is 9 - 14
Series injection voltage is 0.030000
Angle of injection is 0.165724



Case 3: Plant Growth Optiminization Technique for IEEE 14 bus system

Load voltage deviation is 0.673282
Real power loss is 13.393283 MW
L-index is 0.762855
Voltage stability index is 3.000000
Weak bus is 14
Location of UPFC is 13 - 14
Series injection voltage is 0.020265
Angle of injection is 1.030045

Case 4: Hybrid Optimization Technique for IEEE 14 bus system

Load voltage deviation is 0.673229
Real power loss is 13.391747 MW
L-index is 0.922264
Voltage stability index is 2.900000
Weak bus is 14
Location of UPFC is 9 – 10
Series injection voltage is 0.020252
Angle of injection is 0.89036

CONCLUSION:

The hybrid approach becomes proposed for fixing IEEE 14 bus device hassle in electricity transmission system. FACTS gadgets play a great task to control the power flow in transmission line. Advanced Honey Bee technique and plant growth simulation is proposed to optimize the area of UPFC device.. The proposed hybrid technique is carried out in MATLAB operating platform which is examined with IEEE 14 bus bench mark machine. Here, loading instances are taken into consideration to evaluate the proposed technique and the entire system cost, power loss, voltage stability index are as compared with conventional AHB algorithm. The comparative analysis completed for the effectiveness hybrid set of rules for solving objective of optimization.

FUTURE SCOPE:

Further extension of the thesis can be completed by using incorporating present day synthetic intelligences (AI) techniques Such Grey wolf optimization, Symbiotic organisms search set of rules, Fruit fly set of rules, Water cycle and evaporation set of rules, Bacterial foraging optimization, Satin bowerbird optimization and so on…for checking out the IEEE 30 bus system, and it as compared with IEEE 14 bus machine.

ABSTRACT

The energy crisis is the biggest problem in the world today. Renewable energy resources are gaining worldwide priorities to reduce reliance on traditional resources. Solar energy is gaining prompt attention as significant means of increasing uses of renewable energy. Owing to variability in the day night cycle and also owing to seasonal changes, the variability in solar energy occurs daily. World population is increasing quite rapidly. Non-renewable energy sources such as oil and coal have been extinguishing for the past decade, making it a severe problem to supply the planet with sustainable electricity. Yet, solar power plays an important primary energy role. This paper introduces a dual axis solar tracking device from which maximum solar energy can be collected by implementing the work by coding a suitable Maximum Power Point Tracking (MPPT) algorithm for a Monocrystalline solar panel. This work is carried out using microcontroller, Light Dependent Resistor (LDR), dc motor, and Arduino.

1. Introduction

The change in the climatic conditions has reached the critical level in the present scenario. The key explanations for climate change are due to natural causes, and destructions caused by man such as global warming and greenhouse gasses impact the global climate conditions. The need for reliable, plentiful and affordable electricity from renewable energy sources has an important position to play in the country's energy crisis in the last decade. The government has started to reduce the usage of traditional energy sources and promotes the use of renewables. Such an example is solar which is abundant and inexhaustible in nature. Solar panel transforms the solar energy directly into electricity. Solar panels are primarily constructed of materials made from semiconductors [1]. Monocrystalline solar panels are made in silicon wafer formats and are assembled in a large silicon block. The most reliable and tested technology for increasing the performance of solar panels is solar tracking system which align the panels with the direction of the sun. In recent days, it has become popular worldwide to extract the maximum power in the most effective way. It was observed that a dual axis tracker can increase power output by 40 percent – 60 percent over a fixed system. Over the past two or three decades, energy from solar have emerged as a potential renewable source of energy and are now used in a wide range of industries and households. These systems are solar collector-based, designed to absorb the energy from sun and transform it into either electric or heat energy. The power produced in these applications depends on the level of solar energy collected by the collector, and hence utmost care should be taken in designing the tracking schemes which is capable of tracking the sun's direction with high accuracy.

2. Photovoltaic technology

A solar cell or PV cell is a device, which by the principle of photovoltaic action, transforms solar energy into electricity. The word solar cell is often used for devices explicitly designed to absorb energy from sunlight, while the term photovoltaic cell is used when the source is unclear. A photovoltaic cell's current- and power-voltage characteristics are shown in Fig. 1. Photons reach the solar panel and are absorbed by semi-conductive materials, such as silicon. Negatively charged Electrons are easily knocked

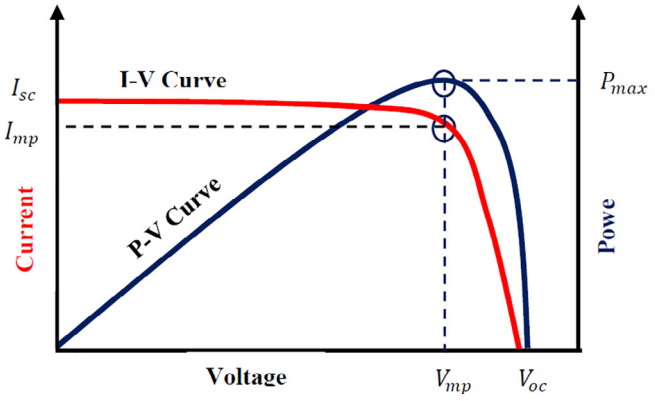

Fig. 1. Characteristics of photovoltaic cell.

out of their atoms to allow them to flow unidirectionally and generate electricity. Isc and Voc are the short-circuit current and open circuit voltage of the panel respectively. Imp and Vmp are the current and voltage at the maximum power point time. Whereas, the positive charged particles flow in the opposite direction in a silicon solar cell. Therefore, a number of solar panels transforms solar energy into a usable amount of DC [3].

3. Methodology and design

Contemplating the concept of constructing the design, the concept conceived mainly is to use solar power as best as possible. The primary requirement out of all expectations is to store solar energy at its maximum level, which ultimately leads to incubation of a new solar tracking system which works autonomously. The key components of this system are as follows

- Panel of Solar Arrays
- DC Motor
- L293D Motor driver
- Microcontroller/ Arduino Board
- LDR
- Current sensor

3.1. Solar panel

Solar panels represent an assembly of photovoltaic cells which excites the electron when the photons strike the solar cells. Most residential application uses crystalline silicon cells or thin-film semiconductor material. Here, the monocrystalline silicon cells are used in the solar panels in which the complete pack of the cell is made by a single silicon crystal [2]. The average sunlight per solar panel is proportional to the sun's angular position relative to the panel [5]. In order to maintain the angle of 90^{O} between solar rays and the solar array, a solar tracking system is intended. The maximum power for calculating the electricity is defined as the product of voltage under open-circuit condition (V_{OC}), current during short-circuit condition (I_{SC}), and fill factor (FF).

$$P_{\max} = V_{OC} * I_{SC} * FF \tag{1}$$

The efficiency (η) is then calculated as

$$E = \frac{V_{OC} * I_{SC} * FF}{P_{in}} \tag{2}$$

3.2. DC motor and driver

A current-carrying conductor when placed in an external magnetic field will experience a force which depends upon the conductor's current and the intensity of external magnetic field. The Driver is a motor module which allows to simultaneously control the direction and speed of motors. Some drivers which can amplify the 5v voltage to 12v are required to drive a motor. This motor driver is built with the L293D IC. Many IC manufacturers these days have H-bridge motor driver available on the market, as L293D is the most commonly used H-bridge driver IC. H-bridge can also be made using transistors and MOSFETs, and so on. This IC is used to control the forward, reverse, left, and right direction of the motor. The driver IC has a 16-pin configuration and produces bidirectional currents required for changing the motor's direction at voltages from 5 to 36 V. Certain applications require power electronic control which induces harmonics in the system and mitigation of harmonics should be properly addressed through suitable harmonic filters [10,11].

3.3. Microcontroller

Circumstances in the field of microcontrollers that we find ourselves in today had their beginnings in the development of integrated circuit technology. The technology has allowed hundreds of thousands of transistors to be stored in one chip. The system used the ATMEGA328P microcontroller. Microcontroller is the centre of the device at large. The ATMEGA328P microcontroller requires a voltage supply regulated at 5 V. The voltage regulator '7805′ helps to provide the microcontroller with a set supply of 5 V. The timer in ATMEGA328P is used for creating delay. In respect to the sun, earth rotates 360° in a day on its own axis and therefore it rotates 15°every hour or every 15 min it rotates 3.75°. Therefore, a short delay of 1.5 min and moderate delay of 15 min should be programmed.

3.4. Light Dependent resistor (LDR)

Light Based Resistor or Photoresistor, a passive electronic component, is essentially a resistor that has a resistor that varies depending on the strength of the light. One type of resistor is LDR. The resistance of this resistor can vary depending on the light that falls upon it. If light decreases on LDR the resistance increases and vice versa. A stable condition is reached when the LDR light intensities are equal. The primary source of energy for light, the Sun, travels from east to west. This Sun movement induces variability in the degree of light intensities that fall on the LDRs. The developed algorithm measures the difference in light intensity falling on the LDRs and then rotates the solar panel to travel along with the trail of the light source.

3.5. Current sensor

A signal which is proportional to magnitude of current is generated in the sensor whenever it senses current. The output of the sensor may be of analog or digital in nature. The initiator signal can also be used by an ammeter to measure the current. These can also be stored for future data collection evaluations, or can be used for monitoring purposes.

4. Maximum power point tracking

MPPT is a technical solution used in solar PV inverters to maximize power output in less than optimal sunlight conditions. Perturb and Observe (P&O) which is the one of the most commonly used algorithm is used here. When the photovoltaic module produces maximum power at certain voltage it is called as maximum power point. The power output of the module depends upon climatic conditions and solar cell's temperature. Photovoltaic cells

share a composite link with their working environment and the maximum generated power [4]. A solar cell's non-linear electric tendencies are indicated by a ratio of the solar cell's maximum power to the sum of V_{oc} and I_{sc}. From the I-V curve it is evident that the PV cells serve as a current constant source till the maximum power point region. Once the maximum point is reached, the curve transforms to exponentially decreasing nature. This algorithm is used to collect the maximum power by setting the required voltage in the PV module. The association between the battery voltage and output voltage is done [9]. They extract the high voltage power from the PV modules and modify them to fulfill the requirement of charging lower voltage batteries. The power is henceforth converted to the best voltage to obtain maximum current in the battery. The algorithm extracts the high voltage power from the PV modules and adjust it to meet lower voltage battery charging requirements. Henceforth, the conversion of power to the required voltage is achieved to get full battery current.

5. Operation of the solar tracker

The automatic solar tracking module consists of LDRs, solar panel, DC motor and Microcontroller. To sense the intensity of light, the corners of the solar panel is equipped with LDRs. The basic property of LDRs is generating low resistance when maximum light intensity. The basic property of LDRs is to produce least resistance when the intensity of solar ray falling on them is maximum. The motor that is attached to the panel shifts it with respect to the position of the sun. The solar panel is positioned in manner so as, the intensity of light falling on the LDRs are compared and the motor drives it towards the LDR which is having high light intensity. If there is more light intensity dropping on right LDR, the panel moves slowly to the right and if there is more light on the LDR which is mounted on left side, the panel moves gradually to the left. Sun is ahead in the noontime and light intensity is the same on both sides. Under this condition, the panel is stagnant without any power output from the motor drive. Fig. 2. shows the block diagram for the automatic Solar Power Tracking System [8].

An Arduino is actually a microcontroller-based kit which, owing to its open source hardware feature, can be either used directly by buying from the vendor or made at home using the components. It is used mainly in communications and in the control or operation of many devices. The most important advantage with Arduino is that the programs can be loaded directly to the device without any hardware programmer needing to burn the program. It is achieved because of the Boot loader's 0.5 KB presence which enables the program to burn into the circuit. What we need to do is download and write the code to the Arduino program. Fig. 3. displays the Arduino Control Circuit. Motor rotation relies on Allow Pins. When Activate 1/2 is Small, motor connected to

0	0	Stop
0	1	Counter-clock wise
1	0	Clock wise
1	1	Stop

the left part of IC will rotate as shown in Table 1 for the given inputs (IP1 and IP2).

The performance of the system is tested under two operating conditions viz, normal daylight and bad light condition.

5.1. Normal day light condition

The solar tracker uses the LDR outputs for comparing the output voltages. As the sun moves in the daytime from east to west, ATMEGA328P's Analog Input 0 should generate higher voltage than the Analog Input 1 for sensing the sun's rotation. This state is known as normal daylight state and after every 15 min, 3.75° rotation is achieved in the panel by the tracker.

5.2. Bad weather condition

During cloudy days or bad weather condition the magnitude of light intensity on LDR will be less and therefore there may not be

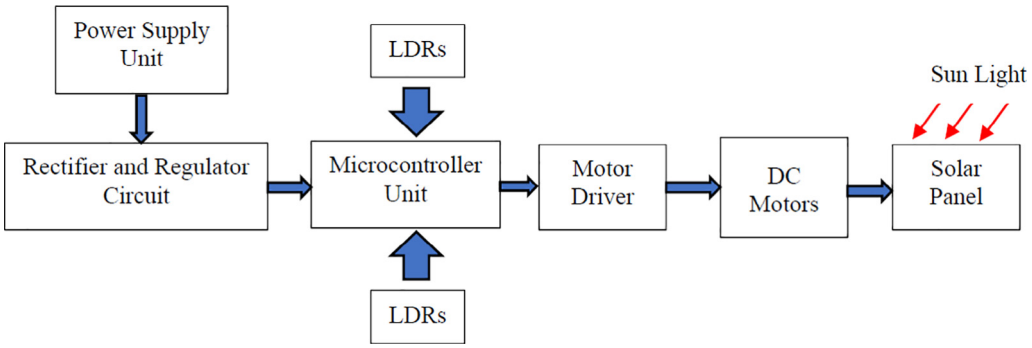

Fig. 2. Block Diagram of Solar Power Tracking System.

sufficient voltages at the point [1213]. Under this condition, the voltage difference at the junction will be lesser than the threshold value and the sun continues to rise westwards. A short delay is provided to fix this problem, which tests the voltage input every 1.5 min from the junction point. For a step rotation of the motor, the microcontroller consecutively checks the variable count 10 times to generate a wait signal which is equal to 15 min which results in a moderate delay.

6. Algorithm

Microcontroller acts as brain of the solar tracking system as a whole. The desired light radiation is received through the CDS sensors. You can then equate the input radiation to the sensors to determine the direction of the sun or the source of light [6 7]. The microcontroller then transmits the output signal to the motor for the desired angle of altitude and angle of elevation. To make the microcontroller read out the input and respond accordingly, an algorithm must be created. This flow charts are then translated into C language and compiled using the Arduino IDE. Fig. 4. shows the flow chart of the method.

7. System Specification and circuit diagram

The technical specification of the proposed system is given in Table 2.

The circuit diagram and the hardware prototype of the proposed system is shown in Fig. 5(a) and (b) respectively.

8. Experimental results and discussions

During normal day light and bad day light conditions, the readings from automatic solar tracking system are taken and analyzed. The observations and readings which have been taken are as below in Table 3 and Table 4. On different days the Table indicates different readings.

Table 2
System Specification.

Parameters	Specification
Weight	75 g
Diode	WG40 Bridge
Transformer	230V/12V AC
Rectifier	W04G Bridge
Filter Capacitor	1000μf & 100μf
Resistance	330 Ω, 10K X
IC Regulator	IC 7805
LDR	PG Series/ CdS

Motor	0-5V
Temperature Rang	0°C – 55°C
Solar panel	V(OC) : 11.05 VI(SC) : 10AP(Out): 10 W

8.1. Under normal day light condition

Table 3 shows the experimental results obtained under normal day light condition to study the performance of a fixed and dual axis solar panel of the autonomous solar tracking system. From the observed readings, it is clear that the voltage output of each LDR varies from one another as the intensity of light varies from east to west. Table 3 reveals that LDR_1 provides low resistance from 7:00am to 1:00 pm, while LDR_3 provides medium value of resistance from (7 – 11) am, respectively. From 7:00am until 1:00 pm, LDR 2 and LDR 4 offers more or less same resistance. Fixed panels deliver maximum output from 11:00am to 3:00 pm, whereas the automatic tracking system panel offers 61%, 93% and 82% efficiencies at 7:00am, 12 noon and 5:00 pm respectively. The per day average temperature reading was 28 °C. The variations in output power during normal day light condition is shown in Fig. 6

8.2. Bad day light condition

Below is also a collection of readings taken on a Bad day light condition. The intensity of light was very low, which leads to low output from the PV system. The experimental results obtained on a bad day light are shown in Table 4. It is inferred from Table 4 that,

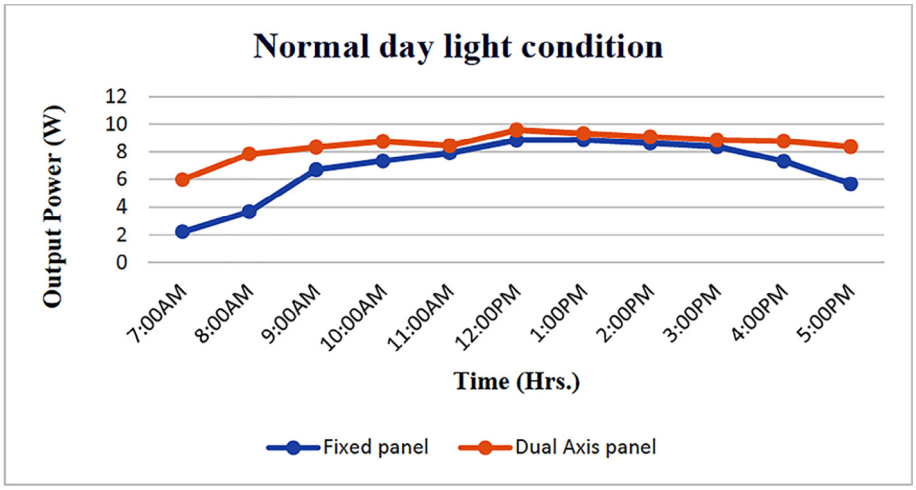

Fig. 6. Variations in Output Power during Normal Day Light Condition.

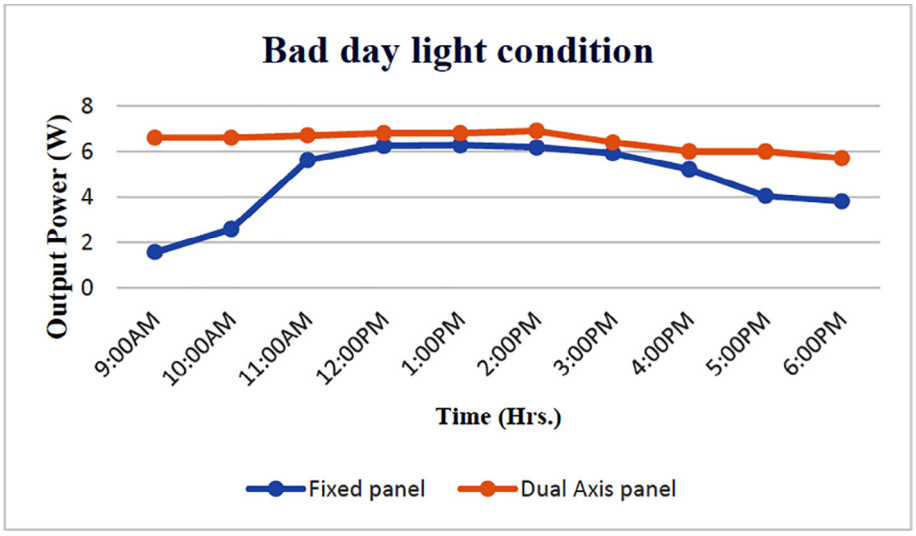

Fig. 7. Variations in Output Power during Bad Day Light Condition.

LDR_1 offers high resistance at (7 to 8) am, low resistance at (9 to 11) am, and medium resistance for remaining time. LDR_3 offers high and medium resistance from 7:00am to 1:00 pm. Its resistance decreases drastically from 2:00 pm to 4:00 pm. Again, the resistance increases at 5:00 pm and 6:00 pm. Throughout the day, LDR_2 and LDR_4 offer quite similar resistance. Due to irregular light nature, all LDRs offers mixed behaviour. Fixed panel only has full output from 12:00 noon to 2:00 pm. The fixed panel's average power output is just 27.88% of the measured power output. The dual axis panel is efficient by 30.2% at 9:00am, efficient by 33.6% at 12 noon and efficient by 31.62% at 5:00 pm. The noted mean temperature reading was 21.18 °C during this day. On a poor day of sunlight or solar irradiation it can be inferred that both the fixed and variable panels, i.e., have less electricity outputs than the other days. The variations in output power during Bad light condition is shown in Fig. 7

9. Conclusion

Readings were taken under different environmental conditions and compared. It can be inferred from experimental results that the automatic solar tracking system is in all ways more effective than the fixed panel system. The paper is evaluated from the readings, and then concluded. On a typical normal day light condition, fixed panels only have maximum output from 11:00am to 3:00 pm. Automatic tracking system panel offers 61%, 93% and 82% efficiencies at 7:00am, 12 noon and 5:00 pm respectively and offers 16.46% more power output compared to the immovable panel. During the bad day light condition, the immovable panel produces an average power output of 2.2 W when compared to 3.26 W of adaptive solar monitoring system. Here, the fixed and automatic tracking has lower power output compared to normal day light condition. The above results suggest that the automated solar tracking system is a much better way to implement than the fixed panel under any environmental situation.

Optimization algorithm

ABSTRACT

Frequency is a variable parameter in a power system, and it denotes the balance among the generation and the requirement. The operator of the system has to maintain the frequency within certain acceptable limits. The tediousness of integrating Distributed Generators (DGs), like solar photovoltaic (PV) system or wind turbines is the intermittency in power system that balances the power and regulates the frequency and voltage. If a number of electric motors are connected along with PV, the frequency of rotor speed will be varied. Hence, this paper intends to propose a Fuzzy Logic Controller (FLC) for controlling the frequency of rotor speed to enhance the power system performance. Hence, the major objective of the proposed model is to provide control over the output signal by reducing the error between the reference signal and control signal. The performance evaluation of the proposed model is done and proved over other controllers with respect to switching time, and the performance metrics, namely settling time, rise time, and percentage overshoot.

1. Introduction

In the present era, the regulated and the centralized utilities of electric power mainly depends on fossil fuels to satisfy the requirement of energy. Traditional power generating plants are normally centralized, and thus the power is needed to be forwarded over wide distances. This results in losses of energy and affects the effectiveness of the system. One of the important limitations of the traditional technique is the discharge of pollutant gases in huge amount that acts as reason for global warming [1]. With the increasing need for energy, renewable energy oriented systems possess high interest in research. Thus, to satisfy the needs of energy, it is important to produce electric power using different renewable sources of energy, like solar, wind, geothermal, and so on.

At present, generation of power using PV system acts as an important method because of number of reasons, like pollution free generation of power, no need for fuel cost, and less cost for maintenance. Hence, it is generally selected as a best alternative as compared with the rapidly depleting reserves of fossil fuels. Even with the present enhancement of the materials of solar cell, the effectiveness in conserving the energy of PV model stays moderate [1]. These effectiveness decreases when there arise no match in load among the input and the output terminal. In general, when a module of PV is connected to the load directly, the operating point does not lead the maximum power of power voltage (PeV) graph. In addition, the MPP changes with the irradiance level of solar and operating temperature of cell. Thus, it is necessary to raise the power conversion efficiency of the module by forcing it to operate at its MPP, without considering the variations in weather conditions. This is carried out using a power electronic converter in the presence of algorithm for maximum power point tracking (MPPT) [2].

Even though Renewable energy sources (RESs) are deployed as zero-emission energy, the uncertainty nature of Distributed Generators (DG) may result in frequency control and stability problems. Frequency stability represents the capability of a system to provide

Please cite this article as: T. Rajesh, B. Gunapriya, M. Sabarimuthu et al., Frequency control of PV-connected micro grid system using fuzzy logic controller, Materials Today: Proceedings, https://doi.org/10.1016/j.matpr.2020.10.255

steady frequency even under severe upset of the system that lead to significant imbalance among the generation and the load. Thus, the stability controlat reduced inertia with higher RESs penetration remains a major concern. To solve this issue, the inertia of Micro Grids is needed to be increased via energy storage. Thus, it is necessary to find out the appropriate inertia constant value for such systems so that the frequency stability is maintained at a minimal cost. In addition, frequency of Distributed Energy Resources (DERs) and loads also have an impact on the Frequency Control of Micro Grids.

In this proposed paper, the micro grid comprises of PV system, which works independently in order to supply power to the loads without any disturbance to the supply. For controlling the three phase VSC, the primary control circuit with the loop for maintaining the power and voltage is used. The developed technique enhances the performance of the system by smoothly handling the flow of power between the distributed generation units and the load. In addition, it maintains the frequency of the micro grid within a particular range even at the time of sudden changes in load and environmental conditions.

2. Literature review

Different types of sources of power are utilized for developing the micro grid to be operated either in autonomous or grid connected mode. The traditional PI controller is used for controlling the voltage source converter (VSC). The general limitation in developing this type of system is the dependency of the modeling of plant. In various cases, the systems are not elaborated clearly. Even after knowing the parameters of the whole system, there occur variations in parameter at the time of system operation, which is considered as the major drawback in design. In addition, it may not perform well during sudden load variations or disturbances. In recent years, advanced controllers, such as sliding mode controller, and predictive controller are commonly utilized to enhance the characteristics of the system. However, the drawbacks associated with these methods are the requirement of tedious analytical evaluations.

To solve the limitations, intelligent methods are generally used. In [4], particle swarm optimization (PSO) was considered for tuning PI controller parameters to enhance the quality of power in the micro grid. In [5,6], the neural network (NN) is used for tuning the parameters of the controller of a SOFC system. FLC is an enhanced technique that does not need the plants mathematical model whose characteristics is not known in a detailed manner. The FLC is generally easy to be implemented with better control accuracy. On enhanced tuning, the FLC is capable of providing enhanced performance compared to the traditional controllers. In addition, the FLC is effective over variations in parameter of the system. In [3,4], MPPT oriented FLC was developed for a PV system and the battery is used for back-up. In the proposed work, the FLC is used to regulate the frequency within acceptable limits [2].

3. Modelling of the components

3.1. Modelling of PV system

The conventional arithmetical design of a PV system by neglecting the interior shunt resistance is expressed in Eqs. (1), (2) and (3).

$$I_o = I_p - I_{rev}\left\{\exp\left[\frac{e}{BIT}(V_o + I_o R_s)\right] - 1\right\} \tag{1}$$

$$I_{rev} = I_{rt}\left[\frac{R}{R_r}\right]\exp\left[\frac{pF_{BG}}{IT}\left(\frac{1}{D_r} - \frac{1}{D}\right)\right] \tag{2}$$

$$I_g = [I_{sc} + T_{SH}(D_c - 25)]\frac{\delta}{100} \tag{3}$$

where, V_o indicates the solar arrays output voltage, and I_o represents the solar arrays output current, I_{rev} specifies the reverse saturation current, I_p denotes the produced current beneath a specified insolation, e refers to electron charge, I_{rt} indicates the saturation current at reference temperature R_r, B signifies the Boltzmanns constant, I indicates the ideal parameter at p-n junction, T denotes temperature, R_s denotes the series resistance of solar array, F_{BG} represents the semiconductor band-gap energy, T_{SH} indicates the temperature coefficient of short circuit current and δ indicates the insolation in mW/cm2. Fig. 1 depicts the structure of PV system being interconnected with the utility grid.

3.2. PV controller

In this paper, a boost converter is utilized for connecting the PV system to the dc-bus and to obtain the maximum power [7–9]. P&O algorithm is the algorithm considered in tracking the voltage corresponding to maximum power and the simulink diagram of the P&O MPPT is depicted in Fig. 2.

The complete diagram of PV setup is depicted in the Fig. 3. For controlling the boost converter, the cascaded control loop comprising of inner loop of current control and outer loop of voltage control is utilized [10–13]. The Cascaded arrangement offers high enhanced control with the reduction of oscillations on comparison with other basic control. The PI controller is used and is developed with the frequency characteristics using the MATLAB tool as shown in Figs. 4 and 5.

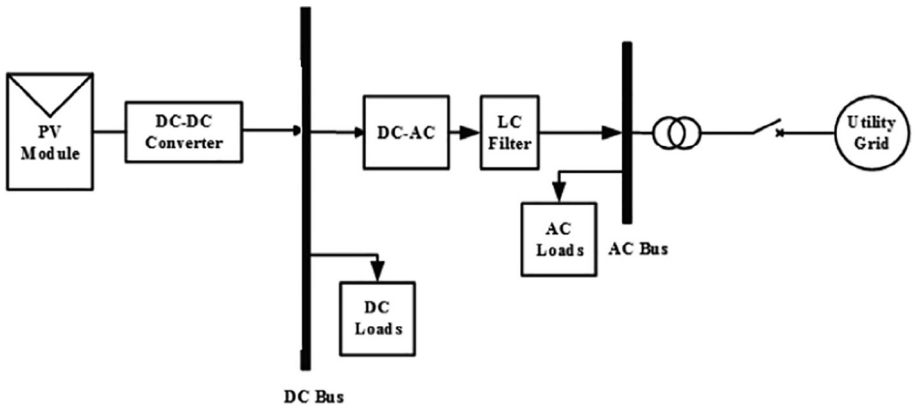

Fig. 1. Structure of PV interconnected with utility grid.

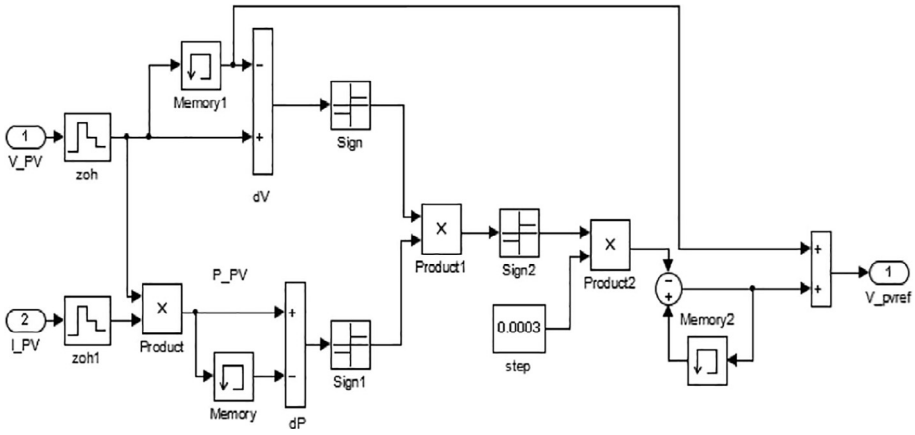

Fig. 2. Simulink diagram of P&O MPPT algorithm.

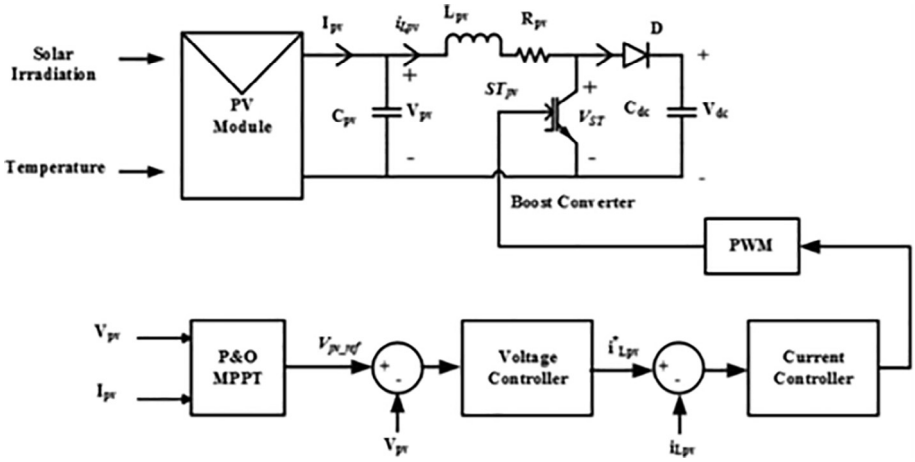

Fig. 3. Control diagram of PV system.

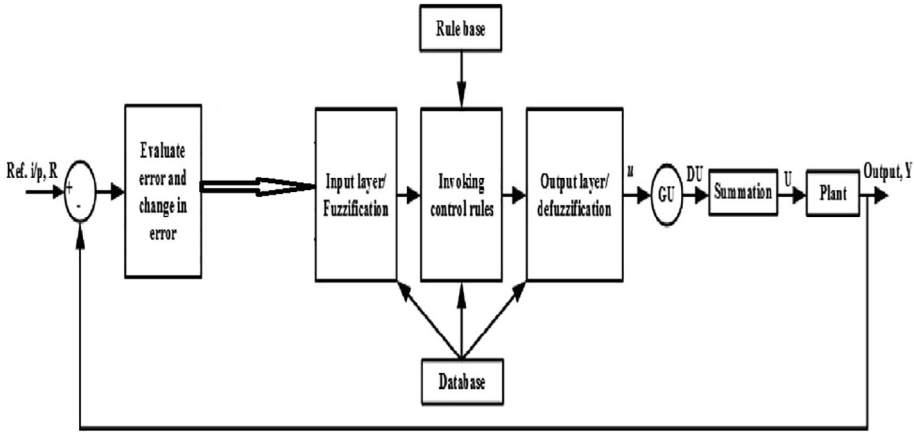

Fig. 4. Fuzzy feedback control system.

4. Proposed fuzzy Logic controller for frequency control

4.1. Fuzzy logic control

In the proposed paper, frequency control using FLC is carried out in order to enhance the performance of the system. The traditional PI controller is normally sensitive to the variation in parameters, and thus it offers low stability margin [3]. But, FLC acts effective to the variations in parameters. In addition, the tediousness in developing the control system of the VSC is eliminated clearly using FLC. It possesses three different stages, such as fuzzification, processing, and de-fuzzification stage. It acts by evaluating the error value and the change in error value among the actual output and reference input. These values are measured to change

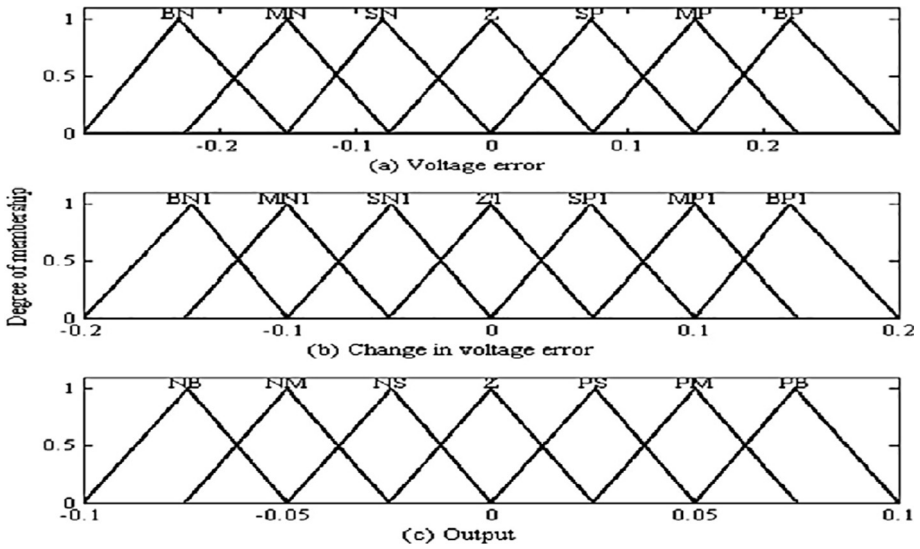

Fig. 5. Membership functions of voltage error, change in voltage error, and output.

them as per unit values [14,15]. Then, it is fed to the input layer, where the crisp values are changed to their corresponding fuzzy set values. The second stage produces the set of rules. Finally, the fuzzy variables are changed as crisp values with the use of de-fuzzification. The basic structure possessing the fuzzy feedback control system is depicted in the Fig. 8.

5. Results and discussions

5.1. Simulation procedure

The term frequency defines the value of voltage changes per second. The adopted frequency control in PV based MG model using FLC isimplemented in MATLAB and the corresponding outcomes were attained.

5.2. Frequency analysis

The frequency of the system is shown in Fig. 6. In general the frequency analysis is held by varying the amplitude with respect to time. System inertia is stated as the capability of a system to show opposition to the variation in frequency because of the resistance created by the kinetic energy of rotating masses in each of the generator. Fig. 7 depicts the power system with the impact of reduction in inertia.

The reduction of inertia increases variation in frequency during sudden disturbances, including loss or variation in the generation or demand. Thus, it is strongly advised to lower the settling time at the time of disturbance. Hence, the need for FC in power system is increased. A fast response of frequency from the side of generation is a commonly recommended solution to solve the issue of increased frequency deviation.

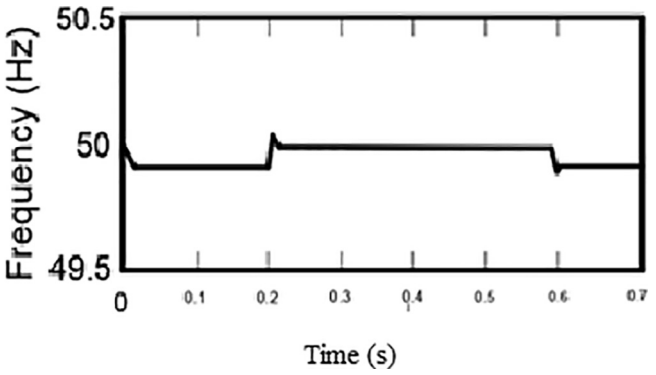

Fig. 6. System frequency.

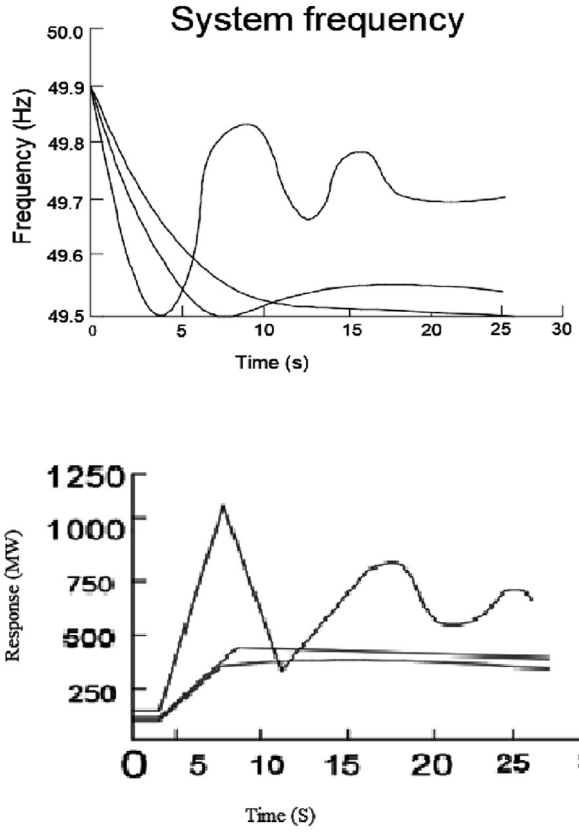

Fig. 7. Power system with the impact of reduction in inertia.

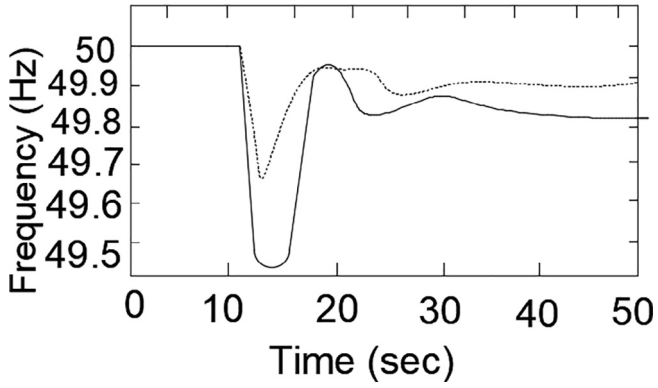

Fig. 8. Frequency control using FLC.

Table 1
Comparative table of existing method with FLC.

Metrics	Condition (1)		Condition (2)	
	PI	Proposed technique	PI	Proposed technique
Overshoot	3.82	0.2	2.58	0.18
Rise time	0.005 sec	0.0068 sec	0.0066 sec	0.0078 sec
Settling time	0.015 sec	0.012 sec	0.015 sec	0.016 sec

5.3. Switching Time analysis

For better frequency control, the value attained with respect to the fault intervals should be minimal. From the observed outcomes, the standard deviation for the presented FLC method is found to be much minimal over the compared models. Thus, the adopted scheme has shown higher efficiency in attaining better frequency control in micro grid systems. The frequency analysis of the presented scheme without frequency control and with FLC control is depicted in Fig. 8.

Table 1 tabulated the outcomes of the proposed frequency control method in terms of metrics, such as rise time, percentage overshoot, and settling time. It is evident from the analysis that the proposed technique provides enhanced control of frequency in power system.

6. Conclusion

This paper proposes the Fuzzy Logic Controller for controlling the frequency of rotor speed to enhance the power system performance. Hence, the major objective of proposed model is to lower the error that occurs among the reference signal and control signal. From analysis, the conventional schemes had experienced the sudden trigger at the respective fault intervals, however, the presented approach have not experienced much trigger. The betterment of the adopted scheme has been proved from the simulation results.

Declaration of Competing Interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.
