ABSTRACT

The necessity for power generation is randomly increasing with the increasing load demand. As the non-renewable sources are getting extinct the use of renewable sources came into existence. To have the load demand to be equivalent with power generation Load Frequency Control (LFC) technique is employed. Using renewable sources will cause deviations in the system frequency. In this a PID combined with the Adaptive Neuro-Fuzzy Inference System (ANFIS) controller is used for controlling the frequency of load connected to two area renewable system for reducing the changes in frequency responses. When the outcomes of the presented controller were differentiated with commonly used PID it was observed that the controller used in this paper has resulted in better performance, reduced settling time and increased robustness than that of the conventional controller for the same system.

Key words: LFC, PID-ANFIS Controller, Renewable system.

1. INTRODUCTION

An electrical power system is a circuit of electrical components used for electrical power supply, transfer and usage. The system that delivers electricity to an extended area is an

example of an electrical system. In these days the demand for electricity is very high therefore various methods have been adopted to increase the generation. The rapid exhaustion of the fossil fuels and their harmful impacts on the environment has lead to the use of the renewable energy sources. Renewable energy is the energy that is obtained from renewable resources that are produced naturally from sunlight, wind, rain, wind, waves, tides, and geo-thermal heat [1-3]. The rapid exhaustion of the fossil fuels and their harmful impacts on the environment has lead to the use of the renewable energy resources. The renewable energy sources effects the performance of the system causing variations in the frequency responses. Therefore it is required to enhance the frequency response parameters of the system for reliable supply.

Frequency control is required for reducing the oscillations in frequency which is mainly caused due to the mismatch of the load demanded and power generation. Load frequency control is used to provide an area to satisfy its load requirements first, then to support in returning the system's steady state frequency to zero. Previously there are various controllers used to settle down these fluctuations to some extent. In this paper a controller which is a combination of PID and ANFIS which is again the combination of both Neural Network and Fuzzy are been used to settle down the oscillations to enhance functioning of the network. It is also able to achieve better stability with two different renewable systems and load variations. This proposed controller is based on the training data that is it will adapt the changes in the environment and will adjust the inputs depending upon the output. In this paper the performance of the two area (one area connected to Photo Voltaic (PV) generation and the other area connected to wind source) renewable system with the specified controller is compared with the efficiency of the same system along with generally employed PID [4-6].

2. MODELING OF TWO AREA RENEWABLE SYSTEM

The power system is split into multiple areas, every area is generally connected to its adjacent area [7]. To connect these adjacent areas transmission lines which are called as Tie-lines are used. The schematic layout of the interconnected power system is depicted in Figure.1.

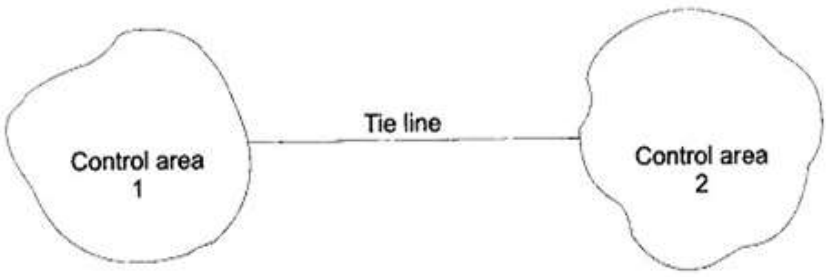

Figure 1 Representing Interconnected system

2.1. PV Generation Transfer Function

Solar power is regarded as most important renewable energy resource with a wide range of possibly numerous benefits. The Photo Voltaic (PV) is used to resemble the source of solar energy according to the reference [8-9]. This PV is a device that produces direct current (electricity) from solar radiations emitted from the sunlight, using semiconductor devices. The network function of the PV is as depicted in the Figure.2.

.

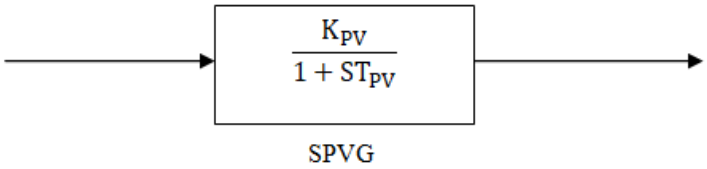

Figure 2 Photo Voltaic Generation Transfer function

2.2. Wind Turbine Generator Transfer Function

These days wind is the largely used renewable energy resource. The wind turbine blades rotate at a fixed or variable speed depending upon the wind that is the velocity of the rotor changes with respect to the velocity of the wind, in order to achieve better efficiency [10]. The electric power output obtained from the generator that is which connected to the shaft of the turbine. The network function for wind turbine and generator is as given in Figure.3.

.

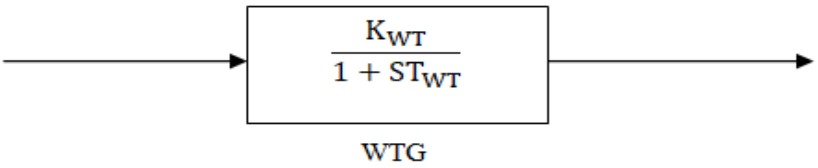

Figure 3 Wind Turbine Generator Transfer function.

The overall system function model for the LFC of interconnected renewable system with PID combined ANFIS is depicted in the Figure.4. Here these two areas consist of PV generation and wind generation which were connected through a transmission line and a step input is given as a disturbance input [11].

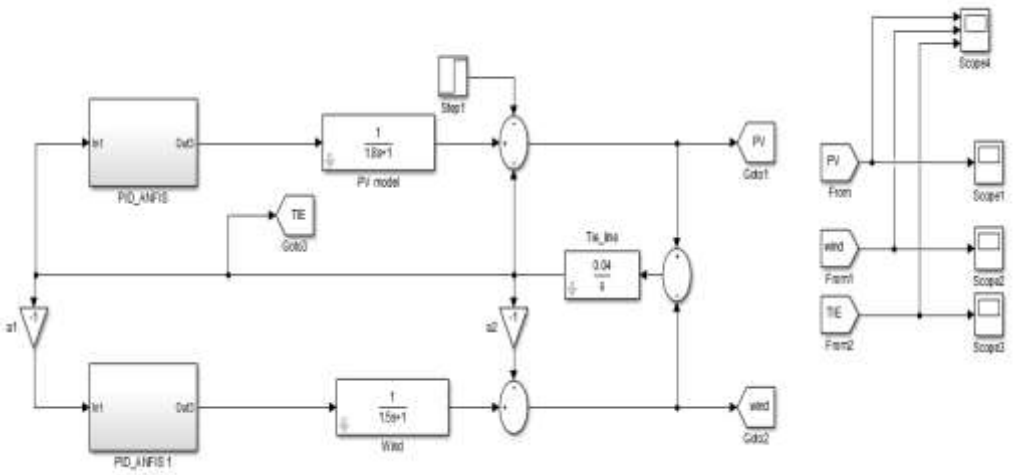

Figure 4 System function model of Two-area Renewable system with presented controller.

3. MODEL AND DESIGN OF PROPOSED CONTROLLER

Here the cascade combination of PID and Adaptive Neuro Fuzzy Inference System (ANFIS) is being utilised for improving LFC for two area renewable systems.

3.1. PID Combined ANFIS Controller

This PID is nothing but a device formed by combining Proportional, Integral and Derivative controller. In this these three controllers were added up to compute the result of the PID. It takes the input from output Δf(S) from feedback. The transfer function of PID in the Laplace form is given below.

$$L(S) = K_p + \frac{K_i}{S} + K_d \quad (1)$$

Where, K_p= value of gain for proportional controller.

K_i= value of gain for integral controller.

K_d= value of gain for derivative controller.

These gain constants are tuning parameters, which are adjusted to obtain the expected output.

The ANFIS is a combination of fuzzy logic controller and the artificial neural network. The fuzzy controller will work well when the membership functions are wisely chosen. Therefore to overcome this situation the adaptive approach of neuro-fuzzy is used. This is multi- layer network which uses both the knowledge gaining power of artificial intelligence and understanding capability representation of fuzzy logic for many modes of memberships [1]. This controller takes the two inputs from the PID controller and results in one output. It uses 'If then' rule base system of Sugeno's type. It uses the rules as following.

$$\text{If } \Delta f \text{ is X1 and } \dot{\Delta f} \text{ is Y1, then } u_1 = p_1\Delta f + q_1\Delta f + r_1 \quad (2)$$

$$\text{If } \Delta f \text{ is X2 and } \dot{\Delta f} \text{ is Y1, then } u_2 = p_2\Delta f + q_2\Delta f + r_2 \quad (3)$$

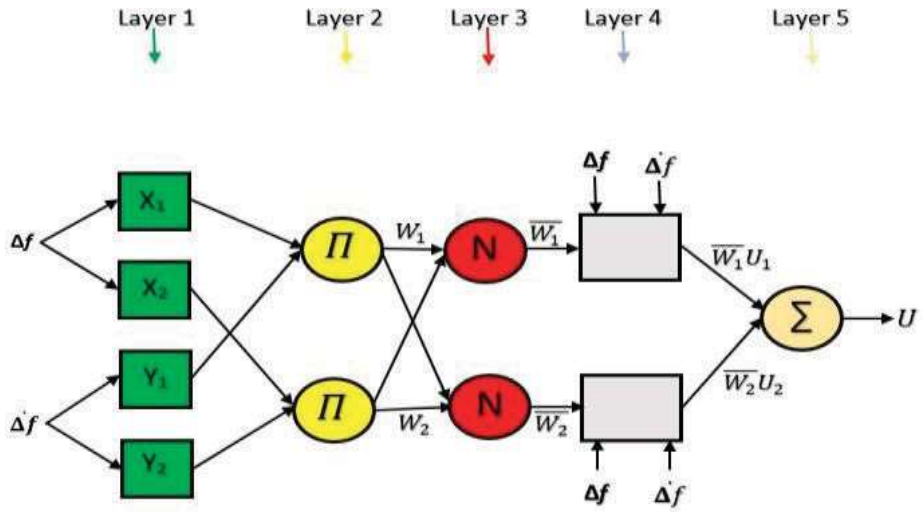

Figure 5 Multi-layer ANFIS controller architecture

Layer 1: The Fuzzification layer where it converts the crisp inputs into the fuzzy inputs that is, it will change the parameter values in reference to the error to produce the required response for each and every function for membership.

Layer 2: This is depicted as π and it is a fixed layer which consists of outputs of first layer which multiplies with one other. The output obtained gives the degree of firing capability.

Layer 3: Here the layer is denoted as N (Normalization layer). The firing strength which is normalized is computed.

Layer 4: Here the layer consists of consequent parameters.

Layer 5: The output for the entire device is obtained here.

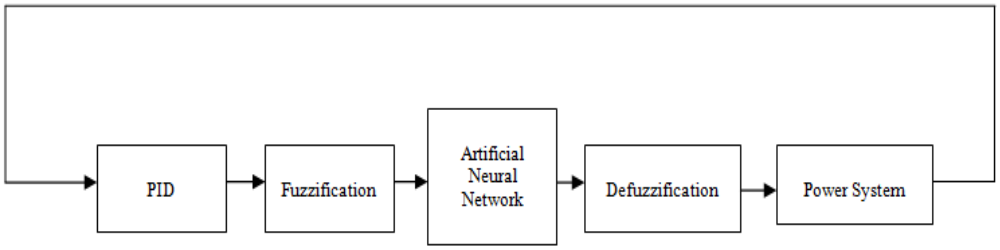

Figure 6 Block diagram of PID combined ANFIS controller.

3.2. Designing of the Proposed Controller

At first the output is given to the PID controller through feedback. The gains of the controller are adjusted and are summed with the fuzzy logic based on Sugeno system. The input-output data obtained had been used for understanding data and Neuro-Fuzzy Designer is used for designing this controller. Detail designing of ANFIS is proposed in the literature [1].

4. RESULTS AND DISCUSSION

For depicting the efficiency of the presented controller, the simulation of presented two area renewable system with the common PID controller device is also carried out separately in the MATLAB Software. The results of the LFC of two area system with presented controller device considering the tie-line are compared with conventional controller simulation results for the same system. Parameters for PID and PID combined ANFIS controller are given in Table.1.

The frequency responses for individual systems respectively are shown in the figures below. The PV output, wind turbine output and tie-line output frequency responses for both the controllers shown in the Figure.7, Figure.8 are compared with each other and the comparison results have shown better performance and stability for proposed PID combined ANFIS controller than that of the conventional PID.

5. CONCLUSION

Here in this, PID which is combined with ANFIS is used for controlling the frequency of the load of specified renewable system. Obtained simulation results are differentiated with PID outputs. The proposed device improves stability and functioning of LFC of renewable system in terms of robustness, settling time, peak time. The efficiency of the explained controller does not depend on any mathematical calculations but mostly depends on the training data. This ability of the controller to adapt the changes and adjust the inputs depending on the training data makes it more effective and thereby, improving the quality of the power being given to meet the load demanded and system reliability.

Table 1 Parameters of the Frequency Response

Parameter	Settling time (sec)		Peak time (sec)		Maximum Peak Over Shoot (%)	
	PID combined ANFIS	PID	PID combined ANFIS	PID	PID combined ANFIS	PID
PV	37.50	112.50	8.300	28.846	1.320	1.661
Wind	37.50	112.50	10.368	36.733	0.402	0.246
Tie-Line	37.50	112.50	13.897	48.856	1.992	1.999

Table 2 Parameters of the two area renewable system

Components	Parameters	Description	Value
PV	K_{SPVG}	Solar photo voltaic generation gain constant	1.8
Wind	K_{WT}	Wind turbine gain constant	1.5
Tie-line	$K_{tie-line}$	Tie-line gain constant	0.04
PID controller	K_p	Proportional gain constant	0.01
	K_i	Integral gain constant	1.52
	K_d	Derivative gain constant	0.53

ABSTRACT

This paper deals with various Techniques used to determine the place of D-STATCOM in a distribution network system at different conditions. Most of the loads in distribution network system are inductive in nature which have lagging power factor which leads to Instability in the voltage, voltage variations, power losses, load variations, poor power factor, security problems which disturbs the overall efficiency and power transfer of the system. Distribution Static Compensator (DSTATCOM) is a D-FACTS device which has been utilized for Reactive power compensation, Minimize the power loss, to improve Voltage profile, Minimize the average voltage total harmonic distortion, Average voltage deviation and Reduction in investment cost. The Optimal Location of D-STATCOM is a challenging task and it plays a crucial role. A suitable place for DSTATCOM is crucially important to ensure sufficient investment for the device in distribution networks that will enhance the Margin for Voltage stability, reduce power loss, reactive power compensation, improve power factor and improve voltage profile. A Lot of Research is going on optimal placement of D-STATCOM in a Radial Distribution network. This review paper gives an idea about the various techniques and it's classification in a distribution network to determine the location of DSTATCOM at different practical conditions.

***Keywords*— DSTATCOM, Optimal placement, Voltage stability, power loss, Distribution system.**

I. INTRODUCTION

Today everyone depending on the electrical energy and it has become part of our lives. Electricity generation, transmission and distribution are very important for electrical power system either it is governed by different bodies, or by a single entity. The underlying motive of the distribution system is to provide adequate energy from transmission to the purchasers. Distribution system has a combination of different types of loads such as lighting loads commercial loads, industrial loads which have high resistance to reactance ratio(R/X).

This makes the power loss to reach a high value and lead to poor voltage regulation and voltage collapse. Reduction of power loss is considered one of the important issues from the point of view for the consumer to lead to best efficiency of the system. Hence, it is necessary to use high accurate equipment with high efficiency for loss reduction and to boost the voltage. There are traditional equipment such as capacitor banks [3], static synchronous series compensator (SSSC), Automatic Voltage Regulator (AVR), series and shunt reactors to improve voltage profile, reduce losses, decrease voltage deviation and improve the efficiency of the system. The shunt capacitors are used for Reactive power compensation in a radial distribution networks. Some disadvantages with shunt condenser are:

- Capability to produce uninterrupted reactive variable power.
- Because of this, utilities have to pay additional costs on capacitor installation.
- It has few operating resonance problems.
- Balancing of load is not possible

To rectify the above mentioned disadvantages, the D-STATCOM Optimal placing is necessary for the best results. Here the paper mainly focusses on optimal placement of only D-STATCOM because of its flexible features such as ability to supply continuous reactive power, power factor control, low power losses, small size, less resistant to resonant problems, automatic operation, good regulation and ability to reduce harmonic distortion. Optimal placement at proper location will lead to improve voltage profile, improve power quality, minimum power loss, improve the reliability and the security of the system.

II. PRINCIPLE AND OPERATION OF D-STATCOM

DSTATCOM is a Distribution Static compensator (or) Distribution static Synchronous compensator. It is a power electronics device which is connected in parallel in a distribution line to compensate reactive power, improve power factor and power quality, minimise losses and improve voltage profile mitigate voltage swell, voltage sag, voltage fluctuations, harmonic distortion. It mainly consists of four components. They are

a. Voltage source converter (VSC)
b. Injection transformer
c. Control unit.
d. Energy storage device.

A. Voltage Source Converter (VSC):

A voltage Source converter is a power electronic device which is connected in parallel to the ystem. It is used to convert DC voltage stored in storage devices to AC output voltages in three phase. It is to inject the missing voltage. It main functions are:

- Voltage generation and reactive power injection.
- Power factor correction.
- Elimination of current harmonics.

B. Injection transformer:

It is a two winding transformer in which one side is connected to high voltage and the other side is low voltage side. The high voltage side is connected to the distribution network in shunt while the low voltage side is connected to the D-STATCOM circuit. The DSTATCOM passes the current into the network through the injection transformer. It also isolates the line from the D-STATCOM.

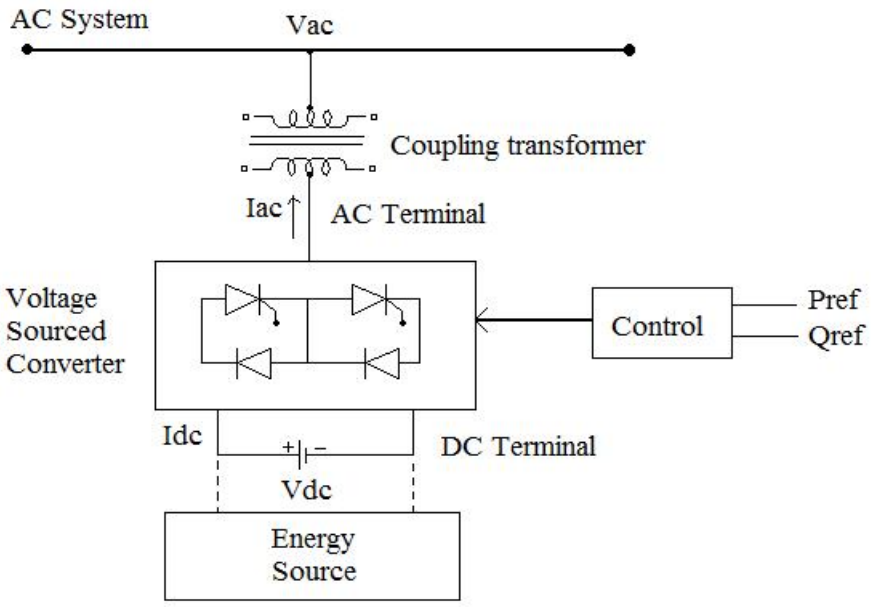

Fig.1: Block diagram of D-STATCOM

C. Control unit:

For proper operation of the D-STATCOM system a controller is used. It is used to operate the inverter in such a way that the phase angle between the line voltage inverter voltage and it is adjusted dynamically such that the D-STATCOM can generates or absorbs the desired VAR at the point of common coupling.

D. DC storage:

The purpose of the energy storage system or dc storage is to provide the VSC with the required energy that will convert the direct quantity into an alternating quantity and fed through the injection transformer to the main distribution line. Batteries are most widely used devices for energy storage, and the battery decides the amplitude of the voltage sag or swell.

III. CLASSIFICATION OF D-STATCOM TECHNIQUES FOR OPTIMAL PLACEMENT

Placing a DSTATCOM in a optimal place is very important to acheive its benefits. The optimum positioning of this device increases the loadability, compensates for reactive energy, improves stability, reduces power loss and improves the quality of electricity. If the device is placed incorrectly it affects the system operation, reliability and security. There are various techniques for optimal placing. They are categorized into three types. They are

1) Modal analysis
2) Analytical Techniques
3) Optimization Techniques

A. Modal analysis:

Modal analysis is nothing but a study of the properties of a system in time-domain simulation. D-STATCOM analysis can be performed to determine the solution for a problem in a distribution network.

B. Analytical Techniques:

Generally these analytical techniques produce an algebraic expression. Here robustification and optimisation could be examined. In these methods the machine is represented with mathematical model with computed numerical answer without delay. These methods gives accurate results and requires less computation time. These kind of techniques are mainly for simplified and limited tools. Analysis of Sensitivity, sensitivity factors, Index approach, Power Stability index, Reactive power Stability index approach are the analytical strategies used [14],[15]. Analytical approaches, however, these are not suitable for large and complex structures, as they work adversely with computational efficiency identification.

C. Optimization Techniques

The optimization system is from the available set of alternatives which locate the fine response. As we know Distribution system is a large network which consists of numerous nodes, it is difficult to manually discover the most suitable place for the placing device that compensate. Several optimization strategies are used in the literature. A variety of approaches some are traditional approaches for optimization, some are intelligent approaches that would be able to build a efficient, reliable, ideal solutions for practical problems and Meta-heuristic techniques are also some strategies. In different areas, those methods are mostly efficient for solving complications. Following are the different optimization techniques[1],[2],[3],[5],[7],[8] such as Flower Pollination Algorithm(FPA), Improved crow search algorithm (ICSA), genetic algorithm (GA), fuzzy logic (FL), JAYA Algorithm, Bat Algorithm(BA), Differential Evolution Algorithm (DEA), particle swarm optimization (PSO), particle swarm optimization based Ant colony optimization method, Effective biologically stimulated Immune Algorithm (IA), Instantaneous Active and reactive modern issue idea (IARCC), Firefly Algorithm, Bacterial Foraging Optimization Algorithm (BFOA) etc.

The authors have proposed various techniques under which DSTATCOM's some techniques placing techniques and sizing are tabulated.

Table 1: Optimization Techniques and advantages

S.NO	Authors	Techniques	Advantages
1	Hosseinian S. H, Jazebi, S., & Vahidi, B. (2011)	Differential evolution algorithm(DEA)	Differential evolution consists of a set of rules in distribution networks which is tested with special abilities. High computational search performance and correct convergence homes.
2	Bhalja, B. R., Zaveri T., & Zaveri, N. (2011)	Instantaneous active and reactive current component (IRACC)theory	These are accurate and powerful for a wide variation in charging and supply situations. It is also effective in lowering the supply VA score balance of supply currents and achieving power problem correction under specific load conditions compared to uncompensated cases.
3	Zaveri, T., Bhalja, B. R., & Zaveri, N. (2012)	Instantaneous active and reactive current component (IARCC) theory	Power factor correction is carried out. Total Harmonic distortion is also reduced
4	Arya, S. R., Singh, B., Chandra, A., & Al-Haddad, K. (2012)	Single phase p-q theory based control algorithm	Suitable for service modes ZVR and PFC with varying loads in time.
5	Masoud Farhoodnea, Azah Mohamed, Hussain Shareef,Hadi ayandehroodi. (2013)	Firefly Algorithm	To improve the system's tension profile and minimize the THDV and total investment costs. Capable of determining the D-STATCOM's most efficient position and optimum size in radial distribution systems.
6	S M Suhail Hussain, M Subbaramiah	Modelling, Load flow technique.	Effective and easy to implement.
7	Jain,A., Gupta, A.R., & Kumar, A. (2014)	Stability Index	Reduction in Active power losses and Better voltage profile.
8	Abhinav Jain ,A.R. Gupta, Ashwani Kumar (2014)	Stability Index	It gives the utilities efficient solution for power loss and tension profile improvement.
9	Yuvaraj, T., Devabalaji, K. R., & Ravi, K. (2015)	Harmony Search Algorithm	It can be extended to n number of buses. It is much better than the current Immune algorithm to find the most efficient answers

10	Tolabi, H. B., Ali, M. H., & Rizwan, M. (2015)	Fuzzy-ACO approach	In comparison with ACO, fuzzy-GA and Fuzzy-PS, simultaneous allocation and multi-target reconfiguration of DSTATCOM and PV is observed to be better.
11	Atma Ram Gupta, Abhinav Jain, Ashwani Kumar 2015 IEEE	For D-STATCOM placement the power loss index method is used. D-STATCOM size is determined through steady state mathematical modelling.	Minimizing the line losses and improving the voltage profile is achieved.
12	Amal Amin, Salah Kamel, Juan Yu, 2018 IEEE Conference	1) The Power Stability Index (PSI) is used to determine DG and DSTATCOM's optimal locations for identifying candidate buses that are more suitable for connecting those devices. 2) Sensitivity Analyzes are used to determine the optimum DG size. 3) The size of DSATCOM is gradually increased by step size until the lowest losses are achieved.	Minimizing the power loss and improving the voltage profile is achieved.

IV. CONCLUSION

DSTATCOM is a power electronics device which is connected in parallel to compensate the reactive power, minimize power loss, improve the voltage profile, minimize the average total voltage harmonic distortion, power factor control, power quality improvement, average voltage deviation, reduction of investment costs etc. A number of techniques is presented here with its advantages. An Improper placement of device always affects the system performance so a suitable location for placing the DSTATCOM is very important and crucial to enhance the voltage stability margin, reactive power compensation, reduce power loss, improve power factor and improve voltage profile in a distribution network at different practical conditions.

Abstract

This paper provides a brief idea of the various methods used to evaluate the position and scale of D-STATCOM under different conditions in a distribution network. As we all know, most of the loads in the distribution network system are inductive, causing lagging power factor that causes power losses, voltage instability, voltage variations, load variations, security issue of the system that affects power transfer performance. Distribution Static Compensator (DSTATCOM) is a shunt connected voltage source converter that has been used to compensate for reactive electricity, reduce power loss, boost voltage profile, minimize total harmonic distortion of average voltage, average voltage variance, cost of investment reduction. D-Optimum STATCOM's Placement is a challenging job and it plays a critical role. In order to ensure adequate investment of the system in networks that will increase the voltage stability margin, minimize power loss and boost the voltage profile, the required position of DSTATCOM is of crucial importance. A lot of research is going on to optimize D-location STATCOM's and sizing in a radial distribution network. This analysis provides an idea of how the position of DSTATCOM can be calculated in a distribution network under various realistic conditions.

Keywords: *DSTATCOM, Optimal placement, Voltage stability, power loss, Distribution system.*

1. Introduction

Everyone now depends for a few days on the use of electricity, which has become part of our lives. For electrical power systems, the generation of electrical energy, transmission and distribution are very important. It is governed by either a number of entities or a single entity. Construction, layout, security of various electricity supply schemes with generation and medical records for the benefit of society. The key motive of the distribution system is to provide exceptional electricity to the customers from transmission. A key portion of the electrical power, however. With the aid of recent studies, it is proven that the energy produced is wasted as I2R losses at the distribution stage. In the distribution network, the majority of loads are inductive in nature. Because of this the problem of network power lags in the countryside. Because of this the voltage

profile may be negative, electricity losses may increase and greater problems may be generated within the distribution network.

The Power delivery system takes away the high capacity of transmission circuits for electrical energy. Below this level, so many electrical loads are connected. The distribution system has a very high R/X ratio relative to the transmission system, causing high voltage drops and power losses.

Increased demand for traditional sources for a few days now, so that it can transition to distributed renewable energy sources. We get 13 percent of electrical energy lost in line losses (I2R) in the distribution sectors from the estimated data. Power loss reduction is calculated from the customer side as the most significant problem.It is important to maintain a consistent and reliable enhancement of the profile of operating voltages in the electricity grid. Using compensating equipment, power loss reduction and voltage profile enhancement can be achieved. Such as shunt and collection reactors, capacitor banks, Automatic Voltage Regulator (AVR) and Distribution Network Versatile AC Transmission (DFACTS) have also been developed for this relatively advanced device. Static Synchronous Series Compensator (SSSC) systems are DFACTS systems.The DFACTS devices are Static Synchronous Series Compensator (SSSC), Distribution Static Compensator

Traditionally, shunt capacitors are used within the distribution networks to cope with the compensation of reactive power. But the disadvantages of the shunt condenser are

Inability to produce uninterrupted reactive variable strength.

As a result, utilities have to pay higher costs for the installation of capacitors.

The related resonance has few operational concerns.

In addition, load balancing is not feasible.

In distribution companies, DSTATCOM (DFACTS) is used to overcome the above-mentioned disadvantages and to compensate for the reactive electricity needs. Recently, the financial way and productive way is using energy electronics mainly based distribution versatile AC transmission machine era to increase the electricity greatly.D-FACTS (Distribution Versatile AC Transmission System) devices are implemented to develop the overall gadget output at strategic locations of the sharing structures. Originally, the concept of FACTS devices was created for transmission systems, but similar concepts have begun to extend to delivery systems.

2. Construction of D-STATCOM

The D-STATCOM Constructional Knowledge and Theory is as follows. It is connected to the main distribution line in the shunt for voltage sag and swell compensation. It is composed of the following elements:

a. Voltage source converter (VSC)

b. Injection transformer

c. Control unit.

d. Energy storage device.

3. Principle of operation of D-STATCOM

The It is a voltage source converter (VSC) connected to the distribution system in shunt by a coupling transformer by means of a linked tie reactance to compensate for the load current and maintain a fixed voltage profile. The VSC converts the dc voltage to a range of three-phase AC output voltages in the storage system via the injection transformer reactance, these voltages are coupled with the ac system and they are in phase

with the line voltage.The phase and magnitude adjustment of the D-STATCOM output voltages enables the active and reactive power exchanges between the DSTATCOM and the AC system to be effectively controlled. This form of configuration enables the system to absorb or produce active and reactive power that is controllable. If the load voltage/line voltage is greater than the desired load voltage, reactive current or power is absorbed by D-STATCOM; if on the other hand, the load voltage amplitude is lower than the desired load voltage, reactive current or power is supplied to increase the load voltage.

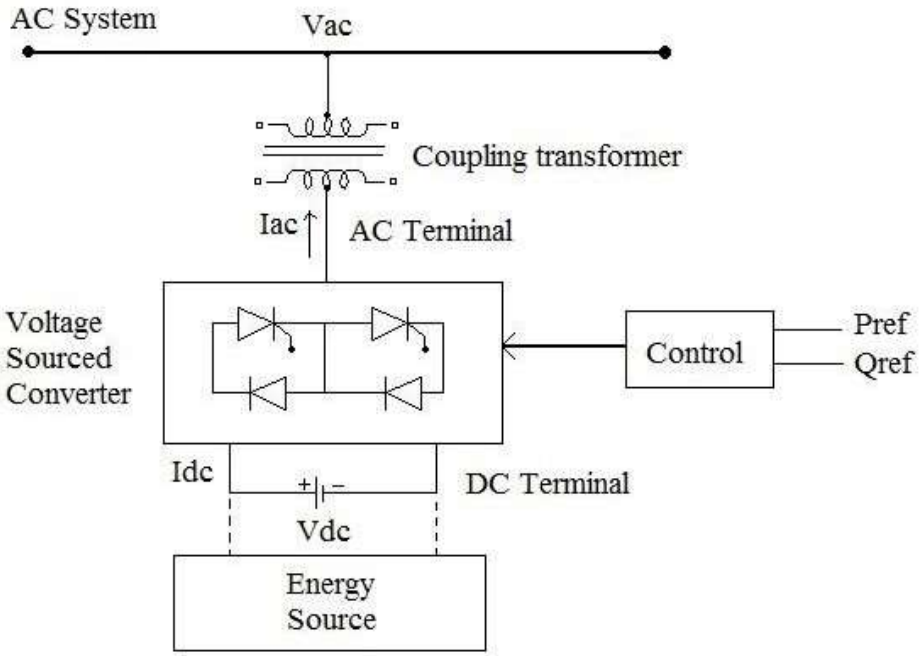

Fig.1: Block diagram of D-STATCOM

Voltage Source Converter (VSC): The VSC attached to the AC system in the shunt converts the storage device's dc voltage. There are three functions it serves:

- Generating voltage and injecting reactive power.
- Power factor correction.
- Removal of current harmonics.

Injection transformer: It is a two-winding transformer with one high-voltage side and one low-voltage side. On one side, while the low voltage side is connected to the D-STATCOM circuit, the high voltage side is connected to the distribution network in shunt. Via the injection converter, the DSTATCOM passes the current into the device. The distribution line is also separated from the D-STATCOM by the injection transformer.

Control unit: For the proper functioning of the D-STATCOM system, a controller is used. The PI controller is used in this paper to research the function of D-STATCOM under the impact of faults and dynamic load.

DC storage: The purpose of the energy storage system or dc storage is to supply the VSC with the required energy to convert the direct quantity into alternating quantities and flow through the injection transformer to the main distribution line. The most widely used

energy storage systems are batteries and the battery decides the amplitude of the sag or swell of the voltage.

4. Optimal Placement of D-STATCOM and sizing

DSTATCOM's proper setting is important for optimizing its benefits. This device's optimum position enhances load ability, compensates for reactive energy, improves reliability, decreases power loss, and improves the efficiency of electricity. It affects the system and function when the unit is incorrectly mounted. The D-STATCOM is classified into three groups of common techniques for placing and sizing. They are

1) Analysis of modals

2) Analytical Techniques

3) Optimization Techniques

4) Metaheuristic methods

5) ANN based Approach

1. Analysis of Modals:

In time-domain simulation, modal analysis is nothing but a study of the properties of a system. D-STATCOM analysis may be conducted to determine a solution to a problem in a distribution network.

2. Analytical Techniques

The analytical methods create an algebraic expression and robustification and optimization can be studied. The computer is depicted in these strategies with the help of a mathematical model and calculates numerical responses without delay. The results obtained by these methods are very precise and also give less processing time. These kinds of techniques are mainly for simple and small devices in which there is less range for the amount of state variables involved. The methodological methods that are applied are the Index approach, the Power Stability Index, the Sensitivity analysis. Analytical techniques, however are not ideal for large and complex systems, as they perform adversely in recognizing computational efficiency.

3. Optimization Techniques

The optimization system is focused on the available set of alternatives to find the correct answer. It's miles hard to find the most suitable size and position of the compensating gadgets manually in common as the dispersal systems have numerous nodes. The literature utilizes various optimization methods. A variety of methods are known as classical techniques for optimization. Intelligent approaches are techniques that might be able to cleverly achieve reliable, efficient, ideal solutions. Meta-heuristic search methods are some of the competing techniques. In different areas, these techniques are most useful for solving complications. The following are numerous methods of optimization such as Genetic Algorithm (GA), Fuzzy Logic (FL), Cuckoo Search Algorithm (CSA), Bat Algorithm (BA), Particle Swarm Optimization (PSO), Differential Evolution Algorithm (DEA), Efficient Immune Algorithm (IA), Instantaneous Lively and Reactive Modern Problem Concept (IARCC), Differential Evolution Algorithm (DEA),The primary management algorithm, Firefly Algorithm, Instant Reactive Power Theory (IRPT) control set of rules, Bacterial Foraging Optimization Algorithm (BFOA) and many others are the single section p-q theory.

4. Metaheuristic methods

The most widely used methodologies for solving D-STATCOM allocation problems are metaheuristics. They are stochastic, population-based optimization algorithms that are generally successful in managing environments that are multimodal, multi-objective, discrete and limited.In[40], the immune algorithm (IA) was used by Taher &Afsari to identify the optimal position and setting of D-STATCOM in distribution networks in order to minimize energy loss, expense, congestion of power and improve the voltage profile. A newly defined objective feature has been added, which includes the cost of installing D-STATCOM and the cost of losing electricity. Compared to GA, in both IEEE 33 and 69-bus delivery systems, IA offers lower objective feature value at light, medium and peak load speeds.IA suffers from a premature convergence problem despite its outperformance over GA, which is a common disadvantage of metaheuristics. In 2014, in order to minimize copper losses and boost the voltage profile, Devi & Geethanjali used particle swarm optimization (PSO) to find the position and scale of distributed generation (DG) and D-STATCOM.The simulations were conducted in five separate test cases on several radial distribution systems. However a comparison of this approach with other methods was not included in this study. PSO is a metaheuristic that instead of the global optimum, is likely to converge into local optimals[7]. Jazebi et al. used the Differential Evolution Algorithm (DE) for reconfiguration and D-STATCOM allocation in 2014 to relieve losses and improve the distribution network voltage profile.The proposed approach was tested on 69 and 83 bus delivery networks where DE outperformed PSO. D-STATCOM allocation has been used in the binary gravitational search algorithm (BGSA) to increase the efficiency of the distribution system. In order to decrease the amount of sags propagated across delivery networks, D-STATCOM placement is performed. Compared with other optimization algorithms, the proposed algorithm has not been validated.In 2015, Kanwar et al. implemented an enhanced cat swarm optimization (CSO) in electric distribution networks for the simultaneous allocation of DGs and DSTATCOM to reduce copper losses and enhance the voltage profile. Cat swarm optimization is a technique of optimization focused on the intelligence of a powerful newly formed swarm that mimics cats' natural behaviour, but generally suffers from low convergence and accuracy.The improved CSO (ICSO) technique is then proposed to effectively solve the problem by changing CSOs' search behaviour. The results of the simulation show the efficiency of the proposed updated CSO with regard to traditional CSOs and PSOs. For optimum allocation of photovoltaic arrays and D-STATCOM, Tolabi et al applied fuzzy-based ant colony optimization (ACO). The goal of this research was to reduce losses, improve voltage profiles and improve the balancing of feeder loads.Fuzzy definitions have been used to deal with different targets. Concerning traditional ACO, fuzzy-based PSO and fuzzy-based GA, the results show the performance of the proposed fuzzy-ACO. The Firefly algorithm is used to assess the optimal location of D-STATCOM to boost power efficiency. The aims of the research are to alleviate harmonics and enhance the profile of voltage. Four D-STATCOM's used in solving the problem of optimum allocation of D-STATCOM.The results showed the firefly algorithm's outperformance over GA and PSO. The harmony search (HS) algorithm, inspired by the music improvisation method, was used in another research work to find the optimum position and size of D-STATCOM with an objective function to reduce copper losses[28]. The approach suggested has been tested for the IEEE 33-bus delivery network.The results of the proposed HS in reducing losses indicate its outperformance over IA. In order to solve the D-STATCOM allocation problem, Chabok and Ashouri suggested a combination of imperialist competition and Nelder-Mead algorithms. Active network power losses and an index of voltage stability were included in the objective feature. For optimal allocation of D- STATCOM's, a hybrid genetic algorithm and ant colony optimization algorithm were designed.The feeding system losses involving power losses in the transmission lines were reduced by this technique. For the IEEE 30-bus system, three D-STATCOMs were used. To reduce overall device losses, the optimal reactive power values produced or absorbed by three D-STATCOM are determined by GA. In smart quest, ACO is used to decide the best point for the network to mount three D-STATCOMs.

5. Artificial Neural Network based methods

For modelling online nonlinear systems with multiple inputs and outputs, Artificial Neural Networks (ANN) are used. In the literature, some applications of ANN-based approaches can be found, such as fault detection, voltage regulation, reactive power control and voltage disturbance detection. These methods are capable of finding the optimum position of D-STATCOM under faults in the distribution network.They are not applicable to optimum D-STATCOM sizing, however. For the optimum allocation of DVR and D-STATCOM in distribution networks, the artificial neural network (ANN) was used to mitigate the voltage sag under faults. Using a feed forward ANN, optimal DVR and D-STATCOM positions have been found. Each bus's pre-fault voltage has been considered as the output target data. For D-STATCOM placement, the bus with the greatest voltage deviation from the target value is the highest.

The authors have suggested different techniques in which DSTATCOM is tabulated for top-rated sizing. Computational time in the methods suggested is extra. Despite this the authors have had pleasant implications for the high-quality sizing and positioning of DSTATCOM for the reduction.

Table 1: Optimization Techniques and advantages

S.NO	Authors	Methodology used	Observations and Advantages
1	Jazebi, S., Hosseinian, S. H., &Vahidi, B. (2011)	Differential evolution algorithm	The differential evolution set of rules in distribution networks has evaluated its special abilities through its high computational search efficiency and right convergence homes.
2	Zaveri, T., Bhalja, B. R., & Zaveri, N. (2011)	Instantaneous active and reactive current component (IRACC)theory	The techniques are effective and strong for a wide range of load and supply circumstances. It is also efficient in reducing the supply VA score balance of supply currents and in achieving power problems.Correction under different load conditions in contrast to an uncompensated scenario.
3	Zaveri, T., Bhalja, B. R., & Zaveri, N. (2012)	Instantaneous active and reactive current component (IARCC) theory	For linear load, correction of power elements is performed. This results in a reduction of the reactive energy supplied from the source. For non-linear load, electricity source component solidarity is achieved.
4	Arya, S. R., Singh, B., Chandra, A., & Al-Haddad, K. (2012)	Single phase p-q theory based control algorithm	Suitable in time varying loads for ZVR and PFC modes of operation.
5	Masoud Farhoodnea, Azah Mohamed, Hussain Shareef,Hadiayandehroodi. (2013)	Firefly Algorithm	To boost the system's voltage profile and to minimize the THDV and the overall cost of investment. In radial distribution

			systems, the most efficient position and optimum size of the D-STATCOM can be calculated..
6	S M Suhail Hussain, M Subbaramiah	Modelling, Load flow technique.	Effective and easy to implement.
7	Jain,A., Gupta, A.R., & Kumar, A. (2014)	Stability Index	Reduction in Active power losses and Better voltage profile.
8	Abhinav Jain ,A.R. Gupta, Ashwani Kumar (2014)	Stability Index	It provides efficient solutions for the improvement of power loss and voltage profile with benefit for the utilities.
9	Yuvaraj, T., Devabalaji, K. R., & Ravi, K. (2015)	Harmony Search Algorithm	For n number of buses it may be applied. For finding most efficient answers it is very accurate Better than the present Immune algorithm
10	Tolabi, H. B., Ali, M. H., & Rizwan, M. (2015)	Fuzzy-ACO approach	In contrast to ACO, fuzzy-GA and Fuzzy-PS, simultaneous allocation and multi-goal reconfiguration of DSTATCOM and PV with fuzzy ACO approach is observed to be better
11	Amal Amin, Salah Kamel, Juan Yu,	Power stability index and Sensitivity analysis	1) To determine the optimal position for DG and DSTATCOM, the Power Stability Index method is used and Sensitivity Analysis is used to determine the distance. 2) Minimization of power loss is achieved and the voltage profile is improved. 3) Radial systems are limited.
12	Atma Ram Gupta, Ashwani Kumar	(a) Optimal D-STATCOM placement based on the new reactive power stability index (b) Determination of bestDSTATCOM size with probabilistic ZIP load model	1) This study enables the engineer with D-STATCOM to prepare the distribution system. 2) Improved profile of voltage and reduction in losses.
13	Majid Moazzami,HosseinShahinzadeh, Gevork B. Gharehpetian, Seyed Hossein Hosseinian	Modified Shuffled Frog Leaping Algorithm(MSFLA) is applied to minimize the objective function to achieve the optimal place and size of these instruments in distribution system.	Stability of voltage and reduction of losses in the delivery networks. Improve the voltage profile and reduce the line current in distribution systems to decrease energy and power losses.

CONCLUSION

DSTATCOM is a shunt connected voltage source converter used to compensate for reactive power, reduce power loss, boost the voltage profile, minimize total harmonic distortion of the average voltage, average voltage deviation, investment cost reduction etc. A suitable position and size to place the DSTATCOM at a suitable size is very necessary to ensure that the system is sufficiently invested in networks that increase the voltage stability margin, minimize power losses and improve the voltage profile of the distribution network.

2	Maheswari. M	Ch-18: Operation and control of Micro-grid	--	--	2018	DOI: 10.4018/978-1-5225-8030-0.ch018	Malla Reddy Engineering College (Autonomous)	IGI Global Publishers
3	V. Suma Deepthi	Handbook of Research on Smart Power System Operation and Control Ch-19: Operation of Micro-grid and control strategies	--	--	2019	DOI: 10.4018/978-1-5225-8030-0.ch019	Malla Reddy Engineering College (Autonomous)	IGI Global Publishers
4	Maheswari. M	Ch-7: Types of Faults and condition Monitoring Methods of Induction Motors	--	--	2019	DOI: 10.4018/978-1-5225-6989-3.ch007	Malla Reddy Engineering College (Autonomous)	IGI Global Publishers
5	Mrs.V.SUMA DEEPTHI	--	PENALTY QUOTED COST APPROACH FOR LOSS ALLOCATION IN A TRANSMISSION LINE BY CONSIDERING THE MUTUAL INDUCTANCE	INTERNATIONAL CONFERENCE ON EMERGING TRENDS ON ENGINEERING SCIENCE, TECHNOLOGY AND MANAGEMENT	2018	--	--	AITAM ,TEKKALI, SRIKAKULAM DT.

6	Mrs.K.ANITHA REDDY	--	HARMONIC EMISSION OG GRID CONNECTED BACK TO BACK ARRANGEMENT OF RECTIFIERS IN DISTRIBUTION NETWORKS	INTERNATIONAL CONFERENCE ON EMERGING TRENDS ON ENGINEERING SCIENCE	2018	--	--	AITAM ,TEKKALI, SRIKAKULAM DT.
7	Mrs.K.ANITHA REDDY	--	CONTROL STRATEGY FOR IMPROVEMENT OF PQ IN DC SYSTEMS INCORPORATING PR CONTROLLER	INTERNATIONAL CONFERENCE ON EMERGING TRENDS ON ENGINEERING SCIENCE	2018	--	--	AITAM ,TEKKALI, SRIKAKULAM DT.
8	MS.K.CHESTAWI	--	CONTROL STRATEGY FOR IMPROVEMENT OF PQ IN DC SYSTEMS INCORPORATING PR CONTROLLER	INTERNATIONAL CONFERENCE ON EMERGING TRENDS ON ENGINEERING SCIENCE	2018	--	--	AITAM ,TEKKALI, SRIKAKULAM DT.
9	MS.K.CHESTAWI	--	HARMONIC EMISSION OG GRID CONNECTED BACK TO BACK ARRANGEMENT OF RECTIFIERS IN DISTRIBUTION NETWORKS	INTERNATIONAL CONFERENCE ON EMERGING TRENDS ON ENGINEERING SCIENCE	2018	--	--	AITAM ,TEKKALI, SRIKAKULAM DT.
10	MR.P.GANESH	--	MODELLING AND DESIGN OF M3C-BASED UPQC FOR POWER QUALITY IMPROVEMENT IN VOLTAGE POWER GRID	NATIONAL CONFERENCE ON EMERGING TRENDS IN ELECTRICAL ENGINEERING	2018	--	--	ANURAG GROUP OF INSTITUTIONS

11	Dr. D. Raja Reddy, Dr. G. S. K. Gayatri Devi, Mr. V. Srinivas	Electronic Devices and Circuits			2018	978-93-83470-11-2	Yes	Spectrum Techno Press

3.4.4 Number of books and chapters in edited volumes/books published per teacher during the last five years (5)

3.4.4.1: Total number of books and chapters in edited volumes / books published, and papers in national/international conference-proceedings year wise during last five years

Sl. No.	Name of the teacher	Title of the book/chapters published	Title of the paper	Title of the proceedings of the conference	Year of publication	ISBN/ISSN number of the proceeding	Whether at the time of publication Affiliating Institution Was same Yes/NO	Name of the publisher
1	Dr. N. Rajeswaran, Mr. Ch. Narendra Kumar, Ms. C. Shilpa	Basic Electrical and Electronics Engineering	--	--	2017	978-81-943685-3-3	Yes	Amaravathi Publications
2	Mrs.K.Anitha Reddy	--	Design Analysis of Resonant Feedback Compensators	International Conference On Electrical Sciences	2017	--	Yes	SNS College Of Technology, Tamil Nadu
3	Mrs.S.Sunanda	--	Bi-Directional Converter For Single-Phase Micro Grid Application	National Conference On Science, Technology & Environment: Prospects And Limitations In The 21st Century	2017	--	Yes	Bineswar Brahma Engineering College , Assam
4	Dr. M.Lakshmiswarupa	--	Optimal Power Flow By A Primal Dual Interior Point Method	International Conference On Power Electronics Drives And Energy Systems	2018	978-93-85100-90-1	Yes	Malla Reddy Engineering College (Autonomous)
5	Mrs.K.Anitha Reddy	--	Distribution Systems Reliability Analysis With Clamped, Lying Capacitor H-Bridge Inverter	International Conference On Power Electronics Drives And Energy Systems	2018	978-93-85100-90-1	Yes	Malla Reddy Engineering College (Autonomous)
6	Mr.K.S.S.Naga Teja	--	Wavelet Based Signal Processing Technique For Classification of Power Quality Disturbances	International Conference On Power Electronics Drives And Energy Systems	2018	978-93-85100-90-1	Yes	Malla Reddy Engineering College (Autonomous)
7	Mr.T.Sanjeeva Rao	--	Harmonic Compensation in Electrical Systems by Active Power Filters	International Conference On Power Electronics Drives And Energy Systems	2018	978-93-85100-90-1	Yes	Malla Reddy Engineering College (Autonomous)

8	Mrs.Y.Sudha	--	Power System Stabilizer And TCSC Controller By Using Back Stepping Algorithm	International Conference On Power Electronics Drives And Energy Systems	2018	978-93-85100-90-1	Yes	Malla Reddy Engineering College (Autonomous)
9	Dr.S.Arumugam	--	Design and Analysis of Multi Modal Controller	International Conference On Power Electronics Drives And Energy Systems	2018	978-93-85100-90-1	Yes	Malla Reddy Engineering College (Autonomous)
10	Mr. P.Kamalakar	--	Digital Simulation of Interline Power Flow Controller System with PI and NN Controller	International Conference On Power Electronics Drives And Energy Systems	2018	978-93-85100-90-1	Yes	Malla Reddy Engineering College (Autonomous)
11	Dr. N. Rajeswaran, Mr. Ch. Narendra Kumar, Ms. C. Shilpa	Basic Electrical and Electronics Engineering			**2017**	978-81-943685-3-3	Yes	Amaravathi Publications

3.4.4 Number of books and chapters in edited volumes/books published per teacher during the last five years (5)

3.4.4.1: Total number of books and chapters in edited volumes / books published, and papers in national/international conference-proceedings year wise during last five years

1	Dr. N.Rajeswaran	--	Hybrid Artificial Intelligence Based Fault Diagnosis Of SVPWM Voltage Source Inverters For Induction Motor	International Conference of Processing of materials, minerals and energy	2016	2214-7853	Malla Reddy Engineering College	Ongole, Andhra Pradesh, India
2	Dr.S. Arumugam	--	Nine Level Diode Clamped Asymmetric Dual Converter Based STATCOM with DC Link Voltage Control	National Conference on Recent Innovations in Electrical Engineering	2016	ISBN: 9789383038497	MREC (A)	Malla Reddy Engineering College (Autonomous)
3	Dr.S. Arumugam	--	A New PWM Strategy for Three Phase Inverters Applied for Induction Motor	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
4	Mr.P.Ganesh	--	Modeling of New Multilevel Inverter Topology With reduced Number of Power Electronic Components	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
5	S.Bharati Reddy	--	Simulation Modeling And Control of Hybrid AC/DC micro grid	National Conference on Recent Innovations in Electrical Engineering	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
6	Mr .T. Suman	--	A PI And Fuzzy Controlled Two-Phase Interleaved PFC Boost Converter	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)

7	D. Ramesh	--	Boost Inverter Circuit With A Coupled Inductor Using Renewable Energy Source	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
8	M.Harinath Reddy	--	Soft Switching Bidirectional DC-DC Converter For Hybrid Electric Vehicle Applications	National Conference on Recent Innovations in Electrical Engineering	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
9	Jeepalem Muni Chandra Sekhar	--	Multilevel STATCOM Based Cascaded Two Level Inverters For High-Power Applications	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
10	Dr. M. Lakshmi Swarupa	--	A New Bidirectional Dc-Dc Converter For Electric Vehicles Applications	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
11	DR M.Lakshmi Swarupa	--	A New Control Strategy For Three-Phase Inverter Applied To Induction Motor of Micro Grid	National Conference on Recent Innovations in Electrical Engineering	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
12	J.Srineswari	--	Harmonic Mitigation In Ship Power Systems Using Passive Harmonic Filters	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
13	Mrs.K.Anitha Reddy	--	Effects of Harmonics on Electrical Equipment & Their Compensation By Using Shunt Active Power Filter	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
14	Ch.Venkateswarlu	--	Modeling of Fuel Cell Connected Distribution Generation System	National Conference on Recent Innovations in Electrical Engineering	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)

15	K. Chetaswi	--	A New Integrated Topology With Less Switches For Dual Mode Electric Vehicle Applications	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
16	A. Madhu Mohan Reddy	--	Coupled-Inductor And Voltage-Doubler Circuits With High Step-Up DC-DC Converter	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
17	T.Venkatesh	--	Power Factor Correction And Comparison Of Converter Topologies For SRM Drive	National Conference on Recent Innovations in Electrical Engineering	2016	ISBN: 9789383038497	Malla Reddy Engineering College (Autonomous)	Malla Reddy Engineering College (Autonomous)
18	Mr.V.Ganesh Kumar	--	Super Conducting Fault Current Limiting For Energy Storage Protection In Micro Grid	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
19	K. Naresh	--	A New Multilevel Inverter Based Wind Generation System With Power Factor Correction	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
20	K. Neelima Praveena	--	A Novel Control Strategy Of Three-Phase, Four wire UPQC With Reduced Switching Losses	National Conference on Recent Innovations in Electrical Engineering	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
21	T.Upendar	--	Multi Input and Multi Output PWM DC-DC Converter	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	Malla Reddy Engineering College (Autonomous)	Malla Reddy Engineering College (Autonomous)
22	Ch. Narendra Kumar	--	Design of UPQC With Minimization Of Dc Link Voltage For The Improvement of Power Quality By PI Controller	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)

23	Mrs.V.Suma Deepthi	--	Green Computing With Thin Client	National Conference on Recent Innovations in Electrical Engineering	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
24	Dr. N. Rajeswaran	--	Speed Control of The Induction Motor Using Artificial Intelligence	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
25	Mrs.K.Anitha Reddy	--	Half Bridge Converter Based Simplified Conditioner for High Speed Rail Way Systems	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
26	Mrs. S. Sunanda	--	Integrating Fuzzy Logic And Expert System for Optimization of Smart Grid Functioning	National Conference on Recent Innovations in Electrical Engineering	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
27	T.Sanjeeva Rao	--	Power Quality Improvement Using Cascaded Multilevel STATCOM With DC Voltage Control	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
28	P.Kamalakar	--	The Double Loaded Resonant Converter For The Application of DC to DC Energy Conversions	National Conference on Recent Innovations in Electrical Engineering	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)
29	K.Ramesh	--	Hysteresis Current Control of Shunt Active Power Filter In Distribution Power System	National Conference on Recent Innovations in Electrical Engineering College	2016	ISBN: 9789383038497	MREC(A)	Malla Reddy Engineering College (Autonomous)

3.4.4 Number of books and chapters in edited volumes/books published per teacher during the last five years (5)

3.4.4.1: Total number of books and chapters in edited volumes / books published, and papers in national/international conference-proceedings year wise during last five years

Sl. No.	Name of the teacher	Title of the book/ chapters published	Title of the paper	Title of the proceedings of the conference	Year of publication	ISBN/ISSN number of the proceeding	Whether at the time of publication Affiliating Institution Was same Yes/NO	Name of the publisher
1	K. Ramesh	--	Analysis, Design and Implementation of A Bi-Directional Double Boost DC-DC Converter With Coupled inductor Technique	International Conference on Emerging Trends in Science, Technology & Management (ICETSTEM 2015)	2015	--	Yes	Malla Reddy Engineering College (Autonomous)
2	P. Ganesh	--	Dual Mode Mechanism With Input Voltage Feed Forward for the Two-Switch Buck-Boost DC-DC Converter	International Conference on Emerging Trends in Science, Technology & Management (ICETSTEM 2015)	2015	--	Yes	Malla Reddy Engineering College (Autonomous)
3	V. Sumadeepthi	--	Comparison of PI and RST Controllers in Double-Fed Induction Generator For Wind Energy Conversion Systems	International Conference on Emerging Trends in Science, Technology & Management (ICETSTEM 2015)	2015	--	Yes	Malla Reddy Engineering College (Autonomous)

4	K. Anitha Reddy	--	Adsptive Fuzzy Logic Controller For permanent Magnet Synchronous Motor With non Linear Friction	International Conference on Emerging Trends in Science, Technology & Management (ICETSTEM 2015)	2015	--	Yes	Malla Reddy Engineering College (Autonomous)
5	S. Bharathi	--	Synchronous Static Series Compensator (SSSC) on Enhancement of Voltage Stability and Power Oscillation Damping for Unbalanced System	International Conference on Emerging Trends in Science, Technology & Management (ICETSTEM 2015)	2015	--	Yes	Malla Reddy Engineering College (Autonomous)
6	K. Chetaswi	--	Lyapunov Design Based MIT Rule for Model Reference Adaaptive Control Systems	International Conference on Emerging Trends in Science, Technology & Management (ICETSTEM 2015)	2015	--	Yes	Malla Reddy Engineering College (Autonomous)
7	K. Chetaswi	--	Optimal Design Technique Based on Linear Quadratic Gaussian Theory	International Conference on Emerging Trends in Science, Technology & Management (ICETSTEM 2015)	2015	--	Yes	Malla Reddy Engineering College (Autonomous)
8	M. Lakshmi swarupa	--	Optimal Location of FACTS devices Considering Cost of Installation and System Loadability by Using Particle Swarm Optimization technique	International Conference on Emerging Trends in Science, Technology & Management (ICETSTEM 2015)	2015	--	Yes	Malla Reddy Engineering College (Autonomous)

9	M. Lakshmi swarupa	--	Fuzzy Logic Based Maximum Torque Control For a Single Phase Induction Motor	International Conference on Emerging Trends in Science, Technology & Management (ICETSTEM 2015)	2015	--	Yes	Malla Reddy Engineering College (Autonomous)
10	T. Sanjeeva Rao	--	Fuzzy Logic Controller Based BLDC Motor Drive With Source Side Power Factor Correction	International Conference on Emerging Trends in Science, Technology & Management (ICETSTEM 2015)	2015	--	Yes	Malla Reddy Engineering College (Autonomous)
11	T. Sanjeeva Rao	--	Simulation of Standalone Inverter for Distribution System With Fuzzy Control	International Conference on Emerging Trends in Science, Technology & Management (ICETSTEM 2015)	2015	--	Yes	Malla Reddy Engineering College (Autonomous)
12	K. Anand Kumar	--	Fuzzy Logic Control of Reduced Rating DVR with A Battery Energy Storage System	International Conference on Emerging Trends in Science, Technology & Management (ICETSTEM 2015)	2015	--	Yes	Malla Reddy Engineering College (Autonomous)

MALLA REDDY ENGINEERING COLLEGE (AUTONOMOUS)
(An UGC Autonomous Institution, Approved by AICTE, New Delhi & Affiliated to JNTUH, Hyderabad). Accredited by NAAC with 'A' Grade (II cycle),
Maisammaguda (H), Medchal-Malkajgiri District, Secunderabad,
Telangana State – 500100, www.mrec.ac.in

Department of Mechanical Engineering

Details List of Publication for A.Y. 2019-20

S.No.	Title of paper	Name of the author/s	Department of the teacher	Name of journal	Year of publication	ISSN number	Is it listed in UGC Care list/Scopus/Web of Science/other, mention	Academic Year
1	Friction and wear behaviour of NiCr/Sic based composites	Katla Rajendra	Mechanical Engineering	Journal of engineering ,computing and architecture	2020	1934-7197	Scopus	2019-20
2	Exploration of indispensable properties of textile-grade glass fibres/white caustic treated banana fibre hybrid composite	Dr.A.Raveendra	Mechanical Engineering	Elsevier(Materials Today)	2020	2214-7853	Scopus	2019-20
3	Numerical study of the heat dissipation of rectangular heat sink under natural convection with different slots	M.Vijay Kumar	Mechanical Engineering	International Journal of Mechanical and Production Engineering Research and Development	2020	2249-6890	Scopus	2019-20

4	Design and Analysis of Petrol Engine Crown Coated with Alsic and Brass	S.Rammohan Reddy	Mechanical Engineering	The International journal of analytical and experimental modal analysis	2020	0886-9367	UGC	2019-20
5	A study report on Fabrication of Hitech-Highway	Nuvvula Harini	Mechanical Engineering	International journal of Innovative research in science, engineering and technology(IJIRSET)	2020	2319-8753	UGC	2019-20
6	A Lithophane Model Making Process to 3D Printers	SiddavatamRammohan Reddy	Mechanical Engineering	International Journal of Mechanical Engineering and Technology (IJMET)	2020	0976-6340	UGC	2019-20
7	Comparison of Shear Rigidity of Epoxy and Vinyl Ester Reinforced Hybrid Honeycomb Core	A.Paul Praveen	Mechanical Engineering	Material Today: Proceesings	2020	2214-7853	Scopus	2019-20
8	Design and Analysis of 4 Cylinder Piston and Connecting Rod Assembly	P.Santhipriya	Mechanical Engineering	IJAST	2020	2005-4238	UGC	2019-20
9	Smart Applications using Robotic and Iot Technologies in Fighting against Pandemic Covid19 in Medical and Societal Sectors	C.Chandrasekhara	Mechanical Engineering	International Journal of Innovative Technology and Exploring Engineering (IJITEE)	2020	2278-3075	Scopus	2019-20

10	Resultant surface roughness of 5% and 10% A17075SiC MMC by using Friction Stir Welding	D.S.Ch. Mouli	Mechanical Engineering	Journal of Xi'an of Architecture & Technology	2020	1006-7930	Scopus	2019-20
11	Synthesize and wet condition based characterizations of GRP / Lye treated sisal fiber hybrid composite	T.Naresh Kumar	Mechanical Engineering	Material Today: Proceesings	2020	2214-7853	Scopus	2019-20
12	An Experimental Investigation of mechanical properties of Teak wood rust and tamarind kernel powder reinforced plymer composite	S.C.Sireesha	Mechanical Engineering	International journal of innovative research in science Engineering & Technology	2020	2319-8753	UGC	2019-20
13	Investigation of the Deep Drawability of Aluminium Sheets by Finite Element Numerical Simulation	Mrs.A. Aruna Jyothi	Mechanical Engineering	IJIRSET	2020	2319-8753	UGC	2019-20
14	'Mechanical Behavior& Analysis of Epoxy, Al2O3 Composites'	K. Bharadwaja	Mechanical Engineering	International Journal of Engineering and Advanced Technology	2020	2249-8958	Scopus	2019-20
15	Dry Sliding Wear Behaviour of Aluminium 7075/SiC/MoS2 Composites at Room Temperature	Dr. Dhatreyi Boyina	Mechanical Engineering	Journal of Engineering, Computing and Archiyecture	2020	1934-7197	UGC	2019-20
16	Influence of variable speed on performance and emission Characteristics of diesel engine using fish oil biodiesel blends	M.vijay Kumar	Mechanical Engineering	International Journal of Recent Technology and Engineering	2020	2277-3878	Scopus	2019-20

17	Optimisation Of Scram Jet Strut Injection	Vasili Srinivas	Mechanical Engineering	Journal of Engineering, Computing and Architecture	2019	1934-7197	UGC	2019-20
18	Thermal Investigation of Hybrid Nano based Phase Change Materials to Cater Cooling Needs for Energy Systems	Yogesh Madaria	Mechanical Engineering	Journal of Engineering, Computing and Architecture	2019	1934-7197	UGC	2019-20
19	Mechanical and Material Properties of Areca/Epoxy Composite	T. Naresh Kumar	Mechanical Engineering	International Journal of Innovative Technology and Exploring Engineering (IJITEE)	2019	2278-3075	Scopus	2019-20
20	Experimental Investigation for Performance Enhancement of Household Refrigerator using Phase Change Material	Yogesh Madaria	Mechanical Engineering	Journal of Engineering, Computing and Architecture	2019	1934-7197	Scopus	2019-20
21	Optimization of Process Parameters on EDM of Titanium alloy	BhikshaGugulothu	Mechanical Engineering	Material Today: Proceesings	2019	2214-7853	Scopus, WOS	2019-20
22	Influence of drinking water and graphite powder concentration on electrical discharge machining of Ti-6Al-4V alloy	BhikshaGugulothu	Mechanical Engineering	Material Today: Proceesings	2019	2214-7853	Scopus, WOS	2019-20
23	Reinforcing Adhesive Plastic-Coated Grins through FRP Compounds	T. Naresh Kumar	Mechanical Engineering	International Journal of Engineering and Advanced Technology	2019	2249-8958	Scopus	2019-20

24	Observation of different experimental parameters effect using friction stir welding through simulation of tailor welded blanks	Aruna Jyothi Anumula	Mechanical Engineering	International Journal of Recent Technology and Engineering	2019	2277-3878	Scopus	2019-20
25	Assessment of dynamic properties of hybrid ribbon reinforced multifunctional composite sandwich plates: Numerical and experimental investigation	A.Paul Praveen	Mechanical Engineering	Thin Walled Structures: Elsevier	2019	-	WOS	2019-20
26	Tensile, Flexural and Surface Hardness Properties of Wool Grit/Silicone Polymer Composites	T. Naresh Kumar	Mechanical Engineering	International Journal of Innovative Technology and Exploring Engineering (IJITEE)	2019	2278-3075	Scopus	2019-20
27	Experimental Research on Abaca/Agave/ Fly ash Nano Powder Reinforced Hybrid Composites	T. Naresh Kumar	Mechanical Engineering	International Journal of Innovative Technology and Exploring Engineering	2019	2278-3075	Scopus	2019-20
28	Experimental Research of Silane Treatment on Bamboo and Aramid Hybrid Composites	T. Naresh Kumar	Mechanical Engineering	International Journal of Engineering and Advanced Technology	2019	2249-8958	Scopus	2019-20
29	Effect of Chemical Treatment on Alpaca Fleece Reinforced Polymer Composites	T. Naresh Kumar	Mechanical Engineering	International Journal of Engineering and Advanced Technology	2019	2249-8958	Scopus	2019-20

30	Experimental Research on Natural Fiber Reinforced Polymer Composite Material Composites	T. Naresh Kumar	Mechanical Engineering	International Journal of Innovative Technology and Exploring Engineering (IJITEE)	2019	2278-3075	Scopus	2019-20
31	Effect of Chemical Treatment on Ramie / Rattan /Silicone Polymer Composites	T. Naresh Kumar	Mechanical Engineering	International Journal of Engineering and Advanced Technology (IJEAT)	2019	2249-8958	Scopus	2019-20
32	Machining Characteristics of Natural Fiber Particle Reinforced Polymer Composite Material using Artificial Neural Network	T. Naresh Kumar	Mechanical Engineering	International Journal of Innovative Technology and Exploring Engineering	2019	2278-3075	Scopus	2019-20
33	Characterization of Roselle & Kevlar hybrid Composites	A. Raveendra	Mechanical Engineering	International Journal of Engineering and Advanced Technology	2019	2249-8958	Scopus	2019-20
34	Experimental Research of Wire Cut EDM for SR & MRR using Taguchi Method	A. Raveendra	Mechanical Engineering	International Journal of Engineering and Advanced Technology	2019	2249-8958	Scopus	2019-20
35	Studies on friction stir welding of Aluminium plates 2014-T6 and 6061-T6	D.S. Chandra Mouli	Mechanical Engineering	Proteus Journal	2020	0889-6348	Scopus	2019-20

36	Manufacturing of Foot step power generation by using rack and pinion motion with suspension spring	Mr. S. Udaya Bhaskar, A. Paul Praveen	Mechanical Engineering	The International journal of analytical and experimental modal analysi	2019	0886-9367	UGC	2019-20
37	Pneumatic based bike gear changing	Mr. S. Udaya Bhaskar, Mr. N Rishi Kanth, Mr. Yogesh Madaria	Mechanical Engineering	The International journal of analytical and experimental modal analysi	2019	0886-9367	UGC	2019-20
38	Rack and pinion motion-based Head light tilting system	Dr.Zaheer Ahamed T, A. Paul Praveen, N. Rishi Kanth	Mechanical Engineering	The International journal of analytical and experimental modal analysi	2019	0886-9367	UGC	2019-20
39	Railway track based power generation with rack and pinion mechanism	Dr.Zaheer Ahamed T, , Mr. S. Udaya Bhaskar, A. Paul Praveen, N. Rishi Kanth, Mr. Yogesh Madaria	Mechanical Engineering	The International journal of analytical and experimental modal analysi	2019	0886-9367	UGC	2019-20
40	SOLAR Grass cutting machine	Mr. N Rishi Kanth, Ms.N.Harini	Mechanical Engineering	The International journal of analytical and experimental modal analysi	2019	0886-9367	UGC	2019-20
41	Solar Powered refrigeration system	Ms.N.Harini, A Vijaya Krishna	Mechanical Engineering	The International journal of analytical and experimental modal analysi	2019	0886-9367	UGC	2019-20

42	STUDY OF ABRASIVE JET MACHINE	A Vijaya Krishna, Mr. Balaji Krushna.P, Mrs. S.C. Sireesha	Mechanical Engineering	The International journal of analytical and experimental modal analysi	2019	0886-9367	UGC	2019-20
43	Thermo electric refrigerater	D.S.CH.Mouli, Sri Deepthi Immaneni	Mechanical Engineering	The International journal of analytical and experimental modal analysi	2019	0886-9367	UGC	2019-20
44	VENDING MACHINE	S. Udaya Bhaskar, Mr. Sandeep Mulabagal	Mechanical Engineering	The International journal of analytical and experimental modal analysi	2019	0886-9367	UGC	2019-20
45	WIND ENERGY VEHICLE	S. Udaya Bhaskar, Ms. S.C.Sireesha	Mechanical Engineering	The International journal of analytical and experimental modal analysi	2019	0886-9367	UGC	2019-20

Abstract: *Ni based Metal matrix composites (MMCs) have attained growing importance in industries and advanced technologies, for tribological applications because of their potential uses in the automobile, aerospace especially for applications to sliding parts.In this project 95 % of Nickel chromium (NiCr) based composite containing 5 % Silicon carbide(SiC) is reinforced in different percentages prepared by powder metallurgy method. In powder metallurgy we used ball milling method for proper mixing of combined powders followed by compaction and sintering. These samples are compacted at 3 different pressures for each sample 60 KN,70 KN,80KN respectively. The samples after compaction are sintered using different times 60min,90min,120min for constant temperature 1000^0c.The prepared samples were examined for micro structural and mechanical properties like hardness and compressive strengths which are important properties for materials.For tribological studies the friction and wear behavior is examined by using pin on disk tribological set up. This showed that tribological properties got improved by increasing the loads and sintering time of NiCr and SiC composites at the temperature of 1000 ^{0}c. The best comprehensive properties of tribology are being obtained when the sample prepared by load of 80KN and sintering time of 120 min which exhibited wear rate(1.1 x $10^{-5}$$mm^3$/Nm) and lowest friction coefficient (0.56).*

Keywords: **Metal matrix composites ,Wear rate ,Friction Coefficient**

1.INTRODUCTION

In the recent trend ,the Nickel based reinforced composites had been the best for the industrial applications namely aerospace, marine and automobile and many more.Various techniques had implemented to improve the microstructure and to obtain desired mechanical properties.The overall aim of the reinforced composites is to be the better performed engineering materials.The reinforced composites which in progress improves the quality of the material and also progress the better international market share.The market demand for high performance ,stiffness and strength of the materials is increasing rapidly with the optimized cost and weight of the materials. The function of the composites is to enhance work ability and to improve the physical and mechanical properties .It possess hight strength ,good ductility and high strength to weight ratio, low thermal expansion coefficient .The composite possess excellent wear resistance ,better fatigue strength and high temperature creep resistance.The composites will be either in the form of metal,ceramic ,plastic and the reinforcement will be in the form of fibre or particles.[1-4].

The reinforcement can be used in the form of metals,carbides and oxides. At present many reasearches are done to improve the metal matrix composties(MMC).Many methods for developing the metal matrix composites are done namely Metal injection moldings ,friction stir process, Liquid fabrication method, solid state fabrication method,mechanical alloying. The metal matix can be reinforced by numerous reinforcements with variety of types like graphite, SiC, Al2O3, TiO, MgO, SiO2, B4C, TiC, WC, h-BN and C in the form of particulates, whiskery structures or fibrous matter.[5-6]

Nickel alloy has wider applications in aerospace ,marine and turbine engines for their excellent tribological and mechanical properties at elevated temperatures.The nickel alloy has its higher density and creep resistance limit for their future applications. However ther nickel based composites can reduce density and meanwhile improve mechanical properties and high temperature of nickel matrix which makes to have the wider applications int market for pumps, valves, marine and aerospace industries and the overcome the problems of the nickel based composites and become cost effective.[7]

R.Tiwari also investigasted that the effect of chromium addition also increased the yield strength and the hardness of the Ni-Al alloys[8]. From the recent trend, SiC has been used as new reinforcing material and is successful in improving the tensile properties. SiC posses good electrical conductivity, thermal , chemical stability,high mechanical strength and low friction properties.It is observed that the addition of SiC can strengthen a metal matrix and improves many more mechanical properties. The grain structure of the MMCs also could be improved by adding SiC[9-10]. The author investigated that the combinations of Ni(1-3.5%)-SiC at different weights and loads found as the ideal combination for the strength and plastic properties[12].The combinations are mainly done by sintering techniques which improved hardness and decreased the density of the composite.It has found that the wear rate of the combinations decrease with the increase in the temperatures[6].The microstructure has become finer with the combinations of Ni-SiC than before. The tensile strength and the hardness got increased by these combinations(13-15).Xinmin investigates pin on disc tribological studies for good and accurate results for wear rate and friction coefficients for standard steel gear materials.[16].

In this research ,several NiCr-SiC composite samples were prepared by Ball milling method and with UTM(Ultra sonic testing machine).Then followed by different loads and sintering temperatures to eludicate the changes in the microstructure and mechanical properties.One major goal of this research is to investigate the strenghteing capabilities if SiC for NiCr metal for improving the the strength and hardness.To investigate the best wear rate and friction coefficients of the samples on Pin on disc machine.To obtain redefined grain structures .

2 .1 Material and Methods

2.1.1 Preparation of Ni- Based composites

The composition of 95% Ni-Cr and 5% of SiC is taken for the preparation of sample. These powders were mixed by Ball milling method.The powders taken according to their respective weights were blended using a blender for uniform distribution of particles i.e 475 grams of Ni-Cr and 25 grams of SiC was blended in a blender. The specimen was made using a die made of EN32 with diameter 12mm. For making of each specimen, 8 gm of blended powder mixture was taken. The powder was weighted using an electronic balance with least count of 1gm. The powders were handelled very carefully to avoid

oxidation and reaction with atmospheric gases. Acetone was used for cleaning of die and zinc stearate was used for lubrication purpose of die. The powder was compacted in the die using 'UNIVERSAL TESTING MACHINE'with maximum capacity of 4000tons ,by applying appropriate loads. During the compaction process,the punch speed was carefully controlled since high force will produce a very less density of specimen so the life of the specimen is less .An ejector was also used for removal of specimen from the die..About 9 samples were prepared by 3 different loads each of 60KN,70KN,80KN by the mixture of NiCr and SiC composites. After compaction Green compacts were rolled in nylon tape to prevent oxidation.

Fig 2.1 Green compacts

Flowchart representing process methodology:

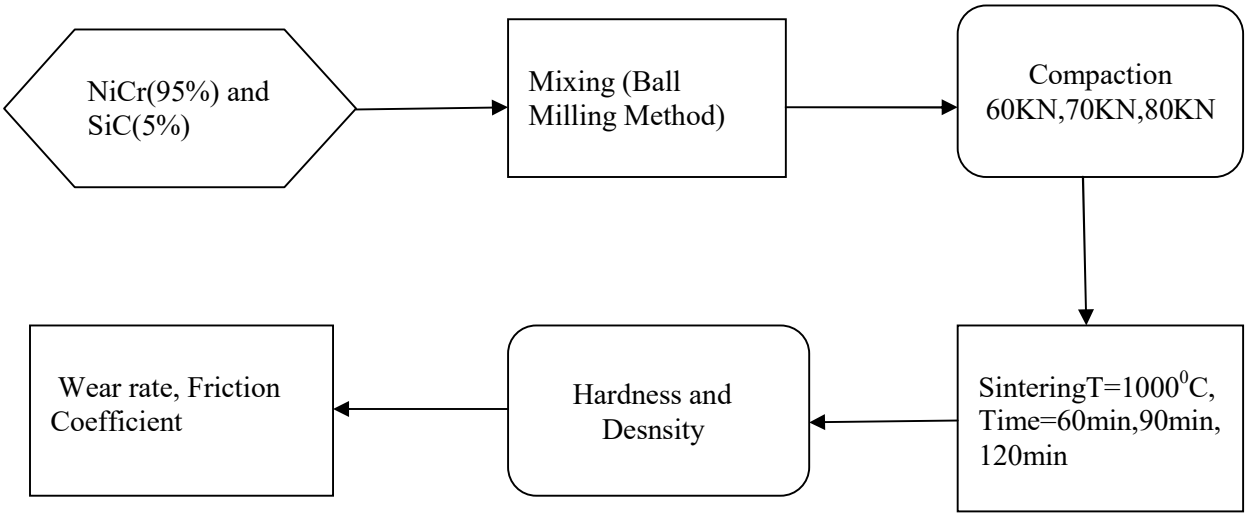

Fig 2.2 Experimental process methodology

2.1.2 SEM Analysis

In the below SEM analysis we can see that Ni-Cr powder mixture consists of 8.57% of oxygen ,2.57%of silicon and 75.69%of Ni. Very low percentage of impurities where found in the powder. similarly in the SEM analysis of SiC it was observed that no impurities were present in the powder. There was no oxygen content in the powder. As a result oxidization of Si and C to SiO2 and CaCO3 could be prevented.

Thus during the making of specimen, the properties of Si and C could be retained in the composite material and prevent any reaction taking place between the powders because of oxidization.(17)

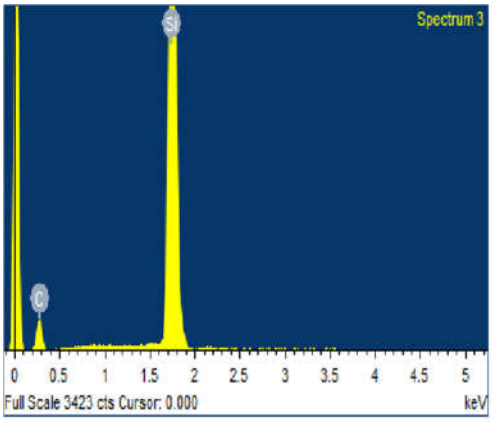

Fig 2.3 SEM micrograph of Sic powder mixture

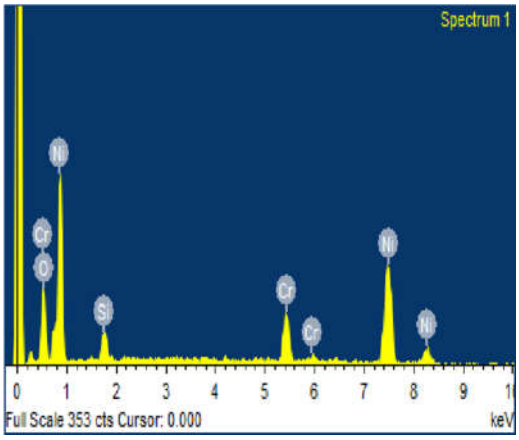

Fig 2.4 SEM micrograph of Nicr powder mixture

2.1.3 Sintering

The prepared green compact samples did not have enough strength, to improve the strength of the green sample go for sintering process. The compacted green samples where sintered in tubular furnace in presence of vacuum..In Sintering process green compacts which was prepared by Compaction was heated at a temperature of 1000°C employed. The specimen were soaked for a time of 60min,90min and 120minrespectively. A pressure of -0.95 bar is created in the tubular furnace to prevent oxidation of specimens.After completion of sintering process samples were cooled in the furnace itself to the room temperature, then the samples taken out from the furnace and the mechanical tests for characterization.A chiller was used for circulation of cold water through vacuum O rings.

2.1.4 Wear rate measurement

Wear rate of the 9 specimens were conducted on Pin on disc setup of Magnum model-TE-165.The specimens were cleaned with acetone before wear tests. A 20 N load is applied at the back holder of the machine and the sample is adjusted at the pin. The wear and tear of the machine is set to zero and the set time of 15 min of machine set for experiment. The disc rotates at the speed of 1000rpm. The disc starts to rotate when the start button is pressed until the time which is already set for the machine.After rotated for the required time on the pin on disc machine the sample gets wear and it is removed from the pin and tested for further purposes. The tests are repeated 3 times and the average value is taken.The same processes is carried out for the same 9 samples respectively.

Table 2.1 Different loads used for compaction and sintering temperature and soaking time at constant temperature of 1000 ^{0}c is given below.

Samples	Load (KN)	Sintering time (min)
1	60	60
2	60	90
3	60	120
4	70	60
5	70	90
6	70	120
7	80	60
8	80	90
9	80	120

Table 2.2 Tribological test parameters used in this experiment

Tribological parameters	Experimental conditions
Applied load (N)	20
Rotational speed(rpm)	1000
Sliding speed(m/s)	10
Specimen diameter (mm)	8
Pin diameter (mm)	8
Pin length (mm)	30
Temp(^{0}C)	25±2
Humidity(%)	67±2

3 Results and Discussions

3.1 Microstructure and Mechanical properties of Ni-Based composites

Metallographic studies of the composite specimen Ni-Cr/SiC produced and specimen made up of Ni – Cr after sintering was carried out .From the above microstructures of the specimen we can observe that SiC was uniformly distributed in Ni-Cr/SiC composite material because of ball milling used for mixing of the powders. Uniform distribution of the elements results in the specimen exhibiting better properties than that of specimen produced by non-uniform distribution of the elements.

Microstructure obtained of the composites are relatively dense. It is observed two different phases in the microstructures Gray phase ,deep gray phase. Gray phase is rich in NiCr and the deep gray phase is rich in SiC composites. The incorporation of SiC composite on to the NiCr resulted in decrease in the density(13). This shows that with the increasing compaction pressure and increasing sintering time as considered from table 2.1 ,the microstructures of the resulting samples became very dense and the poristy

became less.The microstructure became more denser because the bonding between the molecules become stronger and it is seen in the microstuructures as the compaction pressure and sintering time increases.

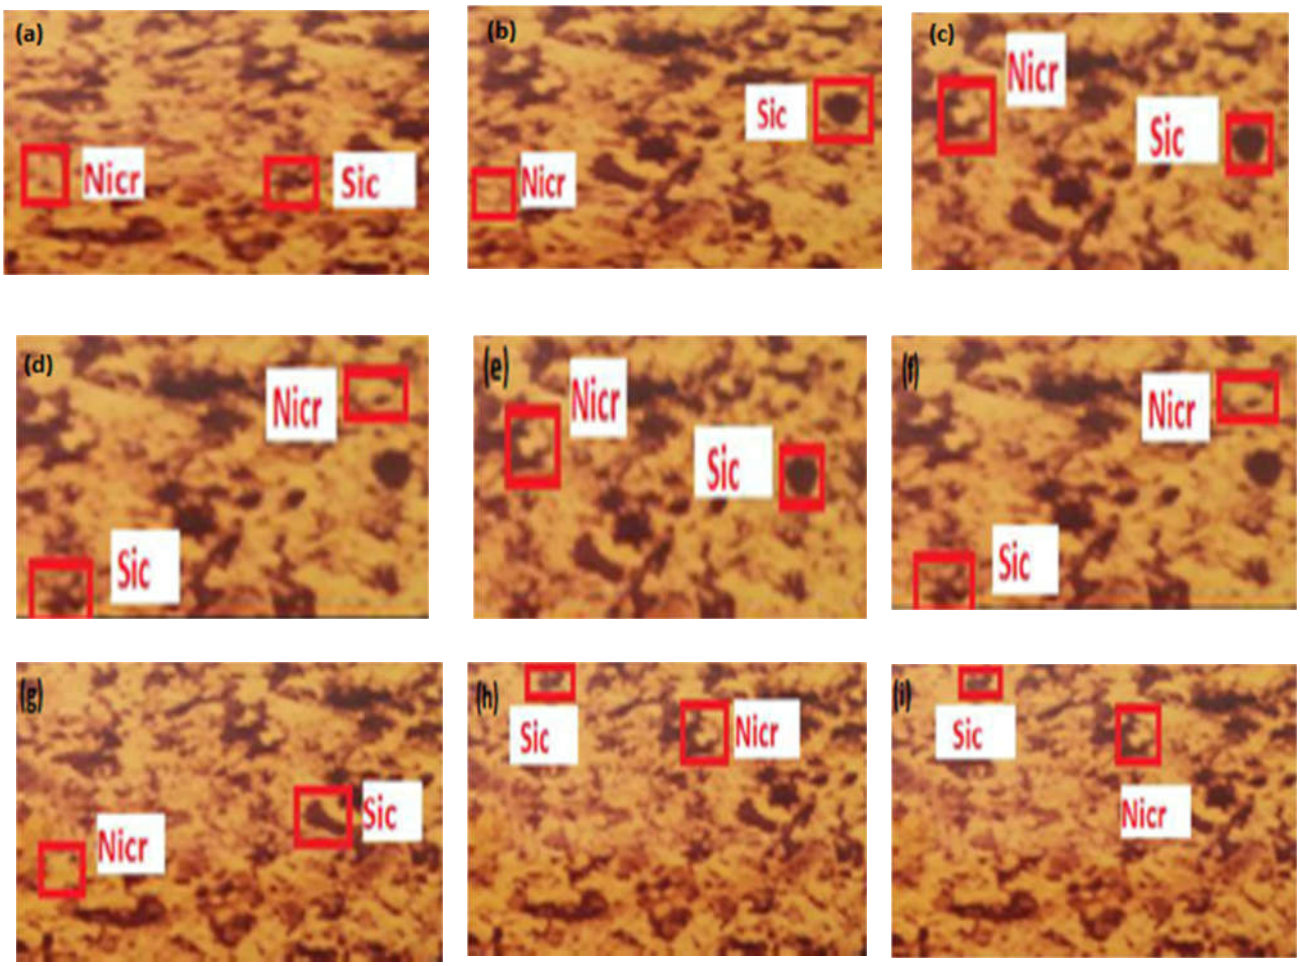

Fig 3.1 Microstructures of specimens tested after sintering (a) Microstructure of 60KN load and 60min sintering time ; (b) Microstructure of 60KN load and 90 min sintering time ; (c) Microstructure of 60KN load and 120 min sintering time; (d) Microstructure of 70KN load and 60 min sintering time ; (e) Microstructure of 70 KN load and 90 min sintering time ; (f) Microstructure of 70 KN load and 120 minisintering time; (g) Microstructure of 80KN load and 60 min sintering time; (h) Microstructure of 80KN load and 90 min sintering time ;(i) Microstructure of 80KN load and 120 min sintering time.

3.2 Measurement of hardness and density

Hardness is considered as the key factors of the wear tests. Greater the hardness the lesser will be the wear rate of the material. There are different methods to find the hardness but finally they give the same results .Ductility of the specimen is found by measurement of the hardness hardness . Brinell scale is used for the measurement of the hardness.This tests uses 10mm(0.39in) dia steel bar as indentor with 3000kgf force.For harder material tungsten carbide ball is used instead of steel bar as an indentor. The test method used is ASTM E 10-2018 .The ball diameter used is 2.5mm and the load used is 15.625 kg.The Brinell hardness teast method is used to determine the hardness of the specimens.The specimens were polished using grades of emery sheet before hardness testing

process.The hardness were measured at three different points and average of the hardness was taken. Densities of the specimens are measure using the Archimedes method.

Table 3.1 Results of hardness and densities

Samples	Hardness	Desnities (g/cm^3)
1	30.3	5.521
2	31.3	4.4991
3	32.7	4.957
4	31.2	5.225
5	32.5	5.125
6	33.7	5.071
7	32.7	5.202
8	33.4	5.019
9	34.5	4.852

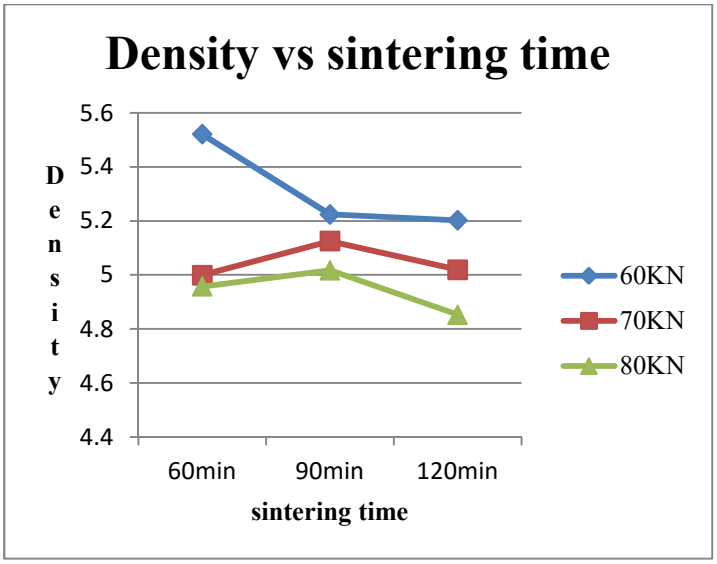

Fig 3.2 Density vs sintering time results of the specimens with the compaction loads of 60KN,70KN,80KN

The fig 3.2 shows that the density variation with the sintering time, it can be clearly seen that as the sintering time increases, the density is getting decreased, this is because as the sintering time of the material increases the porosity of the material will become lesser therefore the density will be decreased. The density variation for 60KN load decreased from 5.521 to 5.202 (g/cm^3). Similarly for 70KN load , the density got decreased from 4.4991 to 5.019(g/cm^3). Similarly for 80KN load ,density got decreased from 4.957 to 4.852(g/cm^3)..This shows that as the sintering time and compaction pressure increases the density will be reduced.

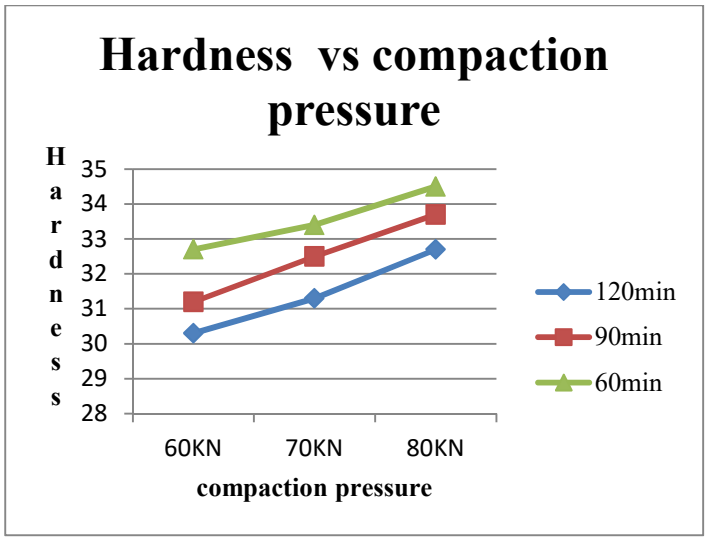

Fig3.3 Hardness vs compaction pressure results of the specimens with variation of sintering times of 60min,90min,120min.

The fig 3.3 describes the variation of hardness and the compaction pressure at 60min,90min and 120min sintering time.From the graph ,it is clear as the compaction pressure increases, then the hardness is also increasing.This is because as the pressure increases, the bonding between the molecules increases ant the material becomes harder. Therefore the hardness is getting increased as the compaction pressure increases, the hardness for 60min sintering time is varied from 30.3 to 32.7.The hardness for 90min sintering time is varied from 31.3 to 33.4.The hardness for 120min sintering time is varied from 32.7 to 34.5.

3.4 Tribological properties of NiCr and SiC based composites

The experiment process parameters are taken from below table. The wear rate ,friction force and coefficient of friction values are calculated for the 9 specimens at different conditions on pin on disc machine. From the below table we can observe clearly that the wear rate values tends to decrease from 3.1×10^{-5} mm^3/Nm to 1.1×10^{-5} mm^3/Nm. It is observed that as the compaction pressure and the sintering time increases ,the wear rate values are getting decreased[11]. This is because as the compaction pressure and the sintering time gets increased, the bonding between molecules gets increased therefore the specimen becomes harder and therefore the hardness of the specimen gets increased and the porosity of the specimen also gets decreased[18-20].As the hardness of the material gets increased the chances of the wear of the material gets decreased. Therefore the result demonstrates that specimen with the lowest compaction pressure and the lowest sintering time has the highest wear rate of 3.1×10^{-5} mm^3/Nm and the specimen with the highest compaction pressure and the highest sintering time has the lowest wear rate of 1.1×10^{-5} mm^3/Nm.

From the below mentioned table 3.2 we can observe that the coefficient of friciton values are higher for higher wear rate of about 0.58 and the coefficient of friction values are lower for the lower wear

rate of about 0.32 .This result demonstrates that as the densities of the specimens increases the coefficient of friction values decreases.(21)

Table 3.2 Representation of tribological parameters

Load(KN)	Sintering time(min)	Wear($x10^{-5}mm^3/Nm$) rate	Friction force(N)	Coefficient of friction
60	60	3.1	13.8	0.58
60	90	2.9	13.2	0.53
60	120	3.0	13.7	0.55
70	60	2.5	12.8	0.49
70	90	2.2	12.6	0.45
70	120	2.0	12.6	0.43
80	60	1.5	11.2	0.39
80	90	1.3	10.1	0.37
80	120	1.1	9.9	0.32

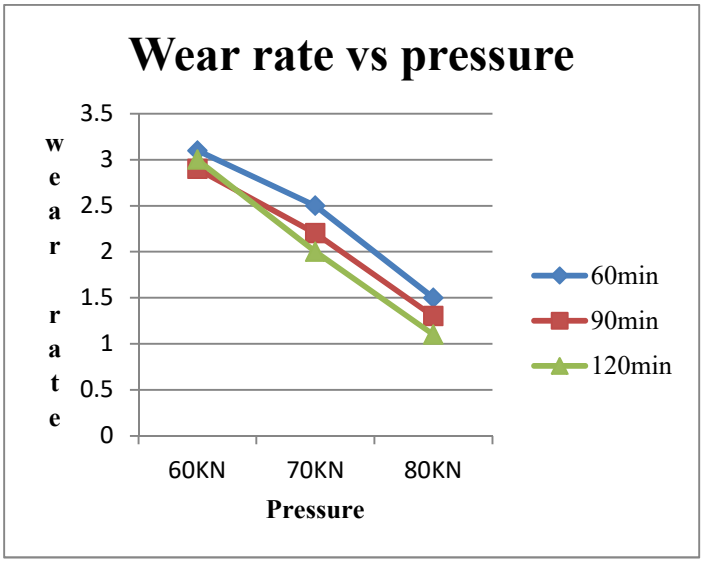

Fig 3.4 Wear rate vs compaction pressure results of the specimens with the variation of sintering times of 60min,90min,120min

From the fig 3.4 ,it is clear that as the pressure increases from 60KN to 80KN, the wear rate is getting decreased, for the sintering time of 60min the wear rate is getting decreased from (3.1 - 1.5) x 10^{-5} mm^3/Nm and for the sintering time of 90min,the wear rate is getting decreased from (2.9-1.3) x 10^{-5} mm^3/Nm and for the sintering time of 120min the wear rate is getting decreased from (3.0-1.1) x 10^{-5} mm^3/Nm. From the fig 3.4 it shows that the material with highest compaction pressure and the highest sintering time has the least wear rate of 1.1 x 10^{-5} mm^3/Nm.

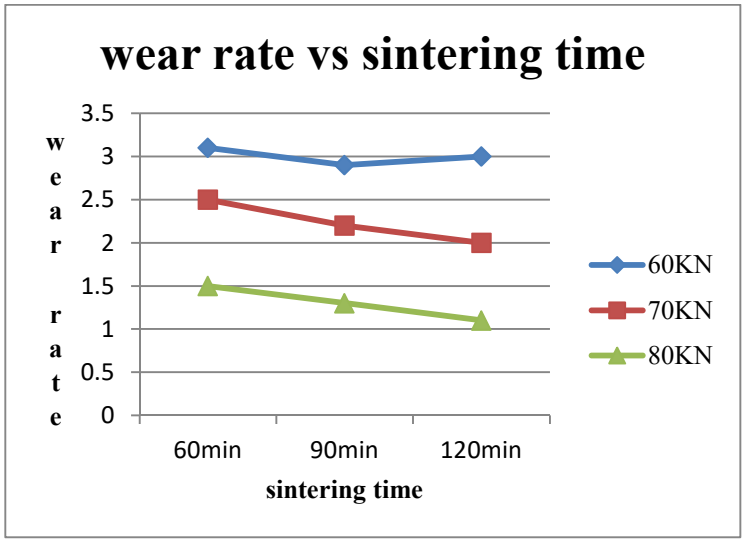

Fig 3.5 Wear rate vs sintering time results with the variation of the pressures of 60KN,70KN,80KN

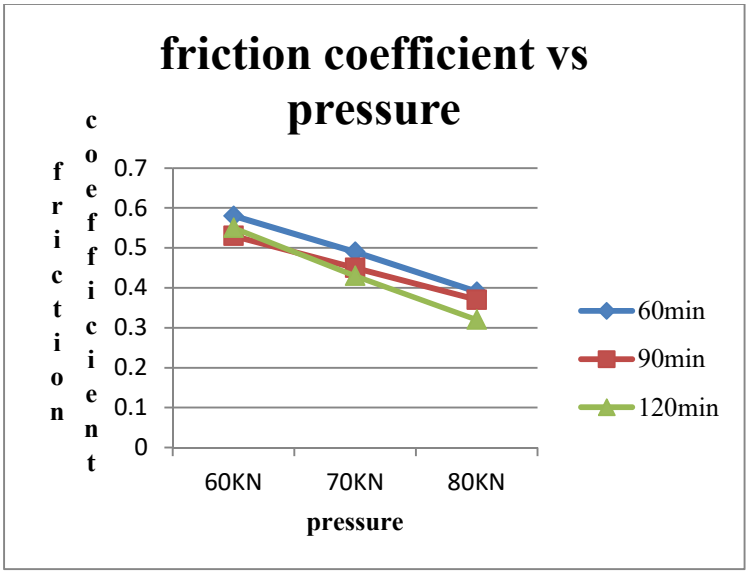

Fig 3.6 friction coefficient vs pressure results with the variation of sintering time of 60min,920min,120min

.

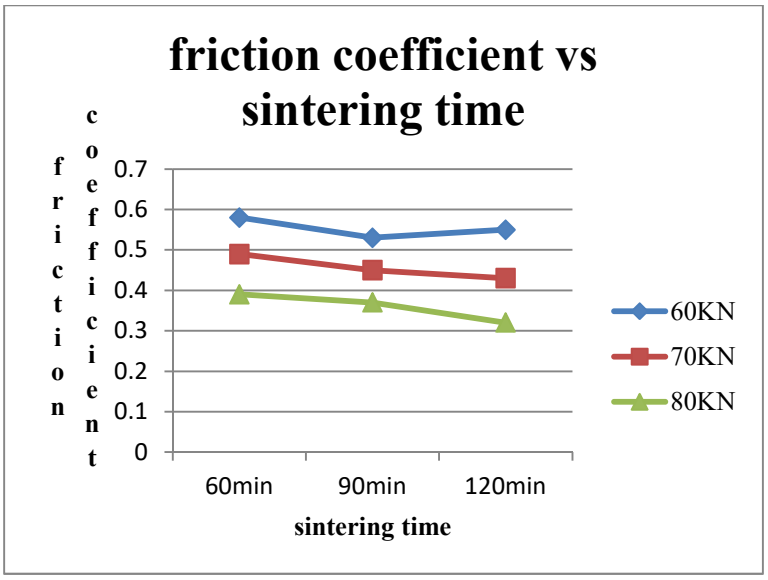

Fig 3.7 friction coefficient vs sintering time results with the variation of pressure of 60KN,70KN,80KN

From the fig 3.5 ,It is clear that as the sintering time is getting increased from 60min to 120min the wear rate is getting decreased. For the pressure of 60KN the wear rate is getting decreased from (3.1-3.0) x 10^{-5} mm^3/Nm. For the pressure of 70KN the wear rate is getting decreased from (2.5-2.0) x 10^{-5} mm^3/Nm. For the pressure of 80KN the wear rate is getting decreased from (1.5-1.1) x 10^{-5} mm^3/Nm. From fig 3.5 it shows that the material with highest compaction pressure and the highest sintering time has the least wear rate of 1.1 x 10^{-5} mm^3/Nm.

From the fig 3.6 ,it is clear that as the pressure increases from 60KN to 80KN,the friction coefficient values is getting decreased. For the sintering time of 60min ,the friction coefficient values are getting decreased from 0.58 to 0.39.For the sintering time of 90min, the friction coefficient values are getting decreased from 0.53 to 0.37.For the sintering time of 120min the friction coefficient values are getting decreased from 0.55to 0.32.From the fig 3.6 it is clear that the material with highest sintering time and the higest pressure has the least friction coefficient of 0.32.

From the fig 3.7 ,it is clear that as the sintering time increases from 60min to 120min,the friction coefficient values is getting decreased. For the pressure of 60KN the friction coefficient values are getting decreased from 0.58 to 0.55.For the pressure of 70KN load the friction coefficient values are getting decreased from 0.49 to 0.43.For the pressure of 80KN load the friction coefficient values are getting decreased from 0.39 to 0.32.From the fig 3.7 it is clear that the material with highest sintering time and the higest pressure has the least friction coefficient of 0.32.

Conclusions

The tribological studies of NiCr/SiC are being studied using wear test process ,the main conclusions of this Nicr/sic composites are as follows

1. The microstructures of the specimens are equally distributed as applied for compaction pressures of 60KN,70KN,80KN and sintering times of 60min,90min,120min.

2. The hardness of the specimen is getting increased as the pressure is getting increased.
3. The density of the specimen is getting decreased as the sintering time is getting increased.
4. The wear rate of the specimens are getting decreased when the pressure is increased and similarly the wear rate of the specimens are getting decreased when the sintering time is increased.
5. The friction coefficient values are getting decreased when the pressure is increased and similarly the friction coefficient values are getting decreased when the sintering time is increased.

ABSTRACT

The need of Materials based research always exist due to its demand at all times. But the supply is limited. In particularly, the supply of material is limited for specific applications. Light weight low strength applications are very wide. This investigation focuses the natural fiber hybrid with artificial fiber based hybrid composite preparation. The banana fibers are used to prepare the composite with Textile-Grade Glass Fiber. The banana fiber is here treated with specific concentration of caustic in the distilled water. The composites synthesized with treated and untreated banana fibers. The alternate fashion of horizontal and vertical is followed for fibers' orientation. The bio epoxy is employed as matrix material with mix of hardener. The prepared composite are characterized by water absorbability, tensile properties, flexural properties and shock absorption capacities.

1. Introduction

The application of composite materials is obvious [1]. Day by day the supply of conventional materials supply is diminished [2]. The existing materials sometimes disqualified as it does not meet the particular application [3]. To fulfill the demand the researchers invent new materials. [4] almond shell powder employed to prepare the particulate composite [5]. The powder of skin removed tamarind seeds suggested for fabricating composites. [6] proved that the treated banana fibers will improves the mechanical properties and experimented. [7] preferred to use of banana fibers treated with caustic solution and selected jute fiber for hybrid composite laterally they suggested banana fiber treated by mallic acid with Textile-Grade Glass Fiber [8]. [9] reported a methodology for third axis reinforcement that is prevention of de-lamination by stitching before compression for removing the excess rasin and air gaps and for ensuring predefined uniform thickness. The caustic treated banana fiber and the artificial Textile-Grade Glass Fiber with specific number of layers and pre defined best bonding orientation of fibers are focused in this research [10].

2. Materials and methods

2.1. Composite matrix

The matrix materials are mainly consists of selectively obtained and specially prepared high quality banana fiber, the commercially available high quality Textile-Grade Glass Fiber for reinforcement [11]. The low cost, best match for banana fiber based composite's bonding agents, the cashew nut cell oil is employed as resin and also bought the suitable hardener for the same [12]. the Fiber, its Tensile Strength (MPa), its Density (kg/m^3), its Young's Modulus (MPa) and Flexural Modulus (MPa) are in the order of as follows Banana Fiber, 54, 1350, 3487, 2000–5000, Glass Fiber 2500–3500, 2.5, 70,000, 70,000–73,000, respectively [74–76]. The poly vinyl acetate is employed as releasing agent [71–73]. The high quality banana fiber was prepared from the naturally harvested banana

stems by rolling, combing and drying; further the fiber qualities were enhanced by chemical treatment [13].

2.2. Quality addition in banana fiber

The low cost and appreciable enhancement was achieved through caustic treatment [14]. Here it was preferred that 1% of caustic volume fraction with distilled water [15]. The high quality banana fibers soaked in the solution for 240 min followed by drying on open space with normal sunrays (do not being at hot sunrays) [67–70] for 120 min that is dried in the morning 8 AM to 10 AM. After that the fibers cut to 5 cm long [16].

2.3. Synthesis of hybrid composite

The preferred selective sequence of layers and orientation of fibers on each layer are alternate fashion of horizontal and vertical [18,19]. A chromium-plated MS, Square shaped molds (of side 30 cm) are placed in the molding table [20–23]. The parting (Wax) agent applied on the mould which will facilitate release the finished [24–27]. Beadings at the corners of models are maintained the preplanned gap [28,29]. The preplanned length of 50 mm followed for both banana fiber and Textile-Grade Glass Fibers [64–66]. The Textile-Grade Glass Fibers used for extreme layers that top and bottom [30]. In between layers banana but their fashions are alternate orientation of fibers in horizontal and vertical directions [31]. The layers are bonded with just prepared paste of mix of 10 part of resin and one part of hardener [32]. Finally entire composite panel was compressed in CTM and kept in the compressed position for 3 to 4h [17], by which the voids filled up, air bubbles removed and excess resin content also removed [33]. Then panels allow drying in sun light with weight for avoiding bending due to shrinkage while drying [34,35]. Hence the composite samples are prepared by the combination of compression mounding and manual layup technique [36–40].

Table 1
Toughness of dry and wet hybrid composites.

Characterization criteria	Treated	Untreated
Observed Energy in joules	12.48	7.95

Fig. 1. Sample specimen of hybrid composite for characterizing properties under impact load.

3. Characterization

3.1. Toughness based Characterization of hybrid composite

The Toughness of the materials is usually characterized by Impact Test Method [28–35]. Charpy Test setup is employed in this investigation [41–44]. The specimen prepared under the standard of ASTM D256 to the dimensions of 2½ × ½ × 1/8 Cubic Inches [45–54]. The energy observed by the specimen is observed. And tabulate in Table 1 [61–63]. The specimen is shown in Fig. 1 [58–60]. The investigation ambient conditions are room temperature and 50% the average RH [55–57].

4. Results and discussions

4.1. Shock absorbability

The impact load or shock load based test namely charpy is employed for this investigation. The results reveal that impact strength of the treated banana fiber based hybrid composites got improved (Refer Fig. 2). That is treated fiber based composite is stronger in withstanding shock load than untreated fiber based hybrid composite (Refer Fig. 2).

5. Conclusion

The exploration of indispensible property of textile-grade glass fibers/white caustic treated banana fiber hybrid composite is dis-

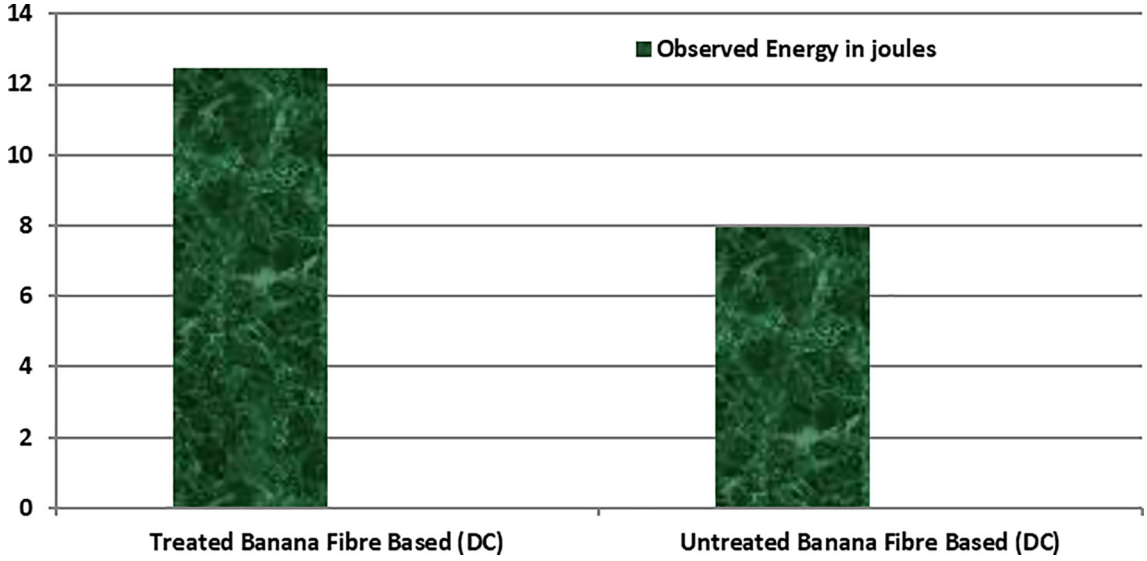

Fig. 2. Impact strength of treated and untreated banana fiber based hybrid composite.

cussed in this paper. The natural abundant Banana fiber and one of the artificially strong Textile-Grade Glass Fibers were hybrid here with bio resin and hardener matrix to form the hybrid composite panels. In which the banana fiber is selectively processed and specially treated for enriching the proposed composite strength. It was experimentally proved that the proposed treated banana fiber based composite performed well and also it was tested in the wet condition and found that the composite increases its strength by absorbed moistures.

ABSTRACT

In the present scenario, the digital life and its usage are increasing rapidly. In all electronics, electrical current flow through the resistive elements says electric chip. When the current flowing through it, the heat is generated under natural convections. Due to the heat generation in electronic parts, the components will be failure during the temperature rise. In power electronics, chips face thermal heat removal challenges. For better conditions and performance, care must be taken to cool chip systems. There is an effective way to remove the heat whenever the heat sink attached above the chip it removes the heat efficiently and it keeps the chip lower in temperature. The performance of the heat sink is related to its slots. In this research work, for numerical simulation under particular plate-fin, with slots work improved than the plane surface, different slots shape enhanced to find better one of the rectangular fins heat sink.

Original Article

1. INTRODUCTION

In every electricalequipment's the flow of current performs based on different functions running in electronics. Whenever current flows thorough a small element in the electronics heat generated. About proper action ofcomputer electronics heat dissipation is moreserious characteristics can be taken after designing and insertion.Heatgeneration is an irreversible process, heatmust be removed with the purpose of maintains the continuous operations. Natural convection, pure conduction or radiation to cools electrical components near some ranges of present electronic devices required more complicated and powerful systems manage with heat. So innovative heat sinks by higher extended surface and more conduct materials, coolant flowing is keys to reduce the hotter spots.

In this research, the attempt was made on enhancing the electronics cooling by use of CFD analysis. The main objectives of current study are to get set of correlations different slots of plate fin heat sink. Based on this some the literature was carried out which has beed discussed further. Chang J e [1] year of 2001 conducted CFD analysis on heat sink with minimum air flow rate on 30 w socket in CPU of desktop computer. A fan is used in the power supply used for complete moment in chassis. For direct air flow over the CPU in the duct then inlet air vents of the power supply. In this ductmore than 10ºC reduction of the CPU case of temperature relative to an unducted design. CFD analysisresultswere confirmed by experimental and predicted CPU casetemperatures agreed with in the 62.90ºCof the experimental value for the ductedcases. At this point they describe the methodologies of CFD analysis's for the heatsink. Project and define the experimentalprocedures to validate the prediction. In year 2005 Prabhu. L [2]Here the

analysis on different geometry of fin design by using ANSYS workbench to analyse the heattransfer performance of the fins those are rectangular, circular and square. Here related to the base temperature heattransfer rate can be compared. Complete material was prepared with Aluminium.

2. TYPES OF COOLING TECHNIQUES

The common problems in product design and get the efficiency of electronics. In electronics some generate heat to reduce the heat there is a treatment known as thermal cooling techniques. Those are passive, active cooling techniques.The Passive cooling technique use natural convection, conduction, radiation to cool the electronic components and the active cooling technique requires the uses of energy exactly dedicated toward cooling the components. The mechanical controlled subsystem provides activecooling. Active cooling techniques provide more cooling capacity. They allowtemperaturecontrol it could be cool down to low surrounding temperatures. An example of active cooling technology work in devices creates a large amount of heats those are computers, gaming devices, televisions.Thepassive cooling technique subsystem is not supported by mechanical equipment's. Conventional passive cooling includes the application of efficient heatspreaders and heatsinks to the electronic packages. Several other novels and advanced cooling techniques used in liquid cooling devices, which pump chilled liquid over specialized CPU mounted heat spreaders. Those fluids are not electrically conductive but they are having excellent heat transfer rate.

3. OBJECTIVES

- The aim of the research work is to investigate through the convective heattransferrate from the heatsink surface to the surroundings, thereby cooling the device.
- Investigate the various fin designs compare overall heattransferrateof the different slot designs of the fins by the use of natural convection
- Analyse the thermal analysis results of each design and find out the best one.

Comparison of the heat transferrate of the rectangular fins with the numerical values. The goal of this study is to achieve clear collection of connections for all slots of flat fin heat exchangers, addition of rectangular slots. Finally, the review of our efforts to create a single connection provides the best results.

4. CFD ANALYSIS PROCESS

In order to perform CFD analysis, the problem must be interpreted and analytical information will be used to explain it mathematically. The CFD software packages would then represent this information and articulate the specified question in technical terms. In the end, the machine will complete the calculation given in the CFD program, and the analyst will analyze, and understand the results of the calculation. Under this theory, three main key componentsperformed to execute a CFD simulation.

Problem Identification

- State the objective of modelling.
- Identify a good designed region.

Pre-Process

- Create a proper geometry model to define the domain.
- Construct a mesh (grid).
- Set up physics (physical structures, materials dominant properties).
- Set of contexts, original and boundary conditions.
- Define the configuration of solvers (numeric schemes, convergence controls).

Using the Solver

- Compute and track approaches before integration takes place.

Post – Analysis

- Examine the data using qualitative counter plots or quantitative XY plots.
- Require modifications to a grid - connected-alone model or grid analysis.

5. BASE MODEL OF HEAT SINK

a. Specifications of Heat Sink

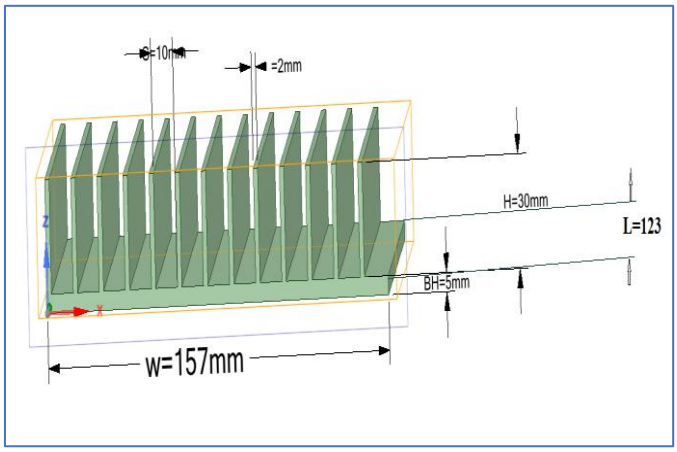

Figure1: Base Model.

Table1: Model Specifications

Specifications	Dimensions
Baseboard Dimensions	123×157mm
Fin Thickness (T)	2mm
Fin Height (H)	30mm
Fin Spacing (S)	10mm
Number of Fins	13
Parameters	Air, aluminium material
Base Height (BH)	5mm
Fluid	Air

The key features of the heat sink are presents in shown in figure1. In this paper fluid is air and material aluminium ispresented. The flat platform size is length (L) and width (w) is 123×157 mm. Thethickness (T) of each fin is 2 mm. Fin heights (H) for all designsare30mm. The base thickness (BH) is 5mm and the fin spacing (S) is6mm.The material used of the

design is Aluminiumwith 13 fins was provided.

Table 2: Material Properties

Property	Aluminium
Density(ρ) (kg/m^3)	2700
Thermal conductivity (w/mk)	202.4
Specific Heat(Cp) (J/kg k)	871
Specific Weight (g/cm^3)	2.7
Melting Point (^{0}C)	660.32
Boiling Point (^{0}C)	2470
Electrical Conductivity (m/ohm-mm^2)	36
Heat of Vaporization (KJ/mol)	284
Molar Heat Capacity (J/mol-K)	24.20

Table 3: Fluid Properties

Property	Air
Oxygen (O_2)	23.2 in volume percentage
Nitrogen (N_2)	75.5 in volume percentage
Argon (Ag)	1.3 in volume percentage
Specific heat(Cp) (KJ/kgK)	1.005
Specific heat (Cv) (KJ/kgK)	0.717
Density(ρ) kg/m3	1.229
Thermal conductivity (mW/m-k)	24.35
Viscosity(v) (cSt))	13.49

A. Mathematical Formulation

By way of boundary layer calculations, the convections are as follows.

Continuity equation

$$\frac{\partial(\rho u)}{\partial x}+\frac{\partial(\rho v)}{\partial y}=0 \tag{1}$$

Momentum Equation:

$$\rho(u\frac{\partial(u)}{\partial x}+v\frac{\partial(v)}{\partial y}=g(\rho zz-\rho)+\frac{\partial}{\partial y}(\mu\frac{\partial(u)}{\partial y}) \tag{2}$$

Energy Equation:

$$\rho Cp(u\frac{\partial(t)}{\partial x})+v\frac{\partial(t)}{\partial y}=\frac{\partial(k\frac{\partial(t)}{\partial y})}{\partial y} \tag{3}$$

The aspect ratio is the most important parameter influincuing the heat and fluid flow when deciding the heat transfer.

The heat* transfer* rate* inside the enclosure is defined as follow:

$Q=hA(T_{wall}-T_f)=mCp\Delta t$ (4)

where,

m= mass flow rate, kg/s

Cp= Specific heat rate, KJ/kg K

Δt= Temperature difference, ^{0}K

h=Convective heat transfer coefficient (w/m^{2}K)

h =Nuk/L (5)

where,

h=Convective heat transfer coefficient(w/m^{2}K)

Nu = Nusselt number

K= Air thermal conductivity (w/m^{2}K)

L= Characteristics length of the channel(m)

Prandtl number:

Pr=ν/α (6)

Prandtl number is dimension less number it's used to explain the thermalboundary layers and relative thickness of velocityfor the natural convection.

B. Boundary Conditions

The boundary position will be set because the pressure inlet is in the state of the atmosphere. The boundary state of the pressure outlet included the calculation of the residual pressure at the outlet boundary.The meaning of the common static pressure is used only at the same time as the flow is subsonic.If the flow needs to become locally supersonic, the stated pressure will no longer be used and the pressure will be extrapolated from the internal flow. Enable other flow quantities to be extrapolated from the inside. A set of backflow conditions is often specified for the reverse flow path at the pressure outlet boundary during the solution phase.Converging problems can be reduced if you assign rational values for the backflow quantity. In the design, colours are indicating for inlet and outlet of pressures as well as heat sink and wall. The boundary condition as shown in figure2.

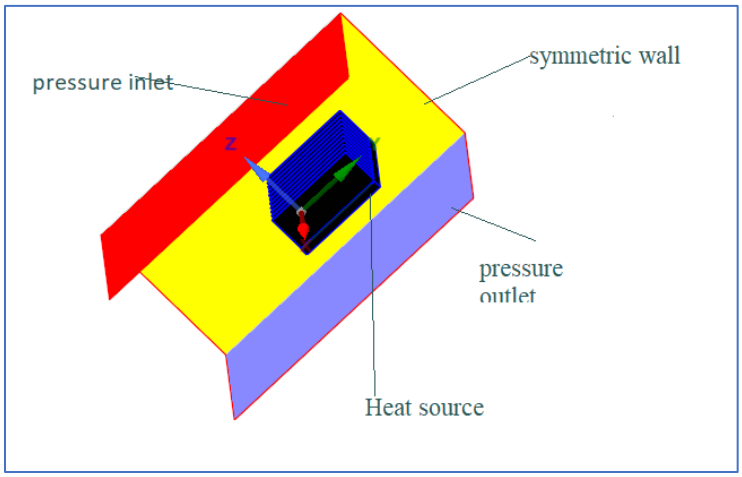

Figure 2: Boundary Condition.

6. OPTIMIZATION OF BASE MODEL

In the heat sink base model, the rectangular heatsink positioned below the atmospheric condition in the laminar flow regime to reduce the temperature with different shapes to the dissipation of heat input as 20w. By using different models to evaluate the less temperature along with the different slots designs are shown in figure 3.

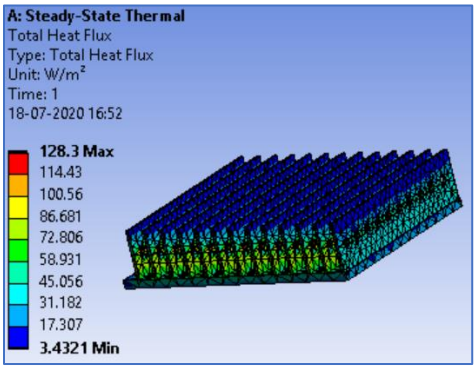

Figure 4(i): Heat Flux Variation for Rectangular Fins with Circulat Slots.

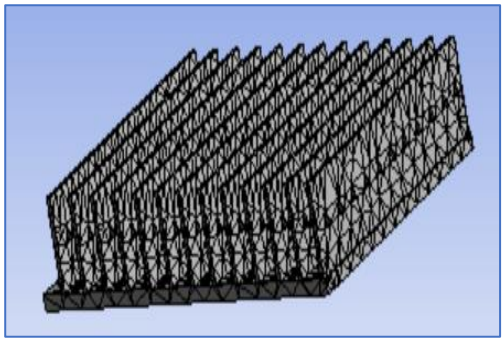

Figure 4(j): Meshing Model for Rectangular Fins with Triangular Slots.

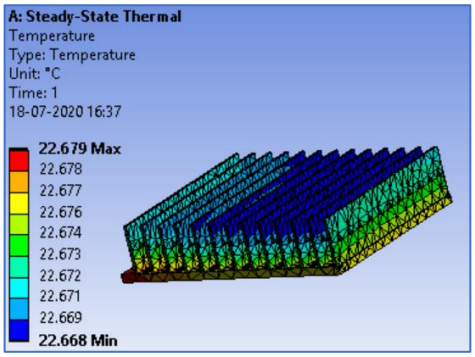

Figure 4(k):Temperature Variations for Rectangular Fins Triangular Slot

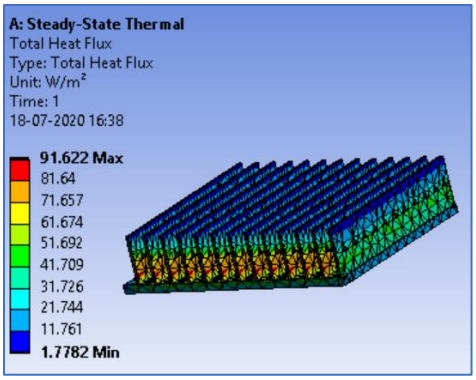

Figure 4(l): Heat Flux Variation for Rectangular Fins with Triangular Slots

The Figures from 4(a) to 4(l) shows the results of Thermal analysis of heat sink which remainedagreed out using after applying all the parameters such as boundaries condition as temperatures and convection.from the above analysis with different orientations compared and rectangular fins with triangular slots got lowest rising temperatures for this we analys the CFD analysis.

Table 5: Numerical Analysis of the Temperature Result

S. No.	Geometry	Number of Fins	Heat Input(watts)	Minimum Temperature of the Models	Maximum Temperature of the Models
1	Without slots	13	20w	295.809 K	259.873 K
2	Rectangular slots	13	20w	295.704 K	259.867 K
3	Circular slots	13	20w	295.691 K	259.853 K
4	Triangular slots	13	20w	295.668 K	295.829 K

From the above table represents the numerical analysis of the temperature results of heat sink of rectangular fins with different orientation effects. In this heat sink consists of 13 numbers of fins with 6 mm spacing between each fin and applied heat input 20w to the every geometry. The below figure 5 has shown that by introducing the slots in rectangular chips the temperature has got reduced. It is further noted that for the triangle slots has shown better results as compared to other modified chips.

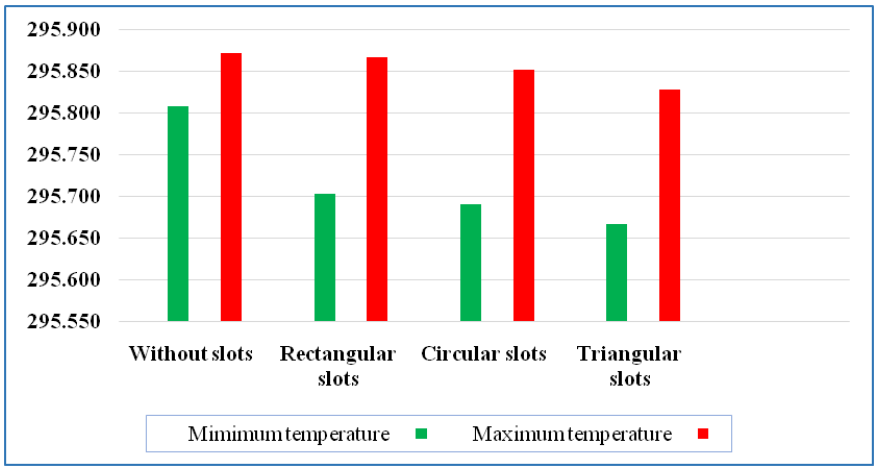

Figure 5: TemperatureVariation for Various Models.

- **CFD Analysis of heat sink**

Below showing figure reperesents the meshing of rectangualr fins with triangular slots which includes heat source.This geometry created in ansys fluent applied unstructured fine mesh and applying all above boundary conditions and parameters we got heat transfer rate and post processing results.

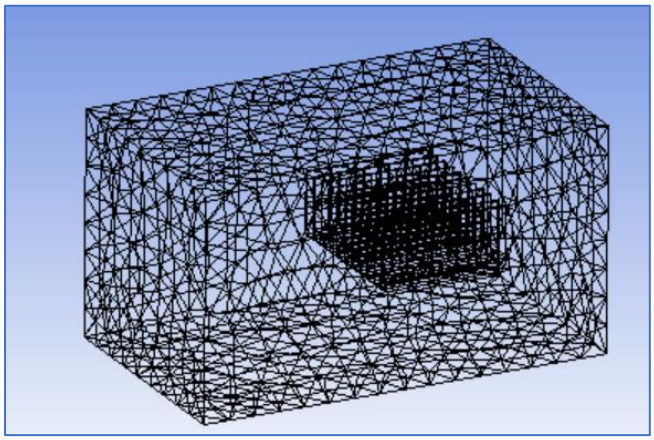

Figure 5(a): Meshing Geometry of Rectangular Fins with Triangualr Slots.

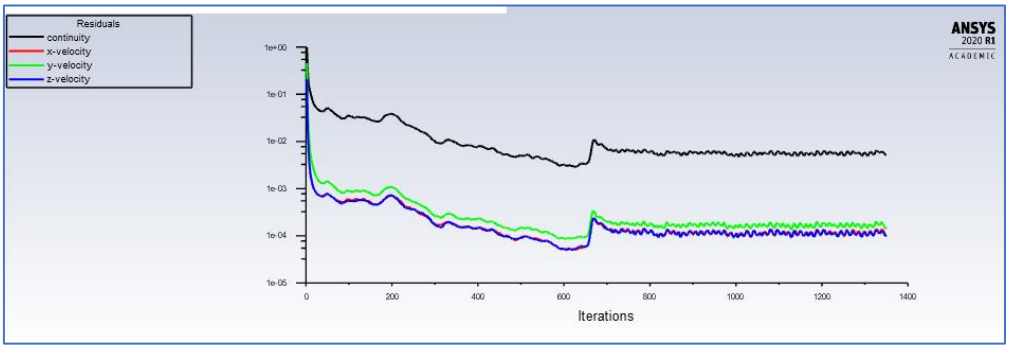

Figure 5(b): Iteration for Converging Graph.

Above figure shows converging graph and conclusion of different cases has been solved.Iterations were taken by using governing equations.Momentum equations from the velocity of x,y,z directions and energy equation.Taken laminar flow and applying boundary conditions to the parameters to the post processing results given below.

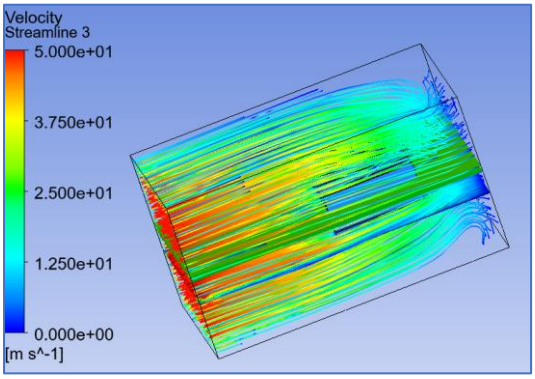

Figure 6: Streamline Flow for a Rectangular Fins with Triangular Slots.

8. CONCLUSIONS

In this paper, the numerical simulations of fins with as well as without slots are taken into consideration with various orientations such as Circular slots, Rectangular slots and Triangle slots to evaluate the increasing temperature of the chip. As of the simulation results, fins with the slotsare operating comparable or even higher under a few orientations, when as compared without slots. Various slots with rectangular fins studied it shows different results, these all slots are compared by plane fin. After comparison of slots and plane fin triangle slot is sustained less temperature of the chip when compared with the remaining slots.

1. Introduction

The cylinder responds in chamber to finish cyclic occasions and transmit gas pores to wrench shaft through interfacing bar. Cylinder is most significant part in an interior burning motor. The working state cylinder in inward ignition is so most noticeably terrible. During burning stroke fuel get lighted with assistance of flash fitting. Because this ignition of gases in chamber warm disfigurement mechanical twisting causes cylinder breaks, tortuosity so forth. It is remarkably basic look at examine pressure appropriation, temperature dispersion, heat move, warm burden, mechanical burden so to limit pressure, limit warm pressure and various loads on running situation cylinder. Interior ignition motor tube is made Al composite. This makes distinction between running and structure clearances. In this examination right off bat we draw cylinder model in Catia programming lastly cylinder is investigated in ANSYS programming.

There are two steps involved in this study:

1. Creating an IC Engine Piston by Using Catia Software.

2. To perform structural and thermal analysis piston by using ANSYS software.

1.1 Piston:

Cylinders Built with highlights that show clear capabilities during motor activity. The cylinder head or crown gains weight and energy brought about by ignition system. The faster directional changes because cylinder pin zone is displayed for lot more power. It undergoes warm extension bring on replace warmth since

head to body cylinder. Cylinder pin zone depends on warmer development cylinder in different areas. This results from warm development characteristics cast aluminum compound and mass in cylinder pin area.

1.2 Issue Statement:

In light writing study performed, adventure into this exploration is spurred by way that Pistons are required to have superior attributes and better exactness they should continue high temperature and stresses. Cylinder skirt may show up misshapening at work, which as rule causes split on upper finish cylinder head. Because disfigurement, best pressure focus is caused on upper finish of cylinder, circumstance turns out to be increasingly genuine when firmness cylinder isn't sufficient, break by and large showed up at point A which may bit by bit expand and even reason parting along cylinder vertical. The pressure conveyance on cylinder chiefly relies upon misshapening of cylinder. Along these lines, so to decrease pressure focus, cylinder crown ought to have enough solidness to lessen distortion. Exponential examination of cylinder is tumultuous and not extremely exact work. Definite hypothetical investigation of cylinder qualities is extremely troublesome. With the utilization fast PCs and numerical strategies, cylinder examination can be made utilizing CAE. That is reason pressure examination is performed utilizing reenactment programming. In this way, FEA will be done for standard cylinder model utilized in diesel motor and streamlining similar will be completed.

1.3 Objective

The fundamental target present work is discovering propose ideal material for cylinder dependent on quality economy thinking about material weight and dimensional issues simultaneously. Subsequent to producing precise limited component model, procedure for streamlining work process was characterized. Focus enhancement was to reach at least warm worries in cylinder.

The proposed work included following steps:

- Study of writing survey of different work detailed.
- The cylinder is planned by method and detail which are set in engine structure information hand books.
- CAD model Piston is made utilizing different apparatuses in catia v5
- Comparison outcome got in above advance for various materials.

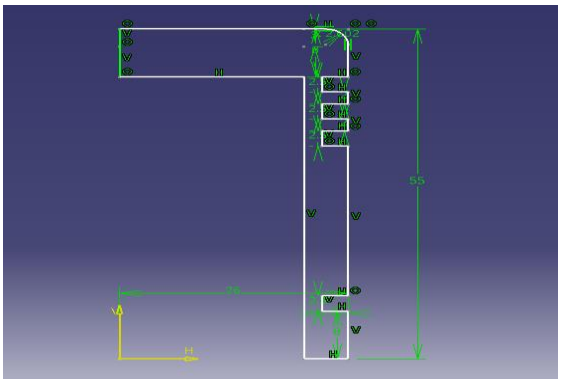
- Choosing ideal structure dependent on material and another parameter.

2. LITERATURE REVIEW

Vinay V. Kuppast1 , Dr.S.N.Kurbet2 , H.D.Umeshkumar3 , Adarsh B.C4, al [2013]A warm analysis piston for its effect on secondary vibration, gas power because firing an IC motor in room causes cylinder to move with required vibration and auxiliary motions. The motion cylinder required from TDC to BDC is directly in nature. This movement seeks for an explanation movement of motor units. Optional movement because the transverse movement cylinder when cylinder moves from TDC to BDC and other ways. The auxiliary motion cylinder is considered normative hotspot for cylinder slap, thus affecting chamber dividers that cause motor vibration and turbulence. In the present test, laborious effort is made to understand effect of heat on fuel inside chamber, cylinder deformation, and heat concerns induced in cylinder. This misshaping cylinder inside chamber causes the hole between the chamber cylinder to fluctuate and the cylinder moves horizontally sway powers. The transverse movement cylinder in chamber is watched tentatively by estimating hole among cylinder and chamber at push side burden condition. Limited component examination (FEA) is considered extraordinary compared to other numerical instruments to display break down physical frameworks. FEA is done to discover cylinder distortion because of warm burden on cylinder for temperature information got from tests. The three dimensional cylinder is demonstrated in CATIA V5 R19 and examined in ANSYS 12 solver. The reproduction results are utilized to anticipate impact of temperature on cylinder twisting its optional movement which are chief wellspring of motor vibration and commotion.

V G Cioată, I Kiss, V Alexa and S ARațiu, al. [2017], Mechanical and warm examination of inside burning motor cylinder utilizing Ansys, The cylinder is one most significant segments of interior ignition motor. Cylinder flop primarily because of mechanical burdens and warm anxieties. In this paper is dictated by utilizing limited component strategy, stress and relocation conveyance due pipe gas weight and temperature, independently and joined. The FEA is execute by CAD and CAE indoctrination. Outcomes are contrasted those acquired by investigative technique and ends have been drawn.

1 KANCHARLA RAJA SEKHAR, 2 G. VIJAY PRAKASH, al. [2016]. Thermal analysis of a piston, A cylinder is



segment Responsive motors, responsive siphons, gas blowers and air chambers, among other comparative instruments. It consists moving section chamber, which is gastightened by cylinder rings Piston that move combustive gases capacity to interfacing pole. To improve proficiency motor there is need to learn about cylinder. Cylinders that are typically made up with amalgam steels that show mesh safe against warm loads and basic burdens. In the task we plan cylinder by utilizing strong works 2016 structure programming and we did basic burden examination and warm investigation by applying different materials, for example, composites on cylinder in ansys workbench programming.

To create good bonding between ferrous metals and aluminum composite liquid metal, process of heat plunge. To improve wetting and steel embedding, first coat with small layer aluminum. Because its unrivaled working efficiency, high warmth conductivity, high protection from wear, elastic iron is used as alloy (BirigtHudelmaier 2000).

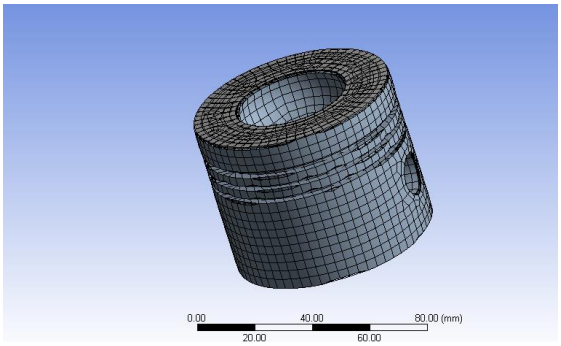
4. ANSYS



ANSYS is widely used finite component test (FEA) programming bundle. Finite Element Analysis is numerical technique to rebuild mind-blowing framework small bits (size client is assigned). The production realizes conditions under which these parts are handled and all unfolds; Giving comprehensive clarity on how framework works. At that time these grades can displayed in arranged or graphical structures. This type investigation can be used for an unreasonably complex structure and regularization framework for regular inspection by hand. Frameworks that fit this class cannot be overly red due their geometry, range operating conditions.

ANSYS is measure FEA that shows apparatus in automatic engineering division at several schools. ANSYS is also use in civil and electrical engineering, just like Physics and Chemistry offices.

ANSYS provides practical method for investigating performance elements or policies in virtual area. This kind item development is named Virtual Prototyping.

6. CONCLUSION

- Modelling and investigation of cylinder has been done in Catia and Ansys programming.
- Simulation has done on cylinder, With various materials individually.
- After considered cylinder result we can presume that aluminum Has better warm warmth motion esteems and low distortion.
- Ceramic materials is giving better low warm blunder esteems looking at aluminum
- Ceramic materials is low weight high quality qualities.

7. FUTURE WORKS

In view time and capacity, work in proposal has few deficiencies.

1) When demonstrating cylinder, overlook main ring fixed with iron ring, affect weight on primary ring.

2) Is not perfect when all DOF piton pin, create more pressure effect aftereffect investigation.

3) Analyze temperature field by count observational recipe rather than trial estimation; it might be few impacts on outcome.

4) When work brace, utilizing default to get examination result isn't exactness on certain pieces of cylinder.

For further work, limitation state cylinder pin can superior substantially other improved, trusted very well may nearer genuine circumstance cylinder. What's more, in conditions permit, trial approach can be utilized to decide convection coefficient cylinder to get reasonable temperature field.

A Study Report on Fabrication of Hitech-Highway

Nuvvula Harini [1]

Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College-(Autonomous), Maisammaguda, Secunderabad, India[1]

ABSTRACT: The effects of vehicular pollution are felt at many levels. This type of pollution does not just affect one particular area of the environment, but several other areas as well. The elimination of vehicular pollution is simply not going to happen. Instead there have been other attempts made in the prevention of vehicular pollution. One such method is explained here in the project work called as the hi-tech highway.

The hi-tech highway consists of an overhead catenary system that will run along the outside lanes of both sides of the road, sort of like the overhead wires that provide power to electric buses, trolleys, trains, etc in cities. Specially outfitted hybrid or all-electric trucks can attach to the system using automated current-transfer devices. Once connected, the vehicles will pull all their power from the overhead lines, effectively becoming emission-free vehicles. Hi-tech highway vehicle turns the future of electric-driven freight transport into reality. In normal operation, hi-tech Highway vehicle draws electric energy from a catenary system using an adaptive established contact with the overhead wire. Wherever if there is no overhead line, the hi-tech Highway vehicle will automatically switch over to their diesel-hybrid drive system. This means that they can be used just as flexibly and universally as conventional vehicle.

The demo model of the project is constructed with a four wheel chassis (vehicle) and is driven by a DC motor. Once the start button is pressed, the mechanical structure will be lifted that is driven by suitable electro mechanical components to make contact with the hi-tech highway line. The vehicle diesel drive mechanism is demonstrated by driving the vehicle through the battery. Once the hi-tech highway mechanism is started, supply from the battery to the motor is disconnected and is connected from the hi-tech highway lines to run the vehicle. The running motor condition of conventional drive or the hi-tech highway drive will be displayed in the LCD that is interfaced to the microcontroller. Depending on the connection establishment with the hi-tech highway, an input is fed to the controller by which the controller switches the supply to the motor through a relay contact automatically. The vehicle is equipped with obstacle detecting sensors in front to stop the vehicle automatically when any obstacle is detected.

In addition, the hi-tech highway line is powered through solar energy with automatic highway lighting system using sensors. The highway lights are automatically controlled depending on the vehicle movement and by sensing the natural light (day or night) to save the precious energy.

KEYWORDS: Hi-tech highway, vehicular pollution, automated current-transfer devices, DC motor, solar energy.

I. INTRODUCTION

With most major auto manufacturers now actively developing electric vehicles, the drive towards a zero emission personal electric transportation future seems very much on the horizon. Road pollution doesn't just come from cars of course; freight vehicles are also major players in choking our highways and byways. Siemens is currently testing a possible solution in Germany that's based on proven railway and tram technology but has been adapted for trucks on roads. Heavy goods vehicles have been fitted with a newly-developed pantograph that can automatically rise to meet overhead cables and transfer electric power to hybrid diesel/electric power trains. Energy recovered from regenerative braking can also be fed back into the system for re-use by other vehicles.

The hi-tech Highway concept is a two part system. The first involves the rollout of a two pole catenary system along one or more lanes on freight transport routes that caters for two-way electricity transmission and ensures a reliable power supply by feeding the overhead wire via container substations. The substations used in the current test project feature a medium-voltage DC switching system, a power transformer, a rectifier and a controlled inverter (for the feedback of the electric energy generated by regenerative braking for real time).

The field trial in Germany is reported to have confirmed full performance potential, independent of weather, conditions and load. The concept proved to be at least as flexible as existing fuel-based road freight transport solutions thanks to the maneuverability of the mobile pantographs, with reduction in carbon dioxide, nitrogen oxide, soot and noise pollution and added fuel efficiency benefits. Keeping up with the flow of traffic doesn't appear to have been a problem

either, with speeds of up to 90 km/h (55 mph) being reached without difficulty under direct transmission of electric power.

For the first time ever, electric trucks powered by overhead cables will run to reduce carbon dioxide emissions. The hitech-highwayelectrifies selected traffic lanes using an overhead cable system. As a result, trucks can be supplied with electricity in the same way as trams. The "e-trucks" are equipped with a hybrid drive system and intelligent current collectors. Powered by electricity from overhead cables, they produce no emissions when operating in the local area. On roads without overhead cables, the vehicles use an electric drive system which can be powered by diesel, compressed natural gas, a battery or with other energy sources. The current collector allows the vehicles to overtake and automatically dock and undock at speeds of up to 90 kilometers per hour.

II. RELATED WORK

The hi-tech-highway concept is particularly effective from an environmental and economic point of view on heavily used and relatively short truck routes, e.g. between ports, industrial estates, freight transport centers and central transshipment terminals. The intention is to set up a "zero emission corridor" for shuttle traffic between the two sea ports and the inland rail transshipment centers around 30 kilometers away. This will help to ease the pressure on the environment in a region which is plagued by smog. The aim is to eliminate local emissions completely, reduce the use of fossil fuels, cut operating costs and establish a basis for using the system on a commercial basis in the future.

The mechanical transmission section can be designed with DC motors or stepper motors, depending up on the load, suitable motors can be selected. Here instead of using stepper motors, high speed reduction gear mechanized DC motors are used, the advantage of using these types of motors is a) increased torque b) consumes less power.

In the present system 12V DC motors are used in which one is used for the vehicle movement and the other for the catenary system lifting mechanism i.e., up and down to dock and undock with the electric lines. These motors are built in with reduction gear mechanism; the maximum speed of the motor is 60 RPM, so that the vehicle runs at low speed for demo purpose.

Motors are controlled depending on the input signals provided to the controller through the push buttons. The enable signals produced by the microcontroller are fed to L293D, specifically designed to drive DC motors. Each motor driver consists of four transistors in an H-bridge configuration, controlled by the microcontroller IC. In each section (out of four switching circuits) two transistors are used to increase the current rating. The L293D is capable of driving the motor at a maximum current of 600 milli-amps. The H – Bridge IC designed to operate from 5V DC to 30V DC, hence any DC motor with in this range can be interfaced with this chip. Description of the project work and the components is provided in the further chapters.

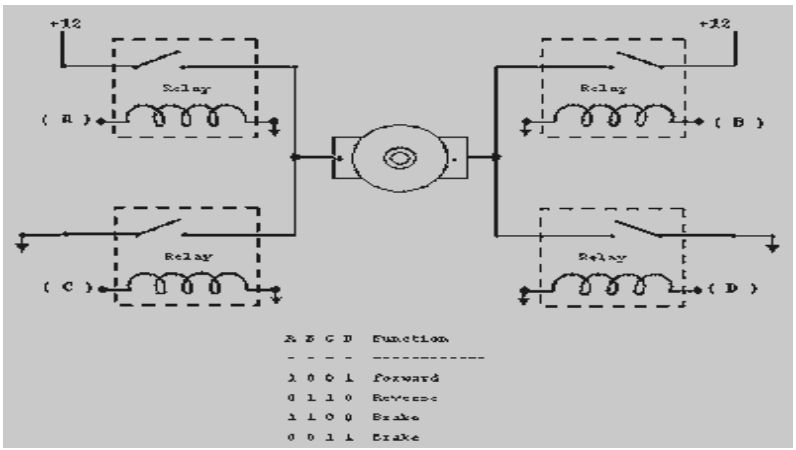
The H – Bridge chip is called as a DC motor driver and a single chip can drive two DC motors. In this project work one motor is used to drive the catenary system thorough the H – Bridge IC and the vehicle driving motor is operated by a relay to switch supply between the electric lines and the battery of the vehicle. To control these motors, four switches (push buttons) are connected in the input of the controller.

III. METHODOLOGY

Let's start with the name, H-bridge. Sometimes called a "full bridge" the H-bridge is so named because it has four switching elements at the "corners" of the H and the motor forms the cross bar. The basic bridge is shown in the figure above. The key fact to note is that there are, in theory, four switching elements within the bridge. These four elements are often called, high side left, high side right, low side right, and low side left (when traversing in clockwise order).

The switches are turned on in pairs, either high left and lower right, or lower left and high right, but never both switches on the same "side" of the bridge. If both switches on one side of a bridge are turned on it creates a short circuit between the battery plus and battery minus terminals. If the bridge is sufficiently powerful it will absorb that load and your batteries will simply drain quickly. Usually however the switches in question melt.To power the motor, turn on two switches that are diagonally opposed. The current flows and the motor begin to turn in a "positive" direction. Switch off these two switches and switch on other two switches diagonally in other direction then the motor starts rotating in opposite direction. Actually it is quite simple, the tricky part comes in when we decide what to use for switches. Anything that can carry a current will work, from four SPST switches, one DPDT switch, relays, transistors, to enhancement mode power MOSFET's.

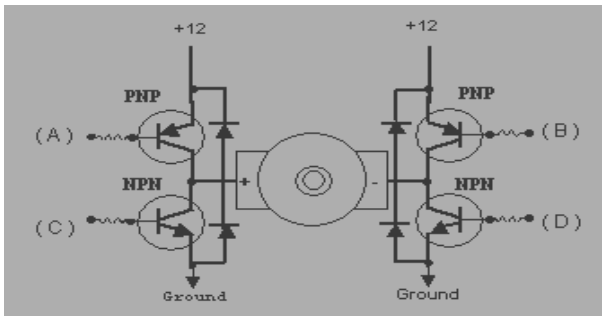
One more topic in the basic theory section is quadrants. If each switch can be controlled independently then we can do some interesting things with the bridge, some folks call such a bridge a "four quadrant device" (4QD). If we built it out of a single DPDT relay, we can really only control forward or reverse. We can build a small truth table that tells us for each of the switch's states, what the bridge will do. As each switch has one of two states, and there are four



switches, there are 16 possible states. However, since any state that turns both switches on one side on is "bad", there are in fact only four useful states (the four quadrants) where the transistors are turned on.

High Side Left	High Side Right	Low Side Left	Low Side Right	Quadrant Description
On	Off	Off	On	Forward Running
Off	On	On	Off	Backward Running
On	On	Off	Off	Braking
Off	Off	On	On	Braking

In the above table the last two rows describes condition about short circuit the motor that causes the motors generator effect to work against it. The turning motor generates a voltage, which tries to force the motor to turn the opposite direction. This causes the motor to rapidly stop spinning and is called "braking" on a lot of H-bridge designs. Of course there is also the state where all the transistors are turned off. In this case the motor coasts freely if it was spinning and does nothing if it was doing nothing.



1. **Using Relays:**

A simple implementation of a H Bridge using four SPST relays is shown. Terminal A is High Side Left, Terminal B is High Side Right, Terminal C is Low Side Left and Terminal D is Low Side Right. The logic followed is according to the table above.**Warning:** Never turn on A and C or B and D at the same time. This will lead to a short circuit of the battery and will lead to failure of the relays due to the large current.

2. **Using Transistors:**

We can better control our motor by using transistors or Field Effect Transistors (FET's). Most of what we have discussed about the relays H-Bridge is true of these circuits. See the diagram showing how they are connected. We should add diodes across the transistors to catch the back voltage that is generated by the motor's coil when the power is switched on and off. This fly back voltage can be many times higher than the supply voltage.
Don't turn on A and C or B and D at the same time.

| e-ISSN: 2319-8753, p-ISSN: 2320-6710| www.ijirset.com | Impact Factor: 7.512|

|| Volume 9, Issue 5, May 2020 ||

Transistors, being a semiconductor device, will have some resistance, which causes them to get hot when conducting much current. This is called not being able to sink or source very much power, i.e.: Not able to provide much current from ground or from plus voltage.

MOSFET's are much more efficient, they can provide much more current and not get as hot. They usually have the fly back diodes built in so we don't need the diodes anymore. This helps guard against fly back voltage frying our ICs.

To use MOSFET's in an H-Bridge, we need P-Channel MOSFET's on top because they can "source" power and N-Channel MOSFET's on the bottom because they can "sink" power. It is important that the four quadrants of the H-Bridge circuits be turned on and off properly. When there is a path between the positive and groundside of the H-Bridge, other than through the motor, a condition exists called "shoot through". This is basically a direct short of the power supply and can cause semiconductors to become ballistic, in circuits with large currents flowing. There are H-bridge chips available that are much easier, and safer, to use than designing our own H-Bridge circuit.

L293D Dual H-Bridge Motor Driver

L293D is a dual **H-Bridge** motor driver, so with one IC we can interface two DC motors, which can be controlled in both clockwise and counter clockwise directions. Since the device is having four half 'H' Bridges, thereby if required four motors can be driven through this single device, moreover the task is to run all four motors in one direction only. **L293D** has output current of 600mA and peak output current of 1.2A per channel. Moreover for protection of circuit from back EMF output diodes are included within the IC. The output supply (VCC2) has a wide range from 4.5V to 36V, which has made **L293D** a best choice for DC motor driver.

IV. EXPERIMENTAL RESULTS

In this IC there are two different power supplies (Vcc1 and Vcc2). Vcc1 is for logic input circuit while Vcc2 is supply for the output circuit. This means that we should apply about 5V to Vcc1 and whatever voltage required by the motor (up to 36V max for this IC) to Vcc2. Each Half H-Bridge has an individual Ground. So we must ground the terminal corresponding to the Half H-Bridge, depending up on the circuit design, if required all four terminals of bridges can be connected to the ground.

Each Half H-Bridge has an Input (A) and output (Y). Also there are enable pins to turn on the Half H-Bridges. Once a Half H-bridge is enabled, then the truth table is as follows:

INPUT A	OUTPUT Y
L	L
H	H

So we just give a High level when we want to turn the Half H-Bridge on and Low level when we want to turn it off. When the Half H-Bridge is on, the voltage at the output is equal to Vcc2.

If we want to make a Full H-Bridge, we must connect the motor (or the load) between the outputs of two Half H-Bridges and the inputs will be the two inputs of the Half H-Bridges.

Suppose we have connected Half H-Bridges 1 and 2 to form a Full H-Bridge. Now the truth table is as follows:

INPUT 1A	INPUT 2A	OUTPUT 1Y	OUTPUT 2Y	Description
L	L	L	L	Braking (both terminals of motor are Gnd)
L	H	L	H	Forward Running
H	L	H	L	Backward Running
H	H	H	H	Braking (both terminals of motor at Vcc2)

V. CONCLUSION

We have designed and implemented a prototype module; and the results are found to be satisfactory. Since it is a prototype module, a simple moving vehicle is constructed. In future this can be implemented not only on highways but also on the normal roads with the electric line.

While designing and developing this proto type module, we have consulted few experts those who are having knowledge in Mechatronics, and these professionals working at different organizations belongs to Hyderabad helped us while fabricating this project work. Since it is a prototype module, much amount is not invested. The whole machine is constructed with locally available components, especially the mechanical components used in this project work are procured from mechanical fabricators and they are not exactly up to the requirement. Some of the modifications must be carried out in design to make it as real working system.

A LITHOPHANE MODEL MAKING PROCESS TO 3D PRINTERS

Siddavatam Rammohan Reddy
Assistant Professor, Department of Mechanical Engineering,
Malla Reddy Engineering College (Autonomous), Telangana, India

ABSTRACT

This paper focuses on to convert photographs into embossed 3D models and then bring them to life using a 3D printer. A Lithophane is a 3-dimensional generation of a 2-dimensional image and 3D representation of a photo can be seen only when it is illuminated from behind. Turning images into 3D objects give us more feeling and literally adds a new dimension. The lithophane can be manufactured by the way of an automated additive manufacturing process, such as 3-D printing. lithophanes are a simple way to enhance your favourite photos. 3D printed photos also known as 3D Printed lithophanes, are an extremely unique and creative application. The process adopted in lithophane is FDM technology, in which different the materials like PLA (polylactic acid), ABS (acrylonitrile butadiene styrene), etc. By heating the filament material to its melting point and it is deposited layer by layer. Combination of many layers will give us a final 3D Printed model.

1. INTRODUCTION

We all know how precious to us the photos and images in our life. transforming these photos into Lithophanes that will light up your image as the lithophane lits up when light passes through it. With 3D Printing Technology today we can easily transform images into a 3D model. 3D printing or additive manufacturing is a process of making three dimensional solid objects from a digital file. In an additive process, an object is created by laying down successive layers of material until the entire object is created.

Rapid prototyping is the fast fabrication of a physical part, model or assembly using 3D Computer Aided Design (CAD). Rapid prototyping technologies are being used in various fields of engineering. These technologies are:

1.Fused deposition modelling (FDM) 2. Stereolithography (SLA)
3.Laminated object manufacturing (LOM) 4.Selective laser sintering (SLS)

FDM works on an Additive principle of laying down melted material in layers to create objects. Material from the filament spool gets extruded towards the nozzle, heated up and then laid layer over layer to form the 3-Dimensional object. FDM is also known as fused filament fabrication (FFF)

The 3D printers that work on FDM technology consist of the printer platform, a nozzle (also called as printer head) and the raw material in the form of a filament. When the FDM printer begins printing, the raw material is extruded as a thin filament through the heated nozzle. It is deposited at the bottom of the printer platform, where it solidifies. The next layer that is extruded fuses with the layer below, building the object from the bottom up layer by layer. The system sends Design-Specific commands to a controller head, which releases the melted thermoplastic accordingly. This process is repeated layer by layer based on specific design coordinates. The molten material becomes a solid object as soon as it is exposed to a cooler environment.

3D printing significantly challenges mass production processes in the future. This type of printing is predicted to influence industries, like automotive, medical, education, equipment, consumer products industries and various businesses.

2. LITHOPHANE DESIGN

Lithophanes can be created in a variety of software tools like 3DP. Rocks, Lithophane maker, Photoshop etc. In this paper, the 3dp.rocks/Lithophane website is preferred because It is simple to use and has 8 different layouts for model design. It makes easy to upload a photo and download a model for 3D printing but for best results, the photo should be edited.

Procedure to be followed:

- Open 3dp.rocks website
- Click on the Images tab and then upload your image. Once the image has been uploaded, it will generate a lithophane model
- Once you return to the Model tab, you'll notice your lithophane is almost ready. You can choose different layouts for your lithophane.
- Select setting tab→ Model Setting →Change parameters like size, Thickness, border etc. →click on the model tab and click on Refresh (This would ensure that the print comes out to your preferred dimensions)
- Select setting tab→ Image Setting →Change negative image to positive image→ click on the model tab and click on Refresh.
- Finally, click "Download" in the Model tab. The browser will download the STL file.

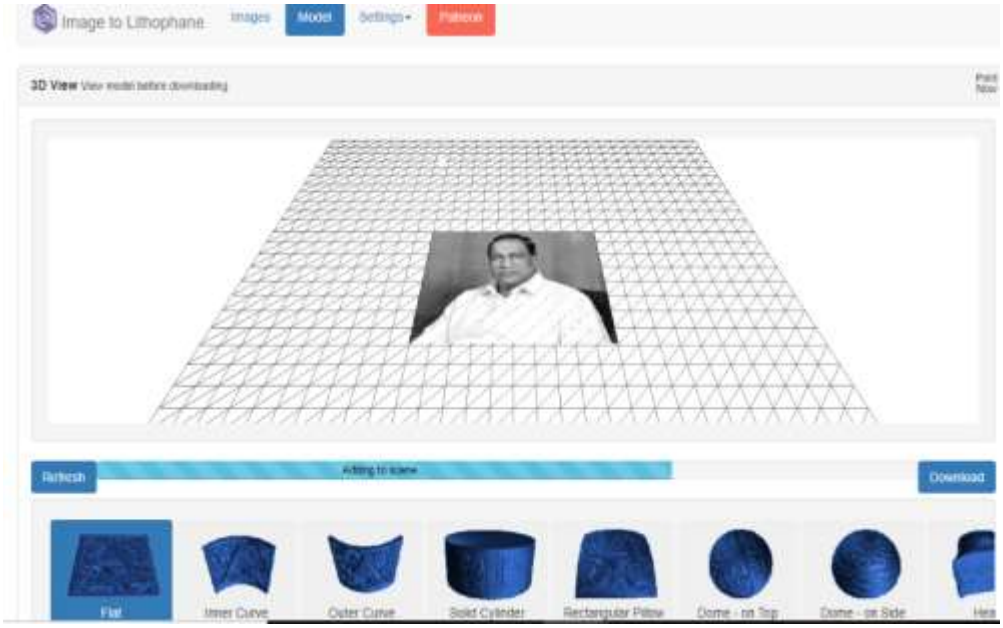

Figure 1 Image Uploading

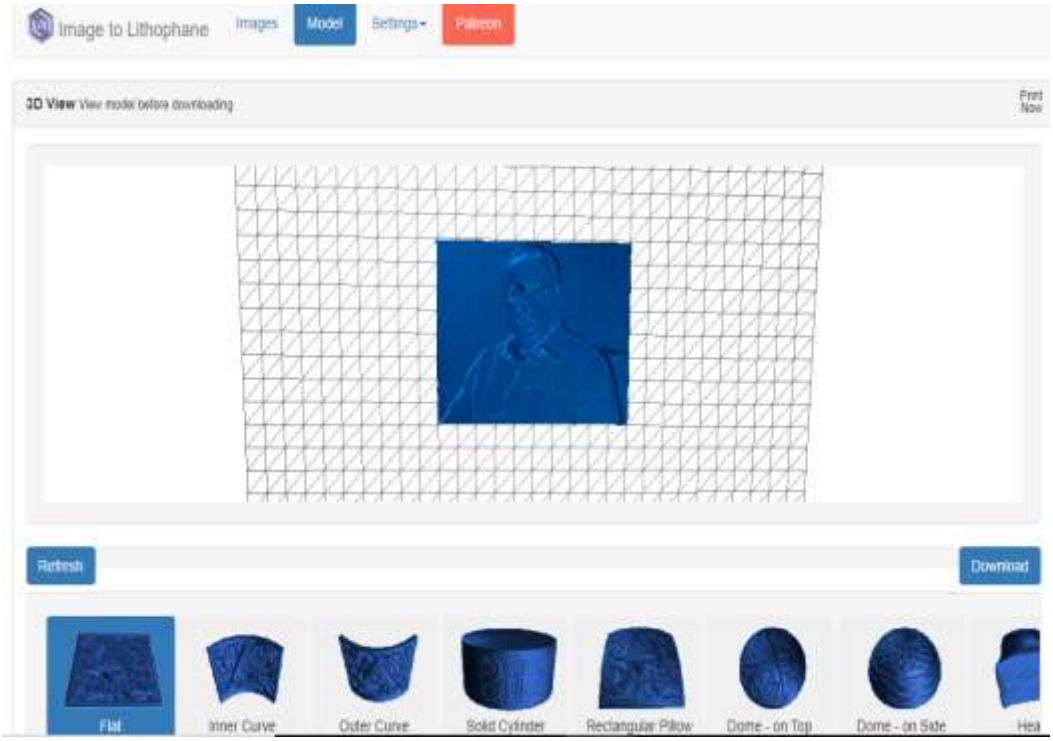

Figure 2 Image to Lithophane Conversion

3. MODEL SLICING AND GENERATION OF G-CODE

There are many 3D slicing software's available on the market. these are CURA, Slic3r, idea Maker, Z-Suite, MakerBot Print etc. Cura 3D is one of the many. Cura was developed, hosted and maintained by 3D printer company Ultimaker. Cura is slicing software for 3D printers. The STL or OBJ file can then be imported into the Cura software .it is slices model into layers to create a file known as G-Code, which is the code that a 3D printer understands. This G-Code is just a text document (in essence) with a list of commands for the 3D printer to read and follow such as hot-end temperature, move to the left this much, right that much etc.

As every printer has a different setup, print area, build plate and nozzle size, the Cura slicing software needs to know these hardware details in a printer profile. Once it has the required details, you can then specify settings like layer height and thickness. (shown in Table1) Based on the vital stats of the printer and your settings, Cura will calculate the path the printhead needs to take to print your model and produce a list of instructions for the printer. These instructions are saved in that G-Code file. The G-Code can then be saved to an SD card or sent to the printer over wireless or cable depending on the printer directly from Cura.

Steps to be followed:

- Open STL file in CURA by Clicking the “Load” button in the top left-hand corner of the viewport.
- The 3D model appears on the platform.
- Rotate and scale the model as per the requirement by Clicking the respective command icons in the lower left-hand corner of the viewport.
- Select “Save Toolpath” to create G Codes for the part. Save the file that is generated, in an SD card.

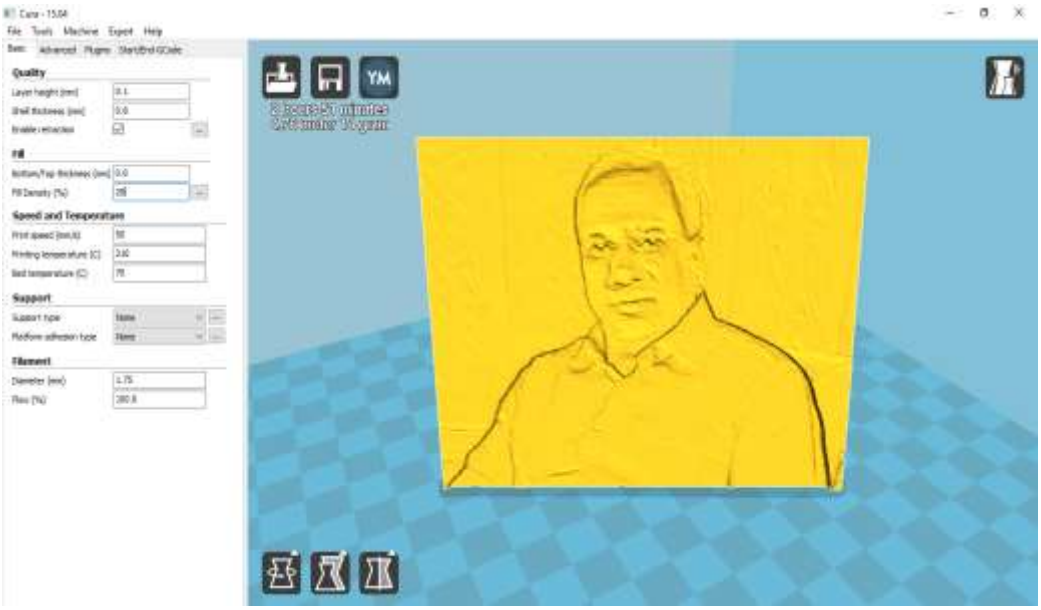

Figure 3 3D Model in CURA

4. LITHOPHANE PRINTING PROCESS

3D Printing is the process where liquid molecules, powder or granulated material is solidified and joined to achieve the desired shape and size in three-dimensions. Normally it’s done one layer at a time to make sure the proportions of 3D are maintained. 3D printing companies include (Brahma3, Thinl3D, JGroup Robotics,3Ding etc.) those companies that manufacture and distribute 3D printers. Most also offer 3-D printing services and some even conduct training programs for 3D printing. 3D printing has the power to change the entire industrial landscape because you don't need to make or buy special moulds or tools. 3Ding is one of India's Largest Manufacturer of 3D Printers of the FABX & Hydra. I used HYDRA- 200 to Print Lithophane. The listed parameters have to enter manually by selecting Machine Tab→Add new machine in Cura software.

Specifications	Hydra 200 Pro
Build Volume	200 * 200 * 200 mm3
Bed Temperature	70^0 C
Print Speed	20 – 80 mm/s
Nozzle size	0.4mm
Connectivity	USB, SD Card
Max. Temp.	300^0 C
Weight	13.5 kg
Power Consumption	60 –80 W
File Type	STL
Material	PLA
Software	Cura
Filament Diameter	1.75mm

Figure 4 Setup

The following procedure may be used to operate the 3D Printer:

- Switch on the 3D printer and allow it to stabilize. Insert the SD card with the G Code file into the SD port of the printer.
- Press the knob on the 3D printer to get the options. Rotate the knob to scroll the options. Select “Preheat PLA” from display by pressing the knob. Wait to get a pre-set temperature of 210^0C.
- Heating melts the plastic in the nozzle that might have been left from previous work. Use a wire strip to clean and clear the nozzle then Feed the PLA material to the extruder through filler to the nozzle.
- Remove and clean the magnetic plate. Fix the plate on bed and adjust the height if necessary.
- Press the knob to navigate through options and select “Print from SD”. Choose the G Code file from SD to be printed. 3D printer will heat the bed automatically and return to the home position. This process may take a few minutes.
- Now, 3D Printer prepares the model and start printing. Wait till the completion of a model on the bed. After model printing, select “Disable Steppers” by using the knob and Rotate the middle slider of the bed to lower the bed.
- Remove the magnetic plate from the bed and Use a knife or a sharp tool to remove the model from the plate.

There are a number of variables that can affect your lithophane including the filament used, model thickness, slicer settings and light source. You can experiment by printing multiple lithophanes and adjusting the z-height.

5. 3D PRINTED LITHOPHANE

The printed lithophane is shown below. I have printed a photo of my Chairman Sri. Ch. Malla Reddy Garu. It looks like a flat piece of plastic with a few scratches on it, but put it in front of a light source like the sun, and you'll see an image.

Abstract

In this study, the dynamic shear properties of a composite honeycomb core material made of glass fiber reinforced (epoxy resin and vinyl ester) polymers without and with reinforcement of carbon nanotubes are investigated. The carboxylic acid functionalized multi-walled CNTs were randomly dispersed into an organic solvent (extra pure acetone) to split and add homogeneously into the vinyl ester resin by using the ultra-sonication technique®. The honeycomb composite test materials were made through the high carbon- chromium corrugation honeycomb die using the vacuum-assisted hand-layup technique. The vibration analysis of honeycomb materials was performed experimentally to obtain the shear moduli along the corrugation (G_{xz}) and joining (G_{yz}) directions based on the dynamic approach. The results showed that the reinforcement of CNTs in the composite honeycomb materials would enhance the shear moduli significantly without any modifications in the mass of the honeycomb structure. The strong interfacial bonding and random addition of CNTs in the composites improve the shear properties considerably than that of honeycomb without CNT reinforcement. This result provides the guidelines for the modern designer on increasing the shear properties of the honeycomb composite structures using the CNT reinforcement.

Nomenclature

CNTs	Carbon nanotubes
HCC	Honeycomb core
MWCNTs	Multi Walled-Carbon nanotubes
GFRP	Glass fiber reinforced polymer
CFRP	Carbon fiber-reinforced polymer
ASTM	American Society for Testing and Materials
wt	Weight
%	Percentage
ω	Angular frequency
ω_{hxz}	Natural frequency along corrugation direction
ω_{hyz}	Natural frequency along joining direction
FRF	Frequency response function
DAQ	Data acquisition
l_c	HCC length
w_c	HCC width
h_c	HCC height
m	Solid block mass
h_m	Solid block depth
a_c	HCC cell side
s_c	HCC cell size
t_c	HCC Cell wall thickness
E_z	Young's modulus
I_{mx}	Moment of inertia
G_{xz}	Corrugation direction
G_{yz}	Joining direction

1. Introduction

The honeycomb structures are widely being employed in aircraft, helicopters, military, rockets, railroad vehicles and especially in automobile structures because of their customized mechanical properties and improved damping capability which couldn't be achievable in isotropic as well as laminated composite sheets. Though, the usage of these type of materials is inadequate due to their limited viscoelastic and damping capability of the hexagonal honeycomb composites. Since the invention of CNTs by Iijima [1], due to their unique mechanical properties, excellent thermal conductivity, and electrical conductivity have got consideration from many designers to manufacture the CNT fortified composites to attain the superior physical properties of the fiber reinforced composites. CNTs are often added to polymers matrices to improve its physical and chemical properties so that they can be used as substitutes for existing materials. Various researches have been carried out in the field of polymer composites. Gupta and Harsha [2] investigated the pinhole defects in CNT-fortified composites using finite element modelling. Armchair and zigzag configurations of CNTs were focused for the analysis. It was observed that Young's modulus reduces with the presence of pinhole defects and the zigzag configuration of CNTs provide a better reinforcement than that of the armchair configuration. Nam et al. [3] studied the effect of CNT diameter on mechanical properties of CNT sheets and composites. The composite material chosen was CNT-epoxy. The reduction in the diameter of CNT increases the properties of both CNT sheets and composites. However, the reduction in the diameter of the CNT did not affect the alignment of CNT. Rawat and Singh et al. [4] examined the impact behavior of CNT based fiber reinforced polymer composites using the LS-DYNA tool for validation. The results from the low and high velocity impact test revealed the existence of CNT fortification in fiber-reinforced composites could offer ahigher impact resistance that of without CNT fortification. Zhou et al. [5] investigated the compression response from composite sandwich structures made of carbon-fiber epoxy and glass fiber epoxy

materials. The compression strength of the carbon composite sandwich structures increases with an increase in corrugation thickness than that of glass composite sandwich structures.

The effectiveness of the elastic properties of the CNT reinforced composites are significantly influenced by ultra sonication and high speed mechanical stirring techniques. Shokrieh et al. [6] used sonication and high-speed mechanical stirring to disperse CNTs into vinyl ester resin, it was found that higher sonication time can lead to the damages of CNTs. Chen et al. [7] incorporated MWCNTs into vinylester resin through high-speed mechanical stirring. The dynamic scanning calorimetry and dynamic-mechanical behaviour tests were carried out to find the curing behaviour of a vinylester with the addition of CNTs. It can be observed that the incorporation of CNTs into vinylester resin could increase the storage modulus and the addition of the initiator in the mixture of vinylester-CNT resin could increase the curing time. Nabinejad et al. [8] presented an experimental study on hybrid composites comprising of multi-walled carbon nanotubes in vinyl ester resin. It can be seen that that at higher percentages of carbon nanotube content, the viscosity of the solution was high and also there was a decline in the flexural strength for higher weight percentages of carbon nanotubes. Gryshchuk et al. [9] studied the electrical, thermal and mechanical properties of the composites. The analysis was carried out for the incorporation of 2 wt% of CNT content in Vinylester (VE), Vinylester-urethane (VEUH) and Vinylester/epoxy (VE/EP). It was found the polymers which have a very firm crosslinking prove to be prone to MWCNTs with high aspect ratios but are suitable for low aspect ratio MWCNTs. Zhu et al. [10] incorporated single walled CNT into Vinylester and then transferred the resin on to glass fibers via vacuum assisted resin transfer moulding process. There was a vast increased in shear strength with 0.015%wt of CNTs and flexural strength also improved. Shokrieh et al. [12] studied the influence of adding various wt. % of multi-walled carbon nanotubes in the vinyl ester composites. The result showed that the addition of least wt. % of CNTs could improve the mechanical properties drastically. However, higher wt.% of CNT content could increase the brittleness of the composites. Wonderly et al. [13] studied the elastic properties of glass fibers and carbon fibers by reinforcing it into the vinylester resin. Various analysis was carried out such as tension, compression, indentation and impact tests on both composites and the results were compared. The carbon fiber composite showed better results than glass fiber composites in all aspects except for transverse tensile strength. Karapappas et al. [14] studied the fracture behaviour of CNT reinforced carbon panel. Three different weight percentages of CNTs were used and dispersed the CNTs into the polymer using high speed mechanical stirring technique. Lower weight percentages of CNTs showed a decrease in fracture properties due to low viscosity while higher weight percentages showed a significant increase in the results. Almajid et al. [15] studied the various mechanical, electrical and thermal characteristics of composites by reinforcing the graphene and CNT into Vinylester resin. The results shown that the CNT samples had better flexural modulus than graphene but graphene samples had better scratch resistance but the resistance declined once the graphene concentration exceeded by 2 wt%. On the other hand, there was a significant increase in corrosion resistance when CNT-graphene composites were coated onto the steel. Rawat and Singh [16] studied the damage tolerance of carbon fiber laminates reinforced with MWCNTs. Different concentrations of MWCNTs were used for the drop-weight test using the Instron-CEAST 9350. It was found that maximum energy absorption was achieved with a minimum CNT doping.

Honeycomb structures have excellent shear strength, bending stiffness and better structural integrity. These structures have excellent fatigue cycles and mostly used in cores of the sandwich panels. Lee et al. [17] studied the mechanical properties and shear deformation of honeycomb composite at elevated temperature. It was found that at high temperature the resin holds the cell walls together and undergoes fracture which leads to the deformation of honeycomb structure. Also, it can be seen that at elevated temperatures the adhesiveness of the resin decreases rapidly due to less binding effect. Banerjee et al. [18] studied various honeycomb cores and found out numerous failure methodologies. The major reasons for failure are considered to be buckling and yielding. Failure maps were constructed for certain core structures based on optimization. It also stated that the addition of reinforcement to honeycomb structures can increase the Young modulus of composite material. Siddiqui et al. [19] studied prepregs of CFRP composites with the addition of carbon nanotubes(CNTs). The effects of surfactant-treated CNTs on cure behavior of epoxy and CFRP prepreg are evaluated. The catalytic activity of CNTs is negligible for a 0.5 wt% filler content. Whereas, it becomes prominent when the CNT content is increased to 1 wt%. The result shown that high speed mechanical stirring and functionalization of CNTs could reduce the viscosity of the CNT-epoxy solution. Sassi et al. [20] investigated experimentally the in-plane properties of adhesively bonded composite joints. It consists of a bi-axial fiber-glass mat in a vinyl ester resin matrix. Samples were tested at four different impact pressures from 1 to

4 bar with strain rates of 210, 312, 528, 713 s^{-1} respectively. The study concludes that the composite materials have shown that strength is dependent on strain rate and dynamic parameters increase with strain rate. Wang and Liu [21] incorporated circular carbon fiber reinforced polymer tubes into a honeycomb core. Detailed mechanical performances were determined and honeycomb cells filled with circular tubes (HFCT) were found to have an increase in energy absorption. Park et al. [22] investigated carbon-fiber epoxy square honeycomb and the parent composite material. The sample was tested in quasi-static compression and dynamic compression at various strain rates using a kolsky bar arrangement. The peak value of wall stress of honeycomb was one third of the parent material for all strain rates. Finite element analysis was done to find out the decrease in wall strength and the cause was found to be stress concentration at slot-root of the honeycomb cell walls. He and Hu [23] studied sandwich panels which include a honeycomb core. The mechanical and structural properties are found out using ASTM standard C393-62. The weight ratio of the whole sandwich structure is deduced and then ASTM Tests are performed. A 50-66.7% weight ratio is decided upon and gives optimum test results. Schwingshackl et al. [24] examined the available methods to find the material property of the honeycomb cores. Since ASTM tests are costly and time consuming, a new method called alternative dynamic approach was adopted to evaluate the honeycomb core. The results obtained through the dynamic approach are on par with existing ASTM test standards. Toozandehjani et al. [25] reviewed different types of composite materials offered for the aerospace industry. An extensive study was conducted with all types of composite materials available and discussed briefly about polymer matrix composite and the reinforcements used. It describes the usage of sandwich panels with the honeycomb core due to their high stiffness to weight ratio which limits the bending.

From the literature, it can be identified that most of there searchers have focused on the evaluation of the elastic properties of honeycomb structures with and without the addition of foam or CNT packed honeycomb core cell pockets made of isotropic/orthotropic materials. However, the evaluation of shear property of CNT reinforced honeycomb core materials has not yet been investigated. These core materials would improve the structural stiffness, honeycomb shear strength and material damping capability considerably without any alteration in the structural mass.

In this study, various shear properties of the various fiber reinforced composite honeycomb materials without and with CNT fortification in vinyl ester and epoxy resins are investigated. The 1 wt% of CNT content is reinforced into the vinyl ester resin and epoxy resin using the ultra-sonication® and hot base heat shearing method. The vibration analysis of various hybrid honeycomb core composite materials were performed to evaluate the shear moduli along the corrugation and joining directions of the hexagonal honeycomb structure using the dynamic approach. Since ASTM tests are costly and time consuming, a new method called dynamic approach was adopted to evaluate the shear properties of the composite honeycomb. Further, the acquired results are well compared with those of vinyl ester and epoxy honeycomb core without the usage of CNTs in the composite material to show the efficiency of using CNT fortification in the regular hexagonal core structure enhancing the stiffness, damping and shear modulus along G_{xz} and G_{yz} directions of the composite structure.

2. Fabrication of Honeycomb Core Composites

The honeycomb cores were fabricated using the functionalized MWCNTs procured from bottom up technologies corporation, Jharkhand® with approximate aspect ratio of 10µm (length) and 17nm (diameter), unidirectional Inter-glassfiber 92145(220 GSM), vinyl ester resin, epoxy resin, hardener at 10:1, benzoyl peroxide as initiator and cobalt naphthenate as promoter. The density of epoxy resin is 1.2 g/cm^3 and vinyl ester resin is 1.8 g/cm^3. The procured CNT – vinyl ester and CNT – epoxy resin matrices were used to prepare the solution. Initially, the CNTs were dispersed into the polymer using heat shearing method. First, 300g of vinyl ester was poured in a 1000ml beaker and heated in the oven at 50°C for 45 minutes. Then, 1 wt% of CNT content were taken in another 1000ml beaker and mixed with 300g of extra pure acetone. This acetone and CNT mixture was stirred at 500rpm for 45 minutes using a mechanical stirrer at room temperature. This was done so that carbon-carbon bonds in CNTs could be disintegrated and dispersed evenly into vinyl ester and epoxy resin matrices. The beaker containing vinyl ester and epoxy resin matrices are takenfromoven and kept aside at ambient condition to attain equilibrium. The acetone and CNT solution are kept inside the oven at room temperature for 60 minutes for the evaporation of acetone existed in both resin

matrices. The 300 g of vinyl ester resin is then added to CNT-Acetone mixture and then stirred at 1500 rpm for 60 minutes, only this time the beaker is kept in chilled water. Similarly, the CNT-epoxy solution was prepared for the fabrication.

The glass fiber was cut with a dimension of 80 mm x 10 mm having [0°/90°] ply orientation for fabrication. The weight of the glass fiber pieces was measured. An equivalent amount of vinyl ester resin is taken and 2 wt. % of hardener, 1 wt% of promoter and initiator are added to the resin. Wax is applied on a smooth surface and 0° glass fiber ply is kept on it. The resin is poured on the glass fiber and spread using a hand roller. Similarly, 90° glass fiber ply is kept on top of the 0° ply and the resin is poured and spread. The stacking sequence of the glass fibers was kept as [0°/90°]. The thickness of the individual layer is 0.19 mm, two plies were used to fabricate a corrugation sheet. A hand layup method was adopted to make the corrugation sheets. The sample is left to rest for 15 minutes. Then the sample is placed inside the high carbon-high chromium honeycomb die and cured for 12 hours. The corrugation sheet was formed after keeping it in the honeycomb die. Following this, the corrugation composites sheets were made using the fiber reinforced CNT-epoxy resin material with the same process carried out for the fabrication of fiber reinforced CNT-vinyl ester corrugation composite sheets are presented in Figure 1.

Further, the fabrication of composite honeycomb structures was carried out using the corrugation sheets of fiber reinforced CNT – vinyl ester and CNT – epoxy resin composites in 0° and 90° ply orientations. The corrugation sheets are then cut at 80 mm length and 10mm width vertically using the ultrasonic SONOFILE® cutter. The half hexagonal strips are then attached together using the Huntsman Araldite2012® to fabricate the composite honeycomb core structures. The test samples of honeycomb core made of glass fiber with and without CNT reinforcement was made with a dimension of 80 mmx 80 mm x 10 mm. Then, the fabricated specimens were kept in the vacuum oven at 75°C for 2 hours to develop a strong bonding between polymer chains of CNT resin matrices of the composite honeycomb materials. The specimen is left to rest for 30 minutes at room temperature after the 2 hours curing process has done for the honeycomb structure.

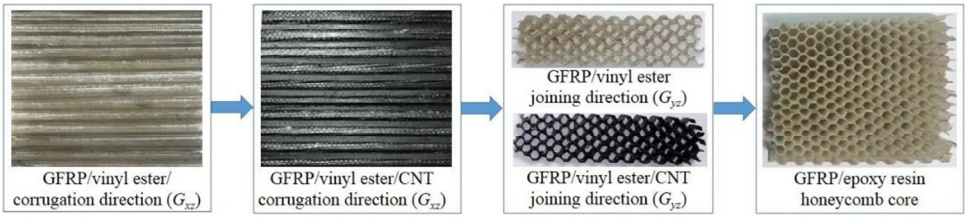

Fig. 1. Steps carried out to fabricate the vinyl-ester and epoxy honeycomb composite with and without CNT fortification

3. Experimental Analysis of Honeycomb Core Composites

The fabricated composite honeycomb structures were used to evaluate the out of plane shear properties along the corrugation and joining directions. The dimensions of the honeycomb core is maintained as 80 mm x 80 mm x10 mm. The test specimens (honeycomb cores) were mounted on the foundation using Huntsman Araldite 2012® and a solid mass is placed on the honeycomb core structure along the transverse direction. The vibration analysis experimental test setup is presented in Figure 2. The dynamic analysis was carried out using the roving Impulse force hammer 086C03 to energize the solid mass rested on the honeycomb core. A miniature transducer, placed in the z-direction, was kept on the sides of the mass to measure the acceleration due to the excitation along the G_{xy} and G_{yz} directions. These signals were amplified into FRF through the 4 channel DAQ-042451. The modal natural frequencies and damping ratio of the test specimens were successively obtained from the dominant peaks from the FRF. The evaluated natural frequency, damping ratio, Young's modulus, moment of inertia, angular frequency and geometrical parameters (Table 1) are substituted in equation 1 to obtain the shear properties of the honeycomb core by using the dynamic approach technique [23].

$$G_{xz} = -\frac{\left(-12I_{mx}\omega_{hxz}^2 h_c + a_c^4\right) m\omega_{hxz}^2 h_c}{\left(3\omega_{hxz}^2 h_m^2 h_c m + 12I_{mx}\omega_{hxz}^2 h_c - a_c^2 E_z\right) a_c{}^2} \tag{1}$$

Where G_{xz} denotes the shear modulus along the corrugation direction. Similarly, the shear modulus G_{yz} can be calculated along the joining direction of the honeycomb core material.

Table 1. Measured geometrical parameters of the composite honeycomb core structures.

Geometrical parameters	HCC length	HCC width	HCC height	solid block mass, *kg*	solid block depth	HCC cell side	HCC cell size	HCC Cell wall thickness
Dimensions are in metre	0.08	0.08	0.01	1.36	0.02	0.006	0.008	0.0006

The results presented in Table 2, shows that the CNT reinforcement in the epoxy honeycomb composite increases the natural frequencies, damping ratios and shear moduli along transverse shear directions *Gxz* and *Gyz* than those of CNT reinforcement in the vinyl ester honeycomb core structure.

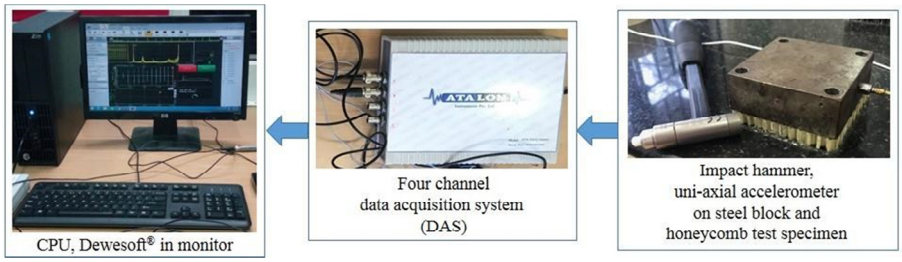

Fig. 2. Photograph of the experimental test setup

Also, the results show that the CNT reinforced honeycomb core structures increase the dynamic responses and shear moduli than those of without CNT reinforcement.

Table 2. Evaluation of natural frequencies, damping ratios and shear moduli of honeycomb composite structures without and with CNT fortification

Type of composite HCC structure	Natural Frequencies (Hz)		Damping ratios (ζ)		Shear moduli (MPa)	
	Corrugation direction, ω_{hxz}	Joining direction, ω_{hyz}	Corrugation direction, ζ_{hxz}	Joining direction, ζ_{hyz}	Corrugation direction, G_{xz}	Joining direction, G_{yz}
GFRP/epoxy/HCC without CNT	692.77	655.57	0.0780	0.0758	183.42	164.30
GFRP/epoxy/HCC with CNT	819.57	755.37	0.0921	0.0870	256.72	216.92
GFRP/vinyl ester /HCC without CNT	587.50	487.50	0.0310	0.0253	131.91	90.82
GFRP/vinyl ester /HCC with CNT	681.25	537.50	0.0541	0.0408	177.37	110.41

It is related to the random distribution of functionalized nanoparticles in the glass fiber reinforced honeycomb material, improves the shear force among the resin matrices and nanoparticles. In addition to this, it is observed that the shear moduli from the corrugation axis are maximum than those of joining axis of the composite honeycomb without consideration of nanoparticles fortification in the epoxy and vinyl ester. It can be due to the enhanced stiffness and better distribution of shear force of the honeycomb composites from the continuous double cell geometry of the hexagonal wall direction.

4. Results and Discussion

The natural frequencies, damping ratio, and shear moduli of the fiber reinforced CNT-epoxy in the honeycomb core materials at the corrugation direction under fixed-fixed end condition increases such as 692.77Hz, 0.0780 and 183.42MPa than that of the without CNT reinforcement. Whereas, the CNT-vinyl ester reinforced in the honeycomb core materials at the corrugation direction under fixed-fixed end condition increases such as 587.50Hz, 0.0310, 131.91MPa than that of the without CNT reinforcement. Similarly, the honeycomb with CNT-epoxy resin and CNT-vinyl ester reinforced in honeycomb core at the joining direction increases than that of the without CNT reinforcement. Further, the results revealed that there is a significant increase in natural frequency, damping ratios, and shear moduli at the corrugation direction than that of the joining direction of the honeycomb structures made of epoxy resin and vinyl ester with and without CNT reinforcement. This can be due to the fact that the corrugation direction (G_{xz}) has a continuous structure, while the assembly of corrugated structure is made into a continuous structure along the joining direction (G_{yz}) by using an adhesive (Huntsman Araldite 2012®).

5. Conclusion

The present study investigates the shear properties of the fiber reinforced honeycomb structures without and with CNT reinforcement in epoxy resin and vinyl ester. The test samples were fabricated with 1 wt% of CNT in the composite honeycomb core materials. The dynamic characterization of honeycomb composite materials has been performed experimentally to determine the out of plane shear properties based on the dynamic approach. The result revealed that the addition of CNT in epoxy honeycomb core increases the shear properties by 28.55% and 24.26% in *xz* and *yz* directions than that of without CNT reinforcement. Similarly, the CNT in vinyl ester honeycomb core increases by 42.70% and 37.99% in *xz* and *yz* directions than that of without CNT reinforcement. This can be related to fact that the strong polymer chain bonding developed between the CNT and resin matrices. However, the CNT-epoxy honeycomb is increased by 30.91% and 49.10% along *xz* and *yz* directions than those of the CNT-vinyl ester honeycomb core. Similarly, the epoxy honeycomb core without CNT reinforcement is increased by 28.08% and 44.72% along *xz* and *yz* directions than those of the vinyl ester honeycomb. It can be due to the poor polymer chain bonding between the fiber and viscous less vinyl ester honeycomb without and with CNT reinforcement. The result demonstrates that the addition of CNT content in the hexagonal honeycomb material increases the natural frequencies, damping ratios and shear moduli due to the improved shear force between the CNT and matrices. Further, it can be observed that the shear properties along the corrugation direction of honeycomb core made of epoxy and vinyl ester with and without CNT is higher than those of the shear properties along the joining direction. This can be due to the improved stiffness and enhanced shear force along the double cell wall in *xz* direction. Therefore, it can be seen that the addition of CNT content in honeycomb core could increase the frequencies, damping ratios and shear moduli simultaneously along both directions of the honeycomb structure considerably.

Abstract

The piston of an IC engine is to receive the impulse from the expanding gas and to transmit the energy to the crankshaft via the connecting rod. The piston must also dissipate a large amount of heat from the combustion chamber to the cylinder walls. The aim of this present work is to Design; Assemble the Piston, Connecting Rod; Crankshaft for a 4-stoke air-cooled Engine by theoretical calculations & also to perform the simulation of this mechanism. Modelling of mechanism is carried out Pro/Engineering software & Analysis is performed in ANSYS. Structural analysis and steady state thermal analysis is performed to calculate displacements & thermal stresses under static loads, Vibration response of structure i.e. (natural frequencies & mode shapes) is also checked by using modal analysis and lastly we perform RBD of mechanism to check the behaviour of structure.

1. INTRODUCTION

For many years, internal combustion engine research was aimed at improving thermal efficiency and reducing noise and vibration. As a consequence, the thermal efficiency has increased from about 10% to values as high as 50%. In recent times with recognition of the importance of air quality, there has also been a great deal of work devoted to reducing emissions from engines. Currently, emission control requirements are one of the major factors in the design and operation of internal combustion engines.Shin-Yong Chen, et al in their research paper "Dynamic Analysis Of a Rotating Composite Shaft" One of the key factors in designing a motor built-in high speed spindle is to assemble the motor rotor and shaft by means of hot-fit. Presented in this paper is a study of the influence of a hot-fit rotor on the local stiffness of the hollow shaft. Dynamic analyses of the rotorhollow shaft assembly using contact elements are conducted. The normal contact stress state between the rotor and the hollow shaft is obtained through the use of contact elements with friction effects included. The normal contact stress, considered as the pr-stress between the rotor and the hollow shaft, is then adopted for subsequent modal analyses. the modal analysis results are verified by a modal testing experiment C. Azoury et al presented a report on the experimental and analytical modal analysis of a crankshaft. The effective material and geometrical properties are measured, and the dynamic behaviour is investigated through impact testing. The threedimensional finite element models are constructed and an analytical modal analysis is then performed to generate natural frequencies and mode shapes in the three-orthogonal directions. The finite element model agrees well with the experimental tests and can serve as a baseline model of the crankshaft. R. J. Deshbhratar, et al analyzed 4- cylinder crankshaft and model of the crankshaft were created by using Pro/E Software and then imported to ANSYS software. The maximum deformation appears at the centre of crankshaft surface. The maximum stress appears at the fillets between the crankshaft journal and crank cheeks, and near the central point. The edge of main journal is high stress area. The crankshaft deformation was mainly bending deformation under the lower frequency. And the maximum deformation was located at the link between main bearing journal and crankpin and crank cheeks. So this area prone to appear the bending fatigue crack. Abhishek choubey, and et al have analysed crankshaft model and 3-dimentional model of the crankshaft were created by SOLID WORKS Software and imported to ANSYS software. The crankshaft maximum deformation appears at the centre of crankpin neck surface. The maximum stress appears at the fillets between the crankshaft journals and crank cheeks and near the central point journal. The edge of main journal is high stress area.

Rinklegarg et al. analyzed crankshaft model and crank throw were created by using Pro/E Software and then imported to ANSYS software. The result shows that the improvement in the strength of the crankshaft as the maximum limits of stress, total deformation, and the strain is reduced. The weight of the crankshaft is reduced .There by, reduces the inertia force. As the weight of the crankshaft is decreased this will decrease the cost of the crankshaft and increase the I.C engine performance.

Sanjay B Chikalthankar et al investigated stresses developed in crankshaft under dynamic loading. In this study a dynamic simulation was conducted on crankshaft, Finite element analysis was performed to obtain the variation of stress magnitude at critical locations. The pressure-volume diagram was used to calculate the load boundary condition in dynamic simulation model, and other simulation inputs were taken from the engine specification chart. This load was then applied to the FE model, and boundary conditions were applied according to the engine mounting conditions. The analysis was done for different engine speeds and as a result critical engine speed and critical region on the crankshaft were obtained. Stress variation over the engine cycle and the effect of torsional load in the analysis were investigated. Results obtained from the analysis are very useful in optimization of the crankshaft.

Sagar R Dharmadhikari, et al made modest attempt to review the optimization of Genetic Algorithm and ANSYS in their research report "Design and Analysis of Composite Drive Shaft using ANSYS and Genetic Algorithm". Drive shaft is the main component of drive system of an automobile. Conventional steel is substituted by composite material which has high specific strength and stiffness. The finite element analysis is used in this work to predict the deformation of shaft. Natural frequency using Bernoulli – Euler and Timoshenko beam theories was compared. The frequency calculated by Bernoulli – Euler theory is high because it neglects the effect of rotary inertia & transverse shear. Hence the single piece High Strength Carbon / Epoxy composite drive shaft has been proposed to design to replace the two piece conventional steel drive shaft of an automobile.

K.Thriveni et al made an attempt this paper to study the Static analysis on a crankshaft from a single cylinder 4-stroke I.C Engine. The model of the crankshaft is created using CATIA-V5 Software. Finite element analysis (FEA) is performed to obtain the variation of stress at critical locations of the crank shaft using the ANSYS software and applying the boundary conditions. Then the results are drawn Von-Mises stress induced in the crankshaft is 15.83Mpa and shear stress is induced in the crankshaft is 8.271Mpa. The Theoretical results are obtained. Von-Mises stress is 19.6Mpa, shear stress is 9.28Mpa. The validation of model is done by comparing with the Theoretical result. FEA results of Von-misses stress and shear stress are within the limits. Further it can be extended for the different materials and dynamic analysis, optimization of crank shaft.

Ashwani Kumar Singh et al conducted statics analysis on a nickel chrome steel and structural steel crank shafts from a single cylinder four stroke engine. Finite elements analysis was performed to obtain the variation of stress magnitude at critical locations. Three dimensional model of crankshaft was created in Pro/E software .The load was then applied to the FE model and boundary condition where applied as per the mounting conditions of the engine in the ANSYS Workbench Abhishek Sharma et al [10] in the present research work vibration analyses have been focused to detect crankshaft fault at the early stage, followed by the literature review of the shaft and the experimental methodologies. A simulation for the study of crankshaft is carried out by acquiring its fault signal and its fast Fourier transform is plotted to show the characteristics frequencies and its harmonics. A comparison of simulated data is also made to validate the experiment based condition monitoring.

2. DESIGN CALCULATION FOR CRANKSHAFT

The configuration of the diesel engine for crankshaft is tabulated in table - 1 belongs, V.Vijayakumar and T.Gopalkrishnan.

TABLE 1 SPECIFICATION OF ENGINE

1	Capacity	Cc
2	Number of cylinders	1
3	Bore stroke	Mm
4	Compression Ratio	
5	Maximum Power	hp
6	Maximum Torque	Nm
7	Maximum Gas Pressure	bar

A . Design of the crankshaft when the crank is at an angle of maximum twisting moment

(1)Force on piston
F=Area of the bore × Max. Combustion pressure
(2)In order to find the thrust in the connecting rod (FQ), we should first find out the angle of inclination of the connecting rod with the line of stroke (i.e. angle Ø).

$$\sin \emptyset = \frac{sin\theta}{\frac{L}{R}}$$

(3)Thrust in the connecting rod

$$\tan \theta = \frac{F_p}{\cos \emptyset}$$

Thrust on the crank shaft can be split into Tangential component and the radial component.
a. Tangential force on the crank shaft,
b. FT = FQ sin (Θ+ Ø)
c. Radial force on the crank shaft,
d. FR = F cos (Θ+ Ø)
(4) Reactions at bearings due to tangential force is given by
HT1 = HT2 =
(5)Similarly, reactions at bearings due to radial force isgiven by,
HR1 = HR2 =
B . Design Of Crankpin
(1)Let dc = diameter of crankpin in mmWe know that the bending moment at the centre of theCrankpin

$$M_c = H_{R1} \times b_2$$

From this we have the equivalent twisting moment

$$T_e = \sqrt{M_c^2 + T_c^2}$$

(2) We know that equivalent twisting moment

$$T_e = \frac{\pi}{16}(d_c^3) \times \tau$$

(3) Design of crank pin against fatigue loading Accordingto distortion energy theoryThe von Mises stress induced in the crank-pin is,

$$T_e = \sqrt{(K_b \times K_c) + \frac{1}{2}(K_t \times T_c)}$$

(4) Here, Kb = combined shock and fatigue factor forbendingKt = combined shock and fatigue factor for torsion

$$T_e = \frac{\pi}{32} \times d_c^3 \times 6\vartheta$$

3. PISTON MECHANISM

Piston is one of the main parts in the engine. Its purpose is to transfer force from expanding gas in the cylinder to the crankshaft via a connecting rod.

Since the piston is the main reciprocating part of an engine, its movement creates an imbalance. This imbalance generally manifests itself as a vibration, which causes the engine to be perceivably harsh. The friction between the walls of the cylinder and the piston rings eventually results in wear, reducing the effective life of the mechanism. The sound generated by a reciprocating engine can be intolerable and as a result, many reciprocating engines rely on heavy noise suppression equipment to diminish droning and loudness. To transmit the energy of the piston to the crank, the piston is connected to a connecting rod which is in turn connected to the crank. Because the linear movement of the piston must be converted to a rotational movement of the crank, mechanical loss is experienced as a consequence. Overall, this leads to a decrease in the overall efficiency of the combustion process. The motion of the crank shaft is not smooth, since energy supplied by the piston is not continuous and it is impulsive in nature. To address this, manufacturers fit heavy flywheels which supply constant inertia to the crank. Balance shafts are also fitted to some engines, and diminish the instability generated by the pistons movement. To supply the fuel and remove the exhaust fumes

from the cylinder there is a need for valves and camshafts. During opening and closing of the valves, mechanical noise and vibrations may be encountered.

Pistons are commonly made of a cast aluminum alloy for excellent and lightweight thermal conductivity. Thermal conductivity is the ability of a material to conduct and transfer heat. Aluminum expands when heated, and proper clearance must be provided to maintain free piston movement in the cylinder bore. Insufficient clearance can cause the piston to seize in the cylinder. Excessive clearance can cause a loss of compression and an increase in piston noise.

Piston features include the piston head, piston pin bore, piston pin, skirt, ring grooves, ring lands, and piston rings. The piston head is the top surface (closest to the cylinder head) of the piston which is subjected to tremendous forces and heat during normal engine operation.

A piston pin bore is a through hole in the side of the piston perpendicular to piston travel that receives the piston pin. A piston pin is a hollow shaft that connects the small end of the connecting rod to the piston. The skirt of a piston is the portion of the piston closest to the crankshaft that helps align the piston as it moves in the cylinder bore. Some skirts have profiles cut into them to reduce piston mass and to provide clearance for the rotating crankshaft counterweights.

PISTON

- Temperature at the center of piston head Tc = 2600c to 2900c
- Temperature at the edge of piston head Te = 1850c to 2150c
- Maximum gas pressure p = 15.454N/mm2
- Bore or outside diameter of piston D = 57mm
- Thickness of piston head $t_h = \sqrt{\frac{3pD\hat{}2}{16\sigma t}} = 5.45mm$

PISTON RINGS

A ring groove is a recessed area located around the perimeter of the piston that is used to retain a piston ring. Ring lands are the two parallel surfaces of the ring groove which function as the sealing surface for the piston ring. A piston ring is an expandable split ring used to provide a seal between the piston an the cylinder wall. Piston rings are commonly made from cast iron. Cast iron retains the integrity of its original shape under heat, load, and other dynamic forces. Piston rings seal the combustion chamber, conduct heat from the piston to the cylinder wall, and return oil to the crankcase. Piston ring size and configuration vary depending on engine design and cylinder material.

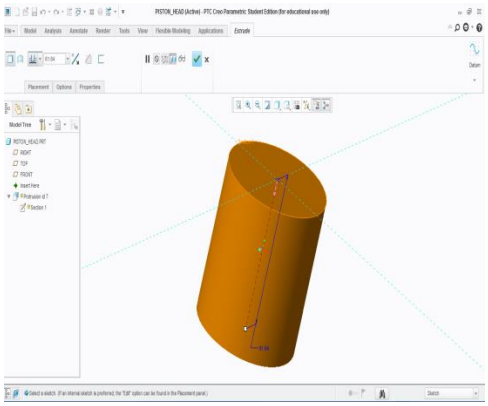
Piston rings commonly used on small engines include the compression ring, wiper ring, and oil ring. A compression ring is the piston ring located in the ring groove closest to the piston head. The compression ring seals the combustion chamber from any leakage during the combustion process. When the air-fuel mixture is ignited, pressure from combustion gases is applied to the piston head, forcing the piston toward the crankshaft. The pressurized gases travel through the gap between the cylinder wall and the piston and into the piston ring groove. Combustion gas pressure forces the piston ring against the cylinder wall to form a seal. Pressure applied to the piston ring is approximately proportional to the combustion gas pressure.

A wiper ring is the piston ring with a tapered face located in the ring groove between the compression ring and the oil ring. The wiper ring is used to further seal the combustion chamber and to wipe the cylinder wall clean of excess oil. Combustion gases that pass by the compression ring are stopped by the wiper ring.

An oil ring is the piston ring located in the ring groove closest to the crankcase. The oil ring is used to wipe excess oil from the cylinder wall during piston movement. Excess oil is returned through ring openings to the oil reservoir in the engine block. Two-stroke cycle engines do not require oil rings because lubrication is supplied by mixing oil in the gasoline, and an oil reservoir is not required.

Piston rings seal the combustion chamber, transferring heat to the cylinder wall and controlling oil consumption. A piston ring seals the combustion chamber through inherent and applied pressure. Inherent pressure is the internal spring force that expands a piston ring based on the design and properties of the material used. Inherent pressure requires a significant force needed to compress a piston ring to a smaller diameter. Inherent pressure is determined by the uncompressed or free piston ring gap. Free piston ring gap is the distance between the two ends of a piston ring in an uncompressed state. Typically, the greater the free piston ring gap, the more force the piston ring applies when compressed in the cylinder bore.

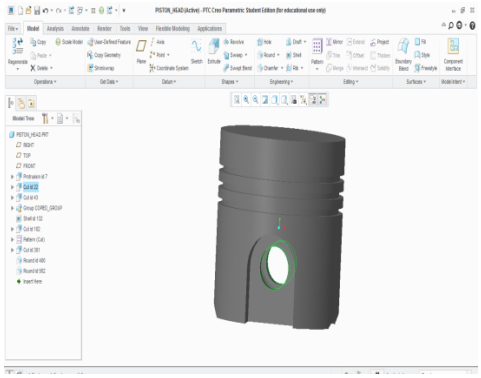
Copyright ⓒ 2019 SERSC



A piston ring must provide a predictable and positive radial fit between the cylinder wall and the running surface of the piston ring for an efficient seal. The radial fit is achieved by the inherent pressure of the piston ring. The piston ring must also maintain a seal on the piston ring lands.

In addition to inherent pressure, a piston ring seals the combustion chamber through applied pressure. Applied pressure is pressure applied from combustion gases to the piston ring, causing it to expand. Some piston rings have a chamfered edge opposite the running surface. This chamfered edge causes the piston ring to twist when not affected by combustion gas pressures.

The piston acts as the movable end of the combustion chamber and must withstand pressure fluctuations, thermal stress, and mechanical load. Piston material and design contribute to the overall durability and performance of an engine. Most pistons are made from die- or gravity-cast aluminum alloy. Cast aluminum alloy is lightweight and has good structural integrity and low manufacturing costs. The light weight of aluminum reduces the overall mass and force necessary to initiate and maintain acceleration of the piston. This allows the piston to utilize more of the force produced by combustion to power the application. Piston designs are based on benefits and compromises for optimum overall engine performance.



- P_W= pressure of the gas on the cylinder wall = 0.042N/mm^2
- σ_t= allowable bending(tensile stress) for cast iron rings = 110Mpa
- Radial thickness $t_1 = D\sqrt{\frac{3pw}{\sigma t}}$=1.93mm
- Axial thickness t_2 = D/10nr = 1.9mm
- nr = no of rings = 3
- width of the top land b1=6.54mm
- Distance between ring grooves,
- $b_2 = t_2$ = 1.9mm
- Total length of the piston
- L = length of the skirt * length of ring section + top land
- Length of ring section = 5 * b_2 or t_2 = 9.5mm
- L = 45.6 + 9.5 + 6.54 = 61.64mm

- Now start the designing of ―Piston ‖, Select Front plane > sketcher > sketching tools, Draw the sketch show below.

- Now select ―circle ‖ in ―sketching tools‖,Draw the profile of piston head with help of design procedure

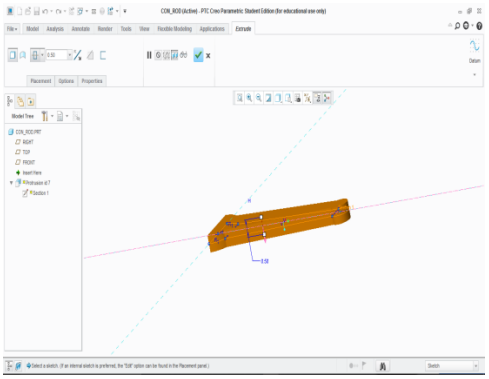
- **Final part model of piston head.**

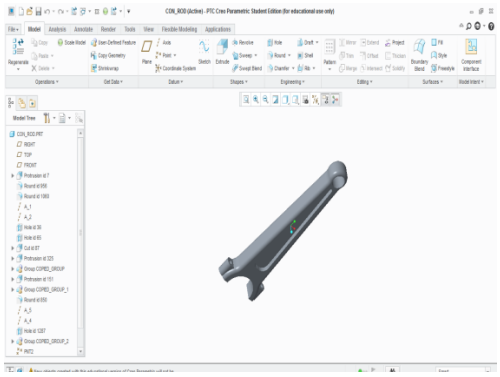
Designing of Connecting Rod



The connecting rod is a major link inside of a combustion engine. It connects the piston to the crankshaft and is responsible for transferring power from the piston to the crankshaft and sending it to the transmission. There are different types of materials and production methods used in the creation of connecting rods. The most common types of connecting rods are steel and aluminium. The most common type of manufacturing processes are casting, forging and powdered metallurgy.

The connecting rod is the most common cause of catastrophic engine failure. It is under an enormous amount of load pressure and is often the recipient of special care to ensure that it does not fail prematurely. The sharp edges are sanded smooth in an attempt to reduce stress risers on the rod. The connecting rod is also shot-peened, or hardened, to increase its strength against cracking. In most high-performance applications, the connecting rod is balanced to prevent unwanted harmonics from creating excessive wear.

The most common connecting rod found in production vehicle engines is a cast rod. This type of rod is created by pouring molten steel into a mould and then machining the finished product. This type of rod is reliable for lower horsepower-producing engines and is the least expensive to manufacture. The cast rod has been used in nearly every type of engine, from gasoline to diesel, with great success.



CONNECTING ROD

- Length of connecting rod = 2times the stroke L = 2 * 58.6 = 117.2mm
- Buckling load ,$W_b = (\sigma_c \, . \, A)/1+a[l/k_{xx}]2$
- Thickness of flange and web of the section t = 3.21mm
- Width of section B=4t=12.84mm
- Height of section H=5t=16.05=16mm
- Area $A=11t^2=113.3mm$
- Height of the big end (crank end)=H_2=1.1H to 1.25H
- H2=20mm
- Height at the small end (piston end)=0.9H
- H_1=14.4mm

- We can made the above sketch with help of line command.

4. INTRODUCTION TO ANSY

The ANSYS program is self-contained general purpose finite element program developed and maintained by Swason analysis systems Inc. The program contain many routines, all inter related and all for main purpose of achieving a solution to an engineering problem by finite element method.

ANSYS finite element analysis software enables engineers to perform the fallowing tasks:

- Build computer model or transfer models of structures, products, components, or system.
- Apply operating loads or other design performance conditions.
- Study physical responses, such as stress levels, temperature distributions, or electromagnetic fields.

Optimize a design early in the development process to reduce production costs.

- Do prototype testing in environments where it otherwise would be undesirable or impossible.

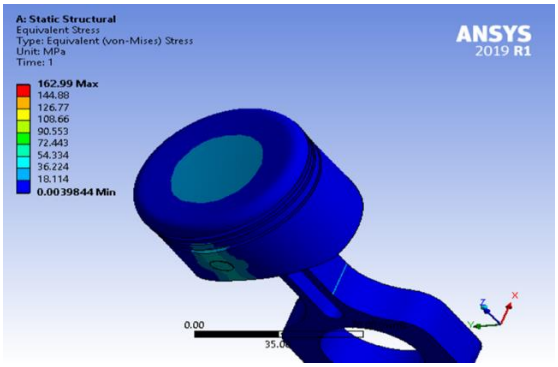
The ANSYS program has a compressive graphical user interface (GUI) that gives users easy, interactive access to program functions, commands, documentation and reference material. An intuitive menu system helps users navigate through the ANSYS program. Users can input data using a mouse, a keyboard, or a combination of both. A graphical user interface throughout the program, to guide new users through the learning process and provide more experienced users with multiple windows, pull-down menus, dialog boxes, tool bar and online documentation.

1. Pre-processor
2. Solutions
3. Post processor

Pre-processing:

The input data for an ANSYS analysis are prepared using a pre-processor. The general pre-processor (PREP 7) contains powerful solid modelling and mesh generation capabilities, and is also used to define all other analysis data with the benefit of data base definition and manipulation of analysis data. Parametric input, user files, macros and extensive online documentation are also available, providing more tolls and flexibility for the analyst to define the problem. Extensive graphics capability is available throughout the ANSYS program, including isometric, perceptive, section, edge and hidden-line displays of three-dimensional structures-y graphs of input quantities and results, and contour displays of solution results.

The pre-processor stage involves the following:



- Specify the title, which is the name of the problem. This is optional but very useful, especially if a number of design iterations are to be completed on the same base mode.
- Setting the type of analysis to be used e.g., structural, thermal, fluid, or electromagnetic, etc.
- Creating the model: The model may be created in pre-processor, or it can be imported from another CAD drafting package via a neutral file format.
- Defining element type: these chosen from element library.
- Assigning real constants and material properties like young`s modules, Poisson’s ratio, density, thermal conductivity, damping effect, specific heat, etc.

Apply mesh: Mesh generation is the process of dividing the analysis continuum into number of discrete parts of finite elements.

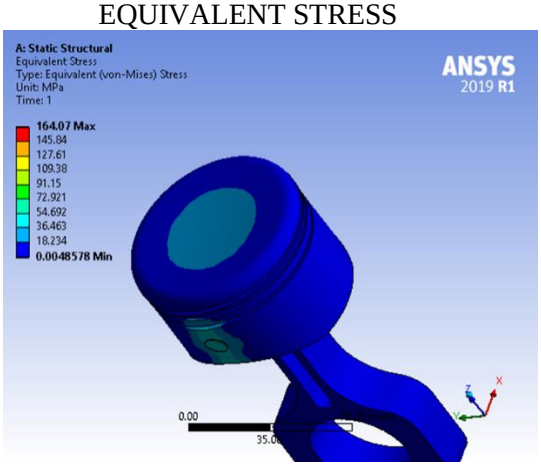
5. RESULTS AND ANALYSIS

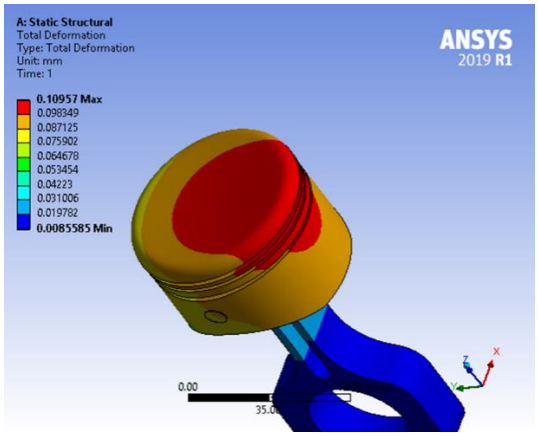
EQUIVALENT STRESS

TOTAL DEFORMATION



Structural aluminium

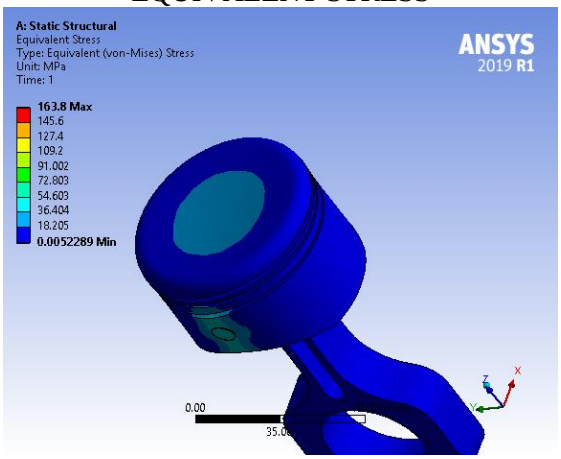
- **Properties of aluminium**



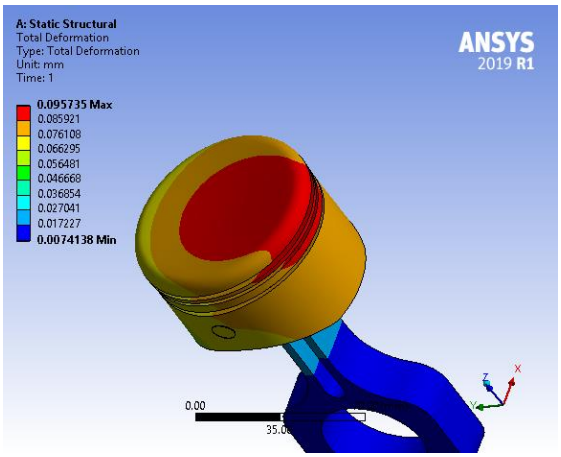
Melting point -933.47k
Boilling point-2743k
Density -2.70g/cm^3
Thermal conductivity-237w/(m-k)
Young's modulus -70Gpa
Shear modulus -26Gpa
Bulk modulus -76Gpa
Poisson ratio -0.35

EQUIVALENT STRESS

TOTAL DEFORMATION



Copyright ⓒ 2019 SERSC



Properties of Copper alloy

Melting point -1357.77k
Boiling point-2835k
Density -8.96g/cm^3
Thermal conductivity-237w/(m-k)
Young's modulus -110-120Gpa
Shear modulus -48Gpa
Bulk modulus -140Gpa
Poisson ratio -0.35

EQUIVALENT STRESS

TOTAL DEFORMATION

Copyright ⓒ 2019 SERSC

	Structural steel	Aluminium Alloy	Copper Alloy
Max. Stress (N/mm^2)	162.99	164.07	163.8
T.D(mm)	0.086	0.10095	0.095

CONCLUSION:

From the above structural analysis three different materials i.e., structural steel, Aluminium alloy and copper alloy by using ANSYS software. it is observed that the equivalent stress and total deformation varies for every material. From the table it is seen that under same load conditions structural steel has minimum equivalent stress than other two as compared to their material properties. Above Results Shows that FEA Results Conformal matches with the theoretical calculation so we can say that FEA is a good tool to reduce time consuming theoretical Work. The maximum deformation appears at the centre of crankpin neck surface.

Smart Applications using Robotic and Iot Technologies in Fighting against Pandemic Covid19 in Medical and Societal Sectors

Rajesh. K, M. GopiKrishna, V.R.Rao, P.Pavani, C.Chandrasekhara

Abstract*: During the past few months, the entire world is being suffering with a dangerous deadly virus named Covid19 or Coronavirus. This pandemic corona virus has washed out thousands and lakhs of people all over the world within months' time and made all the countries GDP and economic growth collapsed. Accordingly, in India and other countries an important research and innovation investments have been made by various science and technological laboratories that are collaborated with various private and government stakeholders to find new ways to eliminate or kill the pandemic corona virus in human bodies and society. All over the world, the doctors and scientists are working very hard to reduce the rate of death and control the rate of corona spread. Alternatively, the engineers, entrepreneurs, industrialists, technocrats are sorting out and finding new ways to bridge the gap between science and technology by inventing new methods and measurements in medical, societal and service sectors The purpose of the proposed study is to showcase the opportunities of using engineering technology in biomedical and societal applications taking all over the world caused by the corona attack. The introduction of Robots and IOTs made the industries and firms fully smart automated and digitalized. In other perspective, robots were also serving medical sectors since many years successfully in heart surgeries, fighting cancer cells etc. and making the footprints for further research and developments. An attempt is made to highlight the methods and applications of Robots & IOT's in large extent in medical and societal areas to safeguard from coronavirus

***Keyword*: Coronavirus, Covid19, IOTs, Robots, Virus evolution**
Dur

I. INTRODUCTION

The current scenario point out that the role of using Robotic technology and Internet of things for the outbreak of Covid19 is very crucial and essential in hospital and societal sectors. This pandemic gave a huge disaster in all the countries leaving dangerous footprint for the next coming years. It is the time for engineers, scientists, and researchers to innovate new methodologies, concepts and ideas making the robots and IOT technology to stand in the front line to serve the virus affected people. As covid19 is a deadly disease like Ebola virus which affected many people lives all over the world. This created a need for developing new technology in the field of Robotics and IOT for serving people in various ways, as they are disinfectant to the coronavirus than human beings.

A. Statement of the Problem

Today the entire world is facing a major epidemic with a wide spread of coronavirus originated from Wuhan, China. The majority of countries are under the lockdown facing a severe disaster of losing economy and people on a large scale. In order to reduce the severity of virus spread, there is huge need of deploying Robots and IOT technologies as they stand in the front line saving the human labor to get infected from the coronavirus as these are highly immune to coronavirus. In this view, different types of research and innovation works are to be carried out to safeguard the people and serve the corona affected patients. The main objectives of the study are: To know the evolution of virus. To get awareness about coronavirus. Use of Robotic and IoT technologies.

II. LITERATURE REVIEW

During the Ebola outbreak that began in 2014, the White house office of science and technology policy and National Science foundation, organized workshops to identify various ways in which robots could make a difference. Guang-zhong yang, [1] dean of the institute of medical robotics at Shanghai Jiao Tong University, said during the epidemic, we really need to ensure that we have a global orchestrated sustainable approach to robotics research. Robots could occupy the place of health workers in certain circumstances, like administering tests who are infected with coronavirus and silent infection is the biggest problem. It helps that robots don't get sick and unless they run out of power, they do not sleep-Yang said. Russel Taylor, a roboticist at johns Hopkins University said sending a remotely operated robot to interact with the patient instead could dramatically reduce the risk. After all, robots are immune to biological pathogens and can be efficiently disinfected with harsh chemicals. In this scenario, engineers would not design a robot specifically for the COVID19 pandemic but the trick is to find solutions that can be broadly commercialized for the next system in the ways that they are economical to have around.

Bill Smart,[1] a roboticist at Oregon State University, explained "you're not directly interacting with the patients where it could go really wrong if the robots breaks, and you're also not denying the patient human contact. He also said robots could still help minimize the risk for front line medical staffers, use of drones by IOT to transport medicine within the hospitals or using robots to deliver meals. Robin Murphy, a roboticist at Texas A&M University, said today investing in robotics development is a lot like investing in a large snowplow. It is expensive and not put to use for much of the year, but when a big snowstorm hits, it proves it worth. It's akin to a problem faced by the scientists who works on vaccines and treatments for emerging infectious diseases. If research into the coronavirus responsible for the outbreaks of SARS and MERS hadn't dried up, options for fighting COVID19 would have been more readily available says many scientists[1]. Computer vision and technology has gotten better, IOT enablers like sensing capabilities, tracking capabilities, scanning capabilities, mobile apps capabilities has gone better, and artificial intelligence has gone even smarter and all this translates into more potential for putting robots into good usage.

III. VIRUS CONTEXT

The study of virus is known as Virology. It is a subfield of microbiology and focuses on the aspects of virus structure, classification and evolution. The word "virus" came from Latin meaning "poison or venom". Viruses were detected after bacteria. Most of viruses range from 20-400NM in size. Special fine filters which hold bacterial cells were impossible to remove infectious agents, which are known as filterable viruses. Viruses have very simple structure and can only be observed by an electron microscope, NMR spectroscopy and X-ray crystallography: the virus particle or virion which has protective outer shell protein and an inner core of DNA (Deoxyribonucleic Acid) or RNA (Ribonucleic Acid). It doesn't need any energy to grow, cunningly it uses biochemical machinery of the host cell to reproduce and the infected cell is killed. The main viral properties are: they are non-living entities, they do not have genetic capability to multiply by division, they cannot make energy or proteins independent of host cell, viral genome are RNA or DNA but not both, they are stable in hostile and dry environment, not damaged by drying, acid, detergent, and heat. It can spread easily via hands, dust fomites, etc., [2] Most of the viruses can be transmitted by respiratory transmission (influenza-A), Faucal-oral transmission (enterovirus), Blood-borne transmission (hepatitis-B), sexual transmission (HIV), animal or insect vectors (rabies). The five basic viral structures are: Icosahedral, enveloped icosahedral, helical, enveloped helical and complex structure shown in the figure (source: Mechanics of microbial disease by Schaechter)

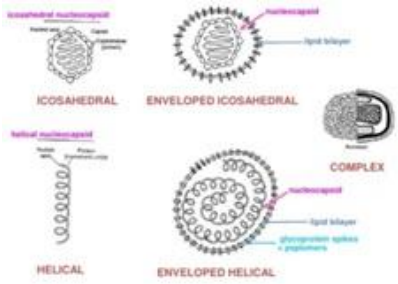

Fig.1. Types of viral structures

Viruses can be classified in many ways: 1.According to host cells they infect-animal, plant, fungal and bacteriophages.2.According to geometrical shape of their capsid, phenotypic characteristics such as morphology, structure, nuclei acid, and viral replication.3. According to Baltimore classification it can be divided into seven categories- double strand DNA viruses, single strand DNA viruses, double strand RNA viruses, positive sense ssRNA, negative sense ssRNA, RNA reverse transcribing viruses and DNA reverse transcribing viruses.4. According to Holmes classification it has three groups- Group-1: Phaginae (attacks bacteria),Group-2:Phytophaginae(attacksplants),Group-3:Zo ophaginae(attacks animals)[3]. The virus infection cycle has following steps: Adsorption or Attachment, Penetration, Biosynthesis of viral nuclei acid and protein, Assembly or Maturation and Release, depicted in the figure:

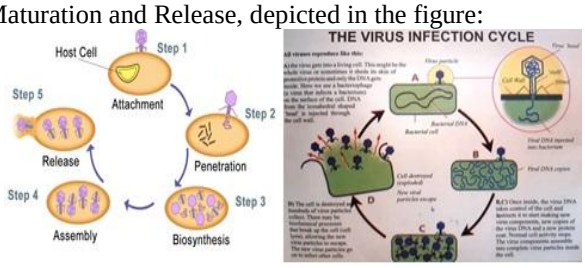

Fig.2. Viral Infection Cycle

In recent decades, several viruses have jumped from animals to human beings and spotted sizable outbreaks, adhering thousands and lakhs of people. The major deadly killer viruses are : Marburg virus (1967, Germany), Ebola virus (1976, Sudan), Rabies virus(1920, India & Africa), HIV virus(1980, Africa), Smallpox virus (1980, Europe), Hanta virus(1993, USA), Influenza (1918, Spanish flu), Dengue(1950, Philippines), Rotavirus(2008), MERS-CoV(2012,SaudiArabia),SARS-CoV(2003,China), SARS-CoV-2(2019, China)[4].

A. Coronavirus Evolution

The name "coronavirus" was derived from Latin word meaning "crown" or "wreath"[48].This name was first used in 1968 by an informal group of virology people in the journal "Nature to designate the new family of viruses." The name refers to the characteristic appearance of an infective form of the virus (virions) which have a large, bulbous surface projection making an image reminiscent of a solar carona [49]. Coronaviruses was first discovered in the year 1930 when an acute respiratory infection of domesticated chickens was shown to be caused by infectious bronchitis virus (IBV)[50]. The structure of Coronavirus is a large spherical particles with bulbous surface projections [51].

The average diameter of the virus particles are about .12 μm (120 nm) and the diameter of the envelope is about .08 μm(80 nm) and the spikes are .02 μm(20 nm) long.

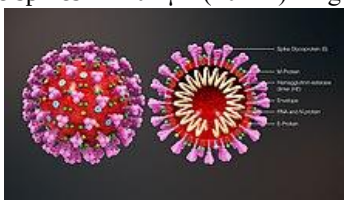

Fig.3. Structure and cross section view of coronavirus

Coronaviruses cause diseases in birds and mammals. But in humans, they cause respiratory tract infections that can range from mild to severe. Mild sickness includes cases of the common cold and fever while more severe sickness can cause severe acute respiratory syndrome (SARS) and sore throat infections. Evolutionary stages: The most recent common ancestor of all coronaviruses was existed as recently as 8000 BCE, implying long term coevolution with bat and avian species [52]. Bats and birds, which are warm-blooded flying vertebrates, are an ideal natural reservoir for the coronavirus pool.

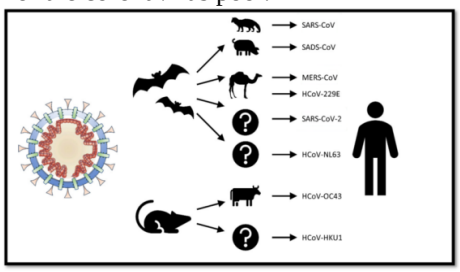

Fig.4. Origin of coronavirus

B. Human Coronavirus

The risk factor of human coronavirus may vary significantly. Some may kill more than 30% of those infected like MERS-CoV, and some were relatively harmless with common cold[53].Some viruses may cause colds with major symptoms like severe fever, sore throat from swollen adenoids [54]. Moreover, seven different species of human coronaviruses are known yet. Out of which four viruses produce symptoms which generally mild and three produce symptoms which are very severe [55].They are 1. Human coronavirus OC43, (HCoV-OC43).2.Human coronavirus HKU1, (HCoV-HKU1). 3. Human coronavirus 229E, (HCoV-229E).4. Human coronavirus NL63, (HCoV-NL63). 5. Middle east respiratory syndrome related coronavirus, (MERS-CoV).6.Severe acute respiratory syndrome coronavirus,(SARS-CoV).7. Severe acute respiratory syndrome coronavirus 2, (SARS-CoV-2). SARS-CoV-2 belongs to large family of viruses SARS-CoV, known as "Coronaviruses" and was first identified in Chinese city, Wuhan in December 2019. These viruses likely originated from bats like SARS-CoV and passes through an intermediate animal before infecting human beings. The disease caused by SARS-CoV-2 called COVID-19. [4]

IV. ROBOTICS CONTEXT

Robotics engineering is a field of engineering which deals with design, construction, application and operation of robots. The mechanism behind robots is called robotics. The robotics goal is to design intelligent machines that help and assist human beings in their day-to-day life and keep us everyone safe and secure. Actually, robotics is an integration of computer, information, electrical, electronic and mechanical engineering. The robotics was derived from the word "robot" means a slave or servant to humans was coined by Czech writer and novelist Karel capek in his paly Rossum's Universal Robots(R.U.R) published in 1920[5].Later Sir Isaac Asimov, a biochemistry professor has proposed three laws and later added zeroth law in his "Runaround "science fiction. Law 0: A robot may not injure humanity or allow humanity to come to harm. Law 1: A robot may not injure human being, unless said by high order law. Law 2: A robot must obey orders given to it by his master. Law 3: A robot must protect itself from its own existence. A robot is defined as a reprogrammable, multifunctional manipulator designed to move materials, parts, tools or specialized devices through variable programmed motions for the performance of variety of tasks [Robot institute of America, 1979] .To design and operate a robot a typical knowledge base system is required: dynamic system modeling and analysis, feedback control system, sensors and signal conditioning, hardware interfacing, actuators and power electronics and computer programming. The key components of a robot manipulator are base, linkage, controller, power conversion unit, sensors, actuators and user interface. Based on the mechanical structure robots are classified as: Cartesian robot which has three linear prismatic joints, Cylindrical robot which has cylindrical coordinate system, Spherical robot which has rotary coordinate system, SCARA which has two rotary and one linear joint and Articulated robot which has three rotary 3d motion just like a human hand.

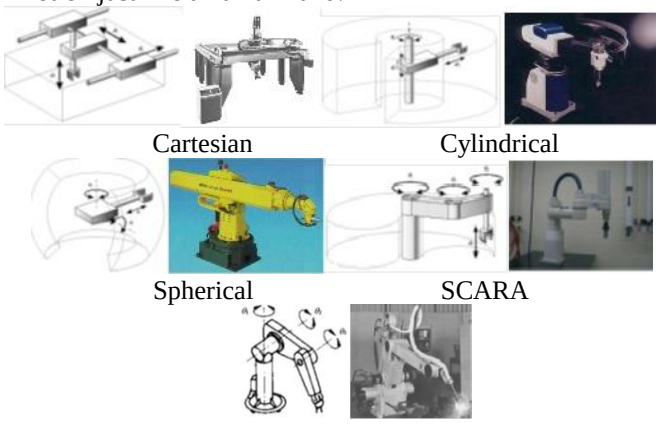

Fig. 5. Classification by mechanical structure [6]

Based on the configuration of robot manipulators, the control systems are designed: limited sequence, playback with point-to-point, playback with continuous path control and intelligent control. The different types of robots have different ways of programming methods such as: lead through (powered and manual) programming, robot programming languages, simulation and off-line programming[7]. Why do we need robots? Tim detert [8] said, we need robots for 4D environments (dangerous, difficulty, dull, dirty) and for 4A tasks(automation,augmentation, autonomous, assistance).The general features and characteristics which should acquire for a robot are: repetitive work cycles, multi shift operations, infrequent changeovers, difficult handling tasks for humans, hazardous work environment for humans and part position and orientation in the work cell.

Bases upon the design, specific task, environment and payloads the current and potential industrial applications include: agriculture, automobile, construction, domestic, entertainment, health care, kitchen automaton, laboratories, law enforcement, manufacturing, military, mining, transportations, utilities, warehouses etc. The usage of robots in various industrial and service sectors in worldwide market is shown below [8].

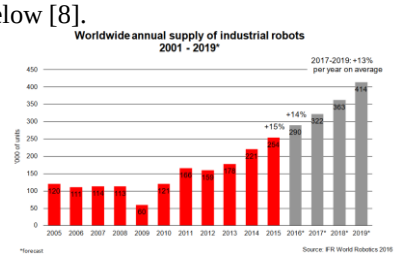

Fig.6. Bar chart of Annual supply of Robots

V. INTERNET OF THINGS CONTEXT

The IOT concept was coined by a member of the Radio Frequency Identification development (RFID) community in 1999, and it has recently become more relevant to the practical world largely because of the growth of embedded and ubiquitous communication, mobile devices, cloud computing and data analytics [9].According to CICSCO, Internet of things is the network of physical objects accessed through through internet, as defined by technology analysts and visionaries. These objects contain embedded technology to interact with internal states or external environment. In simple, it is a network or linking of physical objects. The internet means not only a network of computers, but has evolved into a network of device of all types of sizes of smart phones, vehicles, toys, cameras, home appliances, industrial systems, animals, people, buildings, all sharing and communicating information based on standard protocols in order to get smart real time online monitoring, online upgrades, smart reorganizations, positioning, tracking, process control and online administration[10]. IOT can be categorized into three stages according to the definition: 1.People-to-people(P2P).2.People-to-machines(P2M).3.Mac hine-to-machine(M2M), interacting to internet facilities. The Internet of Things is more than machine to machine communication, sensor networks, wireless sensor networks, , 2G/3G/4G,GSM,GPRS,RFID, WI-FI, GPS, microprocessor , microcontroller, etc. and these are considered as being the enabling technologies that make IOT applications possible. Enabled technologies (ET) considered in [10] can be classified into three broad categories: 1 technologies that enable things to acquire contextual information, 2.technologies that enable things to process contextual information, and 3. Technologies to improve security and privacy. The fundamental characteristics to enable the services of IOT are as follows: connectivity, dynamic changes, enormous scale, heterogeneity, interconnectivity, safety and things related services [11].

A. IOT Architecture

It has different layers of technologies which supports IOT and serves to showcase how various technologies relate to each other and to communicate the configuration, modularity and scalability. The functionality of each layer is described as: 1. Smart sensor layer-lowest layer where smart devices are integrated with sensors and these are having capacities to make measurement such as air quality, speed, humidity, temperature, pressure, flow and movement etc. Most sensors require connectivity to sensor gateways in the form of LAN such as Wi-Fi, Ethernet, personal area network, ZigBee, Bluetooth and ultra-wide band. The sensors which do not require connectivity to backend servers can be provided using WAN such as GSM, GPRS and LTE.2. Gateways and Networks-To transport the massive data, it requires robust and high performance wired or wireless network infrastructure. The various networks are WI-FI, GSM, GPRS and gateways are microcontroller and microprocessor etc.3. Management service layer-Data management is the ability to manage data information flow. 4. Application layer-It covers all smart environments, spaces in the domains such as Agriculture, Supply chain, User interaction, Emergency etc. The figure shows the detailed architecture of Internet of things. [12]

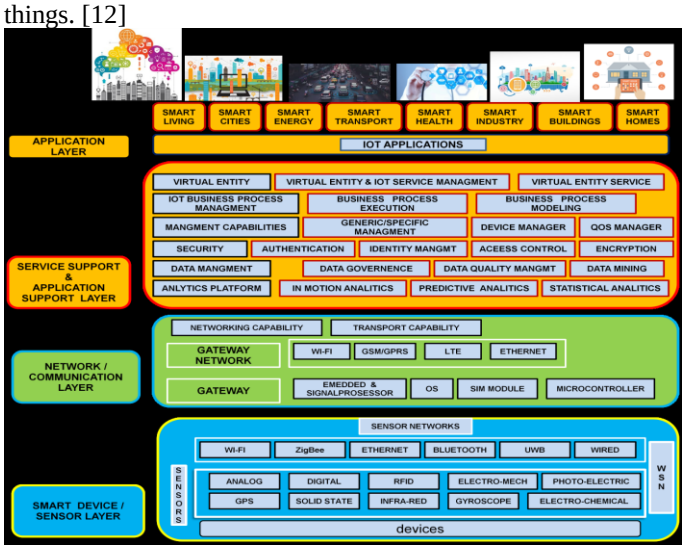

Fig.7. Internet of Things Architectural landscape

IOT has countless benefits for both businesses and consumers are such as automation and control, better human productivity, improved equipment maintenance, operations optimization and automation, comfort and convenience, time saving and money, use of telematics, efficient resource utilization, better tracking and management and access to high quality data[13].The goal of the Internet of Things is to enable things to be connected anyplace, anytime, with anyone and anything ideally using any network and any service[14]. The goals and applications of IOT are shown in the figure[14]15]:

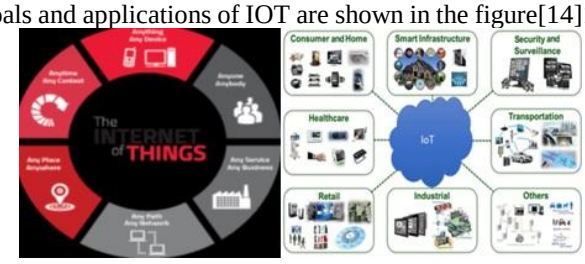

Fig. 8. Goals and Applications of IOT

VI. ROBTOIC TECHNOLGY IN COVID19

The rapid spread of human coronavirus has forced all the countries to apply each and every technology into health care and security surveillance in the society. The use of robots, drones and artificial intelligence technologies are being deployed across the globe to fight against the covid19 pandemic.

As Robotic engineering is still a developing field, many researches, surveys and experiments are being done in the field of health care sector. The robots are standing in the front line in minimizing the risk for medical staff in all applications as they are more immune to contagious spread than human beings. According to the robot structural configuration, there are three major types: stationary (industrial), legged and mobile robots are generally used in many of the manufacturing companies. As per the hospital and service sectors, mobile robots are viable and used widely for coronavirus.

A. Methods and Applications of High-tech Robots in Covid19

UV light Disinfectant Robot: Due to the demand shortage of a thin layer of Personal Protection Equipment (PPE) such as gowns, hand gloves, face masks in the hospitals for medical staff, robots can used to kill coronavirus on their PPEs by sending UV light rays and can be further reused: Virginia Commonwealth University Health system (VCU), America has invented a robot called, called Total Room Ultraviolet Disinfection (TRU-D), stands 5'6" tall which is a mobile robot has sensors and wheels attached to the large frame and fragile uses ultraviolet germicidal irradiation (UV) light vectors to disinfect porous and non-porous surfaces without using of toxic chemicals. The high energy from UV light is absorbed in the cellular RNA and DNA of microorganisms, damaging nucleic acids and preventing them from reproducing therefore they cannot infect humans or PPEs [16].The autonomous UV mobile robots, known as Sunburst UV bots, made by local robotics technology firm PBA Group, built with a lamp module emitting powerful UV-C light helps decontaminate the environment by tearing apart strands of virus DNA. It kills about 99% of bacteria and clinically proven to eliminate coronavirus. The robots move around the places autonomously, guided by light detection, ranging sensors and also self-navigates to its charging station when power is low and can operate for 2.5 hours on a single charge. These can be widely used in commercial places like: hospitals, shopping malls, supermarkets, transport etc. [17] A Denmark based, Danish Technological institute has made Ultraviolet disinfectant (UVD) mobile robot that kills harmful microorganisms and be in a high demand since the corona outbreak. It works autonomously covering all surfaces with UV-C light kills 99.9% of viruses and bacteria within 10minutes [18]. An U.S.based GermFalcon mobile robot, from Dimer UVC innovations is also offering a similar UV disinfection solution for aircraft services that kills bacteria, viruses and superbugs on any exposed area in the aircrafts. It kills 99.99% of viruses within 3minutes on B737/A320 by UV-C light [19]. In Wuhan, Chinese based TMiRob's disinfection autonomous mobile robot, moves around the patients' area and kill the viruses during the ongoing fight against the novel coronavirus[20]

Fig. 9. TruD Sun burst UV, UVD, GermFalcon, TMiRob

2.Delivery Robots: Majority of countries like China, Europe, US, India are using mobile robots to replace and help humans fight coronavirus by delivering PPEs, food, groceries, medicines etc., in hospitals, quarantine centers, public places and nursing homes etc., Postmates, mobile delivery robots deliver food in Los Angles. Beijing-based Zhen Robotics uses yellow robots to deliver groceries. Indian based startup Asimov Robotics, lunched two robots to distribute face masks and hand sanitizer in hospitals, quarantine centers to spread awareness of coronavirus [21]

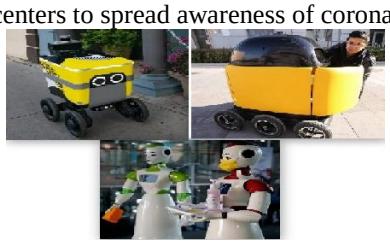

Fig.10. Postmates, Yellow robots, Asimov's

3. Sanitary Robots: There is an urgent need for cleaning and purifying the hospital areas, public areas, shopping malls, airports etc., due to the spread of pandemic coronavirus outbreak all over the world. Scientists and engineers are developing new methods of spraying disinfectant chemicals on the surfaces with the help of mobile robots. Some of the technologies are listed below: Researchers from Nanyang Technological University (NTU), Singapore have developed a wheeled robot named eXtreme Disinfection robot (XDBOT) which can navigate semi-autonomously in any type of environment using LIDAR sensors, hd cameras, a 6-axis articulated arm is controlled by human operator, a large tank with a rotating turret, an electrostatic charged nozzle and can move to 30-50metres with a rotating turret. NTU is still working with Transforma robotics, Hand plus and Maju robotics for news types of sanitary robots [22]. Hangzhou, china using disinfectant robots in large areas. Beijing-based Zhen Robotics, uses yellow robots patrol malls for people not wearing face masks and identifies the temperature reading.[21]

Fig.11. XdBot, Hangzhou, and Zhen robots

4. Surveillance Robots: During the corona outbreak, countries are using patrolling mobile robots in the public areas, common places etc., in order to prevent the risk factor.

These robots alert the people and ask quires related to the lockdown and safeguard human lives. PGuard, the "robocop" [23] initiated by Tunisia's interior ministry, is a remotely operated and equipped with infrared and thermal imaging cameras, sound and light alarm system. It serves like calling out to suspected violators of the lockdown: "What are you doing? Show me you're ID. You don't know there is a lockdown?" A patrol mobile robot "LISOM" in Shenyang, china, hospital checks disinfectant people, temperatures and spaces and sends the alerts to the required personal [21].

Fig.12. PGuard, Lisom robots

5. Delivery and Patrol Drones: A drone is a robot, which is guided remotely or autonomously, often termed unmanned aerial vehicle(UAV) used to deliver food, medicine, goods, transport packages, patrolling and spying etc., in all diversified fields of healthcare, agriculture, film making,military,cargotransport,surveying, demining, target practice and so on. During the corona outbreak, many countries are widely using the services rendered by drones: Shenzhen company MicroMulticopter, deployed more than 100 drones to Chinese cities for patrolling in crowds and traffic areas and identifies who are not wearing masks, spraying disinfectant in public areas, identifying infected coronavirus people having elevated temperature by using thermal sensors.[24]Medtech companies are using robots and drones to provide services and care to quarantined or practicing social distancing. Japanese company Terra Drone ensured medical and other supplies were safely transported without exposing to humans to infection. According to the report by GPS world, using drones speeds up transport by 50% compared to road transport. In the corona outbreak, use of drones and robots would become increasingly essential support for humans in fighting the virus.[24] The figure shows the delivery of medicines by a drone.

Fig. 13. Medical kit delivery drone

VII. IOT TECHNOLGY IN COVID19

At present everyone is aware about the dangerous killer of human species spreading all over the world from the past few months originated from china. Many of the lives were destroyed without mere awareness about their control and diagnostics. As WHO announced it is a pandemic and all governments of the countries are scrambling to keep their citizens safe and secure. Presently, the Internet of things is being used for treatment, curing, diagnosing and detection of coronavirus. The IOT enabled services which are currently being used in detecting and destroying the Covid19 in all the major countries are discussed below.

1. Smart Image processing IOsIP): It is a form of signal processing where the input and output of image processing be a set of characteristics or parameters related to the image [25]. It is a technique to enhance the raw images received from sensors, cameras placed on space robots, satellites, aircrafts, video cameras, cell phones and pictures of day-to-day life of various applications. Image Processing systems are becoming popular due to easy availability of graphics software, powerful personnel computers, large size memory devices, etc. There are two methods available in image processing sequence: analog and digital image processing. The Various techniques used are: image representation, image pre-processing, image enhancement, image restoration, image analysis, image reconstructions and image data compression. The major applications in this field are: document processing, graphic arts, printing industry, remote sensing, non-destructive analysis, forensic studies, material science, film industry, military and medical imaging etc. [26].

2. Smart CCTV (IOsTV): Closed-circuit television, also known as video surveillance, use of video cameras to transmit the signals to the specific place, on limited set of monitors.[27]CCTV systems provide surveillance capabilities used in the protection of assets, systems and people. The systems have many components with a variety of functions, features, and specifications. Key components include cameras, lenses, data distribution, housings and mounts, monitors, switchers, multiplexers and video recorders. The components of CCTV are shown below:

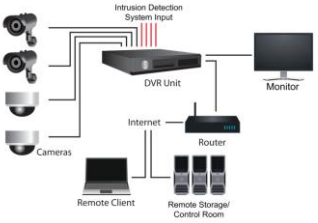

Fig.14. CCTV Component diagram structure

3. Smart Mobile Applications (IOsMA): A mobile application, simply referred as a mobile app is a software application or computer program designed to run on mobile devices like cell phones, tablets and watches. In 2010, American dialect society [28] termed software application as "app" shortly and was listed as a "word of the year". In 2014, government regulatory agencies began trying to regulate and curate applications particularly medical applications. [29] Mobile applications are classified by many methods: Native app, Web-based apps and Hybrid Apps. Most of the devices are sold with many pre-installed apps, such as web browser, email, calendar etc. and the apps which are not pre-installed are available usually through platforms called app stores. The three biggest app stores used in mobile and laptops are Google paly for android, App store for IOS and Microsoft store for windows10 and many more other apps are listed: amazon appstore, blackberry world,ovi for nokia, Samsung apps, electronic app wrapper, f-droid and opera mobile store.

4. Smart Telemedicine (IOsT): Modern information and communication technologies such as computers, cellphones gives how individuals communicate each other, seeking and exchange information and enriching their lives. These technologies have high potential globally to address health problems all over the world. Telemedicine is a term coined in the year 1970, literally means "healing at a distance" [30] signifies the use of IOT & ICTs to improve patient outcomes by increasing access to medical care and information. It is defined as the delivery of health care services, where distance is a

critical factor, by all health care professionals using IOT for the exchange of valid information for diagnosis, treatment and prevention of disease and injuries, research and evaluation, and for continuing education of health care providers, all in the interests of advancing the health of individuals and communities. [31] Telemedicine applications are of two types: according to the timing of information transmitted and according to the interaction between the individuals involved. [32] The majority of telemedicine services focus on diagnosis and clinical management in the array of services like tele radiology, tele pathology, tele dermatology, and tele psychiatry. The information transmitted from telemedicine through IOT can be done in wide variety of media like audio, video, text and images.[33]

5. Smart Human Tracking (IOsHT): Smart monitoring systems have evolved to respond for particular needs in healthcare sector. A tracking system is used for observing the objects and people while in motion and supplying a timely ordered sequence of location data for further processing. Recent advancements in mobile technology allow Global positioning System (GPS), Radio frequency identification (RFID), Real-time location systems (RLTS) and Global mobile system (GSM) provides a real-time location based services for vehicles, assets and humans in various applications. Global positioning system is a satellite navigation system used to determine the ground position of any object. A GPS navigation device [34] is carried by a moving animal or person or vehicle that uses GPS to track the device's movements and determine its location. Mobile applications have three types of GPS trackers: data loggers, data pushers and data pullers. RFID uses electromagnetic fields to automatically identify and track tags attached to the objects or humans. A tag consists of tiny radio transponder, a radio receiver and transmitter. It is one method of automatic identification and data capture (AIDC)[35]. RFID can be used in a wide variety of industrial and domestic applications such as[36][37] access management, tracking of goods, animals and humans, tracking and billing processes, machine readable travel documents, airport baggage tracking, retail management, advertising and promotion tracking, transportation and logistics , human implantation, animal identification, institutions like hospitals, healthcare, libraries, schools and universities, museums and sports.

6. Smart AI Thermal Scanners (IOsTS): These are body temperature detection devices used for detecting elevated temperatures in human body located at different places. These thermographic cameras use infrared radiation from the image created just like normal camera which use visible light. Thermal scanners are integrated with Artificial Intelligence analytics connected to automated web and mobile application alerting. These scanners can be equipped with robots and drones which can works on ground and aerial surveys. These can be applied in many fields like: thermal mapping, medical imaging, non-destructive testing, night vison and tracking etc. As the covid19 pandemic goes rampant across the globe many engineers, researchers, startup companies are seriously involving in launching various AI based thermal tracking devices in hospitals, shopping malls, schools, universities, offices etc.

A. Methods and Applications of IOTs in Covid19

The various real-time applications using IOT technologies across the globe are listed below:

1. A government of India initiative, "Arogya Sethu" app is designed to assist citizens from contact with any infected covid19 person. The app uses GPS and Bluetooth on a smartphone to get the live updates. MapMyIndia, has created "covid19 dashboard" app, it provides state-wise data, treatment centres, isolation centres, hunger relief centres, relief camps on the map [38].

2. A.P launches 'YSR Telemedicine', facility which helps health department to track the symptoms of covid19 people.Dial14410, is the helpline where a doctor will respond through audio or video conference and prescribes the medicines and tests through sms [39].

3. Cambridge and Manchester University [40] launches Firetinas, the first A.I. Thermal scanner against covid19.It uses distance radiation algorithm, so that far way temperature can be read easily. Gurgaon based start-up Staqu has launched new thermal camera by its video analytics platform, JARVIS. It alerts when body temperature raises 37°C and can range up to 100meters to identify people [41]. A company "care.ai", working on A.I. overhead scanners screens bystanders to scans facial attributes like sweating, discoloration and thermal data[42].IIT Roorkee professor, Dr.Kamal Jain created a new surveillance system and an app to alert government if anyone violates quarantine and also can do geofencing around him[43].

4. Germany based start-up Thryve, launched smartwatch app to monitor corona spread. Here, the corona data donation app gathers vital information from smartwatches or fitness trackers to analyze the symptoms [44]. University of Illinois, Professor Brian Cunningham developed a smartphone app for coronavirus testing within 30minutes without the need for a diagnostic lab which can reduce time and saves money.It can used in airports, meetings, functions etc[45].IITMadras, incubated start-up Antariksh Watse Ventures developed an IoT-enabled Smart Bin system(AirBin) to prevent the spread of covid19 through waste generated from hospitals, clinics, public bins, quarantine zones etc.It alerts when the clinical waste overflows to the concerned personal[46].

5.Hyderabad based,T-Hub startups, like Terisoft, blocksapps.ai, blue semi, maruth drones, started many IoT enabled smart devices, apps, thermal screeners, surveillance camera drones etc. to fight against coronavirus pandemic [47].

VIII. CHALLENGES TO ROBOT AND IOT SERVICES DURING COVID19

Due to the severe pandemic covid19 attack we have to encounter two major challenges: The first one, challenges faced by the front line citizens, hospital staff, sanitary workers, and police personal. The second one, challenges faced by the technology to improve better in the future. Some of the issues raised are: market adoption towards using of robots and IoT devices worldwide, level of using the technology, awareness of using the smart services by common citizen, reliability and durability of startup based IoT devices, long standing applicability of robots, maintenance and serviceability, adaptability in day-to-day life, inviting the new changes at living and working places, change of living lifestyles, acquiring more science and technical information, and combatting the future epidemic in prior.

IX. RESULTS AND DISCUSSIONS

The results of these IOT and Robotic applications have proven that there is a huge need and demand in emergency epidemics than human labor, which can assist along with the integration of technical personal. Due to the smart technologies like sensors, transducers, actuators, and microprocessors used in robots, drones, scanners etc., they proved in various medical, societal, shopping malls, public places, schools and colleges working effectively as they are highly immune to bacteria, coronaviruses and super bugs. Finally, we have proven the robots and IoT technologies stood in the front line after the medical doctors, paramedical staff, sanitary workers and police staff which can work, assist and help in unhygienic, high security and remote areas. In the future with the impact of pandemic disasters the robots and Iots with the use of Artificial intelligence plays a major role in medical and societal sectors.

X. CONCLUSION

Because of severe attack of pandemic coronavirus across the globe, everyone has to get secured and to get awareness about the using of high end robotic technology and IoT enabled services at hospitals, shopping malls, public areas, quarantine centres, schools, colleges and many more once the lockdown or quarantine period lifts up. One has to get prepared or get sound awareness of using Science and Engineering services in the society.

AUTHORS PROFILE

Mr.Rajesh kakumanu is currently working as Associate professor, Mech dept. in Chebrolu Engineering College, Guntur. He has 2years of industry and 13years of teaching experience and did MTech from JNTUH and BTech from S.V.U.T in 2005. He has 2 PG Diplomas in Entrepreneurship and IPR. He is a research scholar pursuing from V.T.U, Karnataka. Areas of interest are Robotics, Automation, Green manufacturing, design for manufacturing etc. He has published 14 national and international journals in UGC prescribed and attended various conferences. He is a lifetime member of IAENG.

M.GopiKrishna,Associate professor, Mech dept. BVRIT Hyderabad college of Engineering for Women, Hyderabad. He has 1 year industry and 15years of teaching experience. He has published paper and conferences on Energy conversion with green buildings. Areas of interest are Heat transfer, Robotics and Energy conservation.

Mr.V.Ramalingeswara Rao, Associate professor, Mech dept. Vidhya jyothi Institute of Technology (A), Moinabad, Telangana He has 11 years industry and 17 years of teaching experience. He has published papers in various journals. Areas of interest are Production technology, FMHM, Machine tools and Robotics.

P.Pavani, Assistant professor, Mech dept. Vidhya jyothi Institute of Technology (A), Moinabad, Telangana. She did MTech and has 9years of teaching experience. She published 7 journals national and internationally. Areas of interest are Manufacturing, production and design.

C.ChandraSekhara, Associate professor, Mech dept. MallaReddy Engineering College (A), Maisammaguda, Telangana. He has completed MTech in 2011 and has 11years of industry and 9 years of teaching experience. Areas of interest are IC engines, Biofuels, Heat transfer and Robotics. He has published many journals nationally and internationally.

Resultant surface roughness of 5% and 10% Al7075SiC MMC by using Friction Stir Processing

Abstract. The study of friction stir processing has been presently used in industry and academic research. Friction stir processing(FSP) is used as surface modification technique, 5% and 10% Al7075SiC metal matrix composites were tested for surface finish using Talysurf at varying speeds of minimum, medium and maximum. This document provides the outcomes of 5% surface roughness (Ra), 5% skewness (Rsk), 5% kurtosis (Rku) and 10% metal matrix composites Al7075SiC. Experiments were conducted according to Taguchi's method $L_8(3)^3$ at various speeds.

Keywords. FSP; Surface Roughness (R_a,); Skewness (R_{sk}); Kurtosis (R_{ku}).

1. Introduction

The potential utilization of friction stir processing (FSP) has been growing due to the demands of different manufacturing sectors and academic research quickly in these years. Friction Stir Processing is widely found in making various parts of aerospace, automobile, medical equipment and agriculture. Using experimental techniques and statistical models, parameters for the growth of output characterization are systematically considered. Therefore, correct configurations of friction stir handling parameters are essential before the method occurs in order to achieve better surface roughness. The objective of the paper organization is therefore to optimize process parameters for minimum surface roughness composites of different percentages in FSP for Al7075SiC metal matrix composites.

2. Literature survey

Consequently the Taguchi method which a powerful tool for improving productivity during research and development so that high quality products can be produced quickly and at low cost [1,2][5]. The surface finishing is therefore one of the most important variables in the manufacturing system ; several scientists have carried out numerous studies to improve the surface finish of the FSP system. [3,4][6]. The surface finishing in friction stir processing has been finding to be influenced in varying amounts by a number of factors, such as speed, feed,

work, material, etc. and the dielectric fluid, etc. the orthogonal array of grey relational analysis [7,8] used to investigate the multiple performance characteristics in Friction stir processing. Manufacturing materials such as silicon carbide, zirconium oxide, aluminum oxide, magnesium oxide, etc. have excellent uses in the design and manufacture of high-tech machine parts in aerospace, automotive, biomedical and space cars. [7]. As a result, The ability to process those sophisticated FSP ceramics in the macro-domain is much required. As in the just around the corner scenario, Especially in the field of sophisticated macro-machining procedures, such materials dealing with work pieces made of ceramics and composites are rejected ; consequently, the FSP procedures are unique and promising in macro-machining procedures.. Therefore, the FSP technique involves a number of process parameters such as tool rotational speed, dip depth, tilt angle, feed rate and strength [8]. It is therefore feasible to pick the highest possible parametric combination of the remarkable procedure parameter to achieve the required objective of processing a specific material with enhanced processed surface quality and high precision in dimensions. A great amount of FSP procedures such as surface modification, grain refinement and finishing were performed in the region of one- and two-dimensional processes. [11]. This research includes a fundamental and preliminary survey of the method of FSP to examine growth capacity and select the significant process parameters. The optimal parametric combination of minimal surface roughness and minimum divergence of depth was therefore acquired on the basis of the second-order regression response model.. It is additional ; studies have been conducted in the most advantageous parametric combination based on Response Surface Methodology (RSM) by considering additional parameters, i.e. defocusing position and scanning passes.

3. Material work piece

Aluminium 7075SiC was preferred as the work material of 5% and 10%. This is a nice amount of thermal versatility – treatable alloys are accepted for medium to high strength demands and have excellent quality rigidity features. The dissimilar alloying essentials in attendance in the alloy Al7075 are shown in Table 1 and 2.

Table 1 Work piece 5% Al7075SiC composition

Components	**% by Weights**
Aluminium	93.9 to 95.3
Magnesium	0.8 to 1.2
Silicon	0.5 to 1.0
Iron	0.0 to 0.7
Copper	0.15 to 0.4
Chromium	0.04 to 0.35
Zinc	0.0 to 0.25
Manganese	0.0 to 0.15
Residuals	0.0 to 0.15
Titanium	0.0 to 0.15

Table 2 Work piece 10% Al7075SiC composition

Components	**% by Weights**
Aluminium	85.9 to 90.8

Magnesium	0.8 to 1.5
Silicon	1 to 8.0
Iron	0.0 to 1.0
Copper	0.50 to 1.0
Chromium	0.1 to 1.5
Zinc	0.0 to 0.5
Manganese	0.0 to 0.45
Residuals	0.0 to 0.45
Titanium	1.0 to 0.45

4. Experimental plan

Therefore the experiments be considered according toward Taguchi's L_8 (3^3). Experiments were carried out using the instrument material H13 using the vertical friction machine generated by the U2000 Hochun model.. Different machine requirements are provided in Table 3 and experimental configuration is shown in Figure 1

Table 3 Machine specifications

Title	Description	Specification	Units
Spindle	Spindle drive Spindle speed Spindle taper	Variable 120-1500 NT50	RPM
Capacity	Spindle motor Feed motor Coolant pump	15 5 0.18 3-4	HP HP Kw W
	Lubrication pump		
Machine size	L X W X H Net weight	3000 x 3060 x 2700 8100	mm Kg
Table size	L X W	600 x 2600	Mm
Column	Length	710	mm
Feed		8-450	Mm/ min
Longitudinal travel		2000	mm
Cross travel		710	mm

A 20 mm diameter shoulder with a conical nib of 6 mm diameter and 5 mm long H13 tool material is selected. 5% and 10% Al7075SiC material of 100X25X5 mm thickness are in use as work material and processed FSP samples were shown in figure 2. The 0.8 mm cutoff Talysurf tool worth a well-planned surface roughness. Table 4 illustrates the preferred friction stir processing parameter and their values at three levels.

Figure 1. Friction stir processing machine setup

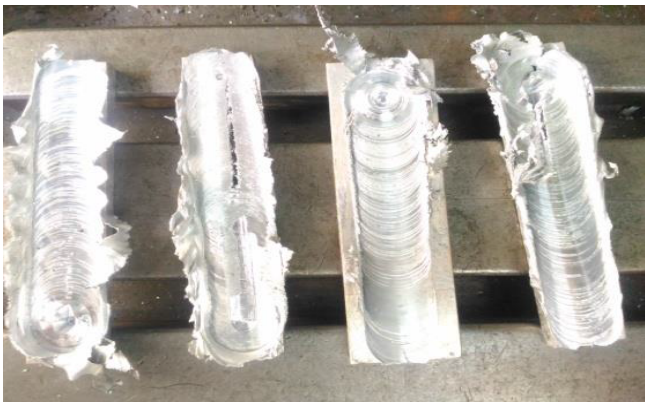

Figure 2. Friction stir processed Al7075SiC specimens

Table 4 Process parameters of FSP

Parameters	Level-1	Level-2	Level-3
Travel speed	500	800	1100
Traverse feed (mm/min)	20	25	30
Plunge depth (mm)	2.5	2.5	2.5

For this reason, surface roughness (R_a), skewness (R_{sk}), kurtosis (R_{ku}) are achieved using Talysurf devices and surface roughness charts are used, the best results can be achieved in this 5% study document and 10% Al7075SiC in Tables 5 and 6..

5. Effect of an amount of FSP passes on surface roughness

Response outcomes, i.e. depth variation in surface roughness (R_a, R_{sk} and R_{ku}), as shown in Tables 5 and 6, a variety of plot comprise be tired and shown in Fig. 3,4,5 and Fig 7,8,9. As shown in Fig 3 and 7, the result of the amount of FSP moves to surface roughness (R_a) in distinct positions defocusing upwards. The figure demonstrates that the roughness of unsmoothed surface of the milling decreases with the amount of FSP passes in each scenario of defocusing positions. At some point in FSP, the height of different micro-sized peaks on the machining surface is increased by increasing the passage of FSP in defocusing conditions. The figure also shows that distinct surface roughness values are attained for any specific amount of FSPs at distinct defocus positions. The increase in defocus position, the FSP surface roughness decreases due to suitability, removing the rough and irregular peaks from the workpiece surface and even creating the surface. The defocus position is higher than 0.4 and 0.8 mm when observed at a higher defocus value, i.e. at 0.8 mm. The FSP's get-up-and-go thickness on the outside of the workpiece is very low when positioning 0.8 mm and this amount of get-up-and-go can not remove the micro-peak from the outside of the FSP. This phenomenon results in the machined surface having a greater quantity of surface roughness. And the surface roughness for various levels of speed at 5% of Al7075-SiC were represented as pie chart in Fig 6.

This impact of FSP number variation passes on the criterion of surface roughness (Ra) is shown in Figure 4 and 8 at different defocusing locations downwards. It is understandable from this plot that the amount of FSP passes has a significant impact on the unique surface roughness (Ra). The surface roughness rate reduces at each of the defocus positions by increasing the amount of FSP passes. It is due to processing on the surface of the workpiece of sharp micro-sized peaks. However, for all defocusing conditions, the surface roughness increases to a small degree after some number of FSP passes. This is because the processing of material from the workpiece surface after confident quantities of passes is not uniform and the processed surface is irregular and uneven due to high intense workpiece stress. At a greater environment of the defocusing situation at 0.8 mm, the volume of the FSP place is very large and the power on the workpiece surface is very little. This low-energy is quite unable to extract from the rough workpiece surface the micro-sized peaks. Hence, the machined surface's roughness value is less than machining at a higher defocusing position under other conditions of defocusing. R_{sk},R_{ku} was seen as a response to another surface roughness parameter to study the FSP surface feature in more detail. Figure 8 demonstrates the impact of upward variation of the amount of FSP passes on surface roughness (R_{sk} R_{ku}) in a variety of defocusing positions. From this plot it is

noted that surface roughness (Rsk Rku) decreases for all defocusing location setting with an rise in FSP passes. It is caused by the irradiated processing of micro-level peaks from the unsmooth FSP zone. From this figure, that the same setting of FSP passes is also pragmatic, the reduced setting of defocusing position outcomes in greater surface roughness value (R_{sk} R_{ku}) compared to greater defocus position environment. This is due primarily to varying densities of energy at distinct focal locations and the quantity of FSP energy required to decrease micro-peak height. However, the roughness of FSP surface (R_{sk} R_{ku}) is comparably high to the defocus circumstances of 0.6 and 0.4 mm at 0.8 mm. This is because of the very low FSP energy that can not remove or decrease micro level peaks from the surface of the workpiece.

The result of different amount of FSP moves on unsmooth surface (R_{sk} R_{ku}) value is demonstrated in Figure 4,5,8 and 9 machining next to different downward defocusing position This demonstrates a plot to improve the amount of FSP pass results at this juncture reduction of surface roughness (R_{sk} R_{ku}) value up to a certain amount of passes. It is the total height of the jagged peak decreasing with the amount of passes on the ground. On the other hand, after a certain number of moves, the roughness of the FSP surface does not differ significantly. The roughness of the surface improves after seventh amount of passes under defocusing circumstances of 0.4 and 0.8 mm. It is again owing to the generation on the FSP surface of small-sized irregular peaks. Hence plot also demonstrates that the end product of defocusing stance is very unplanned on surface roughness condition. The minimum amount of surface roughness is obtained at a defocus location of 0.4 mm and at the eighth digit of FSP, the energy is very little and this energy is not sufficiently expert to take away remaining micro-crests of the unsmooth and uneven workpiece surface. And the surface roughness for various levels of speed at 10% of Al7075-SiC were represented as pie chart in Fig 10.

6. Results and discussion

Consequently, wearing down rates and roughness R_a are mentioned in table-5 and 6, and roughness profiles of 5% and 10% Al7075SiC are mentioned in figures 11(a),(b) and (c), 12(a),(b) and (c) for different speeds (rpm) 500,800 and 1100 respectively.. The results are as expected, but demonstrate the considerably low wearing rates and the roughness of the surface as shown in Figure 11 compared to Figure 12.. Therefore results are attributed to inhomogeneous friction own in the direction of contact of work-tool. In the previous section explain the reason of the theory. The friction surfaces in 5% Al7075SiC be exceptionally rough with under privileged manifestation compare in the direction of 10% Al7075SiC which is extremely smooth with extensive burrs. Figure 11 (a), (b), (c) and Figure 12 (a) (b), (c) The surfaces draw to a close and statistical accuracy of the friction stir processing surface.

Therefore, The erosion mechanism bears the significant resemblance of FSW. It is the gradual declining of erosion rate in FSP is so high that satisfied for work-tool and speed alone may not be the reason but also the feed and plunge depth. The normal speed may amount of friction between work-tool and erosion rate is retained.

The feed and plunge depth give much lesser friction and the poorer metal removal rate. Further exploration of FSP requirements in the wearing-out scheme.

Another interesting and eye-catching observation is the reduced wear rate in 10% Al7075SiC compared to 5% Al7075SiC in FSP. Among the possible reasons, the major one is the least feed and plunge depth on 5% Al7075SiC resulting in low erosion rates. The other options can be the slow speed, the low erosion rates with higher speeds have the apparent reason for elevated feed.

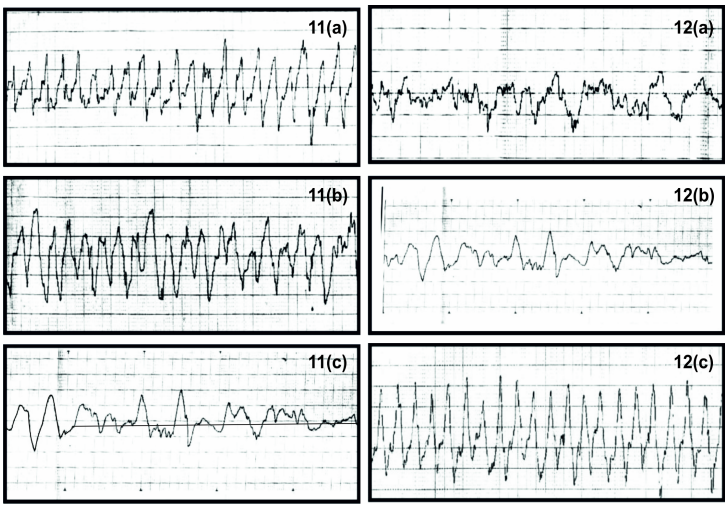

Figure 11 and 12. Surface Roughness Profiles of 5% and 10% Al7075SiC at 500,800 and 1100 rpm

7. Conclusions

1. Friction stir processing (FSP) is highly suitable used for metal matrix composites.
2. In 10% Al7075SiC with higher feed and plunge depth shows inferior erosion rates compared to 5% Al7075SiC
3. Low wearing away rates with decreasing speed in conformity to the theory of friction stir processing.
4. Surface roughness too has a similar tendency as wearing away a rate in the two metal matrix composites of 5% Al7075SiC and 10% Al7075SiC.
5. For the job piece under account, the most favourable combination method parameters for a minimum surface finish of maximum surface finish are acquired at 800 rpm, 0.25 mm dip depth and 25 mm / min feed rate.

ABSTRACT

One of the indispensable thing in the world is but the supply is limited. In particularly, the supply of material is limited for specific applications. Light weight low strength applications are very wide. This investigation focuses the natural fiber hybrid with artificial fiber to synthesize hybrid composite. The sisal fiber is used to prepare the composite with GRP. The sisal fiber is here treated with specific concentration of Lye in the distilled water. The composites synthesized with treated and untreated sisal fibers. The alternate fashion of horizontal and vertical is followed for fibers' orientation. The bio epoxy is employed as matrix material with mix of hardener. The prepared composite are characterized by water absorbability, tensile properties, flexural properties and shock absorption capacities in wet condition.

1. Introduction

Composite plays an important role in the applications of Materials [1]. The conventional materials sometimes fails to meet the specific requirements of the final product [2]. Conventional materials is limited in supply but demand is growing steeply [3]. Invention of new materials may substitute of the conventional materials [4]. [5] suggested to include the almond shell powder with resin to prepare the particulate composite panels [67–70]. [6] prepared such composite synthesized with use of powder of tamarind seeds for making the panels for construction [71–74]. [7] found that Sisal fibers to be treated to improve the desired properties and fabricated with treated fibers [8] and tested for compatibility [75,76]. The sisal fiber treated by mallic acid and hybrid with glass fiber for composite material fabrication [9]. [10] proposed a methodology for reinforcement that prevent of de-lamination by stitching before compression [11]. The Lye treated Sisal fiber hybrid with glass fiber with predefined layers and orientation of fibers to obtain the composite material for applications which under the wet conditions [12].

2. Materials and methods

2.1. Composite matrix

The matrix materials are mainly consists of selectively obtained and specially prepared high quality sisal fiber, the commercially available high quality glass fiber for reinforcement [13]. The low cost, best match for sisal fiber based composite's bonding agents, the cashew nut cell oil is employed as resin and also bought the suitable hardener for the same [14]. The Fiber, its Tensile Strength (MPa), its Density (kg/m^3), [63–66] its Young's Modulus (MPa) and Flexural Modulus (MPa) are in the order of as follows Glass Fiber 2500–3500, 2.5, 70000, 70000–73000, Sisal Fiber, 68, 1450, 3774, 125000–17500 respectively. The poly vinyl acetate is employed as releasing agent [15]. The high quality sisal fiber was prepared from the naturally harvested sisal leaves by decortications, followed by drying further the fiber qualities were enhanced by chemical treatment [16].

2.2. Improving quality of sisal fiber

The low cost and appreciable enhancement was achieved through Lye treatment [17]. Here it was preferred that 1% of Lye volume fraction with distilled water [18]. The high quality sisal fibers soaked in the solution for 240 min followed by drying on open space with normal sunrays (do not being at hot sunrays) for 120 min that is dried in the morning 8 AM to 10 AM. After that the fibers cut to 5 cm long [19].

2.3. Hybrid composite fabrication

The preferred selective sequence of layers and orientation of fibers on each layer are alternate fashion of horizontal and vertical [20]. A chromium- plated MS, Square shaped molds (of side 30 cm) are placed in the molding table [21]. The parting (Wax) agent applied on the mould which will facilitate release the finished [22,23]. Beadings at the corners of models are maintained the preplanned gap [24]. The preplanned length of 50 mm followed for both sisal fiber and GRPs [25]. The glass fibers used for extreme layers that top and bottom [26]. In between layers sisal but their fashions are alternate orientation of fibers in horizontal and vertical directions [27]. The layers are bonded with just prepared paste of mix of 10 part of resin and one part of hardener [28]. Finally entire composite panel was compressed in CTM and kept in the compressed position for 3 to 4 h, by which the voids filled up, air bubbles removed and excess resin content also removed [29]. Then panels allow drying in sun light with weight for avoiding bending due to shrinkage while drying [30]. Hence the composite samples are prepared by the combination of compression mounding and manual layup technique [31].

Table 1
Characterization of dry and wet (G-S-S-S-G) hybrid composite under flexural load.

Characterization Criteria	Treated	Untreated
Flexural strength in MPa	13.3	9.84
Flexural Modulus in MPa	1530	1060

3. Characterization

3.1. Flexural strength based characterization

In the Transverse or Orthogonal loading is used for characterizing by Flexural strength on is for the material in terms of properties by three point bending method [33–40]. The specimen prepared to the standard of ASTM D790 that is 3 mm thick rectangular of size 157x 13sq. millimetres [41–46]. The same FIE universal testing machine UTE-40 type 400 KN capacity was employed for this investigation [47]. The loading speed is 1 mm per minute was set [60–62]. As per standard the 150 mm of gauge length was set [48–51]. The environment conditions are an average relative

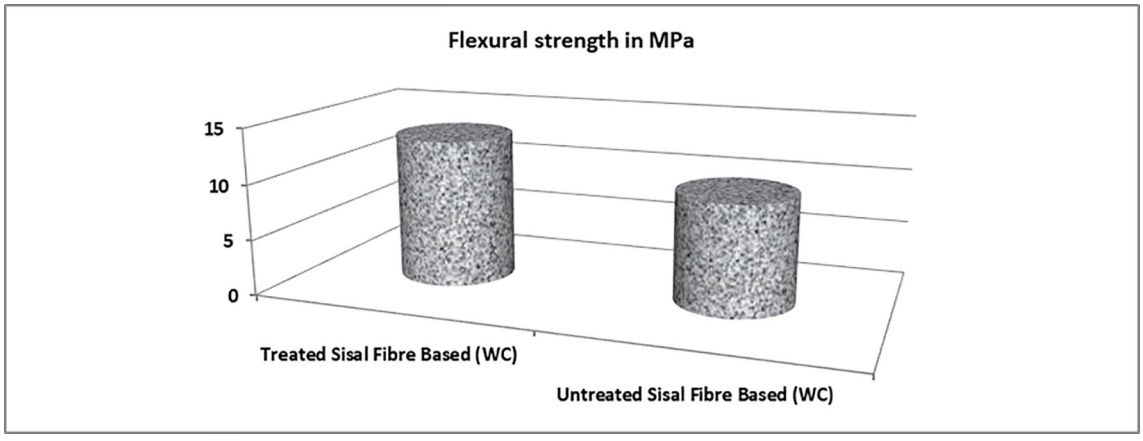

Fig. 1. Flexural strength of treated and untreated sisal fiber based hybrid composite.

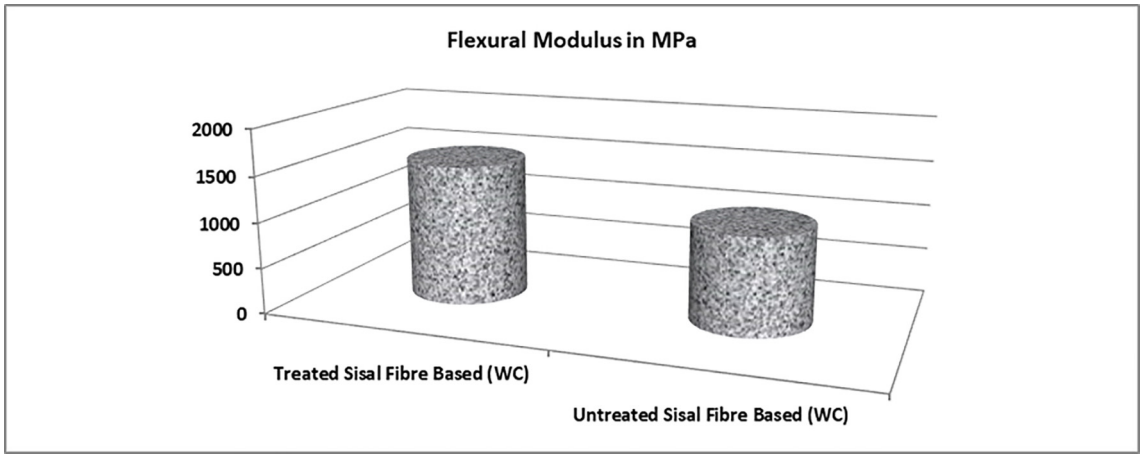

Fig. 2. Flexural modulus of treated and untreated sisal fiber based hybrid composite.

Please cite this article as: T. Naresh Kumar, S. Thirugnanam, R. Pradhan et al., Synthesize and wet condition based characterizations of GRP / Lye treated sisal fiber hybrid composite, Materials Today: Proceedings, https://doi.org/10.1016/j.matpr.2020.02.709

humidity of 50% and the temperature about 35 °C [52–55]. The observations obtained for both dry and wet composite and presented them in the Table 1 [56–59].

4. Results and discussions

4.1. Flexural properties

The Flexural Properties like flexural strength and flexural modulus of the treated Sisal fiber based hybrid composites got improved. The treated fiber based composite is stronger in bending than untreated fiber based Sisal/GRPhybrid composite (Refer Figs. 1 and 2).

5. Conclusion

The paper demonstrated the concepts of synthesize GRP / lye treated sisal fiber hybrid composite and tested for wet condition based characterizations. The flexural properties is focused in this study and explained well. The proposed composites tested and found that the composites performance fund good under normal ambient condition and also tested for wet condition. The wet condition based investigation resulted that the composite synthesized best performed than its dry condition.

An Experimental Investigation of Mechanical Properties of Teak Wood Rust and Tamarind Kernel Powder Reinforced Polymer Composite

S.C. Sireesha[1]

Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College, Hyderabad, Telangana, India[1]

ABSTRACT: The intention of the present experimental research aims at investigating the mechanical behavior of natural fiber composites. In the recent past, Natural fibers attracting the attention of engineers, researchers, professionals and scientists all over the world to use them as an alternative to conventional reinforcing materials, because of their superior properties such as high specific-strength, less weight, economical, availability, equitably decent mechanical properties, non-abrasive, eco-friendly and bio-degradable characteristics. In this experimental work an attempt is made to find the effect of teak wood and tamarind kernel as reinforced particulates on mechanical properties of composites with polyester resin. The analysis is carried out on the mechanical behavior of different combinations of composite material, with different tests such as tensile test, hardness test and flexural bend test. Finally, it is reported that more value in the combination of tamarind dust on flexural bend test. Coming to hardness test it reported more value in teak wood dust and at last in tensile test it varies at different combinations.

KEYWORDS: Natural Fiber, Polymer Composite, Mechanical Behaviour, Flexural Test, Tension Test, Hardness Test.

I. INTRODUCTION

Composites are made from a matrix that is reinforced with an engineered, man-made or natural fiber or other reinforcing material. The reinforcing material and the matrix material can be metal, ceramic, or polymer. Composites typically have a fiber or particle phase that is stiffer and stronger than the continuous matrix phase and serve as the principal load carrying members. The matrix acts as a load transfer medium between fibers, and in less ideal cases where the loads are complex, the matrix may even have to bear loads transverse to the fiber axis. Composites are used not only for their structural properties, but also for electrical, thermal, tribological, and environmental applications.
The following are some of the reasons why composites are selected for certain applications:

- High strength to weight ratio (low density high tensile strength)
- High creep resistance
- High tensile strength at elevated temperatures
- High toughness

A. Polymer Composites

Most commonly used matrix materials are polymeric. In general, the mechanical properties of polymers are inadequate for many structural purposes. In particular their strength and stiffness are low compared to metals and ceramics. These difficulties are overcome by reinforcing other materials with polymers. Secondly the processing of polymer matrix composites need not involve high pressure and doesn't require high temperature. Also, equipment's required for manufacturing polymer matrix composites are simpler. For this reason, polymer matrix composites developed rapidly and soon became popular for structural applications.

B. Natural fiber reinforced composites

The interest in natural fiber-reinforced polymer composite materials is rapidly growing both in terms of their industrial applications and fundamental research. They are renewable, cheap, completely or partially recyclable, and biodegradable. Plants, such as flax, cotton, hemp, jute, sisal, kenaf, pineapple, ramie, bamboo, rice husk, wood rust,

||Volume 9, Issue 5, May 2020||

banana, etc., as well as wood, used from time immemorial as a source of lignocellulose fibers, are more and more often applied as the reinforcement of composites. Their availability, renewability, low density, and price as well as satisfactory mechanical properties make them an attractive ecological alternative to glass, carbon and man-made fibers used for the manufacturing of composites. The natural fiber containing composites are more environmentally friendly, and are used in transportation (automobiles, railway coaches, aerospace), military applications, building and construction industries (ceiling paneling, partition boards), packaging, consumer products, etc.

C. Application of Natural fiber composites

The natural fiber composites can be very cost-effective material for following applications:
Building and construction industry: panels for partition and false ceiling, partition boards, wall, floor, window and door frames, roof tiles, mobile or pre-fabricated buildings which can be used in times of natural calamities such as floods, cyclones, earthquakes, etc.
Storage devices: post-boxes, grain storage silos, bio-gas containers, etc.
Furniture: chair, table, shower, bath units, etc.
Electric devices: electrical appliances, pipes, etc.
Everyday applications: lampshades, suitcases, helmets, etc.
Transportation: automobile and railway coach interior, boat, etc.

II. LITERATURE REVIEW

Natural fiber reinforced polymer composites have raised great attentions and interests among materials scientists and engineers in recent years due to the considerations of developing an environmental friendly material and partly replacing currently used glass or carbon fibers in fiber reinforced composites. They are high specific strength and modulus materials, low prices, recyclable, easy available in some countries, etc.

Pickering et al. [1] conducted a research to study the mechanical properties, especially interfacial performances of the composites based on natural fibers due to the poor interfacial bonding between the hydrophilic natural fibers and the hydrophobic polymer matrices. Two types of fiber surface treatment methods, namely chemical bonding and oxidization were used to improve the interfacial bonding properties of natural fiber reinforced polymeric composites. Interfacial properties were evaluated and analyzed by single fiber pull-out test and the theoretical model. The interfacial shear strength (IFSS) was obtained by the statistical parameters. The results were compared with those obtained by traditional ways. Based on this study, an improved method which could more accurately evaluate the interfacial properties between natural fiber and polymeric matrices was proposed.

Joshi et al. [2] compared life cycle environmental performance of natural fiber composites with glass fiber reinforced composites and found that natural fiber composites are environmentally superior in the specific applications studied. Natural fiber composites are likely to be environmentally superior to glass fiber composites in most cases for the following reasons: (1) natural fiber production has lower environmental impacts compared to glass fiber production; (2) natural fiber composites have higher fiber content for equivalent performance, 16

reducing more polluting base polymer content; (3) the light-weight natural fiber composites improve fuel efficiency and reduce emissions in the use phase of the component, especially in auto applications; and (4) end of life incineration of natural fibers results in recovered energy and carbon credits.

Rana et al. [3] in their work showed that the use of compatibilizer in jute fibers increases its mechanical properties. At 60% by weight of fiber loading, the use of the compatibilizer improved the flexural strength as high as 100%, tensile strength to 120%, and impact strength by 175%. The following conclusions may be drawn from this paper:

1. The sharp increase in mechanical properties and decrease in water absorption values after addition of the compatibilizer.

2. All these results justify that the role of jute fiber was not as a filler fiber but as a reinforcing fiber in a properly compatibilized system.

| e- ISSN: 2319-8753, p-ISSN: 2320-6710| www.ijirset.com | Impact Factor: 7.512|

||Volume 9, Issue 5, May 2020||

3. This system produced a new range of low-energy, low-cost composites having interesting properties and should be given priority over costly and high-energy synthesis reinforcing fiber wherever possible.

Shah and Lakkad [4] tries to compare the mechanical properties of jute-reinforces and glass-reinforced and the results shows that the jute fibers, when introduced into the resin matrix as reinforcement, considerably improve the mechanical properties, but the improvement is much lower than that obtained by introduction of glass and other high performance fibers. Hence, the jute fibers can be used as a reinforcement where modest strength and modulus are required. Another potential use for the jute fibers is that, it can be used as a filler fiber, replacing the glass as well as the resin in a filament wound component. The main problem of the present work has been that it is difficult to introduce a large quantity of jute fibers into the JRP laminates because the jute fibers, unlike glass fibers, soak up large amount of resin. This problem is partly overcome when hybridsing with glass fibers is carried out. Ray et al. [5] in their work, Jute fibres were subjected to alkali treatment with 5% NaOH solution for 0, 2, 4, 6 and 8 h at 300C. It was found that improvement in properties both for fibers and reinforced composites. The fibres after treatment were finer, having less hemicellulose content, increased crystallinity, reduced amount of defects resulting in superior bonding with the vinylester resin. As fibers, the improvements in properties were predominant around 6–8 h treatment whereas as composites, it was maximum when reinforced with 4 h-treated fibers at 35% fiber loadings. The modulus of the jute fibers is improved by 12, 68 and 79% after 4, 6 and 8 h of treatment, respectively. The tenacity of the fibers improved by 46% after 6 and 8 h treatment and the% breaking strain was reduced by 23% after 8 h treatment. For 35% composites with 4 h-treated fibers, the flexural strength improved from 199.1 to 238.9 MPa by 20%, modulus improved from 11.89 to 14.69 GPa by 23% and laminar shear strength increased from 0.238 to 0.283 MPa by 19%. The mechanical properties of natural fiber-reinforced composite depend extremely on the degree of adhesion between the natural fiber and the matrix [6]. There by, poor fiber/matrix interface leads to a weaker material with low strength and life span. In the last two decades, many researchers have focused on improving the interfacial adhesion by modifying the fiber surfaces via physical and chemical treatments to make them more compatible with matrix [7]. These surface treatments also enhance environmental durability (moisture and temperature) and wear resistance of the composite.

III. MATERIALS AND METHODOLOGY

A. Materials

This unit explains the details of processing of experimental process and the composite Followed by their mechanical characteristic features. The materials used in this work are

- Teak wood dust
- Tamarind kernel powder
- K-type polyester resin
- Hardener
- Catalysts

B. Method of Specimen preparation

Tamarind kernel powder and teak wood dust are reinforced with polyester k-type resin, this resin is belonging to the polyester family is utilized as the matrix material. Tamarind kernel powder made by us, first we took tamarind seeds and remove the shell/husk after roasting the seeds and at last grind the seeds according to required size particles. We got teak wood dust from a local supplier. Remove the moisture of teak wood and tamarind kernel powder. Also, the polyester k-type resin and hardener are provided by a local supplier. This manufacturing process is carried out by hand layup technique. Hardener and curing polyester resin is taken in the form of the ratio. Three types of composites have been produced with three different combinations.

- In the first combination out of 250gms wt the ratios of weight of materials taken as 15%Wt of tamarind kernel powder and 85%Wt of k-type polyester resin.
- In the second combination out of 250gms wt the ratios of weight of materials taken as 15%Wt of teak wood dust and 85%Wt of k-type polyester resin.
- Coming to the last combination out of 250gms wt the ratios o weight of materials taken as 10%Wt of tamarind kernel powder, 10%Wt of teak wood dust, and 80%Wt of k-type polyester resin.

While doing stir well without any lumps, and pour in mold. Here we took plastic box as a mold box and pour it after 24 hrs at room temperature it cured. Remove from the mold after process completed. And then cut the specimens according to required dimensions for mechanical testing. The composition of the composite material used for testing is presented in table 1. The reinforcing material is shown in fig 1 and fig 2.

Table 1: Designations of Composite Materials

Composites	Compositions
A1	Tamarind kernel powder (15wt %) + K-type polyester resin (85wt %)
A2	Teak wood dust (15wt %) + K-type polyester resin (85wt %)
A3	Tamarind kernel powder (10wt %) + Teak wood dust (10wt %) +K-type polyester resin (20wt %)

Fig.1. Tamarind Kernel Powder

Fig.2. Teak Wood Dust

C. Mechanical Testing

Types of tests done on specimens

- Hardness test (before heating)

| e- ISSN: 2319-8753, p-ISSN: 2320-6710| www.ijirset.com | Impact Factor: 7.512|

||Volume 9, Issue 5, May 2020||

- Hardness test (after heating at 150ºc)
- Flexural bend test
- Tensile test

Hardness Test (Before Heating)

The hardness test was done on the specimen by using shore hardness tester. A diamond indents in form of conical steel rod and having an angle 30ºc.

Hardness Test (After Heating)

This test is same as that of before heating but the difference is before testing the specimen it is heated up to 150ºc temperature. Then the process should be done.
The fig 3 and fig 4 presents the hardness test specimen and hardness test.

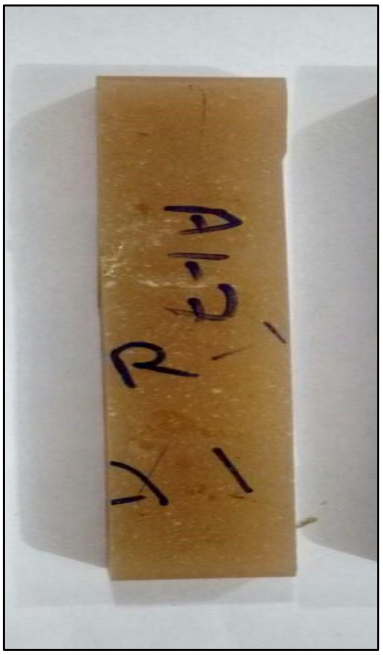

Fig.3. Hardness Test Specimen

Fig.4. Hardness Test

| e- ISSN: 2319-8753, p-ISSN: 2320-6710| www.ijirset.com | Impact Factor: 7.512|

||Volume 9, Issue 5, May 2020||

Flexural Bend Tests

There are two types of flexural tests.

i. In the first scheme, the beam is centrally loaded & basically supported at two ends is called three points bending test.
ii. In the second method, there are two loading points and two end supports are called four points bending test.

In this experiment, we used three-point bending tests it gives result by recording the load applied and it outcomes the strain.The condition of stress depends on the distribution of bending moment and shear force, the specimen subjected to three points are four points bending tests.

Flexural Strengths

In the case of three points bending test, the stress is on the surface of the specimen at failure. The flexural modulus for three points bending tests is

$E_f = S^3m/4bh^3$

Where E_f = flexural modulus

S= support spam

m= slope of load deflection

b= width

h= thickness

Fig.5. Flexural Test Specimen

Tensile Testing

In tensile testing, the load is applied uniaxially and displacement is recorded. The strain and stress derive using stress-strain formula. The information thus collected is utilized to generate the stress-strain curve. In engineering applications, the magnitude of tensile stress is defined as load over the initial cross- section area.

Fig.6. Tensile Test Specimen

IV. RESULTS AND DISCUSSION

This chapter represents the mechanical properties of the teak wood dust, tamarind kernel powder. The test was done on here combinations the processing of test details has been explained in the previous chapter. The results of 3 combinations reported in this chapter. This test's results included flexural bend test, tensile test and, hardness tests before heating and after heating are discussed.

Effect of different types of combinations on hardness test before heating:

The three composites of measured hardness values are shown in the figure. The hardness value of teak wood dust filled K-type polyester resin is more as compared to tamarind kernel powder and the combination of tamarind + teak. Among three different types of combination, the tamarind kernel combination showed less hardness value.

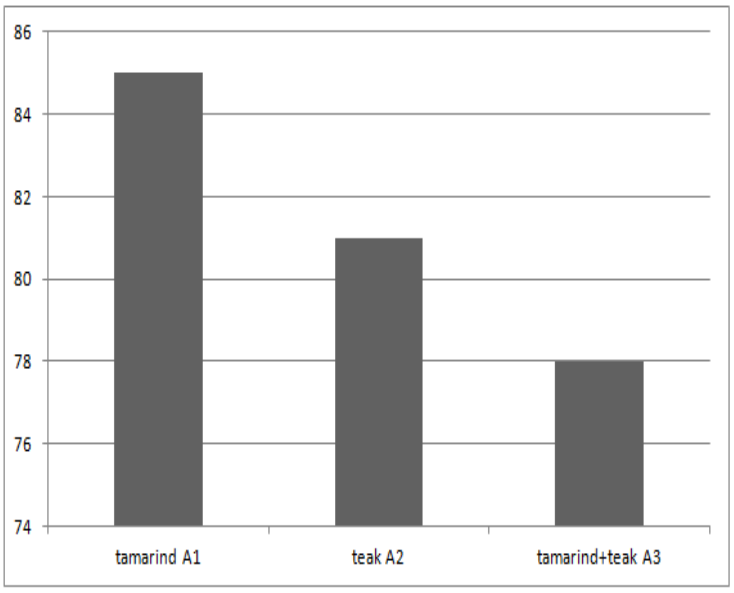

Fig.7. Comparison of Hardness of 3 specimens before heating.

Effect of different types of combinations on hardness test after heating:

Coming to the hardness values of the specimen after heating also is shown in the figure. In this, the combination of teak wood dust filled K-type polyester resin is more as compared to remaining two combinations.

||Volume 9, Issue 5, May 2020||

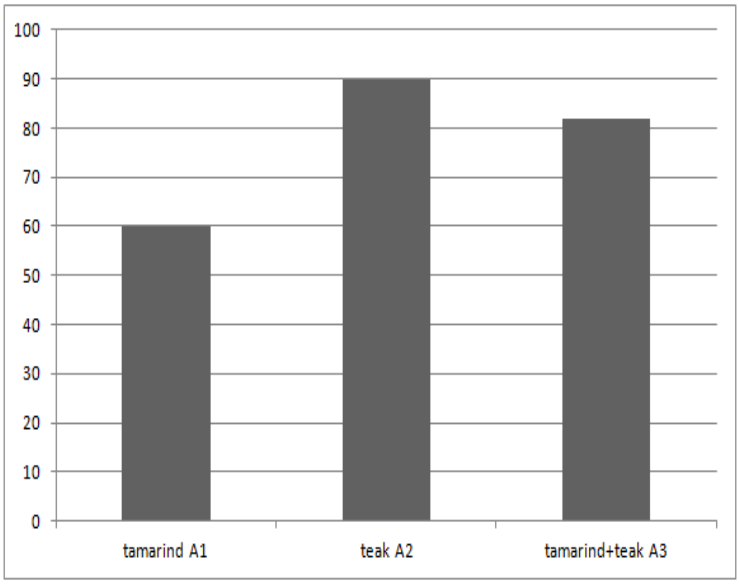

Fig.8. Comparison of Hardness of 3 specimens after heating

Effect of different types of combinations on flexural bend tests:

In this, flexural tests tamarind kernel powder with polyester resin reported more value than the teak wood dust and combinations of teak wood dust + tamarind kernel powder. The less value reported by the combination of tamarind and teak wood dust.

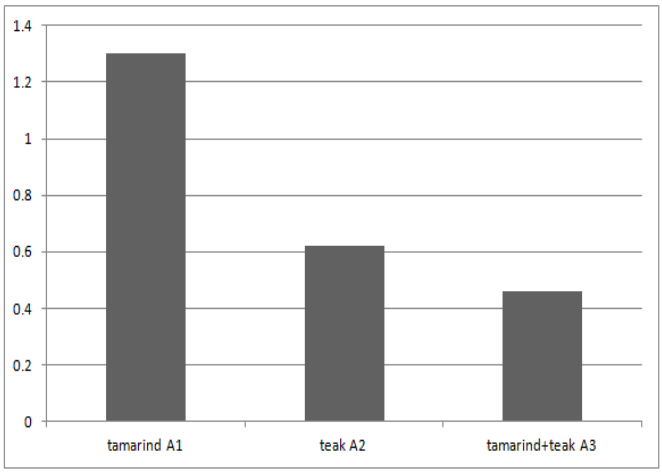

Fig.8. Comparison of Flexural Strength of 3 specimens

Effect of different types of combinations on tensile test:

In this experiment, the input data taken as

Combination of tamarind:

Specimen width mm: 13.72
Specimen thickness mm: 12.7
Cross-section area mm2: 174.244
Original gauge length mm: 50
Final gauge length mm: 50.9

In this, the result showed that ultimate load at 3.320KN, ultimate tensile strength at 19.054n/mm^2,elongation % = 1.800, yield load at 2.400KN and yield stress at 13.774 N/mm^2.

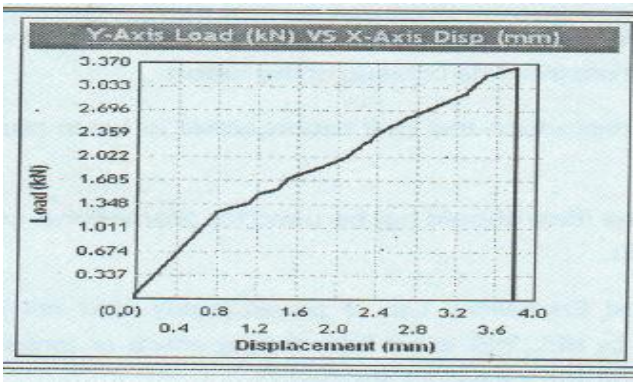

Fig.9. Results of Tensile test on Specimen A1.

Combination of teak:

Specimen width mm: 13.43
Specimen thickness mm: 13.4
Cross-section area mm2: 179.962
Original gauge length mm: 50
Final gauge length mm: 50.86
In this, the result showed that ultimate load at 3.360, ultimate tensile strength at 18.671N/mm^2, elongation % = 1.720, yield load at 3.200KN, yield stress at 17.782N/mm^2.

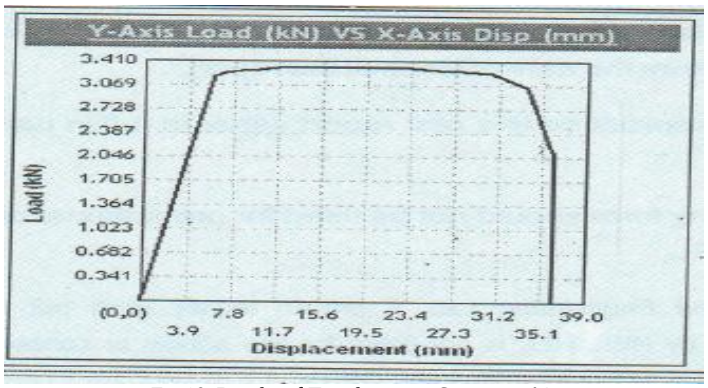

Fig.10. Results of Tensile test on Specimen A2.

Combination of teak + tamarind:

Specimen width mm: 14.9
Specimen thickness mm: 14.7
C/S area mm2: 219.03
Original gauge length mm: 50
Final gauge length mm: 51.4
In this, the result showed that ultimate load at 3.240KN, ultimate tensile strength at 14.792N/mm^2, elongation %= 2.080, yield load at 3.040KN, yield strength at 13.879N/mm^2.

V. CONCLUSIONS

The feasibility of use of teak wood rust and tamarind Kernel powder reinforcement in polymers composites is studied from the experiment. Both the reinforcements exhibited good bonding with the matrix. The polymer when reinforced with Teak rust and tamarind Kernel powder resulting in a composite with good tensile and bending strength to use in structural applications.

Investigation of the Deep Drawability of Aluminium Sheets by Finite Element Numerical Simulation

Aruna Jyothi Anumula [1]

Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College,Telangana,India[1]

ABSTRACT: All sheet metal forming processes occur after permanent plastic deformation resulting in the material properties changing and therefore it is necessary to determine the extent to which a material can further be deformed for subsequent forming operations. The aim of the present work is to evaluate the formability of TWBs made of two dissimilar Al alloys sheets through deep drawing process. The different aluminium alloy sheets AA 6061 and AA 5052 are considered. The modelling of these two sheets is modelled in different length ratios to know the effect of sheets length. The sheet length ratios like 30-70, 40-60, 50-50, 60-40 and 70-30 are considered. The numerical simulations are performed for deep drawing of square cups on sheet width of 75x150, 100x200 and 200x200 mm strain paths at three different punch forces (10, 15 and 20kN) and blank holding forces (60, 70, 80kN). For numerical simulation a commercial FEM dynamic explicit code in which Holloman's power law and Hills 1948 yield's criterion is used. Failure initiation, major limit strains and dome heights are evaluated for all conditions. From the overall results, it has been noted that by increasing the punch force major stain is improved. Failure initiation is happened in AA6061 alloy irrespective of the punch force and blank holding force in strain path.

KEYWORDS: Deep Drawing, TWBs, Forming limit diagram, speed of welding.

I. INTRODUCTION

In the modern development of manufacturing processes, sheet metal forming is one of the major processes. Among conventional sheet metal forming processes, deep drawing processes give distinct results by various materials. A part is said to be deep drawn when its depth is one and half times the diameter of the part. Deep drawing process is an efficient automated process for large productions having the advantage of lowering wastage of the material. Thus reducing cost besides yielding stronger finished products than that are manufactured by casting or machining. It also reduces the cost of assembling by providing combined assembly parts in a single deep drawing process.

Deep drawing is used extensively in the forming of sheet metal into cup or box like structures under tensile and compressive conditions, without altering the sheet thickness. Products of various shapes and sizes such as pots and pans for cooking, containers, sinks, automobile parts like panels and gas tanks are among a few of the applications manufactured by sheet metal deep drawing.

The formability of sheet material during the deep drawing depends on the parameters like blank holder force, lubrication, punch radius, die radius, die–punch clearance, in addition to mechanical properties and thickness of the sheet metal and part's geometry. The proper selection of these variables helps to reduce the defects in the deep drawing process like fracture, wrinkling etc and helps to implement optimum results out of the forming behaviour of the materials used in the process.

II. RELATED WORK

Rodrigues et al [1](2007) compared the formability behavior of friction stir welded aluminum blanks with wide weld beads and Laser steel welded blanks with narrow weld beads. A tailor-welded blank of 1mm thick is made by considering similar and dissimilar combinations of the two steel alloys (DC06 and DP600) and two aluminum alloys (AA 5182-H111 and AA 6016-T4). The formability tests of the AA 5182-H111 and AA 6016-T4 base materials and its similar welds show that they suffer strong wrinkling associated with severe changes in microstructure of the material, thickness of the weld relative to the base material, which induces non-homogenous behavior of the blank and surface finishing. Reza et al.[10] (2012) studied the effects of punch and die temperature on the formability of a cup shaped AA3003 aluminum alloy sheet. The formability improves as the temperature difference between the punch and the die increases. Also the forming speed does not affect localized necking for the given punch velocities in their study

Recently Mostafapur et al[11](2013) conducted investigation to examine the effect on the formability and drawing depth of Al 1050 alloy using the new pulsating blank holder system. When compared with static holder, there was an increase in the depth, strength, formability and accuracy of the final product by using pulsating blank holder.

III. METHODOLOGY

III .a. Mechanical properties of base materials

The sheet material was considered as aluminum and the properties of AA 6061 and AA 5052 alloy were applied to the blanks. The properties of AA 6061 and AA 5052 aluminum sheet are shown in the Table 3.1 and Table 3.2 and also Table 3.3 shows Blank holding force, blank ratios, and Punch force and sheet metal blanks in three levels.

Table 3.1 Mechanical Properties of AA 6061 sheet

Base	*E(GPa)*	*v*	*σ (MPa)*	*K(MPa)*	*n*	R_0	R_{45}	R_{90}	*t (mm)*
AA 6061	69	0.33	277	392	0.08	0.81	0.9	0.71	2

Table 3.2 Mechanical Properties of AA 5052 sheet

Base	*E(GPa)*	*v*	*σ (MPa)*	*K(MPa)*	*n*	R_0	R_{45}	R_{90}	*t (mm)*
AA 5052	69	0.33	174	350	0.14	0.92	0.93	0.85	2

Table 3.3 Blank holding force, blank ratios, and Punch force and sheet metal blanks in three levels

Blank Holding Force (kN)	60, 70, 80
Blank length ratios	30-70, 40-60, 50-50, 60-40 and 70-30
Punch force (KN)	10, 15, 20
Sheet metal blank (mm)	75x150, 100x200 and 200x200

III .b. Forming Limit Diagram (FLD)

The forming limit diagram (FLD) is a crucial tool for characterizing the formability of sheet metal. For a given material the FLD depends on the shape of the yield function. But from the experimental and numerical results the FLD was strongly strain path dependent. The experimental method for determining the FLD was introduced by Keeler (1965,1968). The maximum strains that the sheet materials can sustain prior to the onset of localized necking are referred as the forming limit strains. A FLD is the plot of the major and minor limit strains in the principal strain space. But in all the sheet metal forming processes, experimental determination of the FLD has been tedious and expensive as the strain paths of different materials were non-linear and vary from each other. The simulation results when compared with FLD, focuses the problematic areas such as wrinkling, tearing etc of the component. They were then subjected to redesign of the component or the tool. A typical forming limit diagram is as shown in Figure 1.

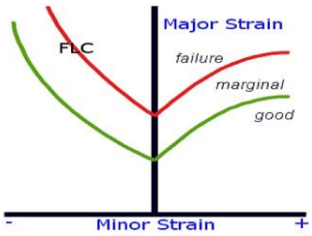

Fig 1. Forming limit diagram (FLD)

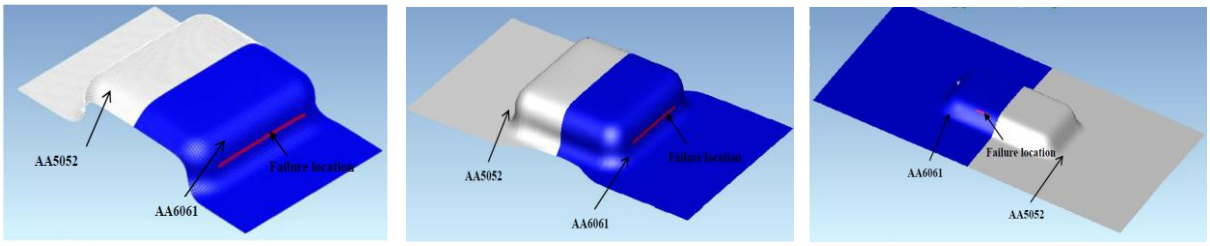
III .c. Simulations Using PAMSTAMP 2G

III .c. i. Finite Element Method and PAM STAMP 2G

Finite element method was mainly used for numerical analysis of sheet metal forming operations. Nowadays there were numerous commercial finite element codes. The simulations of two or three dimensional deep drawing operations mostly use the explicit finite element codes though there were weaknesses in the calculation of various stresses. The explicit finite element code PAM STAMP 2G was chosen for the simulations in this study. PAM STAMP 2G was an integrated solution for carrying out various stamping processes. It works as a unique graphical user interface that imports a CAD file, rework the geometry, mesh different parts, generation of the tools, launch the calculations by specifying the stamping process and finally post-process the results.

| e-ISSN: 2319-8753, p-ISSN: 2320-6710| www.ijirset.com | Impact Factor: 7.512|

|| Volume 9, Issue 5, May 2020 ||



In CAD modelling, the tools required for the test, blank, punch, blank holder and die were generated. Simulations of deep drawing process were simulated using a finite element code, PAM STAMP 2G.The sheet comprised of quadrilateral shell elements with five through thickness integration points of Belytschko-Tsay formulation. The strain hardening law and the plasticity model considered were the Holloman's power law and the Hill's 1948 isotropic hardening yield criterion respectively. Two base material sheets each of size 150x150mm and 200x200mm were taken for all the conditions. The punch radius considered was 8mm and 6mm. A uniform meshing of size 1mm was used throughout the simulations. The yield strength was kept constant and the friction coefficients taken were 0.1, 0.15 and 0.2. The blank holder forces considered were 10kN, 15kN and 20kN. Downward stroke to the punch is given with a velocity of 10mm/min and a total of 18 simulations were performed by varying the friction coefficient and blank holder force. From the simulation results the thickness distribution, punch force, and dome height were evaluated.

IV. EXPERIMENTAL RESULTS

The present study observed the variation of the blank holding force and the blank ratio at three different varying levels while simulating the whole process. The blank holding force and the lubrication condition are effectively evaluated by comparing the punch force and the thickness distribution from the results obtained from the deep drawing process simulations of the AA 6061 and AA5052 sheet by calculating the major strain and minor strain values at each condition of different strain paths.

IV.I. FAILURE INITIATION

Figure 2 (a),(b) and (c) shows deformed strain paths of width 75x150mm, 100x200mm and 200x200mm at punch force of 10kN. In all Figures failure is happened in the AA 6061 sheet whereas failure location is same in all the strain paths. In 75x150mm and 100x200mm the stain paths failure is in the width direction. Initial failure is seen in the AA 6061, it is due to variation in the mechanical properties as compared to AA 5052 alloy. Strain hardening coefficient (n) which is one the effectible formability parameters during the deformation and also play a vital role during the strain localization. If the n value is more the strain localization will be uniform and vice versa. From the Table 1and 2, n value of AA 6061alloy is less compared to AA5052 alloy which lead the faster failure in AA 6061 alloy than AA 5052 alloy. Similar failure phenomenon has seen at punch forces of 15kN and 20kN.

(a) (b) (c)

Fig. 2 (a)Failure location at 10kN punch force in 75x150 mm sheet (b) Failure location at 10kN punch force in 100x200 mm sheet (c) Failure location at 10kN punch force in 200x200 mm sheet

IV.II. Failure Locations

Below is the table showing the failure point, also considered as the punch force for the applied blank holding force along with the different blank ratios. The different strain paths are also mentioned.

Blank holding force (kN)	Blank ratio	Punch Force (kN)	Failure Initiation
60, 70, 80	30-70, 40-60, 50-50, 60-40, 70-30	10, 15, 20	AA 6061

Table 4. 1 Failure locations at different parameters

It is observed from the above Table 4.1 that all the time base material AA 6061 is undergoing into failure which shows that base material AA 5052 has got high forming when compare to base material AA6061 to undergo forming into any considered strain paths for the given blank holder force and punch force in considered blank ratios.

Finally it is concluded that among five different blank ratios as 30-70, 40-60, 50-50, 60-40, 70-30 for the blank holding force (60, 70, 80), punch force (10, 20, 30), strain paths (75x150, 100x200, 200x200) shows the best

forming in 70-30 blank ratio which indicates that at blank ratio 70-30, AA 6061 base material has got the highest forming limit.

V. CONCLUSION

The results obtained by varying all the above parameters are evaluated for the punch force and also for the thickness distribution. And it is concluded that:

- As the blank holding force increases from 10kN to 20kN, the punch force decreases with slight variation for the strain path 200x200mm. The punch force is noticed to increase with increase in the blank holding force for the strain path 150x150mm.
- The thickness distribution is evaluated from the graphs drawn by comparing the thickness with the distance, both calculated in mm. The observations show variation in the thickness distribution for the strain path 150x150mm for variations in the process parameters. But there is no change in the thickness distribution for the strain path 200x200mm.
- The dome height decreased as the coefficient of friction increased from 0.1 to 0.2. The maximum dome height is noted as 23mm for the strain path 150x150mm and as 13mm for 200x200mm strain path. But the variation in the dome height in each of the simulations is very minimum

Mechanical Behavior & Analysis of Epoxy, Al_2O_3 Composites

K. Bharadwaja, S. S. Rao, T. Babu Rao

Abstract: ***In this paper, an intelligent report has been planned for to assess epoxy composite network Epoxy composite execution of Al_2O_3 particles remembered for epoxy composite resin. A ultrasonic blending method applied to accomplish homogenous dissemination of particles addicted to epoxy pitch. Various mechanical and Tribological tests, for example, bending (three(3) point) test, Charpy Impact test & hardness are perform to check mechanical properties & wear execution of Al_2O_{3+} Epoxy composites. These composites showed expanded bowing quality and effect quality because of the absorption of Al_2O_3 particles. In collection, presentation of Al_2O_3 particles into Epoxy gum grid at low qualities brought about noteworthy decrease of wear rate Such type of impacts would be ascribed to the scattering of Al_2O_3 particles into epoxy framework &stacking. The impact of the Al_2O_3 molecule ejection with epoxy lattice tar is additionally portrayed regarding strengthening strategies.***

Keywords: Epoxy composite; Al_2O_3particles; Epoxy; Mechanical properties; Tribological execution.

I. INTRODUCTION

The Epoxy pitch is mainly fundamental thermosetting polymers that have been generally utilized while the framework in Epoxy + Al_2O_3 composites along with other basic materials because of its high quality, huge compound obstruction, and straightforwardness in preparing and in light of the fact that it is accessible since multi year. Separated of this, epoxy tars are one of a kind among every thermosetting gum as a result of numerous elements including shrinkage, no volumeatiles emitted during fix, similarity with an extraordinary number of materials, quality and toughness, security, disintegration and substance obstruction, and electrical protection [1]. practically identical to different thermo sets, epoxy saps likewise structure a system on restoring with various relieving operators, for example, amines, anhydrides, thiols, and so forth [2]. These substance and handling adaptabilities make epoxies valuable in numerous applications, for example, defensive covering, paints, breaking rubbers, and liners cements, hardware, mechanical deck and Epoxy composites. Since numerous years, Epoxy composites have become other materials that improve Epoxy composite material execution by recognizing innovative qualities and permitting interesting association among materials [3-11]. There are various observations that illustrate Epoxy composites demonstrate elevated mechanical & warm properties contrasted with conventional Epoxy+ Al_2O_3 composites [16,]. Basically, fillers have high thickness contrasted with the low thickness of polymer network, accordingly require a lot of fillers superfluous to the framework so as to get better mechanical execution. Additionally, this expansion in filler content prompts an expansion in the heaviness of the Epoxy composite. Then again, polymer Epoxy composites have the one of a kind capacity to improve mechanical properties at low filler content, enabling the material to be lightweight [19]. The primary points of interest of Epoxy composite polymers are its favorable circumstances in physical properties contrasted with ordinary composites. As of late, there is extraordinary mindfulness in improving properties of epoxy grid Epoxy composite with expansion of particles, for example, TiO2 and others [22, 23]. Schadler and Siegel [24] created an epoxy framework Epoxy composite loaded up with TiO2 and revealed a helpful impact on mechanical properties. It was discovered that the expansion of articles can be an increasingly supportive method for enlightening the mechanical and warm attributes. Epoxy/dirt Epoxy composites are the most broadly worked thermo set cross breeds. Researchers change various kinds of tar, natural modifiers, relieving specialists and handling conditions in manage to increase basic tolerating of materials and to streamline the preparing systems. Epoxy composites are these days no longer just private to the research center, they are found in the genuine world [25]. One of the lion's share regular application techniques to accomplish homogenous scattering is ultrasonic blending, which have been, all things considered, utilized in present day years. One of the uses of epoxy, as referenced some time ago, is flooring. This present examination endeavors to research mechanical properties of Epoxy composites by bringing Al_2O_3 particles into epoxy tar, with center around kind of circulation and stacking. The last properties of Epoxy composites may control the path toward new utilization of elite of polymers

II. MATERIALS USED

The hybrid Epoxy composite material used in the current research includes a matrix material Lapox C-51, a low viscosity liquid epoxy resin (equivalent weight = 182-192 g/eq, viscosity at 25°C= 450 - 650 m Pas) along with Lapox K-6 , a room temperature curing amine hardener (density at 25°C = 1.04 Kg/l) supplied by Atul Ltd, Gujarat. The reinforcing material Al_2O_3 particle (190 µm) procured from Fisher Scientific, Mumbai.

III. SPECIMEN PREPARATION

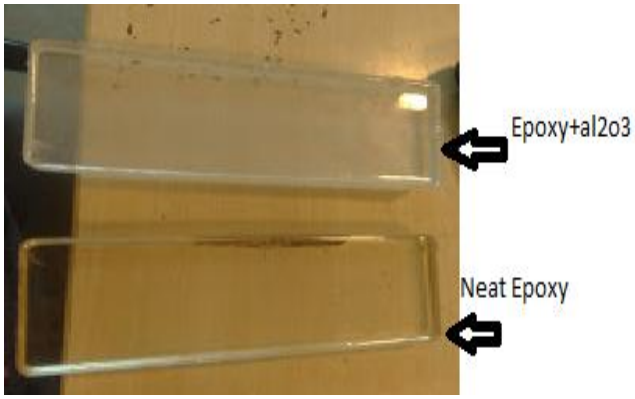

Fig 1

The calculated weight amount of Epoxy+ Al_2O_3 particles was mixed resin through a mechanical stirrer for 10 min to decrease viscosity of resin after that This compound was then mixed Homogenizer (Miccra D-9, speed range of 11 000–39 000 rpm) used for 14 min in order to attain a homogenous dispersion .shown in Fig 1. A curing agent was added to the mixes at surrounding temperature & combined for 5 minutes by means of the mechanical stirrer. So as to acquire ordinary Epoxy composite examples for mechanical testing, the last mix was filled the shut shape, trailed by the relieving procedure around 24 hours with proper releaser applied before filling mould.

Epoxy composite Characterization

Flexural Test

Three-point bending test of the Epoxy+ Al_2O_3 composite samples prepared ASTM D790 using a Deepak Samarth universal testing machine at a deformation rate of 5 m/min at near to room temperature in regulate to calculate flexural properties.

Charpy Impact Test

Notched Impact test conducted using Impact Tester machine, model FIT 300 (EN) according to ASTM D256 standard.The entire composite sample dimensions are 10x10x55 mm

Hardness

The samples for hardness testing were machined from the fabricated Epoxy composites with the dimensions of 15x25x10mm and polished them to 1µm. by using Barcol method.

Scanning electron microscopy(SEM)

In categorize to observe the morphology of fracture surfaces in Flexural Bending test , Charpy impact test,& SEM utilized with the function of obtaining in sequence concerning the consequence of particles on the resultant reinforcing.

IV. TEST RESULTS

Flexural Test

Flexural Bending test utilized for assessing flexural properties of epoxy composites loaded up with Al_2O_3 particles. after number of studies which agree with the positive impact of in adaptable particles on the size of macrometer during stress conduct of framework Epoxy composite. In including, it is celebrated that flexural quality of Epoxy+ Al_2O_3 composites is strengthened with fall of micrometer molecule size because of expanded filler content [28]. This gives far over the ground flexural quality. Fig. 1 shows flexural quality of Epoxy composites loaded up with Al2O3 particles as far as Al2O3 particles content. As per Table 1& Fig. 1, the including of 5% volume Al2O3 into epoxy gum brought about a 10% overhauling in flexural quality contrasted and slick epoxy. Expanding the measure of Al2O3 to 7% volume development improved flexural quality upto 30%. This expanded flexural quality can be licensed to the nature of dissemination and stacking of particles.

Flexural strength results of Al2O3. .. Wt % (Table1)

Sample No.	% of Al_2O_3	Flexural strength (MPa)	Impact strength (KJ/m2)	Hardness strength (B)
1	1	45	1	55
2	2	49	1.8	62
3	3	54	2.1	70
4	4	55	2.3	76
5	5	59	2.9	82
6	6	61	2.6	85

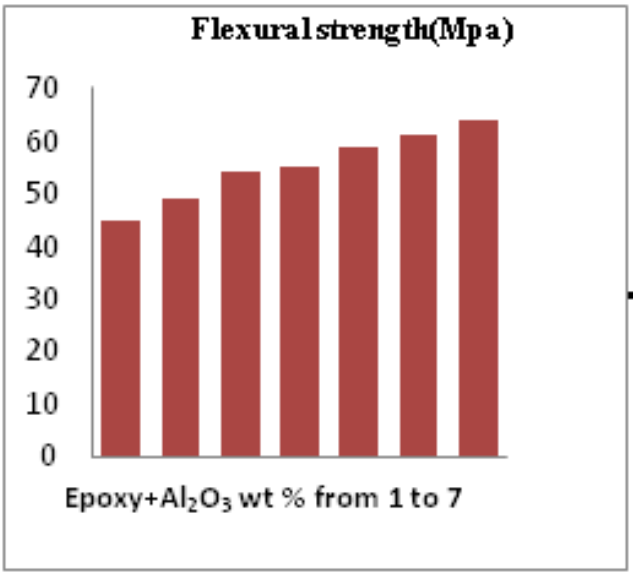

Fig 1

Impact test

The Charpy impact test is one of the most appropriate impact tests that assess the performance of a material issue to shock loading with bending, tension and torsion. Charpy tests are extensively applied in industries due to the simplicity of sample preparation and the opportunity to generate comparative data very rapidly [32]. Notched samples are prepared. The specimen contains a notch, then the calculated impact strength is pretentious by only fracture propagation.

In other words, notches act as stress concentrators. As well, if the original addition procedure not efficient, a comparable trend could be induced by constituent part agglomerates, which continue as stress concentrators within the matrix. If the introduced particles act as burly stress concentrators, the impact force of the composite (epoxy+ Al2O3) is predictable to decline significantly as more particles are introduced. It be supposed to be noted at this point that the utilize of notched specimens in this study emphasizes the measurement of the power required to promulgate a crack through the material. shows Fig.2. impact strength of (epoxy + Al2O3) composites as a role of Al2O3 particle content.

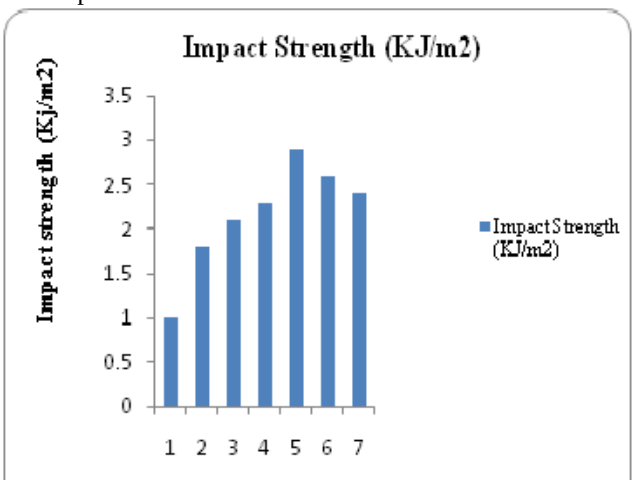

Fig 2

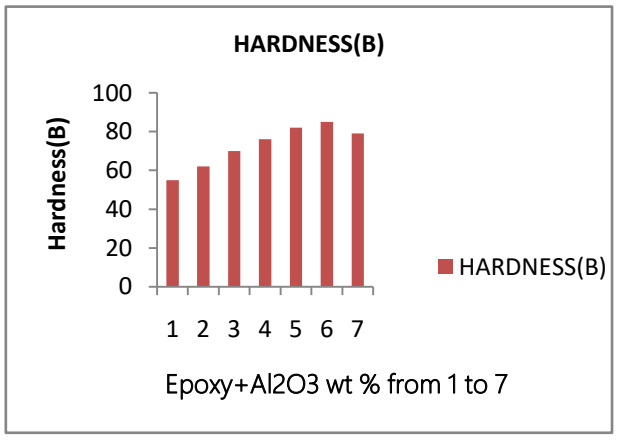
Hardness test

Fig. 3 shows the variations in the hardness of Epoxy with Al_2O_3(composite) filler content. As practical, accumulation of the Al_2O_3 particles improved the hardness, which corresponds to the high hardness & additional identical diffusion of Al_2O_3 filler. Elevated hardness is exhibited by the 6% of Al_2O_3 particles overflowing (Epoxy+ Al_2O_3) composites, while 7 % Al_2O_3 particles Epoxy composite shows decrease in hardness. For the majority cases, increasing filler content increases the rigidity of the Epoxy + Al_2O_3 composite. In this case of high filler ratio, a small drop in hardness value is seen. These observable fact can be delineate by the weak point in the bond the epoxy + Al_2O_3 fillers. Lam et al. found that ornamental the stuffing ratio resulted in attractive collect in the Al_2O_3 particles crammed Epoxy composite & a decrease in the hardness value of the Epoxy + Al_2O_3 composite



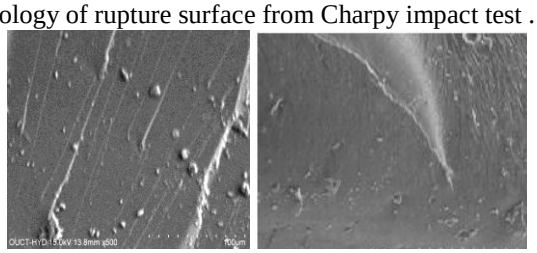


Fig 3

Scanning electron microscopy

Crack capture outline are seen in this manner of transmission. in conclusion, constant ductile mode dissemination takes place in high temperature testing conditions. in addition, plain stress is the prevailing state of tension in (Epoxy+ Al_2O_3) composite, which causes an increase in the stress essential for to yield shearing.. Morphology of rupture surface from Charpy impact test .

Fig .4

(a) epoxy composite with 1% Al_2O_3 particles (b) epoxy composite with 7% Al_2O_3 particles

V. CONCLUSION

In this paper evaluated Mechanical & Tribological performance of composite(Epoxy+Al_2O_3).so as to attain high superiority dispersion of Epoxy+ Al_2O_3 composite, ultrasonic mixing utilized to get the Results, Matrix properties have been pretentious by beginning of particles. Flexural Bending strength, of composite augmented due to mixture of 1% volume Al_2O_3 particles with epoxy matrix. These improvements continued up to 7% volume added into epoxy matrix Impact strength, of composite improved due to blend of 1% volume Al_2O_3 particles with epoxy matrix. These improvements continued up to 5% volume, and decreased in 6 & 7 % volume. added into epoxy matrix Hardness of composite improved due to blend of 1% volume Al_2O_3 particles with epoxy matrix. These improvements continued up to 6% volume, and decreased in 7 % volume. added into Epoxy$_+$ Al_2O_3 matrix. [40].since possibility of agglomeration particles increases in these circumstances. in conclusion, high mechanical properties of Al_2O_{3+}epoxy composite, with superior wear properties, permit the substance to moderately or entirely substitute fibers in predictable fiber-reinforced composites.

Abstract: *Al7075 aluminium alloy is the most favored material used in aero space, defense, automobile and various engineering purposes due to its exceptional properties. Due to poor resistance to wear property, it is restricted to use at various engineering applications. The wear resistances of aluminium alloys are improved by adding of ceramic reinforcement particulates. In the present work Al7075 aluminium alloy is selected as a matrix material and silicon carbide (SiC) selected as primary renforcement which has good compatibility with aluminium alloy and posse's excellent mechanical properties, high electrical resistivity, and good thermal conductivity. On other hand molybdenum disulfide (MoS_2) also used as secondary reinforcement (solid lubricant) to enhance the wear properties of composite materials in dry sliding wear condition at room temperature. The Al7075-3%SiC – 3%MoS_2 composites are fabricated via stir-casting process with increasing of molybdenum disulfide (MoS_2) by 4% and 5% respectively. The dry sliding wear test was carried out for the fabricated composites on Pin-on-Disk apparatus to estimate the wear rate of composites by considering progression parameters as normal load, sliding distance and sliding velocity during experimentation. Further, the wear surface analysis was carried out by optical microscopy analysis. This experimental result reveals that, the effect of molybdenum disulfide (MoS_2) in dry sliding wear condition of fabricated composites.*

1. INTRODUCTION

A innovative set of advanced materials entitled metal matrix composites(MMC) substitute traditional materials because of unusual wear resistance characteristics, strength to weight ratio and in several applications for instance as pistons, cylinder liners and other materials etc. MMCs have been an interesting and competitive field of scientific analysis and research more than the past two decades, with MMCs being practical engineering materials mainly in recent times[1]. Aluminum-based composites contribute to the overall share of commercially produced MMC[2]. Aluminum material is very light metal which is frequently used in various types of industrial appliances and having a density of approximately 2.7g / cc after that to magnesium. This type of metals is frequently applied as the stand material in various manufacturing due to high strength to weight ratio and fast storage. Products based on aluminum are typically combined with durable terracotta constituent parts to create compounds that enhance more suitability of these lightweight materials for use in quite a lot of applications wherever the biggest factor is wear [3]. Aluminum is armored with various kind of durable terracotta constituent parts similar to SiC [4,5,6,7,8], B_4C[9-10], Al_2O_3[11–13] and TiC [14] for the manufacture of composite materials for various applications. In addition to these normal ceramic particles, a

small number of supplementary materials just like mineral admixtures i.e. rock dust, fly ash, marble dust and bagasse ash have been examined by some researchers [15]. Mainly of the work spotlight on enhancing the wear resistance of the aluminum alloy and SiC is used with several materials among the specific ceramic particles, resulting in increased the main property which is resistance of wear. SiC improved AMCs are glowing acknowledged for their heavy strength and resistance to wear put side by side to conventional alloys [16]. Increasing SiC of volume and width diminishes Al6061/SiC composites ' common wear rate [17]. Al alloy's mechanical strength and wear resistance improve as SiC particulates increase. Other than the secondary augment in hardness build it hard to machine the material [18]. In addition to strong ceramic particles, the accumulation of solid lubricant constituent parts such as Gr or MoS_2 improves the wear characteristics of compounds [19–23]. It happens due to the mechanical characteristics are enhanced of bulk due to durable constituent parts and diminished abrasion coefficient due to the configuration of lubrication layer [24–26]. Additional amplify in the graphite (Gr) increases composite rupture strength which reduces wear resistance [27]. Furthermore, as the percentage of Gr reinforcement enhanced, the material's hardness decreases as a consequence of the compound's increased porosity [28]. Therefore, the quantity of unyielding lubricant added be supposed to contained by the maximum value and preserve be worn in combination in the midst of supplementary terracotta reinforcements like SiC and TiB_2. Furthermore, graphite is additional in a large amount revises as reinforcement owing to its enhanced self-lubricating characteristics to trim down friction and rate of wear. Nevertheless, very few attempts were made on MoS_2 alone as a reinforcing part of aluminum matrix compounds, which furthermore contain a self lubricating feature. The most crucial improvement of the MoS_2 in excess of Gr is that to show its strong lubricant nature, i.e., it does not necessitate any peripheral sustainable things i.e oxygen. Even in the vacuum environment, MoS_2 can show its solid lubricant property. However, MMC manufacturing faces many difficulties including similarities among medium and reinforced constituent parts, identical divisions of reinforcement constituent parts on more matrix material; it is very successfully resolved via an assortment of changes during manufacturing systems. Methods of in situ, liquid, solid state are widely utilized to incorporate ceramic particles into the techniques of matrix production. The MMCs were manufacture in liquid stir casting, among other things, incredibly inexpensive and effortless. The reinforced terracotta particles are unvaryingly disseminated and are accomplished of achieving a near net component and the production speed of the element [29, 30, 31].

2. EXPERIMENTAL PROCEDURE

2.1 Raw Materials

For this work, the base matrix selected was Al7075 alloy and procured in the form of ingots from Vision Castings, Hyderabad. Table 1 illustrates the chemical composition of the Al7075 alloy. For this work, The chosen reinforcement material was Silicon Carbide (SiC) and MoS_2 (molybdenum disulfide) from M/s Vision Castings & Pvt. Ltd., Telangana, Hyderabad.

Table 1. Al7075 Chemical Composition (Weight percentage)

Chemical composition	Si	Fe	Cu	Mn	Mg	Cr	Zn	T
Al7075	0.4	0.5	1.6	0.3	2.5	0.15	5.5	0

2.2 Fabrication of Composites

Composites are prepared using stir casting technique through the liquid metallurgy route. Upon successful degassing with solid degassing hexachloroethane tablet, preheated SiC fine particles and MoS_2 of lab-grade spotlessness were additional into the eddy of the molten alloy. A ceramic-coated steel impeller was used for a period of 10 minutes, to achieve molten alloy by mechanical stirring. It achieved a frequency of 400 rpm. A 710^0C pouring temperature was continued and the fused metal used in preheated cast iron molds.

Table 2. Composition and code of prepared materials

S.No	Composition	Code
1	Al alloy	Al
2	Al 7075 + 3% by wt Sic + 3% by wt MoS_2	
3	Al 7075 + 3% by wt Sic + 4% by wt MoS_2	
4	Al 7075 + 3% by wt Sic + 5% by wt MoS_2	

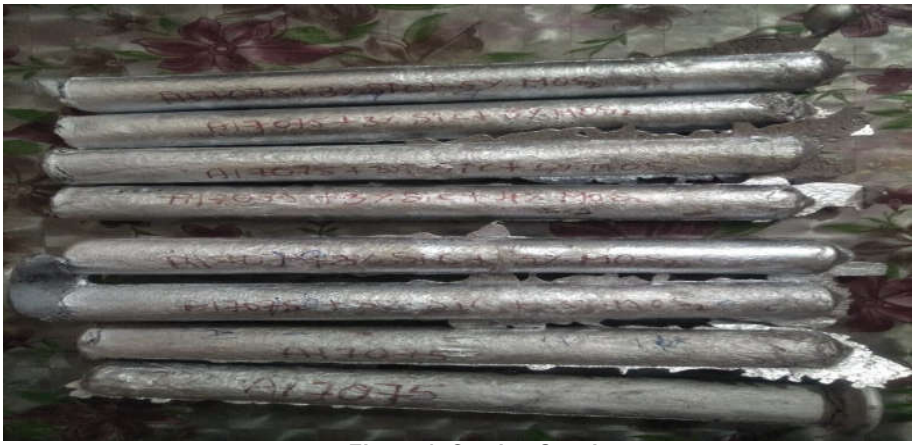

Figure 1. Casting Specimens

3. PHYSICAL AND MECHNICAL PROPERTIES

3.1 Hardness Test

Bulk hardness measurements are performed using standard Rockwell hardness testing machine scheduled to the base metal & composite specimens. The sections were machined at room temperature and load using 500 kg as per ASTM E10-07a. The test showed that the composite specimen's hardness had progressively amplified through an enhancement of up to 5% wt of MoS_2 fine particles in the metal matrix.

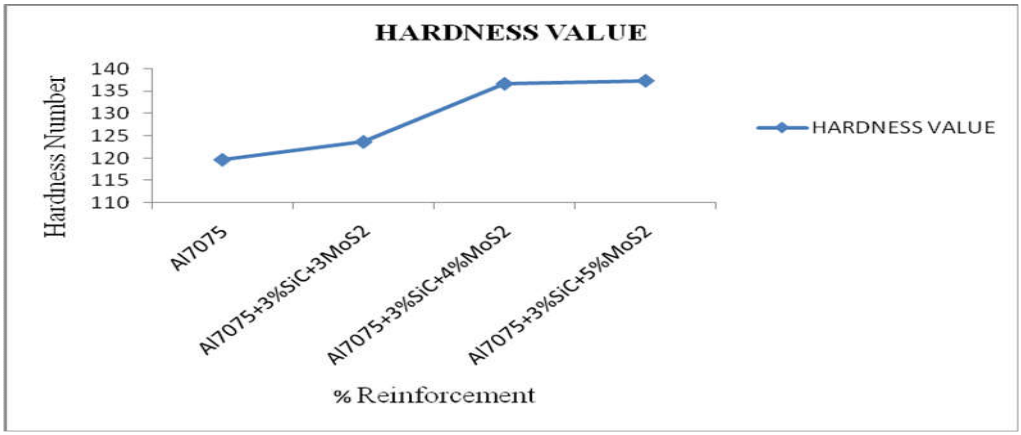

Figure 2. Change in Hardness of the material with percentage reinforcement in hardness

3.2 Tensile Strength Test

The specimens were a machine for obtaining dog boned structure as per ASTM–UTM carried out the standard E8 experiment. All the samples of the tensile test are publicized in Figure 4. The test showed that the ultimate tensile strength improved slowly by rising the percentage of reinforcement applied to the steel matrix by wt. The peak tensile strength of 5% MoS_2 was observed. The ultimate tensile strength pattern is shown in the Figure 3.

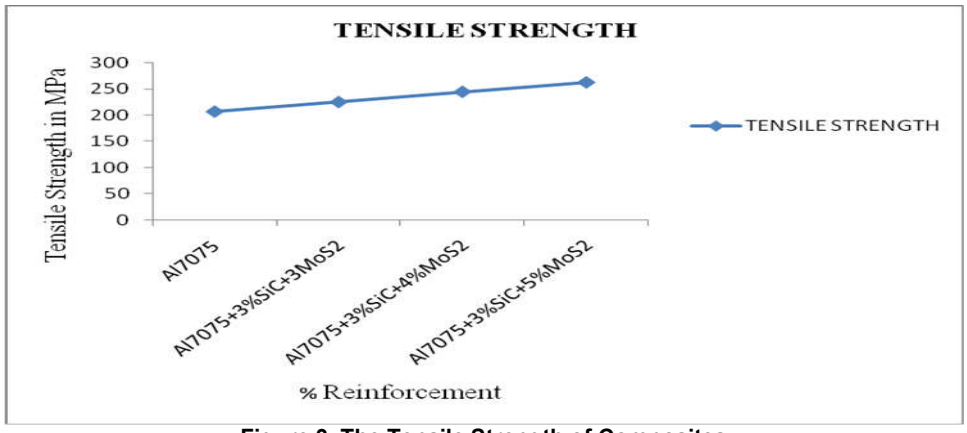

Figure 3. The Tensile Strength of Composites

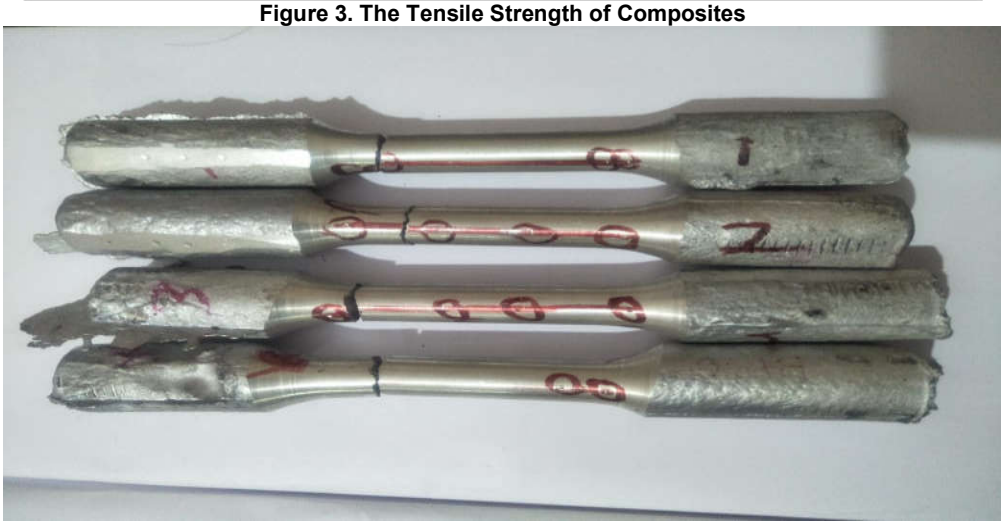

Figure 4. Tensile Test Specimens

3.3 Elongation

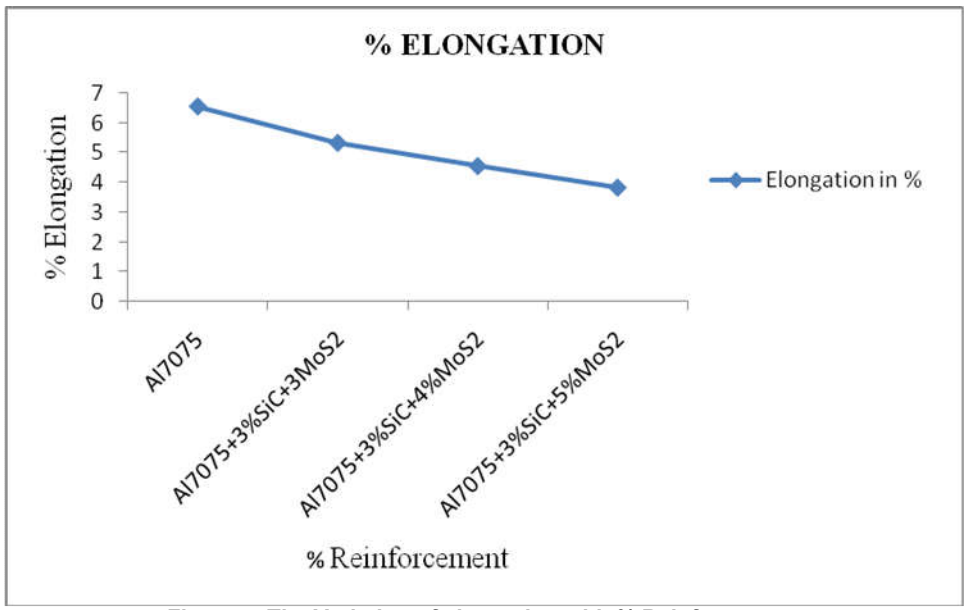

Figure 5. The Variation of elongation with % Reinforcement

Figure 5. Shows the difference of elongation among SiC & MoS_2, the measurement of Ductility of composites by using % elongation. The Ductility of Al alloy is high as evaluate to prepared composites. The elongation of the composites drastically condensed due to raise in weight percentage of reinforcement. The decrease in the ductility due to development voids nucleation by increasing % of MoS_2. At the tip of cracked particles stress concentration is very high, this forms lower ductility as compared to un reinforced composites (Al alloy).

3.4 Density

A rule of mixture is used to determine the potential density values of base alloy and composites. We used Electronic specific gravity balancer to measure the density of alloy and composites. Figure. 6 shows electronic specific gravity balancer.

Figure 6. Electronic specific gravity balancer

The typical theoretical and measured density values of the AA-7075 alloy and its relevant composites were shown in Table 6. Adding Sic and MoS_2 into the base material in such a

case density of the composites was increased evaluate to the base material AA 7075 alloy. This is the reason of high density of AA 7075 alloy.

Table 3. Theoretical and measured densities of AA-7075 and Composites

Samples	Measured Density (g/cm^3)	Theoretical Density (g/cm^3)
AA-7075	2.81	2.82
AA-7075+3%SiC +3%MoS_2	2.86	2.88
AA-7075+3%SiC+ 4%MoS_2	2.89	2.91
AA-7075+3%SiC+ 5%MoS_2	2.9	2.93

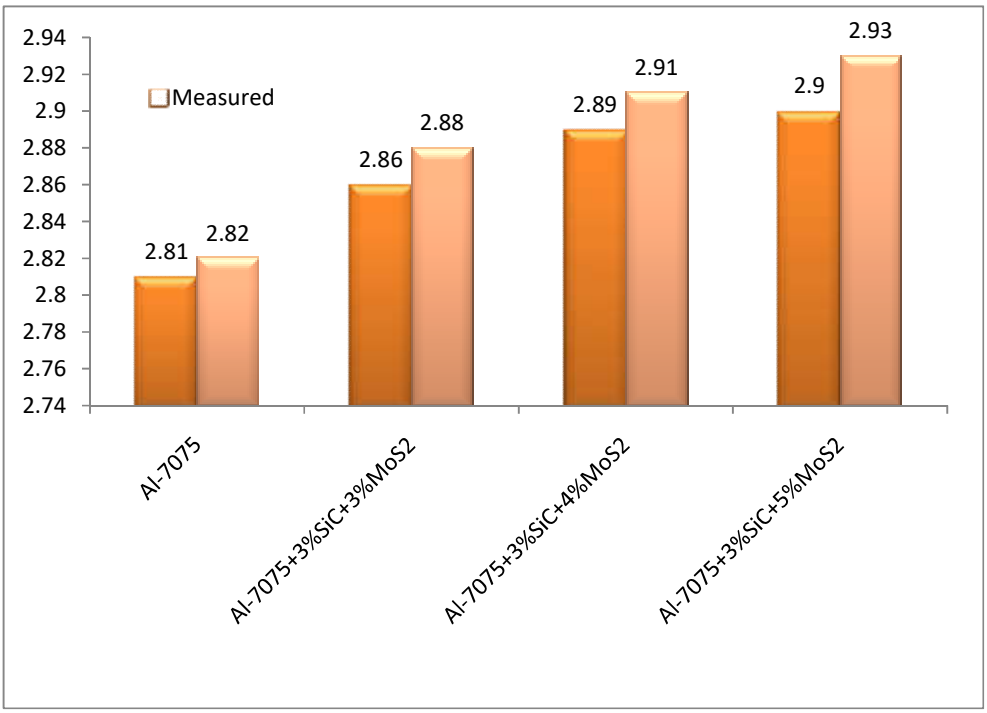

Figure 7. Variation of Density Vs % of Reinforcement

4. WEAR PROPERTIES

In this work we used specimens as per the ASTM G99 and experiments conducted using a computerized wear test machine (pin on disc) as illustrated in the figure 9. Disc of the material is steel. The disc surface was cleaned with high garde emery paper before testing. Figure 8 reveals the dimensions of the wear test samples were 8mm ϕ and 30mm length and Figure 10 shows wear test samples. In this wear test we used different types of paremeters such as load is varied 10N, 15N and 20N, sliding distance is 950 m and sliding velocity is 2.5 m/s. In this test pin was kept stationary perpendicular to the disc and disc was roated.

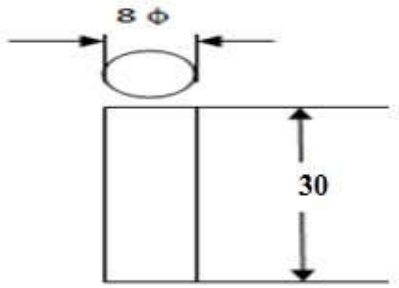

Figure 8. Dimensions of Wear test sample

Figure 9. Pin on Disc Setup

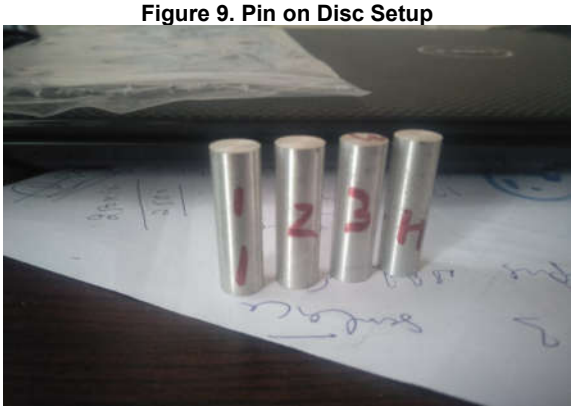

Figure 10. Wear test specimens

Figure 11. Wear test specimens

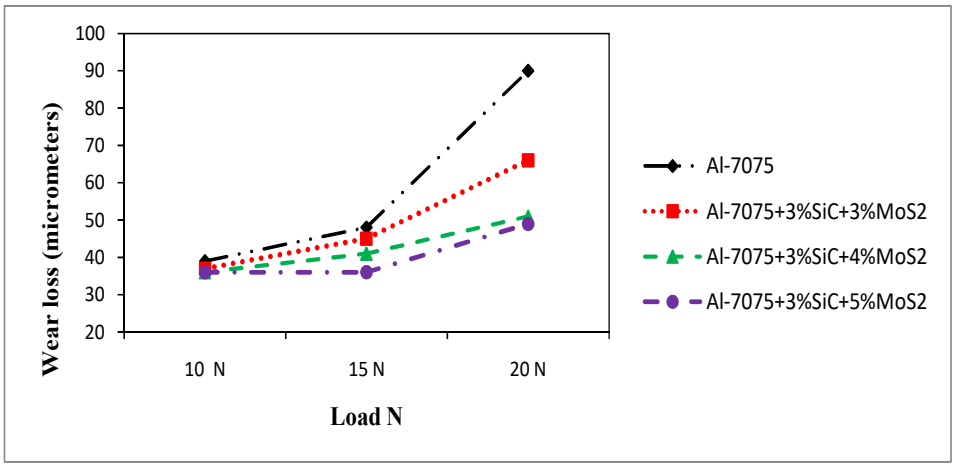

Figure 12. Variation of Wear rate with load at sliding velocity 2.5 m/sec and constant sliding distance 950m

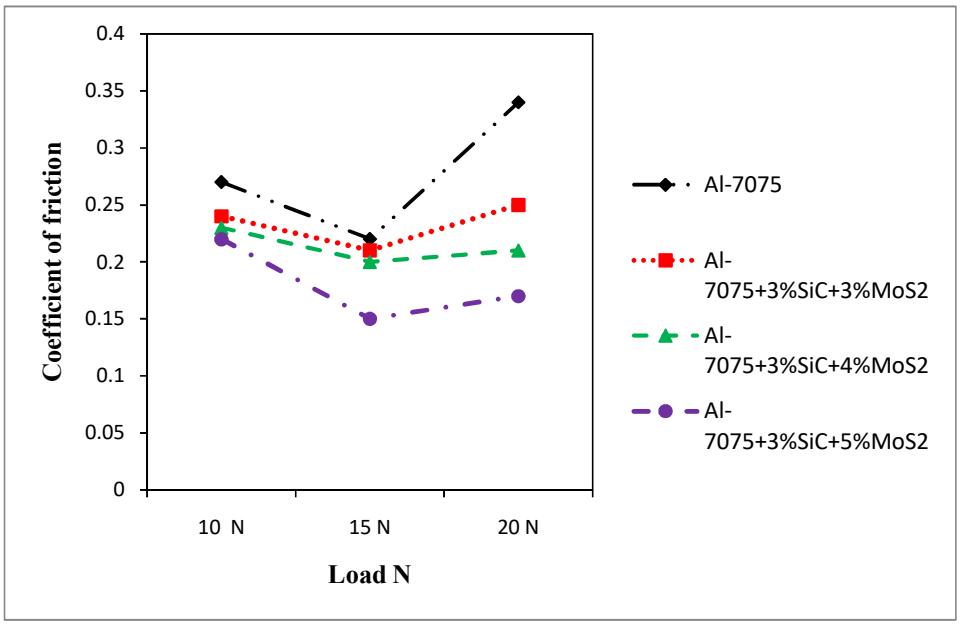

Figure 13. Variation of Coefficient of friction with load

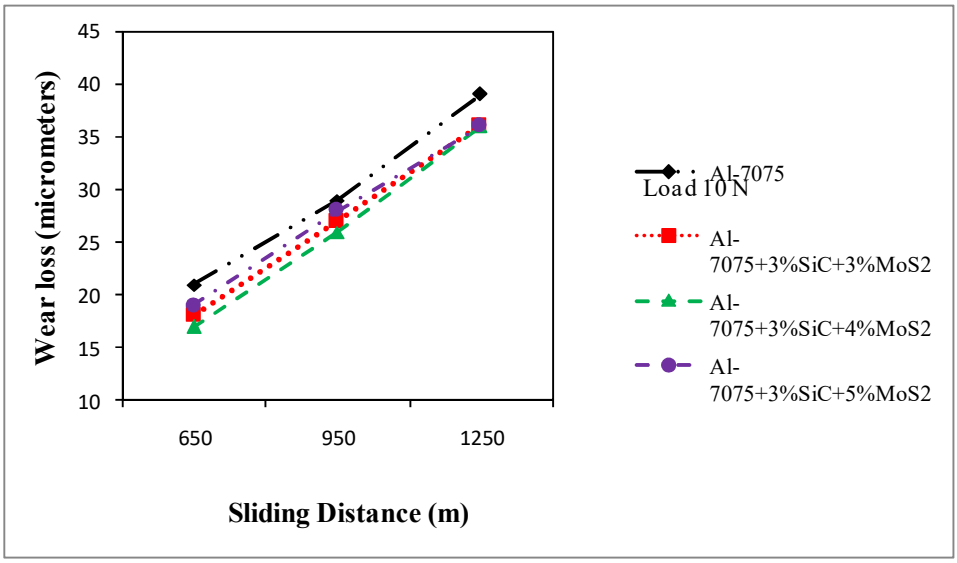

Figure 14. Variation of Wear rate with Sliding distance at sliding velocity 2.5m/sec and at constant load 10N in room temperature condition

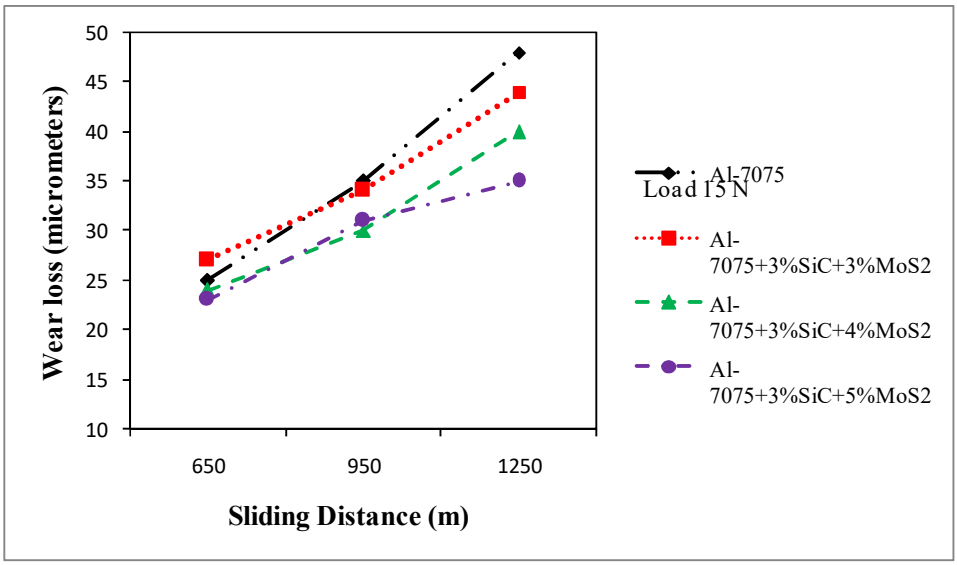

Figure 15. Variation of Wear rate with Sliding distance at sliding velocity 2.5m/sec and at constant load 15N in room temperature condition

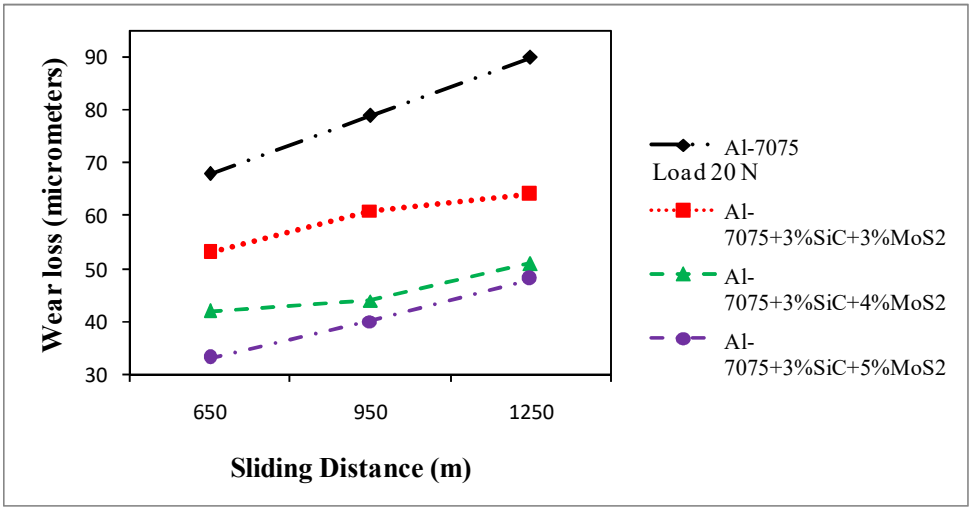

Figure 16. Variation of Wear rate with Sliding distance at sliding velocity 2.5m/sec and at constant load 20N in room temperature condition

The above figures clearly show the difference in wear rate for different loads viz 10N, 15N, 20N with accumulation of wt percent reinforcement to Aluminium alloy. From the statistics above, we can clearly identify that the wear rate decreased in every part of different loads by adding wt percent of reinforcement, as the load rises the wear level often enhanced in all situations. The stress also amplified proportionately at the pin-disk boundary when the load is raised, whereas Al7075 as a lighter material endure very high wear and SiC elements & MoS_2 soild lubricant withdraws the weight functioned after that the boundary connection among Al, SiC and MoS_2 decreases the rate of wear in the abrasive wear system.

5. MICROSTRUCTURE

Morphology, thickness, size and distribution of reinforcing particles have a foremost impact on the properties of particulate composites. The samples were prepared by rigorous buffing and engraving for microstructure analysis, and the specimens were then examined beneath an optical microscope to examine the microstructure. Figures 17-19 display the optical micrograph, which illustrate the even scattering of the matrix reinforcement.

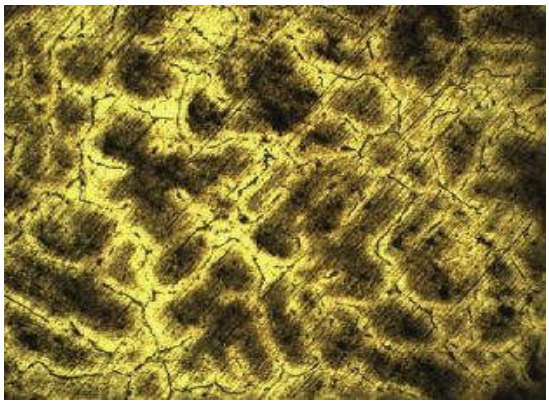

Figure 17. Al7075+ 3% SiC+3%MoS_2

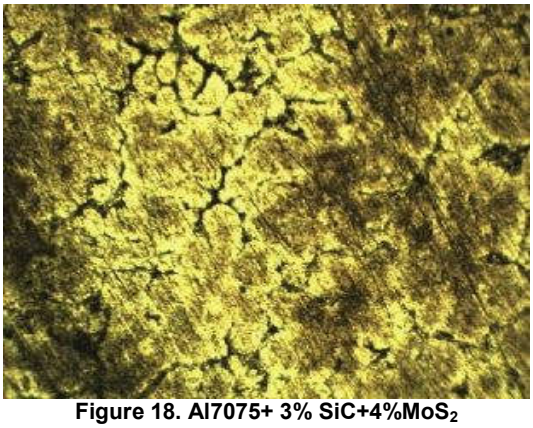

Figure 18. Al7075+ 3% SiC+4%MoS_2

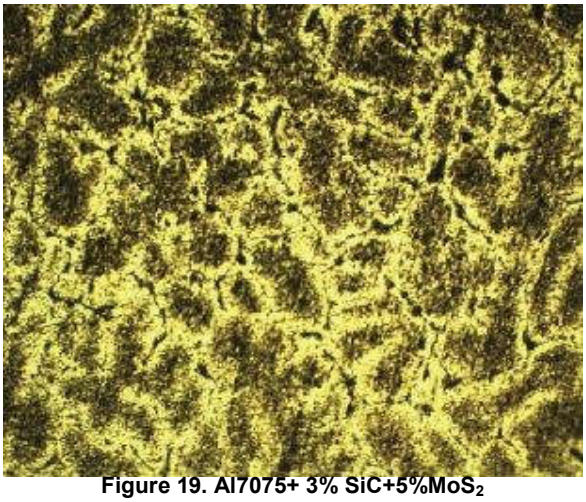

Figure 19. Al7075+ 3% SiC+5%MoS_2

6. CONCLUSIONS

1. Through increasing the percentage of SiC & MoS_2 reinforcement content, density increases. There are not much more variations among the experimental and the theoretical density values and this designate the aptness of the stir casting system for composite preparation..

2. The composites are arranged using the technique of liquid metallurgy (stir casting). in the midst of an amplify in the percentage of reinforcement, the micro hardness increases; this is due to the SiC particle and secondary MoS_2 reinforcement distributed in the soft matrix material. As the reinforcement percentage increases the hardness value when compared to the alloy.

3. By increasing the secondary MoS_2 reinforcement, the tensile strength increases. Due to the addition of 3%, 4% and 5% by mass MoS_2, the tensile strength increases significantly. The composite elongation rate dropped drastically thanks to weight percentage increase in reinforcement.

4. At first, the rate of wear was greater in the nonappearance of SiC & MoS_2 particle asperities. The SiC & MoS_2 elements outlined a protective stratum among the pin and offset face exterior as the sliding distance and load increases, thereby increasing the wear speed. When the pin-disk interface raises the load. As a softer material, Al 7075 endure higher wear, but the Sic particle & stronger lubricant MoS_2 resists the load functional and the bonding crossing point among Al. SiC & MoS_2 in the abrasive wear system decreases wear rates.

Influence of Variable Speed on Performance and Emission Characteristics of Diesel Engine using Fish Oil Biodiesel Blends

M. Vijay Kumar, U. Gopala Rao

Abstract: ***Alternative fuel sources are needed to be developed to meet the escalating demand for fossil fuels. Also from an environmental point of view, these most modern resources of fuels must be environment-friendly. The rapidly increasing consumption of fossil fuel and petroleum products has been a matter of concern for many countries which imports more crude oil. So, there is necessary for the development of new energy sources. The biomass, edible oil, inedible oils from plants and fish fat oil are imperatives and seen to be a potential substitute for diesel fuel. Acid and Base catalyzed transesterification is the most acceptable process for biodiesel production.***

In this project, an attempt towards finding the effect of alternate fuels as a substitute over diesel and reduce its consumption to lessen the environmental effects. Biodiesel has been extensively used in diesel engines as a partial substitute in the past few decades. The present investigation is carried out with blending up fish oil biodiesel with diesel in varying proportions to test out the emission and performance characteristics of direct injection single cylinder, four strokes, and air-cooled diesel engine. The fish oil biodiesel was produced by the transesterification process and obtained fish oil biodiesel blended with diesel fuel with various propagations of B20, B50, B75 & B100. These blended fuels were further investigated in a diesel engine with variable speeds such as 1000rpm, 1250rpm, 1500rpm, 1720rpm, 2000rpm 2250rpm & 2500rpm. In this comparative study, the effects of fish oil biodiesel fuel blends are compared and evaluated with pure diesel.

Keywords: Fish oil biodiesel, Direct injection single cylinder four-stroke air cooled diesel engine, Performance and Emissions.

I. INTRODUCTION

Fossil fuels are the major source of energy, since the economic revolt in the 18th century. Coal is still one of the easily accessible sources, and there was almost unlimited availability when it was discovered. During the 19th century, technology allowed for the processing of crude and it rapidly regained as a substitution fossil energy supply [1-2].

The fuel that was used for heating, was the crudest product spent however, because of the process knowledge advanced, a lot of crudest products entered the market. These crude products, with their high energy content and portability. Electricity can be provided to houses. The demand for Energy is closely joined to economics. With a lot of evolving countries from developing to an industrial country, the worldwide demand for energy has quickly risen. With the development of the economy, comes a standard higher in living and demand. Henceforth the need for economical fuels with fewer environmental effects has risen, resulting in various investigations to provide fuels with cost-effectiveness and comparatively less pollution [3-5].

A. Biofuels

The history of biofuels has its origins from kerosene lamps as a supply of light associated with a historic oil lamp in 1950 created in a place that is believed to be populated. The primary form of a created vehicle, the Ford motorcar, has engines running with Otto cycle designed to operate on plant-based fuels and Dr. Rudolph Diesel in 1894 stated that the compression-ignition engine has to be designed in a way it might be hopped-up by edible fat [6]. His dream was one day farmers may build their fuel to use in agricultural areas, wherever fossil fuel product was inaccessible. Fuel and its high-energy content have become a fuel of desire and also the style of the CI engine was modified to match these properties of the newly created fuel. Because of this provision and also due to the price of diesel (edible fat wasn't given any consideration except at some crossroads throughout the 1930s) the lack of oil pushed the costs up. Miserably, the newly created engine style won't operate on edible fat anymore because of high viscosity [7].

B. Transesterification

Transesterification could be a natural action to manufacture biodiesel from fatty oils. This method consists of reacting to the fixed oil with the alcohol and a catalyst. The foremost ordinarily alcohols utilized for this method is fermentation alcohol and wood alcohol. As a catalyst, a protein, an acid or a base is considered in this process but the analysis recommends employing a base catalyst like sodium hydroxide (NaOH) or potassium hydroxide (KOH) [8]. By fermentation of alcohol, one winds up with carboxylic acid ethyl group organic compound and by fermentation of wood alcohol the product is a carboxylic acid, methyl radical organic compound. Each of those product square measures characterized as biodiesel though their properties are slightly different. Wood alcohol is the commonest alcohol used. The trans-esterification process is caused by the chemical process. Bio-diesel fuel has better properties than that of Petro-diesel fuel as the varying values can be observed in table 1. given below.

II. METHODOLOGY

A. Experimental Procedure

Before beginning the study on the utilization of any different fuels during the process of CI engine, it is very essential in the choice of engine and arrangement of the setup. The information and also the methodology to be approved in every technique and calculations for deciding completely various parameters also are needed. Required investigation needed for Preparatory work. The following procedure steps were followed before beginning the investigation:

- The required specified fish oil for the study was collected and later transesterification processes were followed to obtained biodiesel.
- Most of the important properties were found and were within the limits.
- A single cylinder, four stroke, air-cooled, DI engine and gas analyzer was selected for investigation.
- Further investigation was carried out with variable speed with different propagation of fuel blends, pure fish oil and pure diesel.
- The speed, fuel consumption, gas temperature and emissions reading were noted for variable speeds.

B. Measurement of Exhaust Gas

An AVI DeGas444 exhaust gas instrument was used to record or measure the pollutants; NOx, CO and HC emissions. The HC, CO, were measured with the assistance of sensors functioning on non-dispersive infrared (NDIR) principle and NOx was measured with a chemical science detector.

The gas instruments were initially observed in standard/ideal conditions to confirm the accuracy value of the analyzer. This activity procedure is concerned with the injection of gases of higher concentration and the responses are validated. The composition ranges of CO and HC gases were; 3.6% volume of CO, 2000 ppm gas volume of HC, where as for the NO_x gas it is 2300 to 3000 ppm volume.

C. Blends of Fish oil with Diesel fuel

Blending is a simple technique of employing a mostly highly viscous fuel as an alternative fuel in an exceedingly CI engine by combining it within a fuel produces a low viscous fuel. For the study, the fish oil was blending with diesel in numerous proportions on a volume from 25 percent to in steady steps until 100 percent. The mix was represented because of the fish oil, trailed by the numerical worth that represents the share of the fish oil within the mix. For instance, the numerical worth within the mix B-25 indicates 25 percent of fish oil biodiesel. Likewise, alternative blends were denoted as B25, B50, B75, B100 of fish oil biodiesel. The mixture was stirred well with the assistance of a magnetic stirrer, to urge a mixture is stable which is homogeneous.

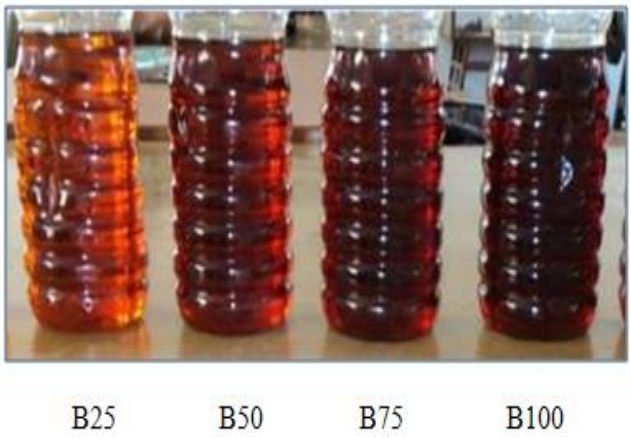

Fig 1. Various samples of the fish oil biodiesel-fuels

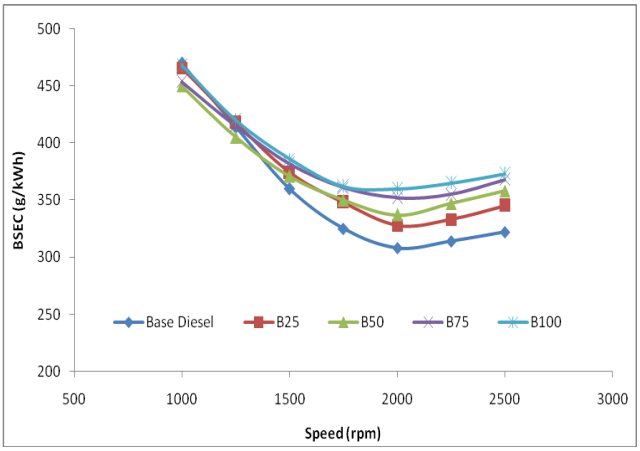
D. Experimental Setup

Fig 2. Engine setup

The investigation was done on a Kirloskar TAF-1 single-cylinder, air-cooled, four-stroke, and, direct-injection internal combustion engine with the variable speed device employed in it and experimentation runs on this engine.

A control panel was close-fitting in the generator to produce the assigned load to the engine. The engine output will be varied by dominant the sphere current. The measuring device was marked statically by the produced current. The post load will be measured by the measuring device with the assistance of a strain gauge system of load cell straddling between the stator coil base and also the frame. A measuring device and a fuel indicator enclosed within the circuit of fuel to live record or measure the consumption of fuel and it provides the power consumption as engine input.

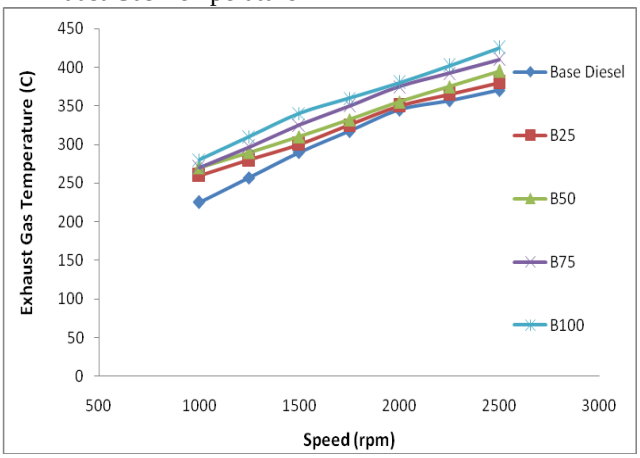
The burette was close-fitting with a 2-method valve. The fuel released from 1 in the fuel tank was directed to the engine and in place "2" the contained with fuel within the measuring device was also directed to engine. For the activity of fuel rate of flow of the engine, the valve was set at the place "2". The fuel rate of flow was measured on a degree basis. The fuel detector detected the time for a certain flow in the system.



III. RESULTS AND DISCUSSION

This article gives about the information about the results obtained from the performance of the engine and its emissions from the single-cylinder, four strokes, air-cooled, DI diesel with variable speed rpm is considered for producing power by burning the blended fuels. Fuel modification techniques are used for mixing the fish oil biodiesel at percentages with diesel fuel.

A. Performance Parameters

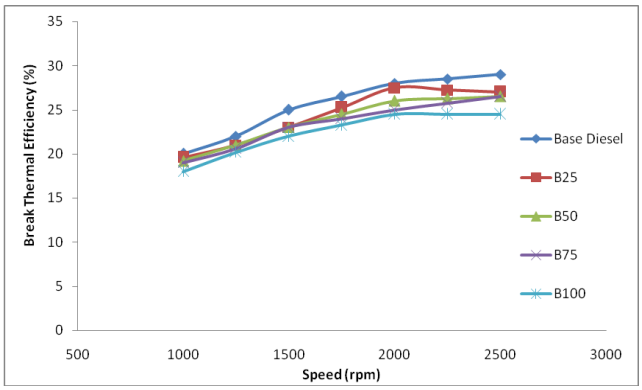


- **Brake Specific Energy Consumption(BSEC)**

The Break specific fuel consumption (BSEC) values obtained for the fuels namely Diesel, B25, B50, B75, B100 at the above-mentioned speeds have increased by about 2.65%, 3.23%, 5.65% and 8.32%. These values indicate that at B100 i.e. pure fish oil biodiesel the value of BSEC is higher when compared to any other fuel in the experiment and this is obtained due to the density of the B100 fuel due to which when sprayed in the combustion chamber the volume turns out to be more. But the values for BSEC of fish oil biodiesel have decreased in the low engine speeds are lower when compared to that of base diesel. But the slightly overall fuel consumption has lowered in the use of fish oil biodiesel blends due to presence of oxygen in the biodiesel, and also due to the efficient combustion timing that is available by the fish oil biodiesel.

Graph 1. BSEC vs Speed

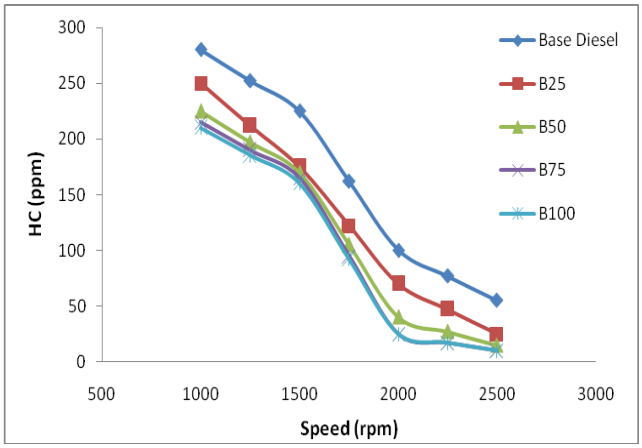
- Exhaust Gas Temperature



Graph 2. Exhaust Gas Teperature vs Speed

The values of the temperature of the gas at the exhaust can provide insights about the heat of the fuels in the combustion chamber during combustion can be of help in analyzing the values of the emission. The aforementioned graph provides the values of the exhaust gas temperatures with the lower values being from base diesel fuel and highest values coming from the B100 fish oil biodiesel at corresponding engine speed. The more the temperature the more is efficiency and the values of the B100 are higher due to the presence of the oxygen in the fish oil biodiesel blend from the origin which now helps in the higher combustion or full combustion producing the higher efficiency and also the values of the EGT decrease with decrease of the percentage of the blend in the diesel.

- **Brake Thermal Efficiency**

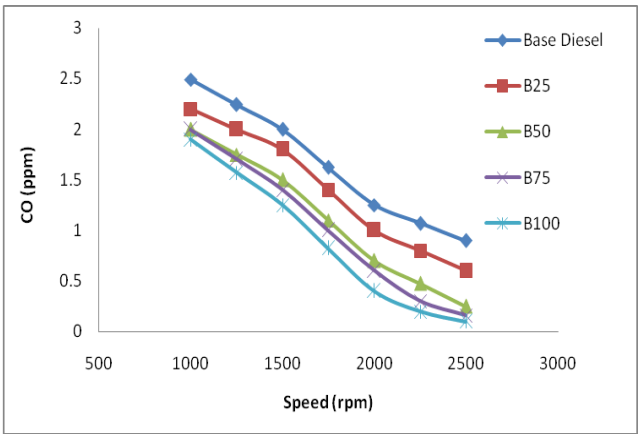


Thermal efficiency is one of the factors to be considered while evaluating the efficiency of the engine on various fuels. As we look into the values obtained, the thermal efficiency of B100 has decreased by 7.3% than that of its counterpart base diesel fuel. This is majorly due to the high density of the biodiesel and lowers effective power, higher consumption of fuel, lower values of heat regarding the Biodiesel. The B25 was shown good results as compared to B50, B75, and B100.

Graph 3. Brake Thermal Efficency vs Speed

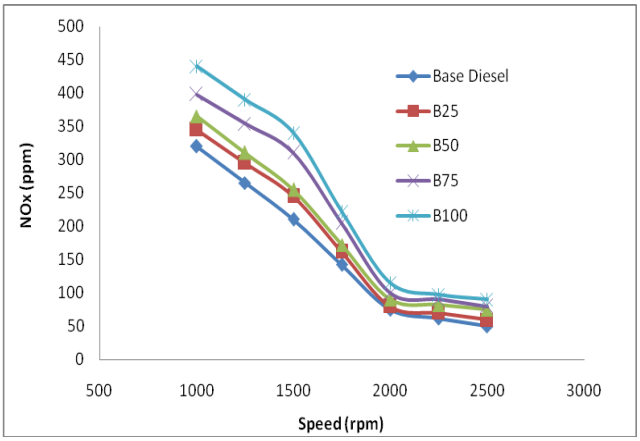
B. Emissions Parameters

- Hydrocarbons Emission



Graph 4. Hydrocarbons Emission vs Speed

HC presence in the emission is due to the incapability to utilize the chemical energy in the combustion chamber. And also due to the incapability of the fuel to burn due to lack of temperature which in turn is a result of insufficient combustion time and unavailability of oxygen but this problem is solved in the usage of Fish oil biodiesel as the presence of oxygen help in complete burning of the fuels thus reducing the emission of HC into the atmosphere. The graph proves the same with the values provide showing that diesel is the highest contributor of HC and the B100 is said to the fuel-producing lowest HC.



- **Carbonmonoxides Emission**

CO emission is one of the important parameters in the consideration of a better fuel. The more the amount of CO, the more is the loss of chemical energy which not only affects the environment but also reduces the efficiency of the engine. When looked into the numbers provided by the graph, diesel is the biggest contributor of CO and with an increase in the percentage of the biodiesel in the pure diesel, the emission values have come down. This is due to the increase of the air-fuel reaction when biodiesel/ fuel is present.

Graph 5. Carbonmonoxides Emission vs Speed

- **Oxides of Nitrogens Emission**

Graph 6. Oxides of Nitrogens Emission vs Speed

The main pollutants formed from the diesel engines are NOx, CO and HC. In this section, the graph provides the values of the NOx pollutants formed. The values seem to prove the existing arguments about the percentage of NOx produced in the performance of the blends and the base diesel fuel. The NOx value for the B100 is highest when compared to any other fuel in the experiment and that of diesel is lowest. The reason for such performance is peak temperature which ought to be the sole reason this is supported by the values of the exhaust gas temperature, which is due to the presence of oxygen in biodiesel.

IV. CONCLUSIONS

The engine performance and emission characteristics of single-cylinder, four strokes, cooled by air, a direct injection diesel engine have a different influence on output at various speeds. The conclusions of every method are given below.

- The usability of waste fish oil was converted into fish oil biodiesel by the transesterification process and later it was performed in a conventional diesel engine to find its performance and emissions.
- Performance parameters of the fish oil biodiesel blends have differed slightly when compared with the base diesel fuel outputs.
- The performance parameters of the B25 blend were very near to the base diesel fuel trends and seem to be favorable blends as compared to all other blends.
- BSFC values have higher in the case of B100, due to the higher density of the fuel blend. While the lowest is recorded for diesel.
- Exhaust gas temperature has also been recorded high in the case of B100 which indicates the high combustion due to the presence of oxygen in fish oil biodiesel.
- Emissions have a great effect on the fish oil biodiesel & diesel blends than base diesel fuel.
- These emission results prove the existing argument about the higher values of NOx for B100 and subsequently lowered with the decrease in blend percentage. NOx values of base diesel fuel are lower than B100.
- The values of Hydrocarbons have decreased in the use of B100 when compared to base diesel fuel.
- The use of blends has proven worth by releasing lower content of Carbon monoxide, Hydrocarbons into the atmosphere in comparison with the pure diesel fuel.

ACKNOWLEDGMENT

The Authors are very much thankful to the chairman of Malla Reddy Engineering College (A) Hyderabad and Director of National Institute of Technology, Warangal for proving the facilities for the completion of the project work.

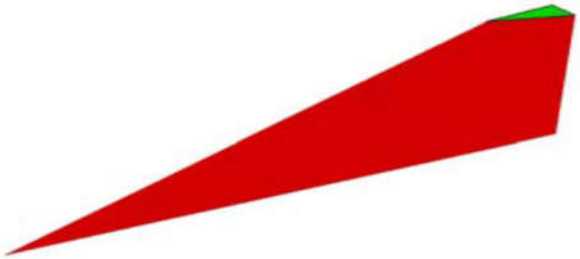
Abstract - The Scramjet engine design is an extension of the Ramjet. However a Scramjet allows the flow through the engine to remain supersonic, whereas in a Ramjet the flow is slowed to subsonic levels before it enters the combustor. The main problem of scramjet fuel injection is that the airflow is quite fast, meaning that there is minimal time for the fuel to mix with the air and ignite to produce thrust (essentially milliseconds). In such cases the simulation of a supersonic reactive flow is an important tool for the investigation and development of Scramjet engines. Numerical investigations have become less expensive than experiments. In this project, mixing and combustion for different shaped strut injector's are being analyzed in Ansys Fluent Software.

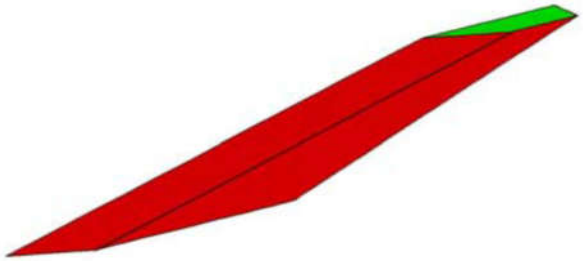
Key Words – Scramjet Engine, Ramjet Engine, Struts, Strut Injection, Supersonic Combustion, Ansys.

1. Introduction



In the History of the supersonic combustion there are two types of systems which is defined and operated in the high velocity regimes Scram jet and ram jet where ram jet sometimes refereed as the Flying Stove an air breathing engine which supports the air intake of forward motion to compress incoming air and support the sub sonic flight systems however the advantage with this type of system is more but when we are using the Ramjet in the system it can only operate at high velocities of system movement it cannot start an engine with the zero velocity condition or stand still therefore ramjet systems need an assisted takeoff that means it need an assisted pushing system like a rocket to pus to the high velocities. However it can work at high velocity speeds at Mach 3 and Mach 6

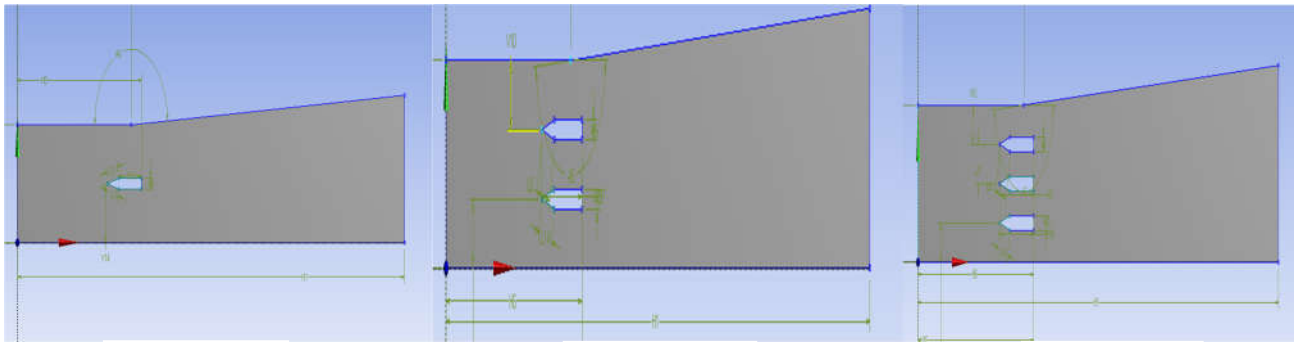
The Scramjet engines can be viewed as a type of ramjet engine whereas when it comes to ramjet the incoming air decelerates before combustion in ramjet systems where in the scramjet the velocity if the air is same throughout the systems. The incoming air which is supersonic is same throughout the engine. The Scramjet consists of 4 major parts: the inlet, isolator, combustor and exhaust nozzle



2. LITERATURE REVIEW

[1] **Dr. Krishna Murari Pandey & Thangavel Sivashakthivel** chipped away at a theme named "Ongoing Advances in Scramjet Fuel Injection - A Review", in which they found out that– Fuel injection process in to scramjet motors is an area of prominent growth. A scramjet engines uses either gas or fluid. The air fuel mixture should be thoroughly mixed to around stoichiometric extents for proficient combustion to occur. The fundamental issue of scramjet fuel infusion is that the airflow is very quick, implying that there is insignificant time for the fuel to blend with the air and touch off to deliver push (basically milliseconds).Hydrogen is the primary fuel utilized for combustion. Hydrocarbons present even more a test contrasted with hydrogen because of the more drawn out start delay and the prerequisite for further developed blending procedures. Upgrading the blending, and in this manner diminishing the combustor length, is a significant angle in planning scramjet motors. There are number of strategies utilized today for fuel infusion into scramjet motors.[2] **K.M.Pandey and T.Sivasakthivel** chipped away at a theme named "CFD Analysis of Mixing and Combustion of a Scramjet Combustor with a Planer Strut Injector". The two-dimensional coupled implicit NS equations, the standard k-ε turbulence model and the finite-rate/eddy-dissipation reaction model have been applied to numerically simulate the flow field of the hydrogen fueled scramjet combustor with a planer strut flame holder under two different working conditions, namely, cold flow and engine ignition.[3] **Yuan shengxue** took a shot at the point "supersonic combustion", in which he found that – The estimation of combustion in supersonic flow demonstrates about entropic increase & all out loss of weight in flame items might diminish alongside the expansion of burning speed. The diagonal explosion ripple edge wouldn't get constrained by wedge point lower frail & driven arrangement circumstances & be resolved distinctly by combustion speed.[4] **Gruineg and F. Mayingar** took a shot about "Supersonic combustion of lamp fuel/h2-blends in a prototype Scramjet combustor", in which they found out that– an important temperature level is somewhat accomplished by the angled shock ripples in the supersonic flow alongside expanding combustion zone proportion. [5] **K.Kumaran and V.Babu** took a shot at the subject of "Examination about certain impact of science representations on the arithmetical expectations of the supersonic combustion of H2", in which they found out that– Multi step science foresees bigger & more extensive layout warmth discharge more of what is anticipated by one step science. The one step science representation is equipped for anticipating general execution boundaries by the help of significantly low computation expense. A superior tradeoff b/w push expansion & combustion effectiveness shall be accomplished with the help of organized combustion.

Conceptual view of Strut (A)



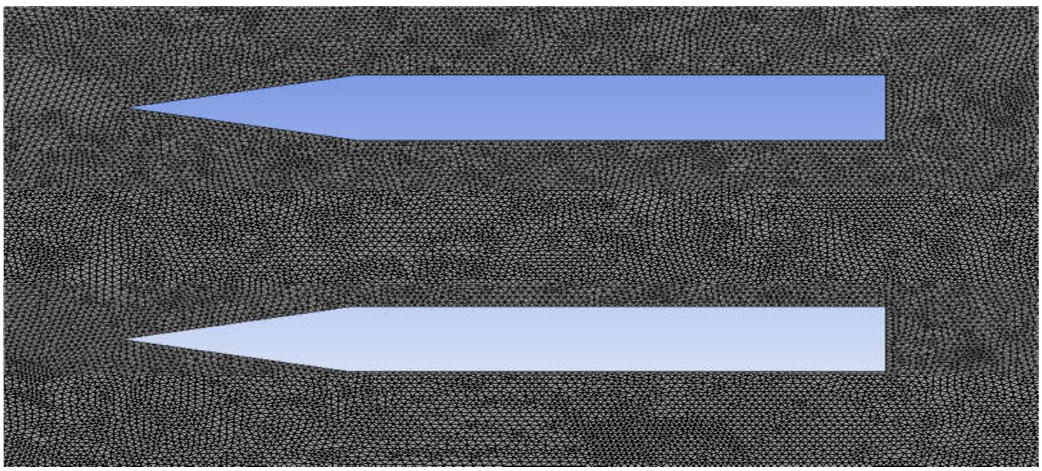
Conceptual view of Strut (E)

PROCEDURE:

In this experiment, the **density of the air fuel mixture** (i.e. air and hydrogen), **Mach number** and **static pressure** inside the scram jet engine's combustion chamber are analyzed with the help of Ansys Fluent Software. The base paper for the project have been taken from one of the K.M Pandey's contribution to the field of scram jet engine technology **"CFD Analysis of a Hydrogen Fueled Mixture in Scramjet Combustor with a Strut Injector by Using Fluent Software"** and few other papers of him. Below is the description of how the experiment is beingcarried out in the environment of Ansys Fluent Software.

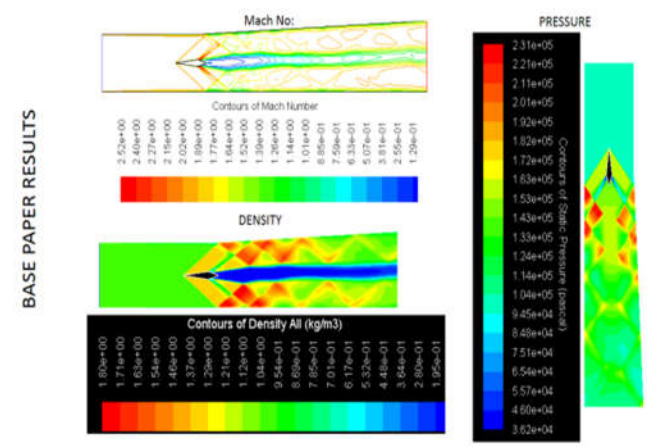
i) **Geometry**:

A simplified combustion chamber is created in the geometry section of the software provided with two types of struts, one being the triangular strut {strut A} and the other is the experimental strut named {strut E}. The above mentioned struts are also categorized into three types based on their configuration in the combustion chamber,

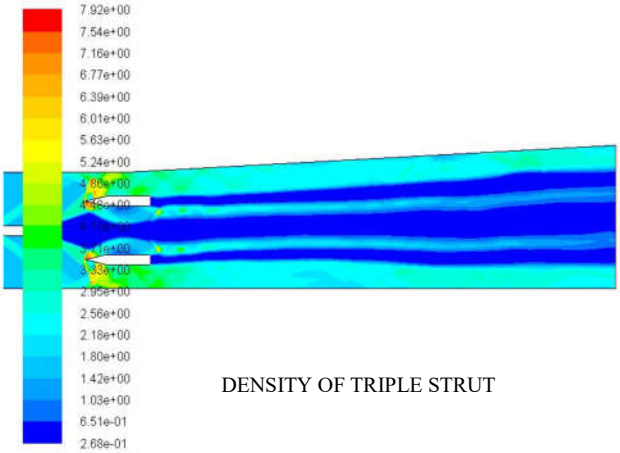


Single strut Double strut Triple strut

Meshing:

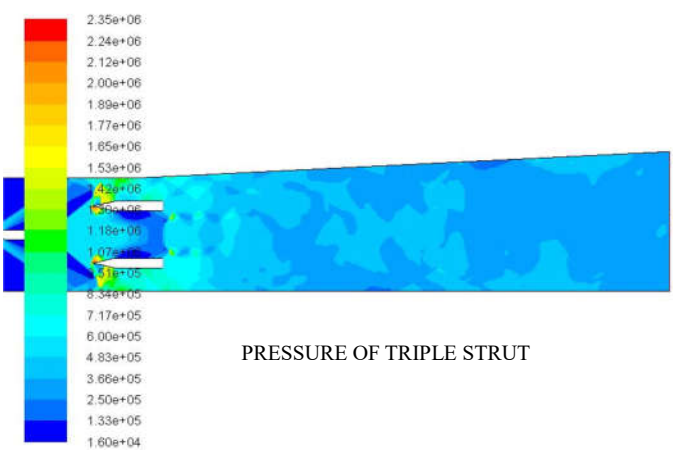


Later, the model is meshed in the meshing section. We have emphasized the strut boundaries to have higher mesh density in the combustion chamber in order to obtain the results more precisely. Such that the changes in the pressure, density and in Mach number around the strut to be more clearly observable.

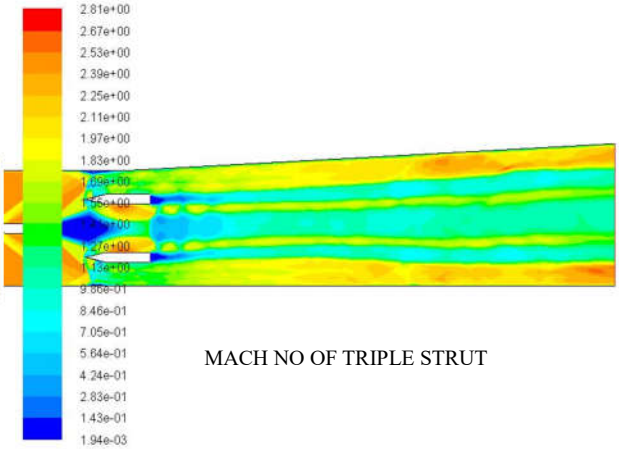


Higher mesh density + less element size = Better results

a) Face size - 0.30mm b) Element size - 0.60mm c) Total elements – 433111



RESULTS:



DENSITY OF TRIPLE STRUT

PRESSURE OF TRIPLE STRUT

MACH NO OF TRIPLE STRUT

OVERALL RESULTS IN TABULAR FORM

PAPER	DENSITY of Strut A	Density Of Strut E	Mach No of Strut A	Mach no Of Strut E	Static Pressure of Strut A	S Pressure of Strut E
BASE PAPER 1	1.80	--	2.52	--	2.31	--
BASE PAPER 2	1.89	--	2.17	--	2.61	--
Experimental Single strut	2.55	3.45	2.55	2.98	4.38	7.01
Experimental Double strut	4.87	4.59	2.56	2.56	1.01	1.02
Experimental Triple Strut	7.09	7.92	2.57	2.81	1.98	2.35

The provided images of result are of Density, Pressure and Mach no for the Triple Strut E Configuration compared against the results of the base papers.

5. Conclusion:

In above investigation the k-w model is used to inspect the mixing in a scramjet model under realistic operating conditions. The configuration used is alike the scramjet engine in the lab where its development and experimentation took place at (Deutsches Zentrum für Luft- und Raumfahrt) Germany. The Configurations in this computational work is made for single double and triple strut is made to employ the behavior and improvement of increasing struts in the combustion chamber to see this change the current work is very helpful in visualizing and comparing the existing and newly employed turbulence model for single double and triple strut injection systems in the scram jet combustion chamber after thorough simulation the completed and compared results with each other there is a significant mixing and improvement in shock wave generation is observed in triple strut model therefore there is more room for improvement in this are due to space constraint we can't go more than three struts unless new arrangements are introduced in the current work the highly performed configuration is Triple Strut E model.

Abstract - Day by day energy needs are increasing and there is a disparity between energy supply and energy request. Buildings are major consumers of energy of approximately 27% in the world wide. And also increasing anxieties about climate transformation and environmental emissions have directed to conserving energy through the development of numerous energy-effectual systems.

Latent thermal energy storage system is one important method amongst different thermal energy storing methods due to excellent features like high energy storage density, storing thermal energy at constant temperature. In spite of these it has very poor thermal conductivity of phase change materials which would reduce energy storage capacity and reduces time for melting and solidification thereby heat transfer from heat transfer fluid to PCMs (Phase Change Materials) decreases.

The main objective of current investigation is to enhance the thermal properties of PCMs with dispersion of hybrid nanoparticles which suit for development of Latent Thermal Energy Storage (LTES). The work proceeds with selection of PCM which suits for passive cooling applications having freezing and melting temperatures around human comfort conditions. Later, hybrid nanoparticles which can enhance thermal properties are synthesized using sol gel process and the as-prepared particles are characterized for studying the crystalline lattice structure of elements and surface morphology using X-Ray Diffraction, Field Emission Scanning Electron Microscope (EDAX Analysis also). The nanoparticles are dispersed in PCM with different weight percentages (0.2%, 0.4%, 0.6% and 1%) using ultra sonic vibrator. The as prepared hybrid nano based PCM samples were thermal investigated like melting, freezing, heat energy storage density, specific heat etc. using differential scanning calorimeter (DSC), Fourier Transform Infrared Spectrometry (FTIR) Results are validated comparing pure PCMs with NPCMs and predicting the optimized one among different proportions of Nano based PCMs for efficient passive cooling applications.

Key Words – X-Ray Diffraction(XRD), Field Emission Scanning Electron Microscope(FESEM), Differential Scanning Calorimetry(DSC), ultra sonic vibrator.

1. Introduction

The climatic change in the earth outcomes to relentless increment popular latest heat load in structures and in energy. Henceforth the solace cooling in building is increasing and the interest for consolation cooling is also expanding rapidly around the globe. The elevated cooling request brings about high top electric power request amid in the sultriest overdue

spring. This request makes any other trouble or takes a look at to electric utilities and their customers. Consequently, current-building administrations is probably deliberate to configuration provide adequate deliver to load and power use control with a selected give up purpose to get the most prudent operations.

heat energy stockpiling approach, it can be say as "putting away low temperature power for later use so that you can join the time hole between energy accessibility and vitality utilize" is taken into consideration as a helpful apparatus to address the request modern day heap of electrical customers.

Within the beyond, researchers were inquisitive about reducing the fee cutting-edge power and shop the diminishing fossil fuels. However, lately, the incentive has transformed from those areas latest reducing CO2 emission, from the environmental viewpoint. Electricity performance and the use of smooth and inexhaustible power, has received the fundamental care state-of-the-art the advanced and growing nations. Inside the current electricity and environment situation there may be simply no want to justify the need for electricity conservation. Growing efficient and cheaper power storage gadgets is as significant as growing new resources present day energy. Thermal storage minimize the time or price mismatch among thermal deliver and energy call for, and it plays a crucial position in energy conservation thermal storage enhance overall performance modern-day electricity systems with the aid of smoothing deliver and increasing reliability. The better performance might cause thermal conservation and enhance fee effectiveness. Modern day the renewable power sources can only offer electricity intermittently.

2. PROCEDURE:

SYNTHESIS OF NANOPARTICLES

Sol-gel process

The sol-gel process contains the development of inanimate networks through the development of a colloid period (sol) and gelation of the sol to form a network in a non-stop liquefied phase (gel). The precursors for synthesis of this colloid have commonly of a metallic component a rounded with the aid of number responsive ligands. The preliminary materialis process to shape a dissoluble oxide and varieties a sol in interaction with water or diluted acid. Deduction of the liquefied from the sol produces the gel, and the sol/gel change controls the element size and shape. Calcinations of the gel produce the oxide.

Sol-gel process discusses to the hydrolyzes and condensation of alkoxide-based precursors such as Si(OEt) 4 (tetraethyl orthosilicate, or TEOS). The reactions worried in the sol-gel chemistry primarily grounded on the hydrolyzes and condensation of metallic alkoxides M(OR)z can be define as monitors:

$$MOR + H2O \rightarrow MOH + ROH \text{ (hydrolysis)}$$

$$MOH + ROM \rightarrow M\text{-}O\text{-}M + ROH \text{ (condensation)}$$

The sol-gel procedure can be categorized by a sequence of different steps.

1. Forming of dissimilar steady solutions of the alkoxide or solvated metal precursor.
2. Gelation resulting from the creation of an oxide- or alcohol- bridged network (the gel) by a polycondensation reaction that results in a significantly rise in the viscosity of the solution.
3. Aging of the gel (Syneresis), meanwhile which the polycondensation reactions go on as far as the gel transfers

into a solidified mass, coexist by abbreviation of the gel network and exclusion of solvent from gel pores. Ostwald mellow (also make reference to as coarsen, is the phenomena by which small molecules are consumed by bigger molecules in the growing procedure) and phase changes may happen simultaneously with syneresis. The aging procedure of gels can exceed seven days and is dangerous to the stoppage of cracks in gels that have been cast.

4. Drying of the gel, when H2O and other unstable liquids are detached from the gel network. This procedure is complex due to essential changes in the shape of the gel.

The drying procedure has itself been fragmented into 4 different steps:

I. The constant rate period,
II. The critical point,
III. The falling rate period,
IV. The second falling rate period.

If isolated by thermal vaporization, the resulting monolith is termed a xerogel. If the solvent (such as water) is removed below supercritical or nearby super critical circumstances, the product is an aerogel.

5. Dehydration, during which surface-bound M-OH groups are detached, there by stabilizing the gel against rehydration. This is generally achieved by calcining the monolith at temperature up to 8000 C.

6. Densification and decomposition of the gels at high temperatures (T>8000 C).

materials procured

Phase change material (PCM)

- Paraffin C16 PCM

Chemicals for copper nano

- Precursor - copper acetate
- Stabilizing agent - polyvinyl pyrrolidone
- Reducing agent – sodium borohydride
- Distilled water was used for reaction
- Speed 450 rpm
- Temperature – 45 degree centigrade

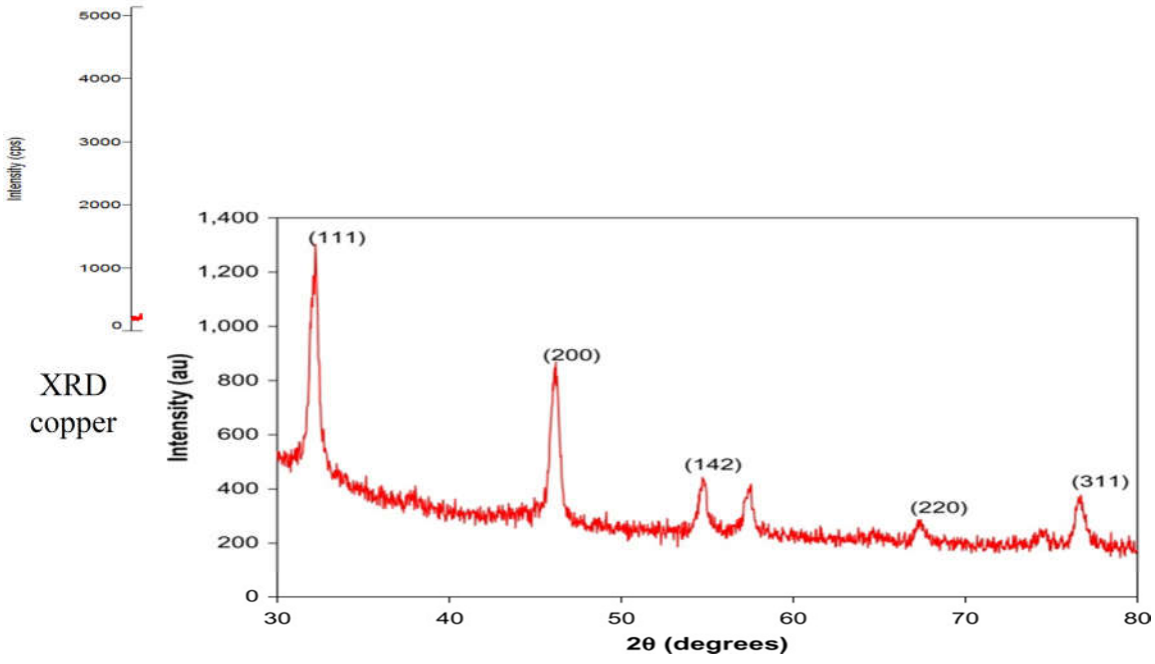
Chemicals for silver nano synthesis

- Precursor – silver nitrate
- Stabilizing agent - polyvinyl pyrrolidone
- Reducing agent – ascorbic acid
- Distilled water was used for reaction
- Speed - 400 rpm
- Temperature – 45 degree centigrade

Stepwise procedure

1. 5g of cupric nitrate +30ml of distilled water (precursor solution 2) are mixed and dissolve it fully using magnetic stirrer at 50 degree Celsius, 350RPM.

2. Simultaneously, prepare a solution of 0.5g Polyvinylpolypyrrolidone (PVP) + 30mL distilled water at ambient temperature.
3. Slowly add the solution obtained from step 2 to the solution from step 1 while continuing the stirring process.
4. 1g of Sodium Borohydride + 30 mL Distilled water (strong reducing agent)
5. Transfer solution obtained from step 4 into a burette.
6. Add this solution drop-wise into the solution prepared in step 4 while continuing the stirring process.
7. Color changes from light bluish to cream color with pale white.
8. Keep titrating till the color change is observed.
9. Decant, if necessary. Wash with acetone and filter out the hybrid nano-particles using double filter paper. Keep the contents for drying.
10. Keep the contents for drying.

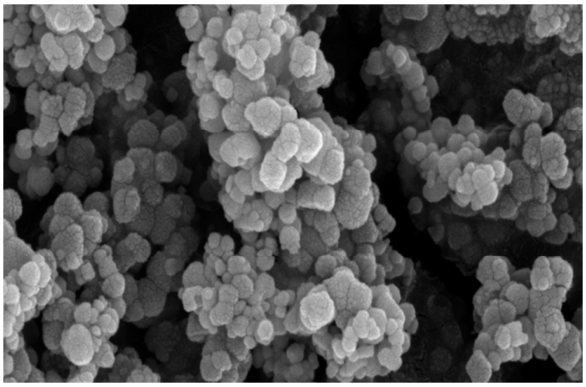


Preparation of Nano based paraffin C16 PCM samples

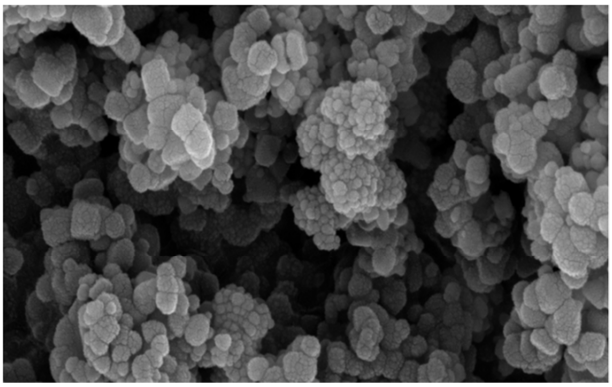
The synthesized solid nanoparticles copper and silver 50-50% were dispersed in the paraffin C16 PCM by using Ultrasonicator. The weight percentages are 0.2, 0.4, 0.6, 0.8 and 1. The samples were then sent for further testing.

3. RESULTS:

The dried solid nanoparticles were given for XRD testing to determine the size and FESEM testing to determine the surface morphology. The nanoparticles were further dispersed in paraffin C16 PCM in different weight ratios and given for DSC testing to determine the melting, freezing point and latent heat of the Nano based paraffin C16 PCM. The weight ratios of nanoparticles dispersed in paraffin C16 PCM are 0.02%, 0.04%, 0.06%, 0.08% and 0.1% by weight. The pure paraffin C16 PCM was also tested to compare the properties.



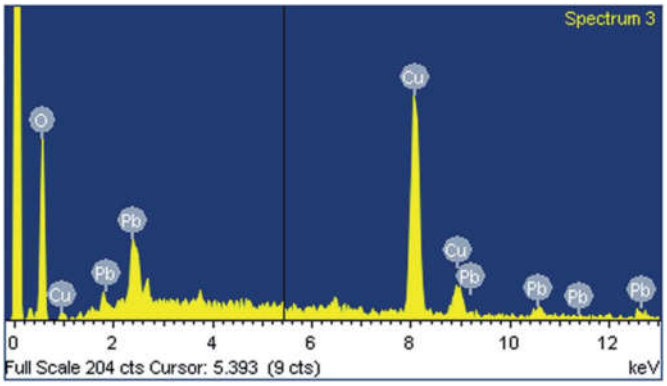
X-ray diffractometer (XRD) RESULTS



XRD result of copper

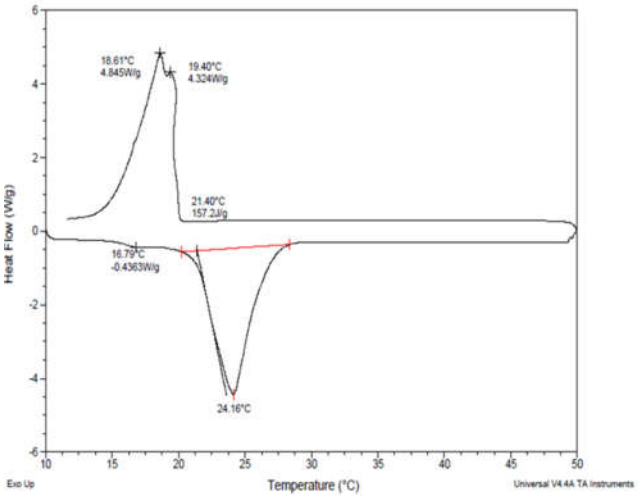
XRD results of silver nano

Field Emission Scanning Electron Microscope (FESEM) results



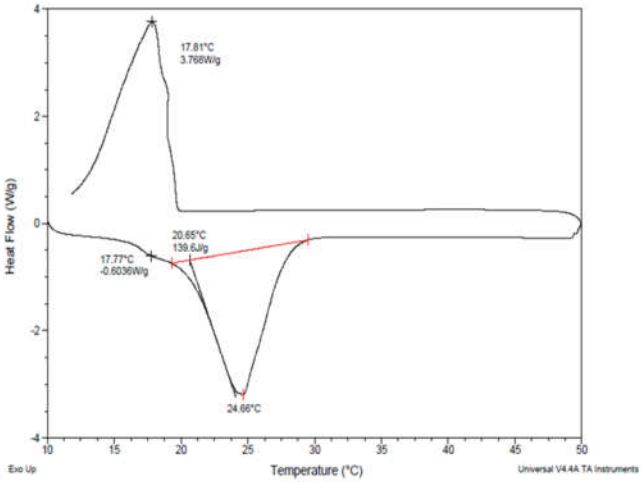
FESEM of Cu nanoparticles

FESEM of Ag nanoparticles

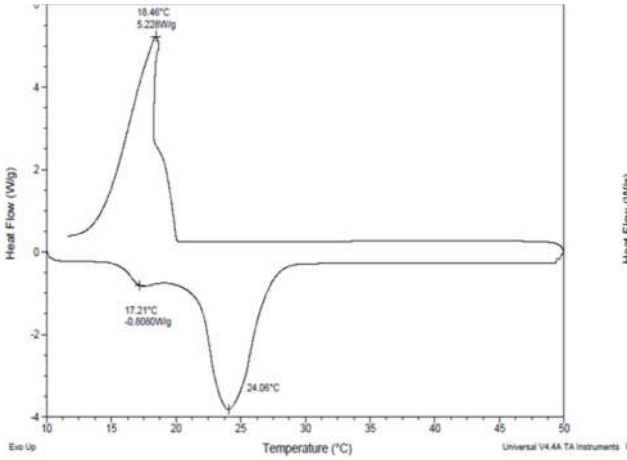


The studies of FESEM reveal that the particles produced were spherical in shape and is of Nano size. The size varies from 30mm to 140 mm with variations for both copper and silver nanoparticles.

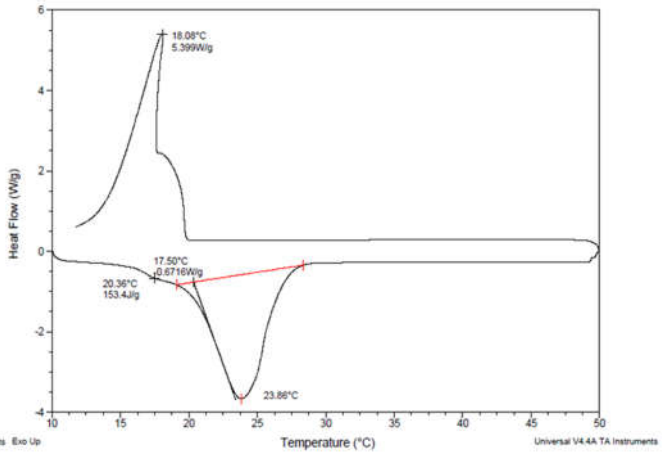
EDAX analysis



The EDAX analysis gives us the amount of crystallization and the weight percent of composition of the hybrid nanoparticles. From the figure above we can observe the crystallization percent of copper. On the top right corner we have the weight percentage of the elements.



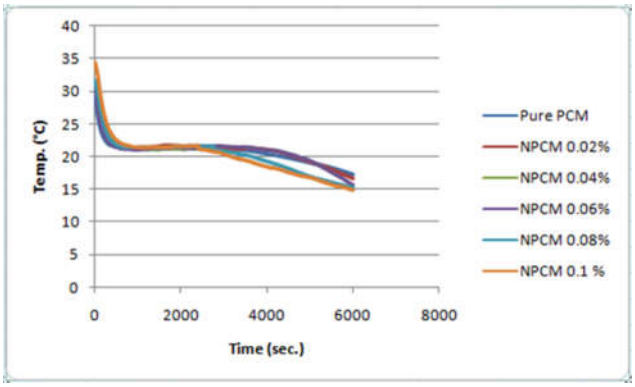
Differential Scanning Calorimetry (DSC) results



DSC for pure paraffin C16 PCM

DSC for 0.2% by wt. N-PCM

DSC for 0.4% by wt. N-PCM



DSC for 0.6% by wt. N-PCM

	Freezing (^{O}C)	Melting (^{O}C)	Latent heat (kJ/kg)	
			Freezing	Melting
Pure PCM	21.22	22.42	181.28	194.99

Melting characteristics of Pure and Hybrid nano based PCM

5. Conclusion:

1. The nanoparticles synthesized for both copper and silver were found to in Nano size with a range from 30nm to 140nm.
2. The SEM results reveal that the copper and silver nanoparticles spherical in shape with high surface to volume ratio, which can enhance heat transfer characteristics.
3. From the DSC results, there is little variation in the melting and freezing points due to addition of nanoparticles but, there is significant increase in the latent heat of the N-PCM until the wt. % of 0.6 beyond which the latent heat decreases. This shows that the optimum value of that amount of nanoparticles that should be dispersed in the paraffin C16 PCM is **0.6%**
4. Based on the above test results, the as-prepared paraffin C16 PCM with nanoparticles can be expected to provide better cooling effect through regulating the temperature within the comfortable range of 23 °C to 25 °C in indoor spaces.

Mechanical and Material Properties of Areca/ Epoxy Composite

T. Naresh Kumar, S. Sathishkumar, A. Jeevarathinam, R. Sivaprasad, R. Praveen Kumar

Abstract: ***The contemporary test targets learning the perfunctory conduct of half breed regular fiber combinations. Tests of a few Areca-Epoxy were made utilizing layup strategy where the assembling of handles was substitute and the weightiness division of polymer % and fiber& network was kept at 90%- 10% , 80% - 20% and 30%-70%.Specimens were cut from the created cover as indicated by the ASTM models for various analyses. For Ductile test and flexural test were cut fit as a fiddle and level bar shape separately.***

I. INTRODUCTION

The enthusiasm for common fiber-strengthened polymer composite materials is quickly becoming both as far as their modern applications and principal look into [1]. They are inexhaustible, modest, totally or somewhat recyclable, and biodegradable. Plants, for example, flax, cotton, hemp, jute, sisal, kenaf, pineapple, ramie, bamboo, banana, and so on., just as wood, utilized from time prehistoric as a wellspring of lignocellulosic filaments, are increasingly more regularly applied as the support of composites [2].

Substantial excellent has revolved into a rudimentary bit of configuration for engineers, since of user-friendliness of multifarious assortment of resources that have analogous possessions and encounter the item plan precise [3-5]. Accomplishment of realistic going-over unaccompanied brands it hard to discriminate the flawless edifice of the last amalgamated [6]. A harmonized approach between measurable prototypical and micromechanical model is wanted. In this paper, subsequent normal fiber and polymer link from past scrutiny is exploited to gauge the mechanical possessions, for instance, thickness, Young's modulus and elasticity [7-9]. Four degrees of fiber stacking are employed to scrutinize the ideal regular fiber strengthened polymer compound [10].

II. SPECIMEN AND EXPERIMENTAL

Areca which remain conveyed and gutted with aquatic and dehydrated. By then the aggregates are gently dispersed with hand sedentary serenely. By then its outside projectile is cleared by the cutting edge and it is expurgated into obligatory estimation [11-13]. We take precise proportion of polymer which we have decided previously and 10% of its hardener [14-16]. By then this mix is blended totally till it transmutes into to some degree warm. Bit extra quantity of hardener is taken for the wastage at the same time. Hardener should taken minutely bearing in mind the way that little further quantity of hardener can destroy the compound [17-19].

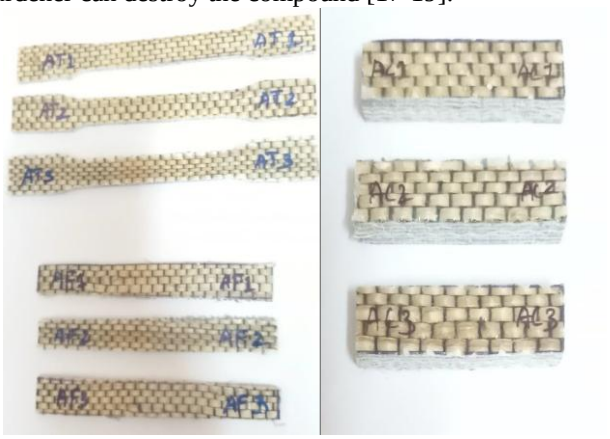

Fig.1 Areca /Epoxy Composite Specimen

Most ordinarily the example lies on a help range and the heap is applied to the middle by the stacking nose creating three point twisting at a predetermined rate. The parameters for this test are the help length, the speed of the stacking, and the greatest redirection for the test. These parameters depend on the test example thickness and are characterized distinctively by ASTM [20].

SEM Fractrography

The surfaces of the examples are analyzed legitimately by examining electron magnifying lens and the compound examples are astride on counterfoils through silver glue.

III. TEST RESULTS

From the Tensile, Flexural and Impact test results shown in Figure 2 to 6 it can be observed that specimen 2 (80% polymer & 20% fiber composition) possess good mechanical properties and also SEM images shown in figure from 7 to 9 it can be observed that good bonding and less porosity between fiber and polymer composites.

IV. CONCLUSION

In this work, the common fiber picked as Areca fiber. Unidirectional mats were created and layered up, course of action with epoxy gum network. The overlay is fabricated utilizing hand lay-up system. The Mechanical properties, for example, rigidity, flexural quality and effect quality are broke down on the created material. Too Miniaturized scale structure of the composite is examined utilizing checking electron magnifying lens (SEM). Specimens were cut from the created cover as indicated by the ASTM models for various analyses. For Tensile test and flexural test tests were cut fit as a fiddle and level bar shape separately. The outcomes showed that one-sided Areca epoxy composite have great tractable, flexural and sway quality. Upgrade of mechanical properties might be achieved by utilizing the treated strands and right technique for creation. The surface morphology demonstrates that the development of voids and holes in every one of the examples composites. Thus in this examination woven fiber mats are utilized in setting up the composites; uniform conveyance of pitch around the filaments and air voids are the significant causes as seen in micrographs.

AUTHORS PROFILE

Mr. T. Naresh Kumar, Assistant professor in Mechanical Engineering Department, Malla Reddy Engineering College(Autonomous), Maisammaguda, Hyderabad. He has 5.6 years of teaching experience. He completed M.Tech in 2013 at MITS, Madanapalle, Jawaharlal Nehru Technological University, Anantapur. He had guided 3 M.Tech projects and published 13 papers in various National and International Journals and Conferences.

Mr. S. Sathishkumar, Assistant Professor in Department of Mechanical Engineering ,Karpagam College of Engineering ,Coimbatore-32. He Completed his B.E. - Mechanical Engineering in 2012 M.E. - Thermal Engineering in 2015 PhD - Mechanical Engineering- (Pursuing). From 04.06.2012 to 10.04.2013 worked as Lecture in Karpagam Polytechnic College. From 18.08.2018 working as Assistant Professor in Karpagam College of Engineering. He has published 17 journals and 17 conference proceedings.

Mr. R. Sivaprasad was born in Madurai, Tamil Nadu, India in 1982.He received B.E. degree in Electrical and Electronics Engineering from University of Madras in 2003, and M.E. degree in Energy Engineering, College of Engineering, Guindy in 2007. Currently he is working as a Associate Professor in the Department of Electrical and Electronics Engineering, Sri Sairam Engineering College, Chennai - 600044, India. He has more than 15 years of teaching experience. His fields of interest are Energy Engineering, Control Systems and Electrical Machines. He has Published 5 international Journal papers.

Mr. R. Praveen Kumar pursuing Ph.D., in Department of Mechanical Engineering, St. Peter's Institute of Higher Education and Research, Avadi, Chennai, Tamil Nadu, India. He is having more than 6 Years of Teaching Experience and Published 15 papers in SCOPUS indexed Journals. His area of research is Metal Matrix Composites.

EXPERIMENTAL INVESTIGATION FOR PERFORMANCE ENHANCEMENT OF HOUSEHOLD REFRIGERATOR USING PHASE CHANGE MATERIAL

Abstract- A phase change material is a substance that can store or release significant amounts of heat energy by changing its phase from solid to liquid vice versa. It has already been proven that incorporation of phase change material with refrigeration systems improves the energy efficiency as well as the quality of the frozen food. However, the attachment of phase change material system with the refrigeration system is a challenging task in different aspects such as PCM thickness, quantity of PCM, PCM phase change temperature selection for optimizing energy consumptions of refrigeration systems are the main concerns of today's researches. Implementation of the Cold Thermal Energy Storage system is one of the effective ways to reduce energy consumption. In this study, a household domestic refrigerator with ceiling type evaporator is considered to equip it with cold thermal energy storage system. According to ASHRAE standard, the temperatures are ranges for the household refrigerator is between 274 and 280 K, and hence water is used as phase change material. Owing to the low thermal conductivity of water impact of the extended surface in the container was investigated. The experimental results of charging and discharging process show the good consistency with the numerical results. Furthermore, it is obtained that using finned cold thermal energy storage system, would reduce compressor's energy consumption about 17.4% per day.

Keywords – Cold thermal energy storage, Phase change material, Latent heat storage, Thermal energy storage system, Heat transfer surface, Latent cold thermal energy.

I. INTRODUCTION

Domestic refrigerators the most commonly used household appliances. These appliances are consuming the more residential electricity throughout the year. In china we can see that the residential electricity usage is about 30 to 40%. Hence, enhancing the energy efficiency of domestic refrigerator is the major issue. We can overcome this issue up to some extent by improving the coefficient of performance of a domestic refrigeration system. We can also reduce the power consumption, by using water as a phase change material in refrigeration system.

Introduction to Phase Change Material:

The materials which are having the capability of storing and releasing the energy when phase transformation occurred are called phase change materials. As the material changes its phase from solid to liquid, energy is absorbed from its local while remaining at a constant temperature. The energy which is absorbed by the material performs to increase the energy of the constituent molecules and their vibrational position. At the diffuse temperature the atomic bonds breakup and the materials progression from a solid to liquid. During solidification process the material transfer energy to its local and the molecules lose energy, position.

Types of PCMs:

There are three types PCMs are, they are

(A) Organic PCMs
(B) Inorganic PCMs
(C) Metal and Metal alloy PCMs

II. LITERATURE REVIEW

The invention of the refrigeration system in the modern world is one of the admirable works which helps to increase the comfort levels of mankind. The great invention makes nature to help us according to our requirements, anyhow increases in energy predicament and ecological pollution, which drives to acceleration of atmospheric temperature. R&AC sector is the major contributor for this issue because they are the major energy taking devices due to their continuous usage. In today's world, the most energy consuming appliances are household refrigerators and are utilizing a major part of the entire universal energy. According to the Liu et al the energy utilization of refrigerators are nearly 15% to 20% of electricity utilization whereas in Malaysia 26% of electricity was consumed. Usage of the PCM as a LHTES system would be the latest alternative for achievement improving of the domestic refrigerator by improving evaporator heat transfer, decreasing efficiency losses of the compressor. In our project work the performance improvement of the domestic refrigerator has been studied in detail. The performance enhancement of the domestic refrigerator is determined by the phase change material box volume, geometry, assimilation, and position. The design of PCM containing chamber is the main challenge for developing refrigeration system. Different shapes of phase change material compartment were used in the previous papers such as rectangular slab or circular slab at different positions of the refrigeration system.

Performance of refrigeration system in accordance with PCM position:

The installation of PCM with domestic refrigerator is a vigorous work. Phase change material can be installed at anywhere among the condenser or evaporator else in the storage chamber. It is known by the study of previous research papers data, which gives the placing of phase change material at evaporator will gives the improvement of the coefficient of performance, at the same time the ON time of compressor also decreased with longer compressor off time. Which will also give fluctuations in the compartment temperature with varying thermal loads. According to the Azzouz et al. [1] constructed the system with phase change material keep retain the compressor off time from 28.5–32.6% and autonomy of 4.7–8.5h. The stable working of compressor and its periodicity ultimately cuts off temperature fluctuations inner the storage compartment and resulting in approximately constant warmth for better food quality.

Current Development of Phase Change Material Placed Domestic Refrigeration System:

As on date so many experimental investigations are performed, to develop a PCM based domestic refrigerator. The quantity of phase change material and position of phase change material gives the COP of domestic refrigeration system. Below table gives the summary of the present studies are given in the below Table.1.

III. METHODOLOGY

For the experimental setup, a domestic refrigerator is having the dimensions of 50×60×105 cm^{3}and walls with thickness of 3.7 cm. The household refrigerator consists of freezer cabin at the top and refrigeration chamber below the freezer cabin. The Thermal Energy Storage system has two PCM cubic containers that are of 1×24×17.6 cm^{3}size and are placed on either sides of the evaporator and another with a specification of 1×34.8×17.6 cm^3 is placed under evaporator cabin that are made out of aluminum plates which are 1.2mm thick. Referring ASHRAE standard [2], it is accepted that refrigerator's environment is held between 1-5 °C, where we used pure water as phase change material. The Thermal conductivity and Latent thermal energies of melting water are 0.59 W/m. K and 334kJ/kg. In such arrangement, air is abstained from direct contact with cold evaporator surfaces at the top and both sides hence the evaporator cools down and also in turn freezes the water inside the PCM containers which then absorbs the energy in the form of heat from the refrigerator's cabin through free convection. The average temperatures of the cabin are shown in Fig.1.

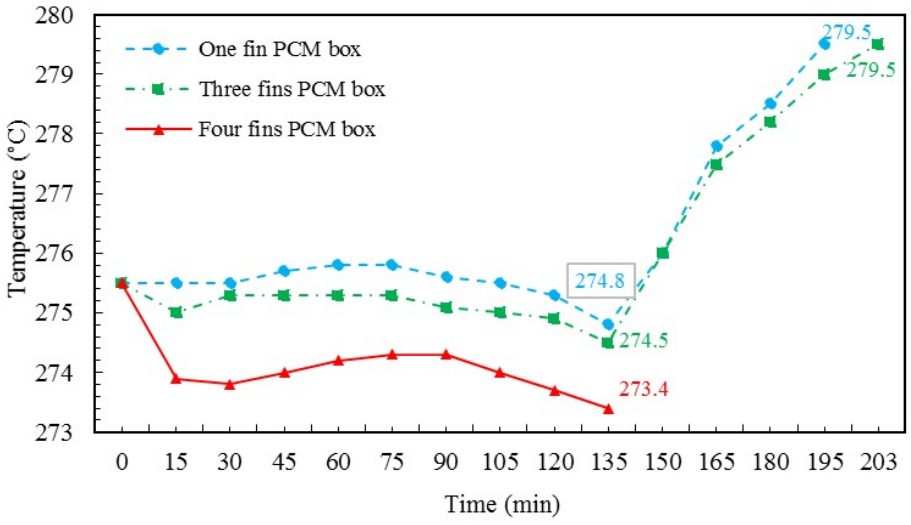

Figure.1. The cabin average temperature with different PCM container configurations

The experimental setup consists of a 16 feet conventional refrigerator, container with PCM, two six channel data acquisition system with ten thermocouples, whose detailed characteristics are illustrated in Table.2.

Table.2. Common place details of the equipment

Equipment		*Properties*
Refrigerator	*Dimensions*	*50×60×105 cm3*
	Power rate	*149 Watts*
Container with PCM	*Dimensions*	*1×24×17.6 cm3*
	Thickness	*1.2 mm*
	Material	*Copper*
Thermocouples	*J type*	

The three finned PCM container of aluminum plates (1.2mm thickness) provided fine heat transfer between phase change material, evaporator emerge during charging time, between cabin's air, PCM during discharging. An opening at the bottom of PCM container helped in injection of PCM and two slits at the front surface to mount thermocouples at two different levels to measure temperature of PCM. Similarly, two aluminum plates on either side of the cabin has a hole for injection and two provisions for thermocouple mounting. During the discharge cycle, the compressor gets turned off and temperature inside the cabin tends to increase. The warm air which is lower density raises up to the level of PCM containers and the cold air with higher density settle at the bottom of refrigerator. The warm air archive CTE from phase change material container thus turning the solidified PCM into liquid and this exchange of heat continues up until all the solid is converted into liquid and the cabin reaches at a mean temperature which is a highest permissible point set in the ASHRAE standard [2]. It is worthy to note that the evaporator cabin was closed and the air in it was kept secluded from the rest of the refrigerator cabin. Operation of refrigerator and CTES systems were assessed by measuring the temperatures of air and PCM at various points with the help of ten J type thermocouples with and accuracy of ±0.5°C for PCM and air, respectively.

Figure.2. The arrangement of PCM and thermocouples inside the refrigerator

IV. RESULTS AND DISCUSSION

Initially 2.35°C temperature was adopted. And the surface temperature of the evaporator was established to -5 °C for the CTC of phase change material. After 2 hours 30 minutes the phase change material frozen totally at the same time the compressor was turned off at this instant. As far as pretend compressor-off, evaporator emerges acts as an established emerge without mounting any position on the evaporator. Hence, at the end of phase change material liquid to solid state, the cold TESS maintains the refrigerator to normal low warmth. As we can see that, the cabin mean temperature was discharged from 2.35°C to 1.85°C during liquid to solid process. Afterward, in the without charging time, the cabin warmth increased to near the highest temperature at 6.35°C during30 minutes. Throughout this period, a solid PCM couldn't change to the liquid phase as per the mean temperature of phase change material at the end of the discharging period at -2.05°C. In this experiment water is used as a phase change material, which has the phase change temperature -0.15°C. Hence, to have solid to liquid phase change process the PCM should contain minimum of -0.15°C temperature.

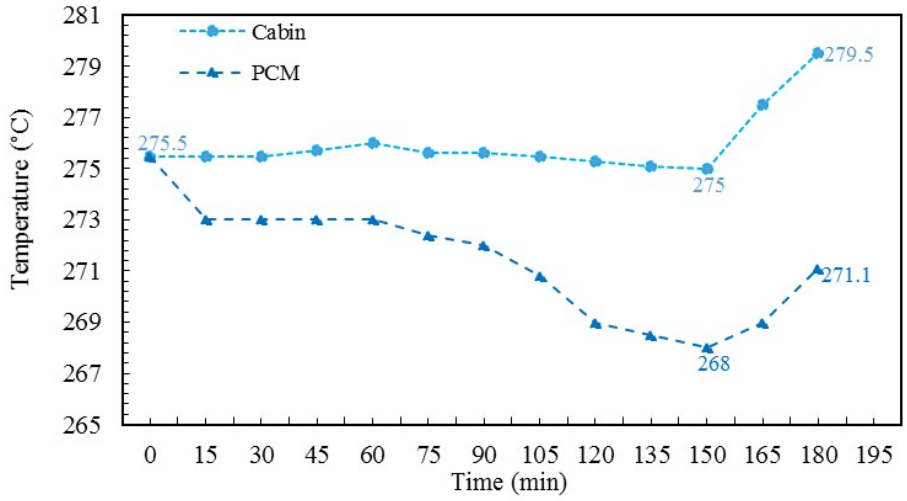

Figure.3. The numerical simulation result for simple PCM container

The experimental tests are attained in two sections:

1. Initially the normal working of domestic refrigerators power ratio was determined because which continues the cabin temperature in the established point. After the completion power ration, the working period of the domestic refrigerator was examined.

2. After completion of the initial test, the performance of the domestic refrigerator was analyzed by installing the CTESS. Throughout this procedure the phase change material storage time, charging and discharging processes were examined. By considering the thermocouples measured values, the behavior of the CTESS was plotted its working cycles.

By the completion of the first cycle, the time taken for the PCM to freeze completely was 135 minutes and at the end of second cycle it was reduced to 52 minutes. Based on these outcomes and the placing positions of the thermocouples, we come to know that 25 % of the PCM got melted at the end of the all discharging stages. For the next cycle during charging process the phase change material

needs only 52 minutes to freeze remained liquid. For the next charging and discharging cycles were taken same time as previous cycles took. This shows that at the end of the charging there is no alter in the volume of PCM available for discharging process. To calculate the volume of the melted PCM during every discharging period, thermocouples were mounted at the different places in the phase change box. As seen in the fig.4, the average temperature of the PCM reached to its melting point by the completion of the discharging period.

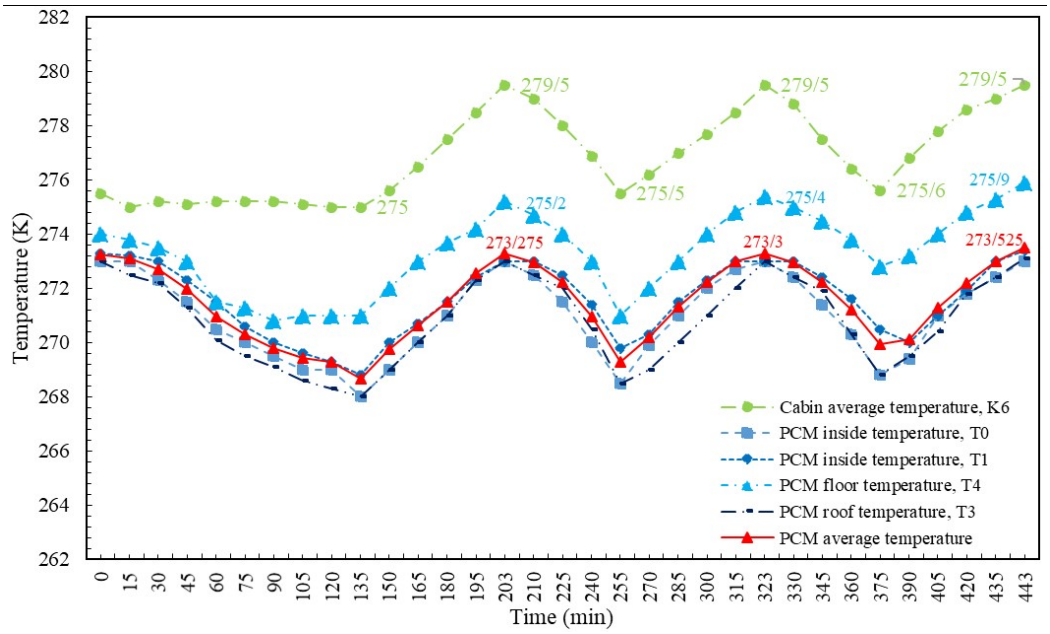

Figure.4. Trends of temperatures during charging and discharging in the experimental investigation.

The purpose of the conducting the experiment is to know the working period of the compressor as well as to have highest energy saving by using fins in cold thermal energy storage systems. Generally, compressor wants to work for 11 minutes in an hour to keep the cabin in normal condition. When the compressor is not in working condition then the cabin temperature increased to 4.15°C, and then reduces to 1.15°C, the compressor starts to work. For the first time of charging and discharging when the cold thermal energy storage system was used the cabin warmth was raised to 6.35°C, to reduce this warmth to normal 1.85°C the compressor needs to work for more than 11 minutes. By using of CTESS, as we can see that the total working period of the compressor was decreased. According to the experimental outcomes, the difference in the time taken by the compressor with CTES system and without CTES system was observed. When the cold thermal energy storage system was used during a day, the time taken for the compressor in which CTES system used shown 3.566 hours and the system without CTES shown 4.316 hours. By this comparison we can conclude that, by using CTESS reduces the working time of the compressor about 45 minutes per day.

V. CONCLUSION

The paper is a manifestation to observe the consequence of improvement of HTS of CTES system experimentally. Based on results obtained from Omid Ghahramani Zarajabad, Rouhollah Ahmadi [3], fin and finless construction of phase change material containers were considered. As per the results, a phase change material container with fin could increase discharge period and in turn decrease

charge period in comparison to a finless container. The most essential outcome is that the phase change material with finned container be capable of fuse in direction of discharge point, thus releasing LCTE. To gauge the digital outcomes an experimental setup of household refrigerator was used with the finned PCM container & 10 J type thermocouples were used to measure temperatures inside and outside the refrigerator. The time required for phase change material to freeze completely, and to maintain the cabins warmth in the STC were obtained by the experimental outcomes. Thermocouples were mounted at different levels to analyzed melting volume of phase change material and for that reason temperatures at discharge time were analyzed. The results obtained showed that 25% of PCM was melted and hence this proportion of PCM accounts for the heat capacity of Cold Storage Thermal Energy system and hence led to the electrical energy consumption. Referring to the compressor's power rating, a figure of 40kWh/year was obtained as the energy savings per refrigerator, i.e. 17.4% of energy reductions were estimated that can show positive effects over environment as well as economy. This could reduce conventional energy consumption.

Dielectric fluid

ABSTRACT

In this research paper, the effect of process parameters on electrical discharge machining (EDM) of Ti-6Al-4V has been investigated. The process parameters were discharge current, pulse on time, pulse off time and three types of dielectric fluid were used, they were deionized water, drinking water and mixed (25% deionized water with mixing of 75% drinking water) has been used for machining of Ti-6Al-4V. Experiments were carried out using Taguchi L_{27} (3^{13}) Orthogonal Layout. The output process performance was material removal rate (MRR) and surface roughness (Ra) was evaluated. Taguchi methodology were used to optimize the process parameters. It has been observed from the analysis, drinking water as dielectric fluid shows maximum material removal rate and reduced the surface roughness. The maximum material removal rate of Ti-6Al-4V was 5.46 mm^3/min and minimum surface roughness was 2.53 μm.

1. Introduction

EDM is termed as Electrical Discharge machine which is a machining process of combination of electro-thermal energy whereas the electrical energy is utilized to generate an electrical spark [1]. The purpose of using EDM is to remove the material and to shape the material [2] from the work piece as we required. The thermal energy is generated due to the high electrical energy [3] of the machine. Using this generated thermal energy and electrical energy [4], the material is to be molten and the unwanted portion of the material is to be removed [5] from the work piece. The material used in the EDM must have the high strength temperature resistant alloys [6] and also electrically conductive. In EDM, the work piece and tool should be [7] electrically conductive. Both of these materials [8] were immersed in dielectric medium [9] like deionized water or kerosene [10]. The workpiece and tool [11] is separated by some distance. After this some voltage [12] or potential difference is applied between the tool and workpiece [13]. Based on the gap between workpiece and tool and the amount of potential difference [14] applied, the electric field is to be established [15]. Normally, this setup is having the positive terminal [16] and also the negative terminal. The tool is connected to the negative terminal of the generator and also the work piece is connected to the positive terminal of the generator. Because the electric field is induced between the tool and workpiece, [17] the free electrons created in the tool are applied to electrostatic forces. If the bonding energy between material and work piece of the electrons [18] is less, then a quantity of electrons is emitted from the tool and this emitted electron is known as cold emission. Then the emitted cold electrons are moving towards the work piece via the dielectric medium and get the velocity and energy. After moving towards the workpiece, [19] there is a collision is induced between the electrons and dielectric molecule and this collision may cause the ionization of the dielectric medium which is based on the bonding energy of the molecule and an electron. Due to collision, more amounts of negative and positive ions are accelerated [20]. This process will enhance the concentration of the ions and electrons in the dielectric medium between work piece and tool [21]. The matter presented in the channel is known as plasma and the electrical resistance [22] of this is very low. Then unfortunately, huge quantity of electrons and ions are to be flow from the tool and the workpiece [23]. This movement of electrons is called as avalanche motion of electrons. Such movement is to be create an electrical spark and the amount of energy is to be dissipated in the form of heat in spark. The high velocity electrons are fall on the workpiece and ions on the tool. The kinetic energy of the ions and electrons are impact with the surface of the workpiece and tool respectively and to be converted into thermal energy or heat flux. Such intense localized heat flux leads to extreme instantaneous confined rise in temperature and to material removal which would be in excess of 10,000 C [24]. The schematic diagram

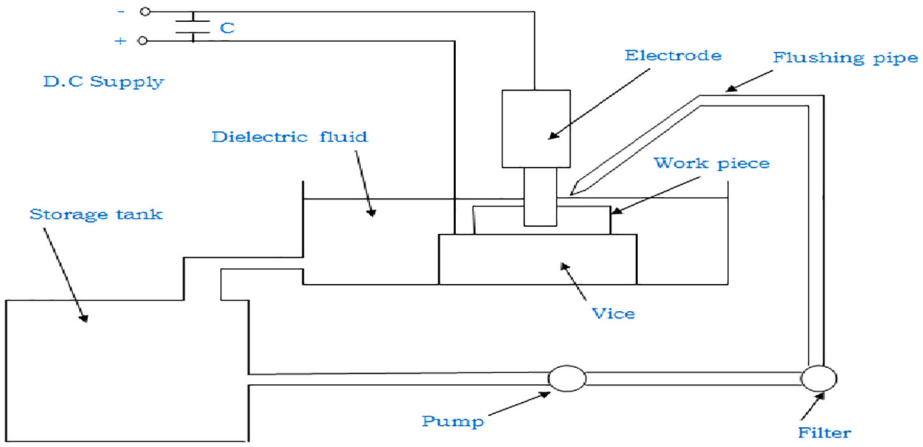

Fig. 1. Schematic diagram of EDM machine.

of the Electrical Discharge Machining used in this research is illustrated in Fig. 1.

2. Selection of the work piece material, electrode material and types of dielectric fluid

The workpiece material employed in this study is Ti-6Al-4V. Copper was used as an electrode material, drinking water, deionized water and combinations (25% deionized water + 75% drinking water) were used as dielectric fluids. The chemical composition and properties of Ti-6Al-4V were shown in Tables 1 and 2, respectively. The dielectric fluid characteristics of drinking water, drinking water properties and deionized water properties were shown in Tables 3–5. The experimental setup used for conducting actual experiments is given in Fig. 2.

2.1. Identification of the important EDM process parameters

The most important EDM Process parameters identified were discharge current, pulse on time. Pulse of time and dielectric fluids were used.

2.2. Determination of the levels for the process parameters and their working range

The working range of the selected process parameters under the present study is given in Table 6.

2.3. Selection of orthogonal array

In the present analysis, an L_{27} ($3^{1\ 3}$) orthogonal array is selected. The selected orthogonal array is presented in Table 7.

2.4. The response measures (i.e. MRR and SR)

The EDM responses was measured in terms of MRR, SR.
The MRR can be calculated as the following formulae.

Table 2

Table 6
Working range of the process parameters and their levels.

Parameters	Levels		
Dielectric fluid (A)	Deionised water	Drinking water	Mixed (25% deionised water + 75% drinking water)
Discharge current (B)	10	15	20
Pulse on time (C)	25	45	65
Pulse off time (D)	24	36	48

$$MRR(mm^3/min) = \frac{WWL(g) \times 1000}{\rho(g/cm^3) \times machining\ time(min)}$$

ρ = Density of work piece material

The SR is referred to the roughness or smoothness and it was measured by surface roughness tester. MRR and SR was evaluated for all the conditions and presented in Table 8.

MINITAB 17 software was used to prepare mean of response tables and mean of S/N graphs for MRR and SR.

Taguchi method allows evaluation of individual parameters effects independent of the other parameters for process parameters optimization. The design parameters prominently affecting the performance measures were determined by using analysis of variance (ANOVA).

In Fig. 3. Where S/N ratio was larger to better was considered for MRR. In Fig. 4 S/N ratio was lower to better was considered for SR.

Fig. 4 shows the S/N response graph for surface roughness.

Significance of each parameter were found by using percentage of contribution of each parameters in ANOVA table. High percentage contribution of process parameters on EDM has prominent effect on the response. ANOVA was applied to find out the significance of main factors and the percentage of contribution were used to analysis the process parameter significantly effects on the MRR and SR. The results of ANOVA for MRR and SR were presented in Tables 9 and 10 respectively.

3. Results and discussions

3.1. Analysis of variance (ANOVA)

The ANOVA were performed to find the effect of process parameters on various performance measures. Percentage of contribution were used to determine the relative significance of various process parameters. From the ANOVA analysis shown in Tables 9 and 10, it is observed that the dielectric fluid (A), discharge current (B) pulse on time (C) were the most significant factor affecting to MRR and SR. It was observed from the ANOVA tables that discharge current (B) and pulse on time (C) have a high percentage of contribution on various performance measures as compared to pulse off time (D).

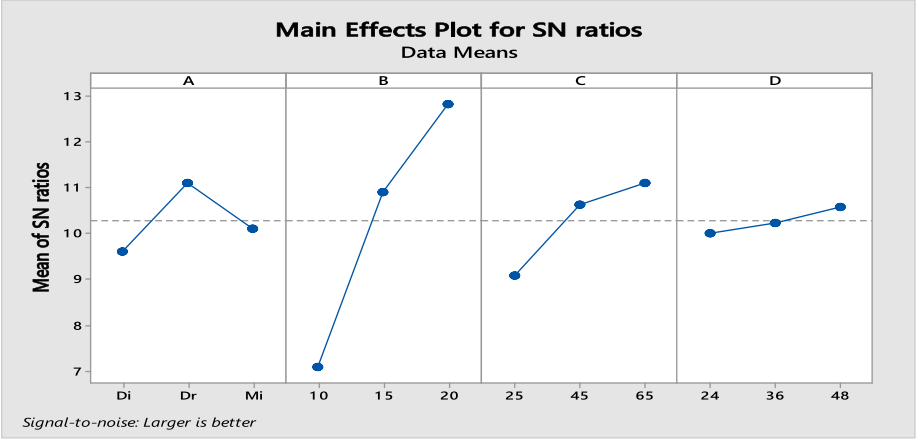

Fig. 3. Influence of EDM parameters on S/N graph for material removal rate.

3.2. Effect of machining parameters on MRR

S/N graphs of MRR was presented in Fig. 3 and the ANOVA was shown in Table 9. It is observed that for deionized water and drinking water, the MRR increases and after that it decreases in the mixed condition (25% deionized water + 75% drinking water) due to decrease in thermal conductivity. It is also observed that, as the current (I) increases from 10A to 20A, the MRR increases significantly. Discharge current controls the heat energy supplied for metal removal, as the discharge current enhances, heat energy also enhances. Thus the MRR increased from 10A current to 20A. The discharge current is sharing 79% and it is the first significant factor. The material removed is directly proportional to the amount of energy supplied in this. Thus it is the most important factor as far as sharing and importance is concerned. As the pulse on time increases from 25 μs to 65 μs, the MRR also increases almost non-linearly. Its contribution is 10%. Pulse off time is the least significant factor and shows minimum contribution. Its contribution towards MRR is 0.7%. It is observed that as the pulse off time increases from 24 μs to 48 μs, the MRR is improved by very small amount. At minimum pulse off time i.e. 24 μs, the dielectric fluid gets less time to deionize and flush away the debris.

St	36.89481381	26		100

3.3. Effect of machining parameters on SR

Fig. 4 presents the S/N graph and Table 10 presents ANOVA for SR. It is observed that for the dielectric fluid as deionized water and drinking water the SR decreases and after that it increases in the mixed condition (25% deionized water + 75% drinking water) which is due to lower thermal conductivity of water. Fig. 4 show that as the discharge current increases from 10A to 20A, the SR increases. As the discharge current increases the bombarding impulsive force of electrons also increases. In case of negative polarity, the bombardment of electrons takes place from work piece to electrode. The SR is higher at 10A as the amount of material deposited is less. When the discharge current is increased to 20A, the larger impulsive force produces deeper and greater craters with more amount of material being deposited. Hence the surface roughness is more. The contribution of dielectric fluid on the SR is 12% and it is the third largest. The contribution of discharge current is 23% and its significance is the second highest. The material removed by using the electrode is directly proportional to the amount of energy supplied. Thus it is the most significant factor. As the pulse on time increases from 25 μs to 65 μs, the SR also increases. Its contribution is 33%. Pulse off time is the least significant factor and shows minimum contribution as far as SR is concerned. Its contribution towards SR is 6%. It is observed that as the pulse off time increases from 24 μs to 48 μs, the SR becomes

Table 11
Optimum values of the machining performance evaluation parameters.

Parameters	Optimum condition	Predicted Optimum value
MRR (mm^3/min)	$A_2B_3C_3D_3$	5.46
SR (μm)	$A_2B_1C_1D_2$	2.53

Please cite this article as: B. Gugulothu, Optimization of process parameters on EDM of titanium alloy, Materials Today: Proceedings, https://doi.org/10.1016/j.matpr.2019.10.150

Table 12
The optimum results.

Parameter	Optimum condition	Predicted Optimum value	Experimental values
MRR (mm^3/min)	$A_2B_3C_3D_3$	5.46	5.90
SR (μm)	$A_2B_1C_1D_2$	2.53	2.98

low. At minimum T_{ON} of 24 μs, the dielectric fluid employed relatively less time to de-ionize and flush away the debris. Thus stability of the machining process and SR is influenced the optimum values of the machining performance evaluation parameters were given in Table 11 and the optimum results were given in Table 12.

4. Conclusions

In this study, the influence of dielectric fluid i.e. deionized water, drinking water and mixed (25% deionized water + 75% drinking water), the process parameters and optimization of titanium alloy (Ti-6Al-4V) in the die sinking EDM was studied by using Taguchi method. From the results it was found that drinking water, discharge current, pulse on time and pulse off time have been found to play significant role in EDM operations. Also, it was found that the optimal levels of the factors for MRR and SR are differing from each other. From ANOVA, pulse on time is more significant than discharge current for SR whereas discharge current is more significant than pulse on time for MRR. On the other hand, interaction between dielectric fluid and discharge current is also significant in case of SR.

Material removal rate
Surface roughness
Recast layer thickness

ABSTRACT

In the present investigation, the influence of drinking water as dielectric fluid and graphite powder concentration on electric discharge machining of Ti-6Al-4V alloy is studied. Taguchi parameter design approach was used to get an optimal parametric setting of EDM process parameters namely, discharge current, pulse on time, pulse off time and graphite powder concentration that give up optimal process performance characteristics such as material removal rate, surface roughness and recast layer thickness. Also individual effect of process Parameters on performance characteristics was studied. Experiments were conducted on experimental setup with modified dielectric fluid circulating system. To identify the significance of parameters on measured response, the analysis of variance (ANOVA) has been done. Further empirical models were developed by performing nonlinear regression analysis to predict the process performance characteristics. Confirmation tests were conducted at their respective optimum parametric settings to verify the predicted optimal values of performance characteristics.

1. Introduction

Ti-6Al-4V shows better mechanical properties even at elevated temperatures. Despite such tremendous property, its applications are quite limited to military, aircraft, space craft and medical fields. The factor limiting its application is high cost and manufacturing intricacies. Ti-6Al-4V is a material which is difficult-to-machine due to its poor electrical and thermal conductivity. It chemically reacts with almost all cutting tool materials. Low cutting speeds, high feed rates, huge quantity of cutting fluids, sharp tools and rigid set up are essential for the conventional machining of Ti-6Al-4V and makes it uneconomical and inefficient [1–3]. EDM can be employed to overcome the problem faced in conventional machining of Ti-6Al-4V [4]. Die-sinking EDM is also used to manufacture the components used for aerospace, automobile, tools and machine tools. EDM is applied for making cavities and miniature holes. With the help of die-sinking EDM, it is possible to make intricate shaped dies with very less machining time. It can machine durable materials like Carbide, Steel, Stellites etc., with considerably good surface finish. EDM can be employed for removing broken taps, drills, studs, reamers, pins. Fragile materials are machined without any damage by EDM [5]. Tariq Jilani et al. Studied the different dielectric fluids and two different tool materials. It has been concluded that best machining was obtained by tap water [6]. Chen S. L. et al. made a comparative analysis of discharge machining ofTi-6Al-4V with Kerosene and distilled water as dielectric fluids. Distilled water as a dielectric fluid showed good performance compared to Kerosene for MRR and RWR [7]. Lin et al. optimized machining parameters in magnetic force assisted EDM based on Taguchi method and found higher MRR, lower RWR and smaller SR as compared to standard EDM. Significant machining and optimum combination levels of these parameters have been determined [8]. Hascalik et al. studied the comparative performance of Copper, Graphite and Aluminum electrodes. Increased surface cracks, MRR, SR and TWR observed with Copper for all process parameters. Higher MRR with Graphite and lower SR in Aluminum were found [9]. Azad et al. experimentally verified that voltage and current had influence on optimization of single quality characteristics and no influence on multiple quality characteristics [10]. Kung et al. analyzed machinability of Cobalt bonded Tungsten Carbide (94WC-6CO) with Aluminum powder mixed EDM. It has

Please cite this article as: B. Gugulothu, G. Krishna Mohana Rao and D. Hanumantha Rao, Influence of drinking water and graphite powder concentration on electrical discharge machining of Ti-6Al-4V alloy, Materials Today: Proceedings, https://doi.org/10.1016/j.matpr.2019.11.035

been concluded that using Aluminum powder mixed with dielectric distribute the discharge energy gets to increase the machining efficiency [11].

Kibria et al distinguished the influence of distinct dielectrics like Kerosene, de-ionized water, B_4C powder + Kerosene and B_4C powder + de-ionized water. MRR and TWR were observed to be more and RLT was less with de-ionized water compared with Kerosene. In case of B_4C powder mixed dielectric, material removal rate increases by de-ionized water, but TWR reduced with Kerosene [12]. EmreUnses et al observed improvement by adding Graphite powder into kerosene on EDM of Ti-6Al-4V [13]. Ekmekci et al Performed comparative study on the surface integrity of discharge machined plastic mold Steel while using Kerosene and de-ionized water as dielectric fluids. Graphite and Copper as electrodes. Formation of white layer was observed on the machined surface in case of all the dielectric fluids [14]. Bozdana et al. studied rapid drilling of holes on Ti-6Al-4V by EDM. Brass and Copper tubular electrodes were used with de-ionized water as dielectric and negative polarity. It has been observed that MRR increased and TWR decreased with Brass electrode than Copper electrode [15]. Jahan et al developed model and investigated the effect of Nano-powders like Graphite powder (Gr), Aluminum (Al) and Alumina (Al_2O_3) separately mixed with Kerosene in micro-EDM of Tungsten Carbide. Particle size, concentration, density, electrical and thermal conductivity of powder were found to be the most significant factors affecting the performance [16].

2. Experimental setups, procedure and equipment:

The die sink EDM (Make: Formatics, Bangalore, India) with power supply unit and controller PSR-20 (Make: Electronica, Pune, India) was used for conducting the experiments. The details of the experimental set up and the closed view of working tank are shown in Fig. 1.

The experimental set up was modified for conducting the experiments in the case of powder mixed dielectric fluid. The schematic diagram of experimental set up for PMEDM is shown in Fig. 1. In this modified experimental set up, powder is mixed into the dielectric fluid in a separate tank. For conducting experiments, the work material Ti-6Al-4V. The workpiece of 160 mm length, 60 mm breadth and 6 mm thickness is selected. The Copper electrode of 12 mm diameter is employed for the experiments. The workpiece material employed in this study is Ti-6Al-4V. Copper is used as an electrode. Drinking water, are used as dielectric fluids.

The hardness of the material is measured at different points and average hardness value was found to be 32–34 HRC. The chemical composition of the Ti-6Al-4V alloy is shown in Table 1. The mechanical and physical properties of Ti-6Al-4V alloy are presented in Table 2. Owing to higher thermal conductivity low electrical resistivity and high melting point, the graphite powder (particle size 20 to 30 μm) is chosen to add into the dielectric fluid. The graphite powder morphology can be observed under SEM and is shown in Fig. 2.

The preliminary experiment result shows that lower MRR is observed when straight polarity was used. Hence, this study is focusing on increasing the MRR of the work piece. Using reverse polarity [17–19]. When the discharge current was kept above 10A, it was observed that the MRR was significant, and when more than 20A current was selected, it resulted in higher MRR necessitating the selection of values. The range selected for the pulse-on time and pulse-off time is based on the pilot experiments and the literature [20]. The pilot experiments were carried out with the addition of graphite powder from 1 to 20 g/L into the dielectric fluid. The working range of process parameters in this study is presented in Table 3.

Three trials of each experiment were conducted to average of these values to minimize the pure experimental error. Machining time has been chosen for conducting each experiment is 30 min, which is sufficient to produce tool shape on work material during EDM machining of Ti-6Al-4V alloy. The experimental layout for the present investigation is presented in Table 4.

3. Results and discussion

It is possible to sort out each process parameter on response at different levels since the experiments are designed in orthogonal nature.

3.1. Influence of process parameters on MRR

The mean of three trails runs of MRR, SR, and RLT are presented in the Table 4.

The effect of process parameters on the MRR are presented in Fig. 3. With the increase in discharge current from 10A to 20A, significant increase in MRR is noticed from the response graphs. Dis-

Elastic Modulus (GPa)	114

charge energy in inter electrode gap is directly influenced by the discharge current. MRR increases at higher discharge current conditions as a result of high current density that is rapidly over heating the work piece that caused because of increase in spark energy [20]. With an enhancement in discharge current, a stronger spark with high thermal energy is produced and a major portion of heat is transferred to the electrodes. Further as current increases, discharge strikes the surface of work piece intensively which creates an impact force on the molten material in the molten puddle and this results into ejection of more material out of the crater [21]. The trend in variation of MRR with enhancement in discharge current is similar with the findings of the pulse on time and is the 2nd significant factor as far as improvement and importance are concerned. It is clear from Fig. 3 that, as the pulse on time increases from 25 μs to 65 μs, MRR increases to a smaller extent due to increase in energy supplied per cycle [22]. Since discharge energy is not present during pulse off time material removal from work piece will not take place. With the increase in T_{on} from 24 μs to 36 μs, MRR increases initially and then decreases. Debris that is not flushed due to short time available will not allow effective sparking at low pulse off time and results in unstable machining process. Debris flushing takes place effectively with the increase in pulse off time and paves way for effective sparking and stable machining. Due to this, with pulse off time of 36 μs, MRR enhances initially and then reduces as quantum of energy supplied to the process decreases.

MRR decreases initially and increases marginally later with the increase in Graphite powder combination from 4.5 g/l to 9 g/l. Excess powder accumulation in the gap reduces the discharge transitivity and results in MRR reduction Fig. 3 shows that input parameters like pulse on time, pulse off time, discharge current, and Graphite powder concentration impact the MRR mean values. Maximum MRR can be achieved when T_{on} is at 65 μs (level 3), T_{off} is at 36 μs (level 2), discharge current is at 20A (level 3) and powder combination is at 4.5 g/lt (level 1). Table 5 presents the input parameters importance on MRR through ANOVA of the data and. Equation (2) gives the regression equation of MRR. For MRR values prediction, the R^2 and R^2_{adj} are in the variability acceptable range and the values found are (98.9%) and (95.1%) respectively. MRR is predicted between the operating ranges of EDM process parameters by using the regression model.

$$MRR = 3.76 - 0.892A + 0.0516B + 0.280C - 0.511D + 0.03052A^2 - 0.001239B^2 - 0.00526C^2 + 0.0400D^2 + 0.00791AB + 0.00494AC - 0.01929AD \quad (2)$$

3.2. Influence of EDM parameters on Ra

The mean values of surface roughness for individual parameters effect values are given in Table 6. Response curve for the individual effect of discharge current, pulse on time, pulse off time and Graphite powder concentration on the average values of Ra is shown in Fig. 4. It is observed from the Fig. 4 that improvement in surface roughness value is noticed by increase in discharge current. It is due to the reason that the increase in discharge current enhanced spark power resulting in the creation of wide and higher cavity which results in enhanced surface roughness. With the increase of Graphite powder combination increase from 4.5 g/litre to 9 g/litre, surface roughness initially decreases and then increases further with the increase of powder concentration. Dielectric fluid insulation strength decreases with the addition of electrical energy and Graphite powders in dielectric fluid results in gap widening between electrodes that stabilizes the discharge condition. Lower surface roughness, shallow craters are produced due to the reduced electrical density by the widened and enlarged discharge channel. More heat dissipation from electrode gap through dielectric fluid takes place because of increase in dielectric fluid thermal

Pulse off time (C)	μs	24	36	48
Graphite powder concentration (D)	g/l	4.5	9	13.5

conductivity due to powder addition and also the thermal conductivity available in the work surface decreases [23]. With the Graphite powder combination increase from 4.5 to 9.0 g/lt, surface roughness is decreased and further Graphite powder combination increases from 9 to 13.5 g/lt increases Ra value marginally. Surface roughness is not significantly affected by the Graphite powder concentration from 9 g/l to 13.5 g/l. Table 6 and Fig. 4.

Fig. 4 indicates that minimum work surface roughness can be obtained when Ton is at 25 μs (level 1), T_{off} is at 24 μs (level 1), discharge current is at 10A at level 1 and powder concentration is at 9 g/litre at level 2. Table 6 shows input parameters influence on Ra from ANOVA of the data which is given. From Table 6 it is noticed that surface roughness is most significantly affected by the

discharge current whereas other powder concentration doesn't have that much effect which is because of the interaction effect between the parameters. Ra values are predicted by developing the empirical model using nonlinear regression analysis. Equation (3) gives the regression equation of SR. The regression equation of Ra is presented is given in Eq. (3). The R^2 and R^2adj values are found to be 98.5% and 93.6% respectively. The R^2 and R^2adj is in the accepted range of values in predicting Ra value.

$$SR = 0.91 - 0.084A - 0.0079B + 0.0531C - 0.105D + 0.01215A2 + 0.000405B2 + 0.001256C2 + 0.00877D2 + 0.00143AB - 0.00607AC - 0.00336AD \quad (3)$$

3.3. Effect of process parameters on recast layer thickness (RLT)

EDM generated heat affected surface has upper layer called as recast layer, phase transformative zone and conversional zone in order given. SEM photo graphs are taken at the cutting machined zone at the edge of the machined surface to measure RLT for all the samples machined. Table 4 shows the RLT average values measured from SEM.

Fig. 5 and Table 7 indicates the parameters effect on the response. With the increase in discharge current, significant increase in recast layer thickness is noticed which can be due to more discharge energy generation causing unstable concentrated discharge resulting in dielectric flushing efficiency decrease in the gap. Also, more heat energy leads to increased molten metal

Total	26	40.9267					100

formation which decreases flushing condition that makes more re-solidified material resulting in the increase of white layer thickness.

As the pulse on time increases from 25 μs to 65 μs, the RLT also increases almost linearly. This is due to the fact that at longer pulse on time, the material removed in vaporized form remains in same state for longer duration of time and effectively flushed away.

SEM values are observed from Table 4 RLT decreases with increase in powder combination from 4.5 g/lt to 9 g/lt and increases with further enhancement in powder combination from 9 to 13.5 g/lt. RLT reduces due to decrease in amount of heat available at work piece, this accounts by lower single spark discharge energy and increased spark frequency with the addition of Graphite powder in dielectric fluid. Recast layer thickness increases with increase in concentration of powder in dielectric up to 9 g/lt to 13.5 g/lt. It can be observed that RLT value is minimum when Graphite powder combination is 9 g/lit i.e. Level 2, T_{on} at 25 μs (level 1), discharge current at 10 A (level 1), T_{off} at 24 μs (level 1). Mathematical model of RLT (response variable) is developed by nonlinear regression analysis which is given in Eq. (4). The values R^2 and R^2_{adj} are in acceptable range which is 91.70% and 85.62% respectively.

However, R^2_{adj} (85.62%) is low due to the inclusion of insignificant parameters in the model. Further, we can predict RLT using by Eq. (4).

$$RLT = 1.02 + 0.138A + 0.0414B + 0.445C - 0.945D + 0.00729A^2 - 0.000361B^2 - 0.00243C^2 + 0.0324D^2 + 0.00240\,AB - 0.01438\,AC + 0.02561\,AD \quad (4)$$

4. Confirmation experiments for influence of drinking water and Graphite powder concentration on electrical discharge machining of Ti-6Al-4V alloy

Material removal rate, surface roughness and recast layer thickness predicted values were confirmed. Table 8 represents the data of confirmation experiments, compared with respective prediction values and the deviations of prediction results.

5. Conclusions

Based on the experimental results in the present work, the following conclusions are drawn:

1. In the case of drinking water with Graphite powder addition, the maximum MRR is 10.567 mm^3/min. The optimum condition of MRR is 10.567 mm^3/min at $A_3B_3C_2D_1$ (discharge current (I) at 20A, pulse on time (T_{on}) at 65 μs, pulse off time (T_{off}) at 36 μs and Graphite powder combination at 4.5 g/l).

Please cite this article as: B. Gugulothu, G. Krishna Mohana Rao and D. Hanumantha Rao, Influence of drinking water and graphite powder concentration on electrical discharge machining of Ti-6Al-4V alloy, Materials Today: Proceedings, https://doi.org/10.1016/j.matpr.2019.11.035

Table 8
Prediction and experimental results of MRR, SR, and RLT at various optimum conditions.

SNO	Optimum parameters				Optimum response	Optimum condition	Predicted value	Experiential value	% of Error
	A (Discharge Current)	B (Pulse On-Time)	C (Pulse Off-Time)	D (Graphite Powder Concentration)					
1	20	65	48	4.5	MRR (mm^3/min)	$A_3B_3C_2D_1$	9.64352	10.567	9.57
2	10	25	24	9	SR (μm)	$A_1B_1C_1D_2$	1.2545	2.231	7.78
3	10	25	24	9	RLT (μm)	$A_1B_1C_1D_2$	7.78446	8.432	8.31

Average of three values

2. The minimum surface roughness is during EDM of Ti-6Al-4V is observed to be 2.231 μm at $A_1B_1C_1D_2$ (discharge current (I) at 10A, pulse on time (T_{on}) at 25 μs, pulse off time (T_{off}) at 24 μs and Graphite powder concentration at 9.0 g/l).
3. The minimum recast layer thickness is 8.432 μm during EDM of Ti-6Al-4V is observed at $A_1B_1C_1D_2$ (discharge current (I) at 10A, pulse on time (Ton) at 25 μs, pulse off time (Toff) at 24 μs and Graphite powder concentration at 9.0 (g/l)
4. When powder concentration is 9 g/lt SR value attains maximum, below that concentration SR increases and then decreases with increase in concentrated powder to 13.5 g/lt.
5. RLT value decreases with Powder combination from 4.5 to 9 g/lt and further enhances with improvement in powder concentration from 9 g/lt to 13.5 g/lt.
6. Based on the results, ANOVA analysis, discharge current is found to be most significant parameter affecting MRR, SR, and RLT. However, powder concentration is having less significance
7. Optimal parametric settings were found for all performance characteristics. Corresponding optimum response values are calculated and also confirmation experimentation was managed at particular optimum parametric location to check predicted optimal value. The matching % error values were estimated and the values are in the range of 7.78% to 9.57%.
8. Different Graphite powder concentration in drinking water is used as the input process parameter, the optimal level of Graphite powder found to be as 4.5 g/l is sufficient to maximize the MRR and 9.0 g/lt to reduce the SR and RLT.

Reinforcing Adhesive Plastic-Coated Grins through FRP Compounds

T. Naresh Kumar, A.K.Saravanan, S. Shylin H. Jose, L. Ravikumar, M. Sudhakar

Abstract: ***This paper portrays the strategy for upgrading the vitality and solidness attributes of wooden and diverse wood basically based glulam frameworks. The need for fortifying structures - timber frameworks comprehensive – is because of weakening through additional transporter use, age and the need for economical advancement done by utilizing turning away destruction and re-creation. Fortified FRP Composite substances were shown to be a viable chance to regular steel plate reinforcing techniques for solid frameworks from results of a determination of scientists during the last two numerous years; this paper investigates utilizing this material for same fortifying reason in timber structures. The sum total of what examples had been inspected underneath 4 factor bowing at a stacking addition pace of 0.5kN, the horizontal diversion had been recorded much of the time. The information preparing comprised of burden, diversion and second shape plots creation which were then utilized for assessment and perceptions.***

Keywords: Reinforcement; CFRP; Adhesive; Grins; Compounds.

I. INTRODUCTION

Timber while contrasted with other generation materials including solid, metallic and block, has one of a kind plastic qualities and thus might be strengthened in the strain zone to effectively use its compressive attributes [1]. In current years logical examinations had demonstrated utilizing fiber reinforced polymer (FRP) composites on the grounds that the most extreme promising innovation for fixing, fortifying or retrofitting existing frameworks to oppose better hundreds and to amend broken flexural auxiliary variables [2]. For maintainable advancement it's been set up that reestablish and retrofit be contemplated sooner than a choice is made to refresh a shape [3]. It is additionally less time eating to fix than to refresh, diminishing supplier interference periods. In the equivalent yr, past to above, posted a paper on prestressed FRP sheets as outside fortification for timber patrons [4]. Likewise referenced the wet blanket conduct of FRP- reinforced wood [8-10]. Examined the power and firmness of wood pillars fortified with carbon fiber and glass fiber composites [5] that equivalent year posted work they'd accomplished at the auxiliary portrayal of half breed FRP-glulam boards for scaffold decks. In 2003 [6] considered the plan of (FRP) Strengthened wooden bars. A methodology for flexural support of antique wooden bars with CFRP substances [7] contemplated the fix of wooden heaps the utilization of pre-assembled FRP composite shells. In 2006 [8] contemplated the results of routinely attaching FRP strips to timber people as a fortifying trademark. That indistinguishable a year, [9] took a shot at a couple glulam givers supported via carbon fiber fortification by methods for first taking strolls haul out keeps an eye on four sets of glulam givers at uncommon tying down lengths; 100, one hundred fifty, 200 and 250mm at that point performing four factor bar tests on ten glulam pillar examples the utilization of close to floor set up fortifications (NSMR) as the fortifying texture [10-13]. This paper depicts a test investigate variable width on remotely fortified carbon FRP supported glulam shaft members.

II. MATERIALS USED

1) Plywood

The strengthened glulam texture comprised of twenty-four compressed wood bar areas, arranged for trial flexural giving it a shot; examples had been cut in lengths of 400mm with four particular widths fluctuating among 50, a hundred, one hundred fifty and 200mm. The thickness of the handle fabric utilized wound up 25mm [14].

2) Carbon FRP

The sheet is furnished with groundwork and overlaying gums and organization a piece of the Selfix Carbofibe Externally Bonded Reinforcement System [15].

Table 1: Mechanical Properties of the CFRP Used

Mechanical Properties	Mean value
Ultimate tensile strength (MPa)	1900.0
Elastic modulus (GPa)	222.5
Ultimate strain capacity (%)	0.9

III. SPECIMEN PREPARATION

The compressed wood constituents were diminish to sizes comprising six shaft individuals for every width and gutted off with the helpful asset of a pointy sand paper to make certain a level, uncontaminated and degreased floor [16]. Saw earth particles were expelled with the asset of a hand vacuum purifier [17]. In like manner, the CFRP strengthening texture become sliced to the equivalent widths as the pillars anyway at a

term of 300mm and vacuumed prepared for solicitation [18].

IV. TEST PROCEDURE

A picture of the sunbeam assessment procedure is placed in Fig. 1. The mid-span dislodgment was leisurely through the utility of a knob instrument situated at the sunbeam middle line [19-21].

Fig. 1 – Beam investigate game plan.

The bars have been stacked to disappointment at the 4 point twisting investigate gear; the heap additions had been 0.5kN.

V. TEST RESULTS

Any reasonable person would agree that with most fortifying techniques there will in general be an ideal point of confinement whereby any expansion in support never again gives the ideal impact as far as expanded execution [22]. Accordingly, look into specialists set aside some effort to break down test results to decide the ideal support level with an end goal to improve structure as shown in fig.2; this is a critical disclosure and reveals to us that any further increment in width never again brings about a productive increment in burden bearing limit. It is believed that further investigation into this region is legitimate [23-25].

Table 2: Normal failure freight and refraction consequences after trials

Specimen Description	Average Failure Load	Average Deflection at Failure
50x25x400mm control	3.00kN	4.38mm
50x25x400mm CFRP	3.75kN	3.11mm
100x25x400mm control	6.00kN	3.36mm
100x25x400mm CFRP	8.50kN	2.68mm
150x25x400mm control	8.00kN	2.54mm
150x25x400mm CFRP	12.00kN	2.49mm
200x25x400mm control	12.00kN	3.39mm
200x25x400mm CFRP	16.00kN	2.91mm

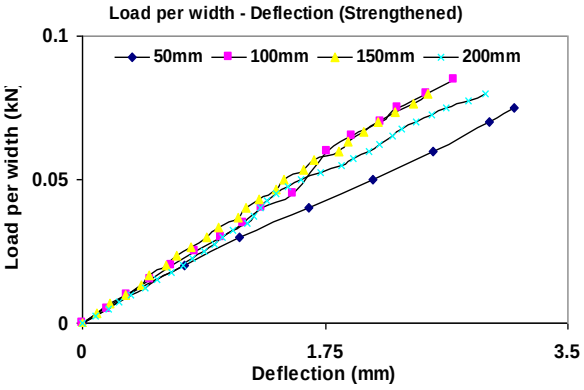

Fig. 2 – Load redirection diagram for CFRP strengthened employ bars

VI. CONCLUSIONS

This paper has displayed test results planned for setting up the adequacy of CFRP composite frameworks flexural fortifying of glulam bars. Four elective width estimations for the overhauling framework have been examined. In all cases, a similar cement plan was utilized in one single activity, which included lay-up, utilization of vacuum and holding of the CFRP layer. Each of the twenty-four compressed wood pillars were exposed to four-point stacking and the overhauled utilize bar widths came to and surpassed the plastic breakdown heap of like-width un-fortified handle bars. The widths of somewhere in the range of 100mm and 150mm showed the best increment in burden bearing limit when reinforced with the one layer CFRP. Further examinations are as of now sought after to look at different shaft widths, reinforced with more than one layer of CFRP composites wanting to further improve the bar properties.

Observation of Different Experimental Parameters Effect using Friction Stir Welding Through Simulation of Tailor Welded Blanks

Aruna Jyothi Anumula

Abstract*: *In the present scenario, the industries of automobile are focusing in decrease in the weight of the automotive body by using which we can increase the efficiency of fuel orally. Many researchers are working keeping this as motto, many joining techniques and engineering materials are used to decrease the decrease in weight for increasing the fuel efficiency. By synchronizing this, there is a technique called tailor welded blanks (TWB) is recommended highly by many automobile industries and researchers have been chosen this technology. In the current work, the motto is the behavior of forming in the TWBs using the process of friction stir welding (FSW) in two welding speeds (90 mm/min and 100 mm/min). The simulations of forming were conducted using the test called limiting dome height (LDH). Eight strain paths were considered for the simulation with maximum size of 200×200 mm to minimum size of 25×200 mm. The base metal Forming limit diagrams, the sheets of FSW are plotted and compared. From the results of simulation, it has noted that base material has lesser formability than FSW sheets. At 100 mm/min welding speed, FSW sheet fabricated and has noted increasing the formability than the welding speed of FSW sheet at 90 mm/min.

Index Terms*: *FSW sheets, Forming limit diagram, speed of welding.

I. INTRODUCTION

The new joining process in solid-state called Friction stir welding (FSW) has been developed at The Institute of Welding in 1991. Now a day's FSW process took the lead to join the non-ferrous materials in addition to advanced high strength ferrous material. This process involves many process parameters, especially tool related and welding parameters plays a vital role during the joining [1],[2](Mishra and Maa (2005) and Nandan et al. (2007)). There were many studies carried out on the process parameters effect on joint formation, mechanical properties compared to base metals, microstructure analysis over different zones, formability of FSW sheets etc, on the different materials.

A few formability studies based on numerical and experimental analysis were carried out on the sheet of FSW made of aluminum alloys and concluded that FSW sheets are having better formability than base metal. For example, Lee et al. (2009) estimated the results of formability of Tailor weleded blank FSW, via experiments and simulation of numerical. In that work, they took blanks of FSW made of, 5083-H18, 6111-T4, 5083-O, AZ31 magnesium alloy sheet materials and dual-phase steel (DP590). The increased ductility in the weld aid the results of AA5083-O, AA5083-H18, and AZ31 Tailor welded blank sheets. Similar work (Chung et al. (2010) and Kim et al. (2010)) was accomplished to look into the performance of formability for four automotive sheets, viz.,5083-H18, 6111-T4, 5083-O, DP590 and 5083-O steel sheets, each having one or two varying thicknesses. Kim et al. (2010) studied the formability performance in FSW aluminum alloy 6111-T4 sheet with 1.5 mm thickness with respect to material directional combination. They compared the material direction combinations in three different types.

Recently Janaki Ramulu et al. (2013 b) carried out an initial investigation on the effect of tool rotation speed and welding speed on the formability of Friction Stir Welding sheets made of AA 6061. Based on the experimental data the current work aimed the speed of welding effect on the formability of Friction Stir Welding sheets and compared with base material formability. The two levels of the speeds of welding (90 mm/min and 100mm/min) experimental data have considered at which better weld properties are seen from Ramulu and Ganesh (2013) research work.

II. METHODOLOGY

A. Base material and friction stir welded blanks mechanical properties

For the present work, AA6061 aluminum alloy base material and FSW fabricated at two different welding speeds was considered. The base material mechanical properties and FSW blanks were shown in the Table.1. All the properties were taken from the available literature (Ramulu et al. (2013 a, b, c) and Ramulu and Ganesh (2013)).

B. Modeling of limit dome height test simulation

In a test of Limit Dome Height (LDH), the sheet was deformed by a hemispherical punch with diameter of 101.6mm inside a die opening diameter of 105.7mm. Simulations were performed for eight strain paths with sheet dimensions of 200x200, 175x200, 150x200, 125x200, 100x200, 75x200, 50x200 and 25x200mm. The required tools for Limit Dome Height test are die, punch, blank holder, draw bead and blank generated in a CAD package Solid Works and meshed in PAM STAMP 2G using Delta Mesh facility. The base material contains elements of quadrilateral shell in Belytschko–Tsay formulation

Table. 1 AA 6061 Base material and friction stir welded (FSW) blanks mechanical properties

Blank	FSW parameters	Yield Strength (σ) (MPa)	N	K (MPa)	R0	R45	R90
Base Material	--	0.271	0.1	0.42	0.79	0.95	0.851
FSW 1	TRS: 1400 rpm Welding Speed: 90 mm/min Plunge depth: 1.9 mm Shoulder Diameter: 18 mm	0.182	0.3	0.535	1	1	1
FSW 2	TRS:1400 rpm Welding Speed: 100 mm/min Plunge depth: 1.9 mm Shoulder Diameter: 18 mm	0.184	0.28	0.535	1	1	1

with five through-thickness points of integration. Hill's and Holloman's strain hardening law 1948 isotropic hardening yield criterion used as the plasticity model. Throughout the simulation the same size of mesh 1mm was used. It was found that necking criterion is sensitive to size of mesh and limit strain is optimum to the mesh size of 1–5mm is based on the thickness gradient. Throughout the study the constant coefficient of friction μ taken as 0.2. The force of Blank holder (100kN) was taken in such a way that neither the blank tears nor draws in near draw beads during the prediction of forming.

A. Failure criterion and Forming limit diagram (FLD) construction

The obtained displacement at failure can be from the gradient of thickness – based necking criterion. The necking in the sheet metal occurs when the gradient of thickness (ratio of thickness of nearest elements or circles) falls below 0.92. Here the ratio of thickness is equals or less than 0.92 are taken as necked elements (Ramulu and Ganesh (2011)).

Major limit strain and minor limit strain were evaluated from the deformed sheets using TGNC during simulation for each steel grade sheets. According to the TGNC the ratios of the two meshing elements thickness is calculated and major strain and minor strain were considered where thickness ratio 0.92 or lesser has obtained. For constructing FLD, on y-axis major strain values and on x-axis minor strain values were taken. FLD was plotted by joining these limit strain co-ordinates. This procedure was followed for all the materials.

III. RESULTS AND DISCUSSION

A. Forming limit diagrams (FLD)

A FLD is used in forming of sheet metal for estimating the sheet metal forming behavior. The diagram seeks to give a graphical description of material failure tests, such as a limit dome test. In FLD, there are two important zones called as drawing side and stretching side. In this work three FLD are constructed from the LDH simulation test results.

B. Base material FLD

Fig.1 shows the forming limit diagram of the base material. It is observed that FLC is slight decreased towards the in-plane stretching from the drawing side whereas it increased towards stretching side. The minimum major strain is noted at plane strain i.e. 100x200 mm strain path as 0.0653 mm and maximum major strain is at biaxial stretching i.e. 200x200 mm as 0.315 mm. in whole formability of the base material is increased in the stretching zone as compared to the drawing zone.

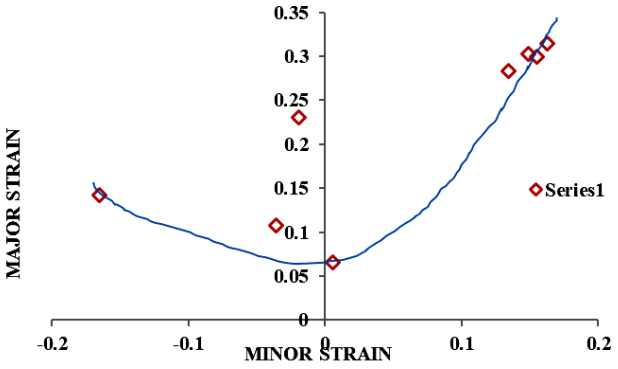

Figure 1 Forming limit diagram of AA 6061 base metal

C. FSW blanks FLD

Fig.2 & 3 shows the FLD's of the Friction Stir welded sheets made of AA 6061. Fig.2 is made the speed of welding at 90 mm/min whereas 100 mm/min is of Fig. 3.

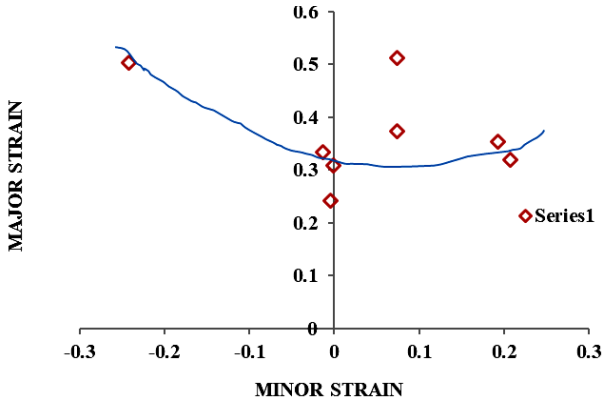

Figure 2 Forming limit diagram of FSW blanks fabricated at 90 mm/min welding speed; 1400 tool rotational speed; 1.9 mm plunge depth using 18 mm shoulder diameter

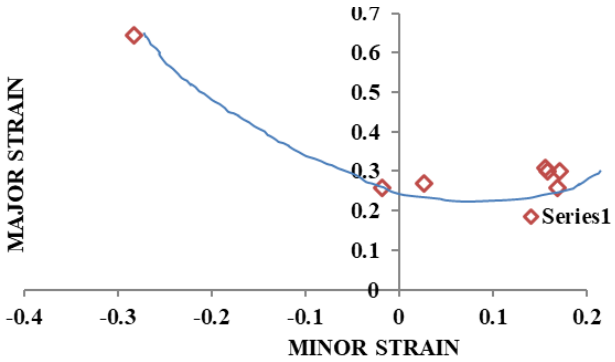
It is clear that drawing side and stretching FLC is almost similar in Fig. 2 and minimum is reported at the plane stain zone as 0.26 mm and maximum at 0.511 mm at biaxial stretching.Whereas in the other FSW condition, it is seen that drawing zone to stretching zone forming was come down as shown in Fig.3.

maximum major strain is noted as 0.64 mm for 25x200 mm strain path and minimum is at plane stain zone as 0.299 mm.



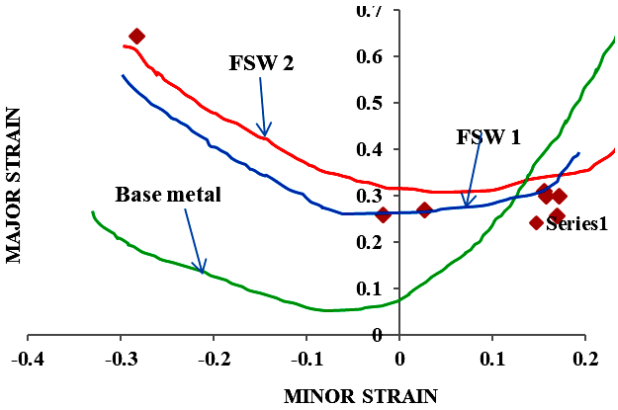


Figure 3 Forming limit diagram of FSW blanks fabricated at 100 mm/min welding speed; 1400 tool

rotational speed; 1.9 mm plunge depth using 18 mm shoulder diameter

Figure 4 Comparison of three FLCs

D. FLD's comparison

The comparison among the three FLC's is made in the Fig.4. It is clear that formability of base is showing the less formability than FSW sheets forming. FSW1 is showing better formability in stretching side whereas FSW2 is better in the drawing side. The overall formability is for FSW1 than other two FLC's. it indicates that by increasing the speed of welding for FSW joints, the formability will come down.

IV. CONCLUSIONS

From the current numerical simulations, the conclusions are drawn in the following way.

- From the forming limit diagram of the base material, formability is increased when strain path width is increased. The same observation is noticed in other FSW sheets also.
- The overall formability of base material is less compared to the FSW sheets.
- The formability of FSW sheet is better at 90 mm/min than the FSW sheet at 100 mm/min
- By increasing the welding speed of the FSW sheets, formability is decreased.

ABSTRACT

This study investigates numerically and experimentally the effect of longitudinal ribbon reinforcement in conventional honeycomb structure on the various dynamic characteristics of a hybrid composite sandwich plate. Longitudinal strips are considered to be embedded along the transverse directions at various locations of a honeycomb core material without and with carbon nanotubes (CNT) reinforcement in a composite sandwich plate. The governing differential equations of motion of the various hybrid honeycomb composite sandwich plate configurations with strips inserted in conventional honeycomb structures as core layer having top and bottom face composite layers are derived using higher order shear deformation theory (HSDT) and solved numerically using a four noded rectangular finite element. Further, experimental investigations are performed by fabricating the various strips embedded hybrid honeycomb core material with and without CNT reinforcement to evaluate the shear and loss moduli using the alternative dynamic approach. The efficacy of the developed finite element formulation is demonstrated by comparing the experimental and numerical results obtained in terms of natural frequencies and loss factors for the various prototypes of honeycomb composite sandwich plates. Also, the effect of variation in CNT content and thickness of longitudinal ribbon reinforcement in conventional honeycomb core material and ply orientation of the face sheets on the various dynamic properties of hybrid composite structures are studied under various end conditions. This study proposes that the ribbon reinforcement location and the addition of CNTs in honeycomb core materials strongly influence the stiffness, damping and transverse vibration displacements of the ribbon reinforced hybrid composite sandwich plates.

1. Introduction

An increasing demand for the development of efficient, cost effective, corrosion resistant and reliable materials is being widely realized to control the vibration in various transportation modes where the structure needs to be stiff and lightweight. Such a structure can be made by reinforcing the strips in conventional honeycomb core materials in the sandwich configuration. The environmental fatigue and excessive vibration in those structures are controlled adequately by enhancement of damping with CNT reinforcement in honeycomb core materials without any significant change in weight of those structures. This is due to the fact that the distribution of CNT randomly in honeycomb composites increases the shear force between the resin matrix and nanoparticles. These structures have better load carrying capacity that are being realized due to their demand in various industrial applications to tailor the stiffness and damping properties under various dynamic environments. The effects of fiber type, resin quality, number of stacking layers, ply orientation, type of core material and variation in core thickness could influence the vibration frequency spectrum of the composite sandwich plates.

Schwingshack et al. [1] investigated numerically and experimentally the transverse shear properties of orthotropic sandwich panel with aluminum honeycomb core using the alternative dynamic approach method. It was observed that the shear modulus along longitudinal and transverse directions could improve the dynamic properties of the structure. Nia and Sadeghi [2] examined experimentally the mechanical characteristics of honeycomb sandwich structures with and without usage of soft flexible foam in honeycomb pattern as core materials. It was seen that the effectiveness of the cell size, thickness of hexagonal walls and panel of the core structure filled with soft foam could

influence the capacity of energy absorption, average crushing strength, and wavelength over the core without foam reinforcement. Sadowski and Bec [3] investigated numerically the static and dynamic responses of polymer foam-filled aluminum honeycomb core sandwich plates. It was shown that the honeycomb core filled with foam could improve the eigenvalues of the sandwich structure. Natarajan and Manickam [4] analyzed the free vibration and flexural responses of a sandwich plate made of FGM viz., metallic and ceramic face sheets and core materials under thermal and mechanical loadings using HSDT. It was concluded that the increase in the volume fractions of metallic and ceramic material could influence the flexural stiffness of the sandwich plate. It was also seen that the increase in core thickness could decrease the displacement and stresses developed in the structure. Zhen et al. [5] presented numerically the free vibration responses of composite sandwich plates. It was seen that the C^0 finite element in HSDT are more accurate in predicting the dynamic responses than those of three dimensional elasticity solutions. Stocchi et al. [6] observed numerically and experimentally the effectiveness of the sandwich structure with the honeycomb core made of natural fabrics. It was seen that the jute reinforced honeycomb cores significantly improves the elastic properties and sustains the compressive static loads. Han et al. [7] presented numerically the effectiveness of the sandwich honeycomb core with hybrid corrugation made of aluminum materials. It was observed that combined aluminum honeycomb corrugation could improve not only the compressive strength but also the energy absorption. Liu et al. [8] examined experimentally and theoretically the bending failure behaviors of composite sandwich structures with pyramidal truss core made up of metallic material under the thermal environment. It was observed that the bending failure load could be decreased with increase in temperature due to the degradation of properties of the resin and fiber-resin interface. Liu et al. [9] studied experimentally and analytically the mechanical responses of the composite sandwich structures with Y-shaped core layer made up of CFRP composites. It can be observed that the specific strength of composite sandwich structure with Y-shaped CFRP core layer is greater than that of the Y-shaped steel core layer.

Lu and Meng [10] investigated numerically and experimentally the dynamic responses of electrorheological (ER) fluid composite sandwich plate. It was observed that the natural frequencies and modal damping of the sandwich plate are significantly increased by the applied electric field. Hasheminejad and Maleki [11] presented the free and forced vibration responses of composite sandwich plate with ER fluid. It was seen that the natural frequencies and damping of the sandwich plate are greatly influenced by increasing the applied electric field than the thickness of core layer. Eshaghi et al. [12] reviewed the dynamic responses of fully and partially treated ER/Magnetorheological (MR) sandwich structures. It was concluded that the partially treated low density sandwich structures could provide better stiffness and damping properties than those of the fully treated ER/MR sandwich structures. Further, the semi active controllers could attenuate the resonant deflection of the sandwich structures while the active controllers could suppress the complete vibration of the adaptive structures. Manoharan et al. [13,14] examined numerically and experimentally the dynamic responses of fully and partially treated MR fluid sandwich composite plate. Yeh [15] presented numerically the vibration responses of sandwich plate with magnetorheological elastomer under various magnetic fields. The results revealed that the modal loss factors and natural frequencies of the sandwich plate are greatly influenced by the magnetic field intensities. Vemuluri and Rajamohan [16] presented numerically and experimentally the vibration responses of the tapered sandwich composite plate with MR elastomer as the core material. It was seen that the frequencies and damping ratio could be enhanced due to the changes in taper angle of the face layers, variations in aspect ratio, and variation in the ply orientations at the face layers of MRE sandwich plate in addition to the application of external magnetic field intensities over the structures. Vemuluri et al. [17] investigated numerically the optimal layout of partially treated magneto rheological elastomer composite sandwich plate under various magnetic fields. It was observed that the natural frequencies and loss factors of the sandwich plate are greatly influenced by the location of MRE pockets under magnetic field intensities. Arumugam et al. [18] investigated numerically the vibration and instability analysis of the MR sandwich composite plate. It was noticed that the primary and secondary instability regions could be altered due to the increase in magnetic field. Even though many investigators have analyzed the various core layer materials such as aluminum based honeycomb patterns, MR fluid and MR elastomer, the usage of these materials is limited due to their limited viscoelastic and damping characteristics and external power requirements. After the discovery of CNT by Iijima [19] in 1991, their unique physical properties have brought a huge attention from numerous designers to develop CNT reinforced hybrid composite materials to achieve the enhanced elastic and damping properties of the structures.

Thostenson et al. [20] reviewed the recent developments made in the hybrid composite materials with reinforcements of nano particle, nano platelet, nano fiber, and CNT in the traditional fiber composites. It was concluded that CNT reinforced nanocomposites are more effective materials than those of other fillers due to their superior physical and mechanical properties. Lehman et al. [21] reviewed the effectiveness of dispersion of nanoparticles, bonding between CNTs and composites, and the chemical functionalization on the characteristics of CNT reinforced polymer composite materials. It was concluded that the mechanical properties of nanocomposite are significantly influenced by the weak bonding, dispersion and functionalization of CNT reinforcements in composites. Singh et al. [22] studied the effectiveness of aspect ratio of CNTs on the stiffness of the composite and identified that the longer CNTs (length $>$ 350 μm) in epoxy composite material have better elastic properties than those of shorter CNTs in epoxy composite. Zhou et al. [23] observed a significant increase in damping factors of the composite structures with least amount of CNT reinforcement in the polymer composite. Various investigations have demonstrated that the random dispersion of multi-walled CNT in the composite could enhance the transverse shear, flexural behavior, damping and thermal characteristics of the hybrid composites [24]. Khan et al. [25] demonstrated experimentally the significant increase in the damping characteristics of carbon fabric reinforced composites with the reinforcement of 0.5% and 1% wt. of nanoparticles in the composite material.

Rahaman and Kar et al. [26] examined the dynamic characteristics of CNT coated glass fabrics reinforced polymer based composite structures. It was observed that the CNT coated fibers could increase the storage modulus and glass transition temperature of the composite materials. Jakkamputi and Rajamohan [27] observed experimentally the modal vibration responses of glass fiber reinforced polymer (GFRP) composites with and without 0.5 wt% of CNT reinforcement in a composite laminate exposed to higher thermal environment. It was seen that the natural frequencies decrease while the damping ratios increase by increasing temperature. Praveen et al. [28] investigated experimentally the material, mechanical and dynamic characterization of GFRP composites without and with 1 wt% of CNT reinforcement. The results revealed that the elastic properties, natural frequencies and damping factor of CNT-GFRP composites are higher than those of the GFRP without CNT reinforcement.

Nagasankar et al. [29] investigated theoretically and experimentally the dynamic responses of the propylene honeycomb sandwich structures. It was observed that the transverse shear damping could be improved significantly with increase in thickness of core layer. Zhou et al. [30] investigated analytically and numerically the dynamic responses of honeycomb sandwich composite plate filled with viscoelastic damping material. It was demonstrated that stiffness could be influenced not only by the thickness of aluminum reinforcement but also with the inner angle of the honeycomb geometry. Droz et al. [31] presented numerically and experimentally the vibration characteristics of sandwich composite plate with Nomex honeycomb core layer. The

results revealed that the Young's modulus and shear modulus obtained from the inhomogeneous wave correlation method using vibration technique is more accurate and closer to the existing mechanical test results. Dai et al. [32] examined numerically and experimentally the vibration behavior of honeycomb sandwich plates. It was shown that the resonant response frequencies are significantly increased by the increase in thickness of the face layers. Zhang et al. [33] studied numerically the dynamic responses of honeycomb sandwich plate under cantilever boundary conditions. The results revealed that the chaotic, periodic and multi-periodic motions are existed in the cantilever sandwich plate when subjected to in-plane and transverse excitations. Bai et al. [34] presented numerically and experimentally the vibration responses of a composite sandwich structure with Nomex honeycomb core under thermal environment. The results revealed that the natural frequencies decrease while the damping ratios increase with the increase in the glass transition temperature. Praveen et al. [35] made an effort to investigate numerically and experimentally the vibration responses of multifunctional hybrid honeycomb-based composite sandwich plate. Even though various researchers have studied the performance of various hybrid sandwich structures, an effective passive vibration control mechanism with adaptable damping could be accomplished by reinforcing the ribbon based honeycomb composite in critical parts of a huge structure.

In this study, the dynamic responses of the various types of ribbon reinforced hybrid honeycomb composite (RHC) sandwich plate are investigated. Various ribbon reinforced glass fiber polymer composite honeycomb core material with and without CNT reinforcement as the core layer and top and bottom face sheet layers of composite plates are considered. The governing differential equations of motion of the various hybrid honeycomb composite sandwich plate configurations are derived using higher order shear deformation theory (HSDT) and solved numerically using the rectangular finite element (FEM) with nine degrees of freedom at each node. Further, the mechanical properties of various honeycomb core materials with and without CNT reinforcement and composite face sheet materials are experimentally evaluated using the alternative dynamic approach. The effectiveness of the developed FEM formulation is validated by comparing the results in terms of natural frequency and loss factor obtained experimentally on the various prototypes of composite sandwich plates. Also, various parametric studies are performed to study the effects of variation in CNT wt% and thickness of core material on the dynamic characteristics of honeycomb composite sandwich plate. Further, the forced vibration responses of three different configurations of hybrid honeycomb composite sandwich plate under harmonic excitation are analyzed at various wt% of CNTs to demonstrate the efficacy of CNT reinforcement and embedment of strips in the conventional honeycomb core materials in enhancing the stiffness and damping properties of sandwich structures simultaneously and attenuate the transverse deflection.

2. Mathematical modelling of ribbon reinforced honeycomb core hybrid composite sandwich plates

A novel sandwich composite plate comprising honeycomb core reinforced with ribbon sheets as the middle layer and the laminated composite as the top and bottom face sheets are considered for the development of mathematical modelling based on higher order shear deformation theory [35]. Further, CNTs are considered in the core material of the sandwich plate. Since the composite core material is commonly soft but stiff in shear, the Young's moduli of the honeycomb core material is considered to be negligible than those of the face layers of composite. The normal stresses acting in the composite honeycomb layer are also neglected. The top and bottom layers of the hybrid honeycomb sandwich plate consist of many layer (composite plies) and are modelled as an equivalent single layer theory as shown in Fig. 1 (a) & b)).

Fig. 1 represents the three different configurations of a hybrid sandwich composite plate of length L and width B with ribbon reinforcement at various locations viz., single ribbon reinforced between the two hexagonal pattern (RHC 1), single ribbon reinforced along and between the hexagonal pattern (RHC 2) and double ribbon reinforced along and single ribbon between the hexagonal pattern (RHC 3) of honeycomb structure. Further, the ribbon and hexagonal pattern core materials are considered to be reinforced with CNT. The top and bottom face layers of the sandwich plates are made of orthotropic materials. The composite face layer thicknesses, h_t and h_b and honeycomb layer thickness, h_c are considered to be very small compared to their length L and width B of the complete sandwich plate. The slip between composite face sheet and honeycomb core layers is ignored. All composite layers in the top and bottom face sheets are considered to be well bonded together. The damping due to the composite face layers is assumed to be negligible and the energy dissipation in the core layer is assumed to exist due to the transverse shear only. Furthermore, the transverse displacement at any given cross section is assumed to be uniform along the sandwich plate.

2.1. Total strain energy of the sandwich plate

The in-plane displacement field equation of the mid-plane of the top and bottom composite face sheets with higher order form can be presented as:

$$u_i = u_{0i} + z\theta_x - \frac{4z^3}{3h^2}\phi_x$$

$$v_i = v_{0i} + z\theta_y - \frac{4z^3}{3h^2}\phi_y \quad (i = t,\ b)$$

$$w = w_0 \tag{1}$$

where u_t,v_t,u_b and v_b denote the axial deformations at any point about x and y axes presented as a function of z which are referred from the neutral axis of the top (t) and bottom (b)face sheets of composite sandwich, respectively. u_{0t},u_{0b},v_{0t} *and* v_{0b} are mid-plane deformations at the top and bottom composite face sheets about x and y directions, respectively. θ_x and$\theta_y$are the slopes about y and x axes of the sandwich composite plate. ϕ_x and ϕ_y are the higher order terms about y and x axes. w_0 is the mid plane transverse deflection of the sandwich composite plate. h is the thickness of composite plate.

The ribbon reinforced honeycomb core layer with and without reinforcement of CNT are considered as equivalent single layer in a sandwich composite plate. The schematic representation of transverse shear deformations of the sandwich plate along xz and yz planes are shown in Fig. 2.

The total strain energy of the sandwich plate can be represented as the summation of the strain energy due to axial deformation, transverse deflection at the top (t) and bottom (b) face sheets and transverse shear deformation at the core layer such that:

$$U = \left(\frac{1}{2}\int_0^L\int_{-\frac{B}{2}}^{\frac{B}{2}} (\{\varepsilon_{t,b}(x,y)\}^T [W]\ \{\varepsilon_{t,b}(x,y)\})\, dxdy\right) +$$

$$2\left(\frac{1}{2}\int_0^L\int_{-\frac{B}{2}}^{\frac{B}{2}} (\{\vartheta(x,y)\}^T [k]\ \{\vartheta(x,y)\})\ dxdy\right) +$$

$$\left(\frac{1}{2}\int_v ((\gamma_{xz})_c^T [(G_{xz}^*)_c]\ (\gamma_{xz})_c + (\gamma_{yz})_c^T [(G_{yz}^*)_c]\ (\gamma_{yz})_c)\ dv\right) \tag{2}$$

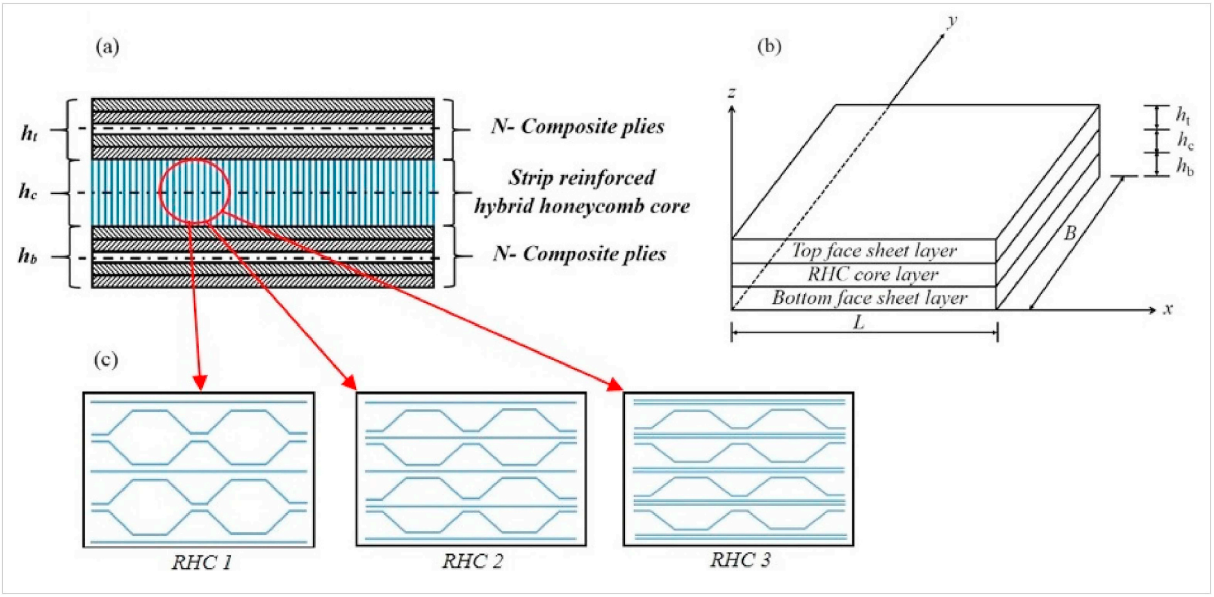

Fig. 1. (a) Illustration of ribbon reinforced hybrid honeycomb sandwich composite plate with *N*-number of composite laminas (b) GFRP ribbon sheets reinforced hybrid honeycomb composite sandwich plate (c) Cross sectional view of the various core layer configurations RHC 1, RHC 2 & RHC 3.

where

$$[W] = \begin{bmatrix} A_{ij} & B_{ij} & E_{ij} \\ B_{ij} & D_{ij} & F_{ij} \\ E_{ij} & F_{ij} & H_{ij} \end{bmatrix} \quad (i,\ j = 1,\ 2,\ 6)$$

$$(A_{ij},\ B_{ij},\ D_{ij},\ E_{ij},\ F_{ij},\ H_{ij}) = \int_{-h/2}^{h/2} Q_{ij}(1,\ z,\ z^2,\ z^3,\ z^4,\ z^6)\ dz$$

$$[k] = \begin{bmatrix} A_{ij}^s & D_{ij}^s \\ D_{ij}^s & F_{ij}^s \end{bmatrix} \quad (i,\ j = 5,\ 4)$$

$$(A_{ij}^s,\ D_{ij}^s,\ F_{ij}^s) = \int_{-h/2}^{h/2} Q_{ij}(1,\ z^2,\ z^4)\ dz$$

$$(\gamma_{xz})_c = \left(\frac{u_{0t} - u_{0b}}{h_c}\right) - \left(\frac{h_t + h_b}{2h_c}\right)\theta_x + \left(\frac{h_t + h_b}{6h_c}\right)\phi_x + \left(\frac{\partial w_0}{\partial x}\right)$$

$$(\gamma_{yz})_c = \left(\frac{v_{0t} - v_{0b}}{h_c}\right) - \left(\frac{h_t + h_b}{2h_c}\right)\theta_y + \left(\frac{h_t + h_b}{6h_c}\right)\phi_y + \left(\frac{\partial w_0}{\partial y}\right)$$

where $[W]$is the membrane and bending stiffness matrix with the higher order terms, A_{ij} is the extensional stiffness matrix, B_{ij} is the coupling stiffness matrix, $D_{ij}$is the bending stiffness matrix, E_{ij}, $F_{ij}$and $H_{ij}$are the stiffness matrix which relate the higher order terms, $[k]$is the shear stiffness matrix. $\{\varepsilon_{t,b}(x, y)\}$ is the normal strain field vector of the top and bottom face sheets, $\{\vartheta\ (x, y)\}$ is the shear strain vector for the face sheets, $[Q_{ij}]$is the coefficient of transformed material as presented in Appendix A. $(\gamma_{xz})_c$ and $(\gamma_{yz})_c$ denote the transverse shear strains of the core about *xz* and *yz* directions. $(G^*_{xz,yz})$ is the complex shear modulus along corrugated (*xz*) and joined (*yz*) directions. The shear stress and strain properties of the various honeycomb core materials are strongly influenced by the addition of CNTs and strip reinforcements. The complex shear modulus [36] is represented as the summation of the storage modulus $(G'_{xz,yz})$ and loss modulus$(G''_{xz,yz})$, such that:

$$G^*_{xz,yz} = G'_{xz,yz} + jG''_{xz,yz} \tag{3}$$

where

$$G'_{xz,yz} = -\left(\frac{(-12(I_{mx,my})(\omega_{hx,hy})^2 h_c + a_c^4)\ m(\omega_{hx,hy})^2 h_c}{(3(\omega_{hx,hy})^2 h_m^2 h_c m + 12(I_{mx,my})(\omega_{hx,hy})^2 h_c - a_c^2 E_z)\ a_c^2}\right)$$

$$\frac{G''_{xz,yz}}{G'_{xz,yz}} = \frac{\delta}{\pi} \tag{4}$$

$(G'_{xz,yz})$ denotes the shear storage modulus of the hybrid honeycomb

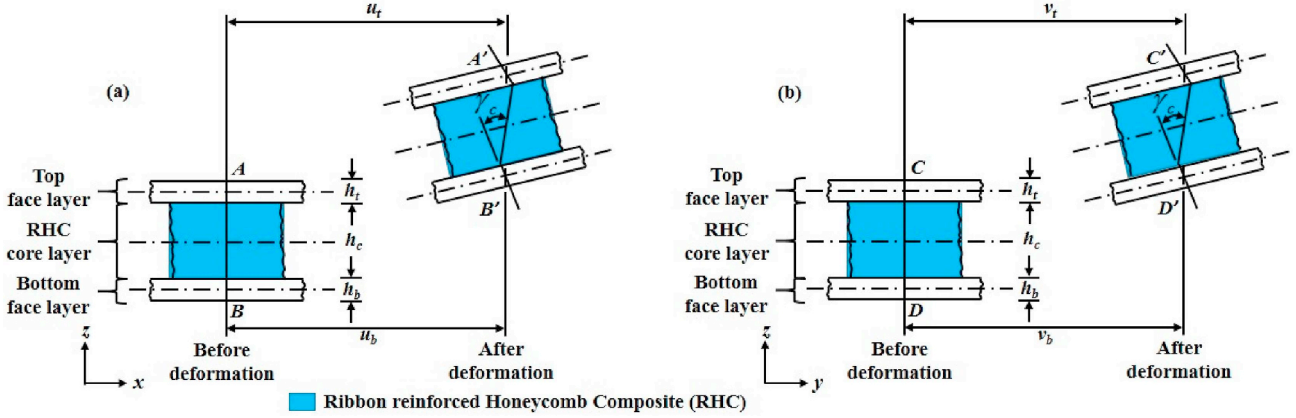

Fig. 2. Schematic representation of ribbon reinforced honeycomb composite sandwich plate model under transverse shear deformation (a) *xz* plane (b) *yz* plane [35].

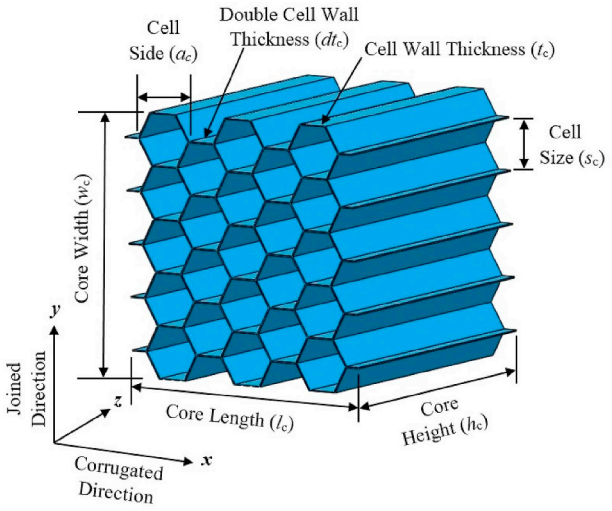

Fig. 3. Diagrammatic illustration of honeycomb core geometry [35].

material which could be evaluated by substituting the known values of Young's modulus of the core along the out of plane directions (E_z), fundamental resonant frequency measured along x and y directions($\omega_{hx,hy}$), mass moment of inertia along x and y directions($I_{mx,my}$), m is the mass of the metal block, h_m is the height of the metal block mounted on the honeycomb material and other geometrical parameters as presented in Fig. 3. Fig. 3 represents the hybrid honeycomb core structure of length (l_c) and breadth (w_c) considered for modelling. (δ)denotes the logarithmic decrement and $j = \sqrt{(-1)}$.

2.2. Total kinetic energy of the sandwich plate

The total kinetic energy equation of the top and bottom face sheets and core layer can be expressed as:

$$T = \left(\frac{1}{2}\int_0^L \int_{-\frac{B}{2}}^{\frac{B}{2}} \rho \{\dot{d}_{t,b}(x,y)\}^T [I_{t,b}] \{\dot{d}_{t,b}(x,y)\}\, dxdy\right) + \left(\frac{1}{2}\int_v \rho_c z^2 \left\{\left(\frac{(\gamma_{xz})_c}{\partial t}\right)^2 + \left(\frac{(\gamma_{yz})_c}{\partial t}\right)^2\right\} dv\right) \quad (5)$$

where $\{\dot{d}_{t,b}(x,y)\}$ is the displacement vector for the top and bottom face sheets, $[I_{t,b}]$ is the translational and rotational inertia matrix as presented in Appendix A, $\rho_c$is the density of the core layer and $\rho$is the density of each ply of the top and bottom face sheets [35].

3. Governing equation of motion using finite element formulation

A four-noded rectangular element with nine degrees of freedom (DOF) at each node is considered to develop the governing differential equations of motion of sandwich composite plate and solve numerically. The nine degrees of freedom are presented as $[u_t, u_b, v_t, v_b, w, \theta_x, \theta_y, \phi_x, \phi_y]$, where u_t,v_t,u_b and v_b denote the axial deformations at any point in the x and y directions of the sandwich composite plate.w is the transverse deflection of the sandwich composite plate. θ_x and$\theta_y$are the slopes about y and x axes of the sandwich composite plate. ϕ_x and ϕ_y are the higher order terms about y and x axes sandwich composite plate.

The in-plane and transverse displacement can be expressed in terms of nodal displacement vectors and shape function as:

$$\{d\} = \sum_{i=1}^{4} [N_i]\{d_i\}_{t,b} \quad (i = 1,2,3,4) \quad (6)$$

where

$$\{d_i\}_t = \{u_{0t1}, v_{0t1}, w_1, \theta_{x1}, \theta_{y1}, \phi_{x1}, \phi_{y1}, \cdots u_{0t4}, v_{0t4}, w_4, \theta_{x4}, \theta_{y4}, \phi_{x4}, \phi_{y4}\}^T$$

$$\{d_i\}_b = \{u_{0b1}, v_{0b1}, w_1, \theta_{x1}, \theta_{y1}, \phi_{x1}, \phi_{y1}, \cdots u_{0b4}, v_{0b4}, w_4, \theta_{x4}, \theta_{y4}, \phi_{x4}, \phi_{y4}\}^T$$

where$\{d_i\}$denotes the displacement vector of the element; $[N_i]$ represents the shape functions for the sandwich plate elements as presented in Appendix A [35].

The relation between strain and the displacement field for an element can be presented as:

$$\{\varepsilon\}_{t,b} = [B_i]\{d_i\} \quad (i = 1,2,3,4) \quad (7)$$

$$\{\varepsilon\}_{t,b} = \left\{\left(\frac{\partial u_{0t,0b}}{\partial x}\right), \left(\frac{\partial v_{0t,0b}}{\partial y}\right), \left(\frac{\partial u_{0t,0b}}{\partial y} + \frac{\partial v_{0t,0b}}{\partial x}\right), \left(\frac{\partial \theta_x}{\partial x}\right), \left(\frac{\partial \theta_y}{\partial y}\right), \left(\frac{\partial \theta_x}{\partial y} + \frac{\partial \theta_y}{\partial x}\right), \left(\frac{\partial \phi_x}{\partial x}\right), \left(\frac{\partial \phi_y}{\partial y}\right), \left(\frac{\partial \phi_x}{\partial y} + \frac{\partial \phi_y}{\partial x}\right)\right\}^T$$

where $\{\varepsilon\}_{t,b}$denote the element strain vector for the top and bottom face sheets; $[B_i]$ is the strain displacement matrix.

The element stiffness matrix can be obtained from the strain energy equation of the top and bottom face sheets and the core layer for the composite sandwich plate by substituting Eq. (7) in Eq. (2) such that:

$$k^e = \left(\int_{-b}^{b}\int_{-a}^{a} [B_{t,b}(x,y)]^T [W][B_{t,b}(x,y)]\}\, dxdy\right) + 2\left(\int_{-b}^{b}\int_{-a}^{a} [B_s(x,y)]^T [k]\ [B_s(x,y)]\, dxdy\right) + \left(\int_{-b}^{b}\int_{-a}^{a} [B_c(x,y)]^T [(G^*_{xz,yz})_c]\ [[B_c(x,y)]]\, dxdy\right) \quad (8)$$

where $[B_{t,b}(x,y)]$, $[B_s(x,y)]$ and $[B_c(x,y)]$are the strain displacement matrices in the bending, shear and core shear respectively, a and b denote the length and width of the four noded rectangular element of the sandwich plate, $[(G^*_{xz,yz})_c]$is the transverse shear properties of the core.

The element mass matrix can be obtained from the kinetic energy equation of the top and bottom face sheets and core layer for the laminated composite plate by substituting Eq. (6) in Eq. (5) such that:

$$m^e = \left(\int_{-b}^{b}\int_{-a}^{a} [N_i(x,y)_{t,b}]^T [I_{t,b}]\ [N_i(x,y)_{t,b}]\, dxdy\right) + \left(b\frac{h_c^3}{12}\int_{-b}^{b}\int_{-a}^{a} [N_i(x,y)_c]^T [I_c]\ [N_i(x,y)_c]\, dxdy\right) \quad (9)$$

where I_t, I_b, I_c are the translatory and bending inertia matrices of face sheets and shear of the core inertia respectively as presented in Appendix A [35].

The governing equations of motion of the hybrid honeycomb sandwich composite plate is obtained by assembling the element mass and stiffness matrices and the force vector together for all the elements such that:

$$[M]\{\ddot{d}\} + [K]\{d\} = \{F\} \quad (10)$$

where$[M]$, $[K]$ and $\{F\}$denote the global mass and stiffness matrices, and the global force vector of hybrid honeycomb sandwich composite plate configurations, respectively.

From Eq. (10), the governing differential equations of motion can be rewritten for the free vibration of the honeycomb sandwich composite

plate configurations such that:

$$[M]\{\ddot{d}\} + [K]\{d\} = \{0\} \tag{11}$$

The generalized solution for Eq. (11) can be expressed as:

$$\{d\} = \{\varphi\} e^{j\lambda_i} \tag{12}$$

where $\{\varphi\}$denotes the arbitrary constant and e is the exponential term.

The reduced form of the characteristic equation of the eigenvalue problem can be presented by substituting Eq. (12) in Eq. (11) such that:

$$[K]\{\varphi\} = [M]\lambda_i^2\{\varphi\} \tag{13}$$

where $[K]$ is the global stiffness matrix expressed with combination of real $[K_r]$ and imaginary $[K_i]$ parts of the stiffness matrix such that:

$$[K] = [K_r] + j[K_i]$$

Further, the loss factor of the hybrid sandwich structure at each mode is given by:

$$(\eta_i) = \left(\frac{\{\phi_r\}_i^T[K_i]\{\phi_r\}}{\{\phi_r\}_i^T[K_r]\{\phi_r\}}\right)$$

where $\{\phi_r\}_i$ is the normalized eigen vector with respect to each mode 'i'; λ_i and η_i are the square of the natural frequency and loss factor at each mode.

4. Experimental investigation

4.1. Evaluation of elastic properties of composite face sheets

An experimental test was conducted on three different prototypes of hybrid composite ribbon reinforced honeycomb sandwich plates. The fabrication materials E-glass fiber (92145 fabric), epoxy resin (LY556) and hardener (HY951) are manufactured by the Interglass® and Hunstman®. The top and bottom face sheet layers were made up of unidirectional E-glass fiber and epoxy resin with 10:1 ratio of hardener using hand layup method. Further, curing of the face sheet laminates was done by using vacuum assisted oven with 750 Hg pressure at 75 °C. The ply orientation of face sheet layers for all configurations of sandwich plate (RHC 1, RHC 2 and RHC 3) is $[0^\circ/90^\circ/0^\circ]_s$ with 0.26 mm ply thickness. The composite face sheets are assembled with honeycomb core using the Huntsman 2021® Araldite under 750 Hg pressure at 75 °C with the vacuum assisted oven. The mechanical properties of various composite face sheets with 0.280 vol fraction were identified using ASTM E-1876 [37] procedure and the results are presented in Table 1.

4.2. Identification of mechanical properties of composite honeycomb core material

The core structures of glass fiber reinforced polymer composites were made without and with reinforcement of MWCNT using hand layup method. Initially, 0.5 wt% of MWCNT was added into the solvent (extra pure acetone) and stirred thoroughly using the mechanical shear mixture for 30 min. Then the mixture was sonicated using the ultrasonic liquid processor having 12.5 mm diameter of titanium probe with pulsed on-off cycles with period of 5 s for 1 h at room temperature to separate the entangled MWCNT. The measured quantity of epoxy resin (LY556) was added into the mixture of MWCNT/acetone and the mixture was sonicated again using the ultrasonic liquid processor for 2 h to achieve the dispersion. Then, the mixture of acetone/epoxy/CNT was kept in hot air oven at 75 °C operated for 48 h to evaporate the solvent (acetone). Further, the homogenous dispersion of CNTs in epoxy resin was enhanced by using shear mixture for 30 min. The hardener (HY951) was then added into the homogenously sheared epoxy/MWCNT mixture with 1:10 ratio. Finally, the glass fiber reinforced polymer composite core structure having $[0^\circ/90^\circ]$ ply orientation with 0.26 mm ply thickness were fabricated without and with MWCNT reinforcement using hand-layup method, by adding 1:10 ratio of hardener into the epoxy/MWCNT mixture, prepared earlier and reinforced with E-glass unidirectional fabrics (220 GSM). Following this, the fabricated specimens were partially cured in the room temperature for 20 min which was then mounted into the high carbon-high chromium steel honeycomb die and then cured at room temperature for 5 h. After this, the specimens were post cured in oven at 75 °C operated for 2 h using the vacuum assisted oven. Further, the cured corrugated composite sheets were taken out from the oven and kept at room temperature for 24 h before the cutting of laminated composite into required geometry. The required dimension 80 mm × 80 mm x 10 mm of honeycomb core material is achieved by using the ultrasonic cutter (Sonofile®). The fabrication of core structure was carried by joining the corrugated and ribbon sheets without and with CNT reinforcement using the huntsman 2021® fast setting araldite. This procedure was followed for the fabrication of various configurations of honeycomb core materials by joining the corrugated and ribbon sheets without and with 0.5, 1 and 1.5 wt percentage of CNT reinforcement having $[0^\circ/90^\circ]$ ply orientation with 0.26 mm ply thickness of glass fibers and epoxy composites using a high carbon-high chromium steel honeycomb die as presented in Fig. 4. The various geometrical parameters used during the fabrication of various configurations of honeycomb core materials are presented in Table 2. The experimental analysis in Fig. 5 was carried out on various hybrid honeycomb core materials to identify their transverse shear properties.

The resonant response frequencies from the dominant peaks in the frequency response function (FRF) of the various hybrid honeycomb cores with and without CNT reinforcement under fixed-fixed boundary condition were acquired by using the DEWESOFT 7.1.1® experimental analysis software. The measured natural frequency data were analyzed for the evaluation of the complex shear modulus of the hybrid honeycomb material for the prototypes of sandwich structure. The shear storage modulus ($G'_{xz,yz}$) of the hybrid honeycomb material is evaluated along the corrugated (xz) and joined (yz) directions from the alternative dynamic approach [1] for the various prototypes of the composite sandwich structure, which is proportionate to the average energy stored per unit volume of the honeycomb material during a deformation cycle. Further, the damping factor was calculated at each dominant resonant peak response by using the half power bandwidth method. The loss modulus ($G''_{xz,yz}$) could be evaluated by substituting the known values of shear storage modulus and the logarithmic decrement in Eq. (4), which is proportionate to the energy dissipated per unit volume of honeycomb material over a cycle. The complex modulus of the various honeycomb core without and with CNT reinforcement along xz and yz directions in terms of storage ($G'_{xz,yz}$) and loss moduli ($G''_{xz,yz}$) obtained from the measurement are represented in Table 3.

It can be seen from Table 3 that the incorporation of CNT in various ribbon reinforced hybrid honeycomb composite increases the

Table 1
The mechanical properties of top and bottom face sheets of the various sandwich plates [35]

E-glass fiber and resin matrix	E_1	22.92 GPa	Resin	E	3.45 GPa	MWCNT	E_{cnt}	4.45 GPa (Young's Modulus)
	E_2	5.70 GPa		ν	0.30		ν_{cnt}	0.28 (Poisson's ratio)
	ν_{12}	0.26		G	1.33 GPa		G_{cnt}	1.67 GPa (Shear Modulus)
	G_{12}	2.25 GPa		ρ_r	1200 kg m^{-3}		ρ_{cnt}	2514 kg m^{-3} (Density)
	G_{23}	2.06 GPa					L_{cnt}	10 μm (Length)
	ρ	1592 kg m^{-3}					D_{cnt}	16.96 nm (Outer Diameter)

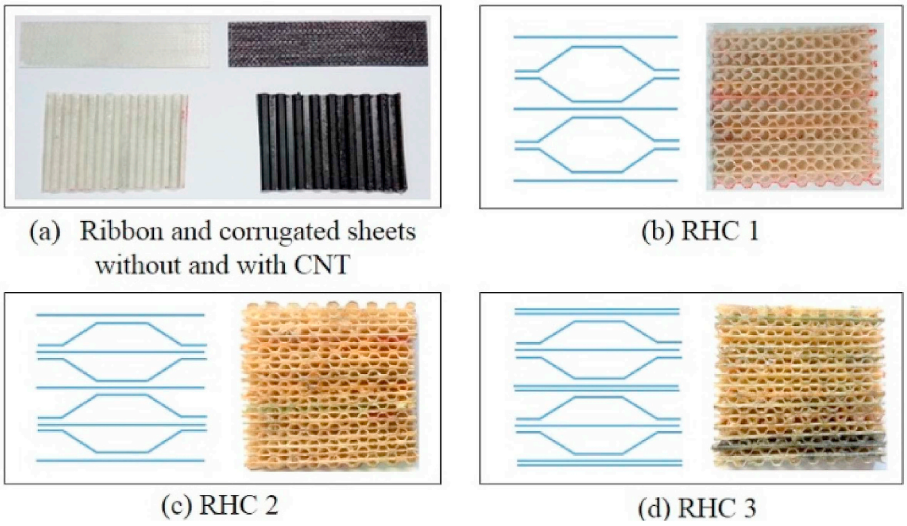

Fig. 4. Various ribbon reinforced honeycomb core materials without and with CNT reinforcement.

transverse shear stiffness along *xz* and *yz* than those of without CNT reinforcement which subsequently enhances the complex shear moduli of the honeycomb core material. This can be due to the fact that the dispersion of CNTs randomly in GFRP composites, as shown in Fig. 6, improves the inter-lamina shear force between the epoxy matrix resin and CNT. This can also be attributed to the fact that the shear storage and loss moduli of the structure as in Eq. (4) increases with the increase in CNT wt% which leads to increase in complex shear modulus as in Eq. (3).

The various storage and loss moduli of the various hybrid honeycomb core material with ribbon reinforcement at various wt% of CNT could be represented with empirical relations presented as:

Core Layer Configuration – RHC 1

$$(G'_{xz})^{RHC1} = (1e^{12})n^2 + (2e^{09})n + 6e^{8}$$

$$(G'_{yz})^{RHC1} = (1e^{12})n^2 + (4e^{09})n + 3e^{8}$$

$$(G''_{xz})^{RHC\,1} = 87n^2 + 6.481n + 0.2477$$

$$(G''_{yz})^{RHC\,1} = 40n^2 + 8.548n + 0.2253 \quad (14)$$

Core Layer Configuration – RHC 2

$$(G'_{xz})^{RHC2} = (1e^{12})n^2 + (7e^{09})n + 8e^{8}$$

$$(G'_{yz})^{RHC\,2} = (2e^{12})n^2 - (7e^{09})n + 5e^{8}$$

$$(G''_{xz})^{RHC2} = 23n^2 + 6.593n + 0.2803$$

$$(G''_{yz})^{RHC2} = 6n^2 + 6.722n + 0.2605 \quad (15)$$

Core Layer Configuration – RHC 3

$$(G'_{xz})^{RHC3} = (5e^{11})n^2 + (2e^{10})n + 1e^{9}$$

$$(G'_{yz})^{RHC3} = (4e^{11})n^2 + (2e^{10})n + 6e^{8}$$

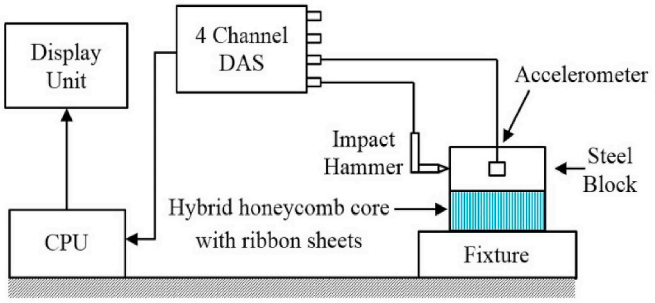
$$(G''_{xz})^{RHC3} = 20n^2 + 4.492n + 0.3335$$

$$(G''_{yz})^{RHC3} = 29n2 + 3.987n + 0.3115 \quad (16)$$

where "*n*" denotes the CNT content in weight percentage reinforced in the honeycomb core material with ribbons; *e* is the exponential term.

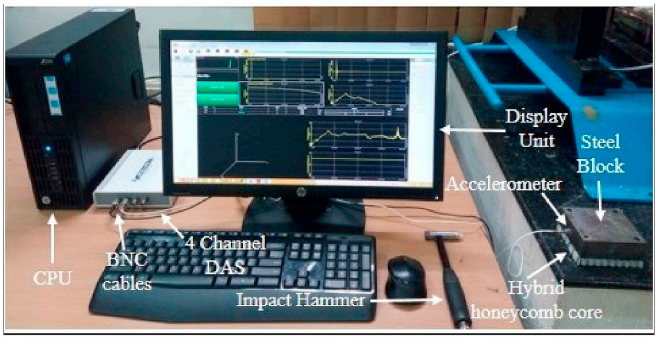
Further, it can be observed that the various complex shear moduli along the corrugated direction (*xz*) is higher than that of joining direction (*yz*) of the various configuration of honeycomb core layer materials irrespective of the CNT content. This can be due to the better stiffness and shear force distribution of the honeycomb with ribbon materials along the continuous triple cell wall in corrugated directions.

4.3. Validation of the developed mathematical modelling



The various ribbon reinforced hybrid honeycomb composite sandwich plate configurations of length (*L*) 300 mm, width (*B*) 200 mm and thickness 5 mm were fabricated without and with 0.5 wt% of CNT reinforcement in honeycomb core layers (Fig. 7). The volume fractions of the top and bottom face sheets with 0.26 mm ply thickness having $[0^{\circ}/90^{\circ}/0^{\circ}]_s$ ply orientation of unidirectional glass fiber were identified as 0.286.

The hybrid honeycomb sandwich plate was clamped at steel fixture. So that, the vibration analysis can be performed under all four ends clamped (CCCC), two ends clamped and two ends free (CFCF), three ends free and one end clamped (CFFF), and all four ends free (FFFF) boundary conditions as represented in Fig. 8. The transient response acceleration was obtained with uni-axial accelerometer located at the tip of top surface of composite sandwich plate by exciting the honeycomb structure using impact hammer (5800SL). A four channel digital data acquisition system (ATA-DAQ042451) was utilized to identify the natural frequency and loss factor from the dominant resonant response peaks of the functional response graphical data by using the Dewesoft 7.1.1® experimental test software as shown in Fig. 9 (a) & (b). Further, the damping factor corresponding to each dominant peak response was identified by adapting the half power bandwidth method. Following this, the logarithmic decrement relations was adapted to obtain the loss factor.



The numerical simulations were carried out by considering the mechanical properties (Tables 1 and 3) of different configurations of hybrid sandwich composite plate. The mesh size of 13 × 13 was used to obtain the computational results. Further, the convergence requirements were satisfied by performing the simulations at various mesh size. The resonant response frequencies and loss factors are presented with respect to the mode numbers (*m, n*) which are associated to the mode shapes acquired along the longitudinal (*m*) and transverse (*n*) directions of the ribbon reinforced hybrid honeycomb composite sandwich plates.

	1	1183.24 (1 + j 0.3717)	842.12 (1 + j 0.3512)
	1.5	1390.53 (1 + j 0.3979)	1011.02 (1 + j 0.3789)

A comparison of first four natural frequencies and loss factors of various configurations of hybrid honeycomb core sandwich plates are evaluated numerically and experimentally as represented in Tables (4–7). Very good agreement between the FEM and experimental test results of various ribbon reinforced honeycomb composite sandwich plate configurations with and without reinforcement of CNT namely RHC 1, RHC 2 and RHC 3, was observed. The percentage deviation between the numerical and experimental test results could be due to manufacturing inaccuracies such as the fabrication of top and bottom face sheets, and core layer materials with hand layup method, measurement of shear and loss moduli of hybrid honeycomb composite core material for the sandwich plates.

It can be seen that the natural frequency and loss factor of CNT reinforced hybrid honeycomb sandwich composite plate configuration "RHC 1" at 1st mode increase by 13.45%, 19.03% and 20.07% under

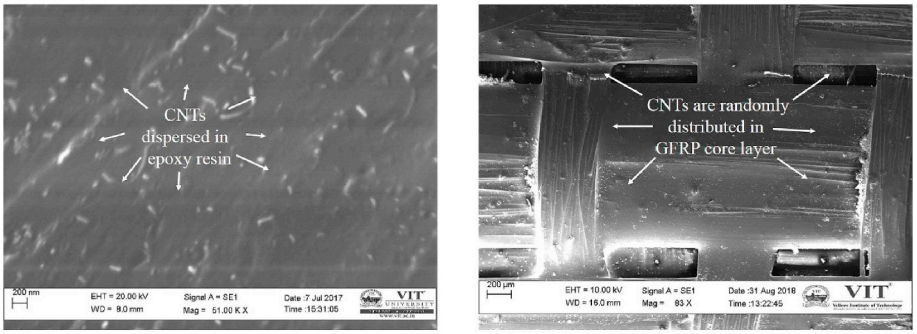

Fig. 6. SEM images of the (a) CNTs randomly distributed in Epoxy (b) CNTs randomly distributed in GFRP-HCC.

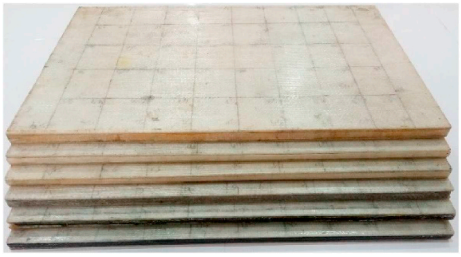

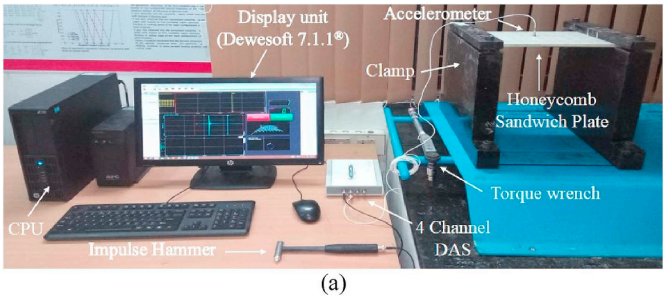

Fig. 7. Photograph of the fabrication of various ribbon reinforced honeycomb composite sandwich plate configurations without and with CNT reinforcement.

FFFF, CFFF and CFCF boundary conditions and 21.69%, 22.95% and 25.12% under CFCF, CFFF and FFFF boundary conditions, respectively, as compared to those of GFRP-honeycomb sandwich plates. It can also be seen that the natural frequency and loss factor of CNT reinforced hybrid honeycomb sandwich composite plate configuration "RHC 2" at 1st mode increase by 15.08%, 20.67% and 22.43% under FFFF, CFFF and CFCF boundary conditions and 24.32%, 27.51% and 24.91% under CFCF, CFFF and FFFF boundary conditions, respectively, as compared to those of GFRP-honeycomb sandwich plates. Further, it can be observed that the natural frequency and loss factor of CNT reinforced hybrid honeycomb sandwich composite plate configuration "RHC 3" at 1st mode increase by 18.23%, 21.27% and 25.19% under FFFF, CFFF and CFCF boundary conditions and 30.65%, 32.62% and 34.04% under CFCF, CFFF and FFFF boundary conditions, respectively, as compared to those of GFRP-honeycomb sandwich plates.

A significant increase in natural frequency and loss factor at all the modes of hybrid sandwich structures could be realized with the addition of CNTs. This can be accredited to the existence of CNT in honeycomb material that limits the polymer chains motion which subsequently enhances yield strength of the material and shear force distribution. This results in a significant increase in stiffness and damping of the hybrid sandwich plate than those of sandwich plate without CNT reinforcement. This can also be related to the fact that the increase in shear storage modulus with addition of CNTs could increase the total strain energy as seen in Eq. (2) which increases the natural frequency of the structure. Similarly, an increase in loss modulus could increase the dissipated energy as seen in Eq. (4) which yields increase in loss factor with the addition of CNT.

Further, it can be seen that the natural frequency and loss factor of the double ribbon reinforced hybrid honeycomb composite sandwich plate "RHC3" increase significantly than those of the other two configurations RHC 1 and RHC 2. This can be attributed to the fact that an increase in ribbon reinforcement at the honeycomb core layer increases both stiffness and shear force distribution among the honeycomb structure. This is also evident with the increase in storage and loss moduli of the core materials as seen in Table 3 and Eqs. (14)–(16). Even though the addition of ribbon reinforcement at the honeycomb core layer increases both the mass and stiffness of the sandwich plate, the increase in mass of the structures is dominated by the increase in stiffness of the hybrid composite structure and hence increase in natural frequency is being observed.

Furthermore, it can be observed that the CFFF and CCCC boundary condition lead to the lowest and highest natural frequencies, irrespective of ribbon reinforced honeycomb sandwich plate configurations. This can be due to the fact that the boundary condition CCCC yields the highest stiffness for the sandwich plate, whereas the boundary

condition CFFF yields the lowest stiffness for the sandwich plate due to the flexibility of the end conditions. It can also be seen that loss factors under CFCF boundary condition are higher than those under CFFF boundary conditions irrespective of ribbon reinforced honeycomb sandwich plate configurations. The loss factor is a ratio of the energy dissipated per radian to the total strain energy of the structure. The energy dissipated per cycle of operation dominates the total strain of the sandwich structures which leads the loss factor to be higher in CFCF end conditions than those of under CFFF end condition.

5. Results and discussion

The developed finite element formulation is being used to study the various dynamic characteristics of the hybrid honeycomb composite sandwich plates with different honeycomb configurations as core layers. These characteristics are highly influenced by not only the geometrical and material properties, but also by the variation of CNT wt %, longitudinal strips reinforcement in core material and core layer thickness. The effect of CNT wt% on the transverse vibration response of the various configurations of the hybrid honeycomb sandwich composite plates are also studied. The various elastic properties of face sheet layers used for the numerical simulations are represented in Table 1. The complex modulus of the various ribbon reinforced honeycomb core layers with and without reinforcement of CNT used for the simulation is presented in Table 3. The dimensions for all the configurations of sandwich composite plates considered for the numerical simulations are 300 mm × 200 mm x 5 mm. The ply orientations of the composite face sheet layers are considered as $[0^{\circ}/90^{\circ}/0^{\circ}]_s$ for all sandwich plate configurations RHC 1, RHC 2 and RHC 3, with a ply thickness of 0.26 mm. The volume fraction for all the ribbon reinforced composite sandwich plate configurations considered for face sheet layers are identical.

5.1. Effects of variation in wt% of CNT content on natural frequencies and loss factors of various ribbon reinforced honeycomb sandwich plates

A numerical simulation is carried out to identify the influence of the addition of CNT on the natural frequencies and loss factors of various honeycomb composite sandwich plates under CFFF boundary condition with variation from 0 to 1.5 wt% of CNT content, and the results are presented in Table 8.

It can be seen that the natural frequency and loss factor at the first mode of the hybrid honeycomb sandwich composite plate configurations RHC 1, RHC 2 and RHC 3 with 1.5 wt% CNT under CFFF boundary condition are higher than those of GFRP-honeycomb sandwich plates without CNT content by 5.34%, 6.27% and 6.43%, 13.94%, 16.11% and 17.10%, respectively. A significant increase in the resonant frequencies and loss factors are identified in various configurations of the hybrid sandwich composite plates. This can be due to the stick slip mechanism between the nano wall layer and interfacial sliding motion of epoxy-CNT at the honeycomb material. This can also be related to the fact that an increase in wt% of CNT at the honeycomb core material increases the shear storage modulus which could increase the total strain energy as seen in Eq. (2). Similarly, an increase in wt% of CNT increases the loss modulus and consequently increases the dissipated energy of the structure as seen in Eq. (4) which yields a significant increase in loss factor at all modes presented. Further, it can be seen that the natural frequencies and loss factors of the CNT-ribbon reinforced hybrid honeycomb sandwich plate “RHC 3” is higher than those of the other two sandwich plate configurations (RHC 1 & RHC 2).

5.2. Effects of variation in core thickness on natural frequencies and loss factors of various ribbon reinforced hybrid honeycomb sandwich plates

The numerical simulation is carried out to study the influence of honeycomb core thickness in the ribbon reinforced honeycomb composite sandwich plate configurations (RHC 1, RHC 2 and RHC 3) on the natural frequencies and loss factors with 1.5 wt% of CNT reinforcement under CFFF boundary conditions, and the results are presented in Table 9. It can be seen that fundamental natural frequency of configuration RHC 1 under CFFF boundary condition increase by 16.14%, 21.30% and 31.05%, while the loss factor decrease by 15.42%, 14.47%, and 13.49% respectively, with an increase in the core layer thickness of the CNT reinforced hybrid honeycomb composite sandwich plates from 2.5 mm to 10 mm with an increment of 2.5 mm. Similarly trend has also been observed for the configurations RHC 2 and RHC 3 under CFFF end condition. An increment in natural frequency and decrement in loss factor for all configurations of the hybrid honeycomb sandwich plates with increase in thickness of the core layer at all modes is observed. This can be due to the fact that the increase in thickness of the core material increases the stiffness of the sandwich structure. Even though, the mass is being increased with increase in thickness, the increase in stiffness may dominate the increase in mass of the structure which leads a significant increase in natural frequency. Further, as the thickness of core materials increases, both the strain energy and dissipated energy increase. However, the increase in dissipated energy is being dominated by the increase in strain energy of the structure which leads to decrease in loss factor with the increase in thickness of core material.

5.3. Transverse vibration responses of ribbon reinforced honeycomb sandwich plates

The transverse responses of a ribbon reinforced honeycomb composite sandwich plate configuration RHC 3 are investigated with four different wt% of CNTs (0%, 0.5%, 1%, and 1.5%) under CFFF boundary condition. The honeycomb sandwich plate is exposed to a sinusoidal excitation of magnitude 1 N provided at a distance of 100 mm × 100 mm from the left lower end corner. The forced vibration response of the ribbon reinforced hybrid composite sandwich plate is calculated over the frequency range of 1–700 Hz under various wt% of CNTs and various plate configurations, and the results are presented in Figs. 10 and 11. It can be observed that the natural frequency increases

Table 8
Variation of natural frequencies and loss factors of various ribbon reinforced honeycomb composite sandwich plates without and with CNT reinforcement at various volume fraction under CFFF boundary conditions.

Core material configurations	Mode (m,n)	Natural Frequencies (Hz)				Loss Factors (η)

	(2,1)	461.57	472.71	478.56	492.85	0.0955	0.1134	0.1223	0.1441
	(2,2)	579.22	588.99	594.09	606.29	0.0669	0.0788	0.0849	0.1001

with an increase in wt% of CNT reinforcement in the honeycomb sandwich plate configuration "RHC 3", which can be accredited to higher stiffness. It can also be observed that the peak responses of the ribbon reinforced hybrid honeycomb sandwich plate decrease in all the modes with increase in the wt% of CNT, which can be accredited to higher loss factors, and enhancement in stiffness.

It can be seen that the natural frequencies and loss factors increase in the order of RHC1, RHC 2, and RHC 3 (Fig. 11). It can also be observed that the addition of CNT-ribbon reinforcement in RHC 1, RHC 2, and RHC 3 along the corrugated direction, dominates the stiffness and damping. Further, it can be seen that configuration "RHC 3″ yields the highest natural frequencies and lowest amplitudes among the three samples of the hybrid honeycomb sandwich plate. This demonstrates that hybrid honeycomb sandwich structure can be effectively used in the attenuation of vibration of multi-layer structures. Hence, it can be concluded that the amplitude of vibration could be passively suppressed using the hybrid honeycomb sandwich plates and this can be expediently applied to a portion of large structural components in order to identify the efficiency of vibration control.

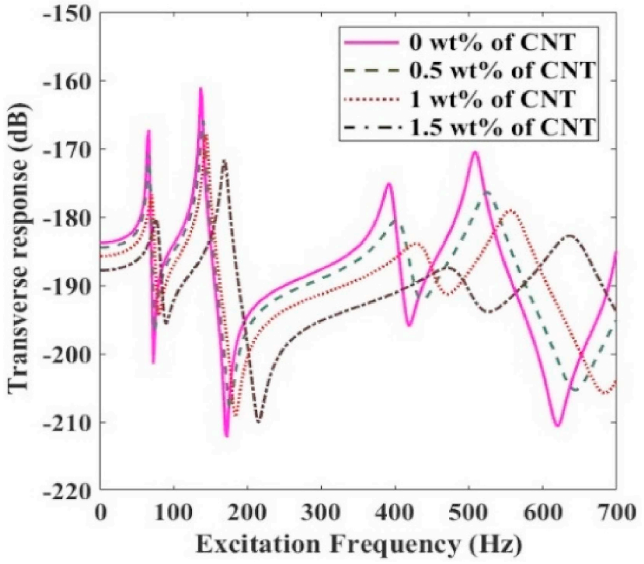

Fig. 10. Effect of CNT addition on the transverse vibration responses of double ribbon reinforced honeycomb composite sandwich plate configuration (RHC 3) under CFFF end condition.

6. Conclusions

This study investigated the dynamic characteristics of the three different ribbon reinforced hybrid honeycomb composite sandwich plate configurations. The governing differential equations of motion of ribbon reinforced hybrid honeycomb composite sandwich plates were represented in a finite element formulation using HSDT. Experimental investigations were also carried out on the various configurations of a ribbon reinforced hybrid honeycomb composite sandwich plates. A very good agreement was noticed among the results obtained using the present FEM and experimental results. The various parametric studies comprising the effect of variation in CNT wt% content, effect of honeycomb core thickness and transverse vibration responses on the

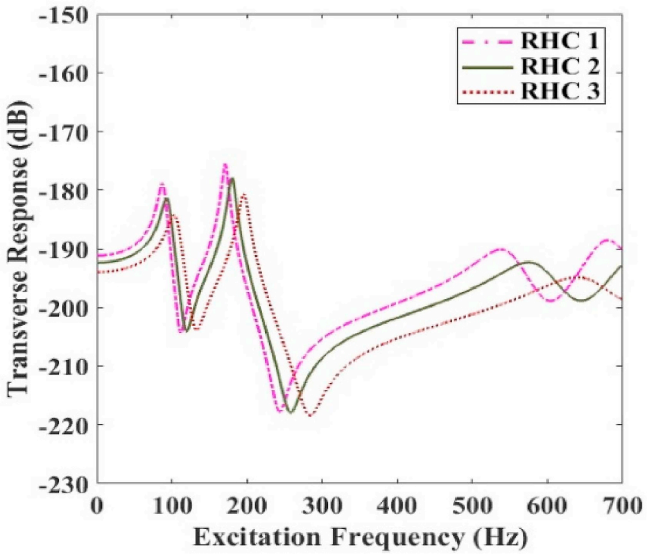

Fig. 11. A comparison of transverse vibration responses of three different configurations (RHC 1, RHC 2 and RHC 3) of ribbon reinforced honeycomb sandwich composite plate with 1.5 wt% of CNT under CFFF end condition.

natural frequencies and loss factors of the three different configurations. The several conclusions from the investigations are presented as follows:

- The complex shear modulus of the honeycomb structure increases with the increase in wt% of CNT which yields increase in shear and loss moduli.
- The natural frequencies and loss factors increase with the increase in wt% of CNT reinforcement in various configurations of the ribbon reinforced honeycomb composite sandwich plates.
- The strip reinforcement in the three different honeycomb core materials leads to increase in the natural frequencies and loss factors simultaneously, irrespective of the addition of CNT.
- Among the various ribbon reinforced honeycomb composite sandwich plate configurations, RHC 3 yields the highest stiffness followed by RHC 1 and RHC 2 due to the distributed strain energy.
- An increase in the thickness of core layer decreases the loss factors of the sandwich structures.
- A significant deviation in the natural frequencies is identified with the reinforcement of single and double ribbons at the various locations of honeycomb composite sandwich plate configurations.
- The transverse displacements of the various configurations of the hybrid honeycomb sandwich plate decrease with increase in CNT wt %.
- The peak responses of the honeycomb sandwich plates endorse that the amplitude of vibration could be suppressed considerably using the passive control methods.

Hence, it can be concluded that the applicability of ribbon reinforced hybrid honeycomb composite to critical parts of a huge structure to achieve a more efficient and compact control mechanism of vibration with adaptable damping has been evidenced.

Appendix A

The strain displacement field vectors for the top and bottom face sheets can be represented as:

$$\{\varepsilon\,(x,y)\}_{t,b} = \begin{Bmatrix} \left(\frac{\partial u_{0t,0b}}{\partial x}\right) & \left(\frac{\partial v_{0t,0b}}{\partial y}\right) & \left(\frac{\partial u_{0t,0b}}{\partial y} + \frac{\partial v_{0t,0b}}{\partial x}\right) \\ \left(\frac{\partial \theta_x}{\partial x}\right) & \left(\frac{\partial \theta_y}{\partial y}\right) & \left(\frac{\partial \theta_x}{\partial y} + \frac{\partial \theta_y}{\partial x}\right) \\ \left(\frac{\partial \phi_x}{\partial x}\right) & \left(\frac{\partial \phi_y}{\partial y}\right) & \left(\frac{\partial \phi_x}{\partial y} + \frac{\partial \phi_y}{\partial x}\right) \end{Bmatrix}^T \tag{A.1}$$

The shear strain displacement field vector for the top and bottom face sheets can be presented as:

$$\{\vartheta\,(x,y)\}^T = \left\{\left(\frac{\partial w_0}{\partial x} + \theta_x\right)\left(\frac{\partial w_0}{\partial y} + \theta_y\right)\left(-\frac{4}{h^2}\phi_x\right)\left(-\frac{4}{h^2}\phi_y\right)\right\}^T \tag{A.2}$$

The transverse shear properties of the core layers can be presented as:

$$[(G^*_{xz})_c] = \begin{bmatrix} G^*_{xz} & 0 \\ 0 & G^*_{xz} \end{bmatrix} \quad \text{and} \quad [(G^*_{yz})_c] = \begin{bmatrix} G^*_{yz} & 0 \\ 0 & G^*_{yz} \end{bmatrix} \tag{A.3}$$

The coefficient of transformed material can be presented as:

$$[Q_{ij}] = [T_1]^{-1}[\bar{Q}_{ij}]_k[T_1]^{-T} \quad (i,j = 1,2,6)$$

$$[Q_{ij}] = [T]_2^{-1}[\bar{Q}_{ij}]_k[T_2]^{-T} \quad (i,j = 5,4) \tag{A.4}$$

where

$$[T_1] = \begin{bmatrix} \cos^2\theta & \sin^2\theta & 2\cos\theta\sin\theta \\ \sin^2\theta & \cos^2\theta & -2\cos\theta\sin\theta \\ -\cos\theta\sin\theta & \cos\theta\sin\theta & \cos^2\theta - \sin^2\theta \end{bmatrix}$$

$$[T_2] = \begin{bmatrix} cos\,\theta & sin\,\theta \\ -sin\,\theta & cos\,\theta \end{bmatrix}$$

where T_1 and T_2 are the transformation matrices which have been used to obtain the material properties on the fiber direction.

$$[\overline{Q_{ij}}]_k = \begin{bmatrix} \overline{Q_{11}} & \overline{Q_{12}} & 0 \\ \overline{Q_{12}} & \overline{Q_{22}} & 0 \\ 0 & 0 & \overline{Q_{66}} \end{bmatrix} \quad (i,\ j = 1,\ 2,\ 6)$$

$$[\overline{Q_{ij}}]_k = \begin{bmatrix} \overline{Q_{55}} & 0 \\ 0 & \overline{Q_{44}} \end{bmatrix} \quad (i,\ j = 5,\ 4)$$

$$[\overline{Q_{11}}] = \left(\frac{E_1}{1 - (\nu_{12} * \nu_{21})}\right);$$

$$[\overline{Q_{12}}] = \left(\frac{(\nu_{12} * E_2)}{1 - (\nu_{12} * \nu_{21})}\right)$$

$$[\overline{Q_{22}}] = \left(\frac{E_2}{1 - (\nu_{12} * \nu_{21})}\right);\ [\overline{Q_{66}}] = (G_{12})$$

$$[\overline{Q_{55}}] = (G_{13});\ [\overline{Q_{44}}] = (G_{23})$$

where $[\overline{Q_{ij}}]_k$ denotes the constitutive matrix at the lamina.

The displacement vector for the top and bottom face sheets can be presented as:

$$\{d_{t,b}(x, y)\}^T = \left\{\left(\frac{\partial u_{0t,0b}}{\partial t}\right)\left(\frac{\partial v_{0t,0b}}{\partial t}\right)\left(\frac{\partial w_0}{\partial t}\right)\right.$$

$$\left.\left(\frac{\partial \theta_x}{\partial t}\right)\left(\frac{\partial \theta_y}{\partial t}\right)\left(\frac{\partial \phi_x}{\partial t}\right)\left(\frac{\partial \phi_y}{\partial t}\right)\right\}^T \tag{A.5}$$

Inertia matrix for the top and bottom face laminate can be presented as:

$$[I_{t,b}] =$$

$$\begin{bmatrix} I_{011} & 0 & 0 & I_{111} & 0 & -(I_{311}\,c_1) & 0 \\ 0 & I_{011} & 0 & 0 & I_{111} & 0 & -(I_{311}\,c_1) \\ 0 & 0 & I_{011} & 0 & 0 & 0 & 0 \\ I_{111} & 0 & 0 & I_{211} & 0 & -(I_{411}\,c_1) & 0 \\ 0 & I_{111} & 0 & 0 & I_{211} & 0 & -(I_{411}\,c_1) \\ -(I_{311}\,c_1) & 0 & 0 & -(I_{411}\,c_1) & 0 & (I_{611}\,c_1^2) & 0 \\ 0 & -(I_{311}\,c_1) & 0 & 0 & -(I_{411}\,c_1) & 0 & (I_{611}\,c_1^2) \end{bmatrix} \tag{A.6}$$

where

$$I_{011},\ I_{111},\ I_{211},\ I_{311},\ I_{411},\ I_{611} = \int_{-h/2}^{h/2} \rho\,(1,\ z,\ z^2,\ z^3,\ z^4,\ z^6)\ dz;$$

$$c_1 = \frac{4}{3h^2}$$

Inertia matrix for the core layer can be presented as:

$$[I_c] = \begin{bmatrix} c_3^2 & 0 & C_1 & 0 & c_3 & C_2 & 0 & C_3 & 0 \\ 0 & c_3^2 & 0 & C_1 & 0 & 0 & C_2 & 0 & C_3 \\ C_1 & 0 & c_4^2 & 0 & 0 & C_4 & 0 & C_5 & 0 \\ 0 & C_1 & 0 & c_4^2 & 0 & 0 & C_6 & 0 & C_5 \\ 0 & 0 & 0 & 0 & C & 0 & 0 & 0 & 0 \\ C_2 & 0 & C_4 & 0 & 0 & c_5^2 & 0 & C_6 & 0 \\ 0 & C_2 & 0 & C_4 & 0 & 0 & c_5^2 & 0 & C_6 \\ C_3 & 0 & C_5 & 0 & 0 & C_6 & 0 & c_6^2 & 0 \\ 0 & C_3 & 0 & C_5 & 0 & 0 & C_6 & 0 & c_6^2 \end{bmatrix} \tag{A.7}$$

where

$C = \rho \times t_c$; $C_1 = c_3 \times c_4$; $C_2 = c_3 \times c_5$; $C_3 = c_3 \times c_6$; $C_4 = c_4 \times c_5$; $C_5 = c_4 \times c_6$; $C_6 = c_5 \times c_6$; $c_3 = \left(\frac{1}{h_c}\right)$; $c_4 = -\left(\frac{1}{h_c}\right)$; $c_5 = -\left(\frac{d-h_c}{h_c}\right)$; $c_6 = \left(\frac{d-h_c}{3(h_c)}\right)$

The shape functions for the sandwich plate elements can be presented as:

$$N_1 = \left(\frac{1}{4}\right)(1-\xi)(1-\eta);$$

$$N_2 = \left(\frac{1}{4}\right)(1+\xi)(1-\eta);$$

$$N_3 = \left(\frac{1}{4}\right)(1+\xi)(1+\eta);$$

$$N_4 = \left(\frac{1}{4}\right)(1-\xi)(1+\eta) \tag{A.8}$$

The strain displacement matrices for the sandwich plate elements can be presented as:

$$[B_{t,b}(x,y)] = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ \frac{\partial N_i}{\partial x} & 0 & \frac{\partial N_i}{\partial y} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{\partial N_i}{\partial y} & \frac{\partial N_i}{\partial x} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{\partial N_i}{\partial x} & 0 & \frac{\partial N_i}{\partial y} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{\partial N_i}{\partial y} & \frac{\partial N_i}{\partial x} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \frac{\partial N_i}{\partial x} & 0 & \frac{\partial N_i}{\partial y} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{\partial N_i}{\partial y} & 0 \end{bmatrix}$$

$$(i = 1,\ 2,\ 3,\ 4) \tag{A.9}$$

$$[B_s(x,y)] = \begin{bmatrix} 0 & 0 & 0 & 0 & \frac{\partial N_i}{\partial x} & N_i & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{\partial N_i}{\partial y} & 0 & N_i & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & c_2 \times N_i & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & c_2 \times N_i \end{bmatrix}$$

$$(i = 1,\ 2,\ 3,\ 4) \tag{A.10}$$

$$[B_c(x,y)] = c_3\begin{bmatrix} N_i & 0 & -N_i & 0 & e\frac{\partial N_i}{\partial x}\cdots \\ 0 & N_i & 0 & -N_i & e\frac{\partial N_i}{\partial x}\cdots \\ \cdots -(d-h_c)N_i & 0 & \frac{d-h_c}{3}N_i & 0 & \\ \cdots & 0 & -(d-h_c)N_i & 0 & \frac{d-h_c}{3}N_i \end{bmatrix} \quad (A.11)$$

where

$$[N_i(x,y)] = \begin{bmatrix} N_i & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & N_i & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & N_i & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & N_i & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & N_i & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & N_i & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & N_i & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & N_i & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & N_i \end{bmatrix}$$

$$(i = 1,\ 2,\ 3,\ 4) \quad (A.12)$$

where $e = \left(\frac{h_c}{a}\right)$; $[(G^*_{xz,yz})_c] = \begin{bmatrix} G^*_{xz} & 0 \\ 0 & G^*_{yz} \end{bmatrix}$; $[(G^*_{xz})_c] = \begin{bmatrix} G^*_{xz} & 0 \\ 0 & G^*_{xz} \end{bmatrix}$; $[(G^*_{yz})_c] = \begin{bmatrix} G^*_{yz} & 0 \\ 0 & G^*_{yz} \end{bmatrix}$

Tensile, Flexural and Surface Hardness Properties of Wool Grit/Silicone Polymer Composites

T. Naresh Kumar, M.K. Aravindan and A. Abraham Eben Andrews

Abstract*: Grit fortified polymer Compounds obligate numerous tenders as a class of auxiliary ingredients as a result of the instance of manufacture, generally minimal effort of generation. The grit which fills in as a fortification in strengthened plastics might be engineered or regular. An examination has been completed to utilize Wool grit which is a characteristic grit copiously accessible in India. The target of the contemporary graft is to think about the impact of grit stacking and mechanical conduct of Wool grit fortified Silicone Polymer Compoundss. This paper demonstrates the assessment of elasticity, flexural quality and external rigidity of the Wool-Silicone Polymer Compounds. It likewise finishes up the impact of grit stacking on elasticity, flexural quality and external rigidity of the Wool Silicone Polymer Compounds.

Key words*: Wool Grit; Silicone Polymer; Tensile test; Flexural test; Hardness test.

I. INTRODUCTION

Whenever at least two ingredients with various properties are consolidated together, they structure a Compounds material [1-4]. Compounds are multifunctional material frameworks that give qualities not realistic from any discrete material [32-35]. They are firm structures made by physically joining at least two good ingredients, distinctive in piece and qualities and once in a while in structure [5-9]. The Compounds are multiple ingredients which contrast from combinations by the way that the individual parts hold their qualities however are so consolidated into the Compounds as to exploit just of their properties and not of their deficiencies, so as to acquire improved ingredients [10-15].

This broadside demonstrates the conduct of mechanical properties under grit stacking [36,37]. Assessment examples are set up by hand lay-up strategy utilizing Wool as regular grit fortification in polymer network utilizing Silicone Polymer sap and hardener [15-20]. Regular Wool strands treated by sodium hydroxide to expel dampness. Grit sheets remained arranged and afterward blue-penciled into wanted contour and measurements [21-25].

Revised Manuscript Received on August 05, 2019.

II. EXPERIMENTAL

Examples for tractable, flexural and rigidity tough remained set up in polymer framework Compounds alongside Wool normal grit. Following table 1 demonstrates the organization of different examples arranged [21-23].

Table 1: Illustration Configuration

Configuration	No. of Trials
Silicone Polymer	15
Silicone Polymer (95%) + Wool Grit (5%)	15
Silicone Polymer (90%) + Wool Grit (10%)	15
Silicone Polymer (80%) + Wool Grit (20%)	15
Silicone Polymer (75%) + Wool Grit (25%)	15
Silicone Polymer (70%) + Wool Grit (30%)	15

Table 2: Summary of tests

Assesment	Machine Used	Operational Variables	No of Sampling Verified	Standard Used
Malleable	1.0kN UTM	Weight cell = 600KN Rate = 6mm/min	30	ASTM D638 [24]
Flexural	1.0kN UTM	Weight cell = 600KN Rate =1.32mm/min	30	ASTM D790 [25]
Hardness	Rockwell hardness tester, PSI New Delhi	l indentor size = ¼ inch	30	ASTM D785 [26]

Categorization of Mechanical Possessions:

Malleable and flexural assessments are done on Instron 3382, 1.0kN UTM at a hotness of 23±2˚C, and with comparative stickiness of 38±5% [22-27]. Tough systems is done in ASTM D638 for tractable tests and ASTM D790 for flexural tests. Rockwell Rigidity assessment is through as per ASTM D785

[28-31].

Consequences:

The possessions of Wool grit fortified Silicone Polymer Compoundss with various grit stacking underneath this examination exhibited in table 3.

Table 3: Mechanical qualities of Compounds

Grit Content (%)	Orientation (degree)	Tensile Strength (MPa)	Flexural Strength (MPa)	Hardness (HRL)
0	Random	18.16	19.03	46
5	Random	26.22	27.88	49
10	Random	37.98	37.48	56
15	Random	45.28	43.82	62
20	Random	*53.61*	*51.47*	*67*
25	Random	46.91	48.15	68

Impact of grit stacking on elasticity:

Figure 1 demonstrates the impact of grit stacking on elasticity of Wool grit Compounds substantial.

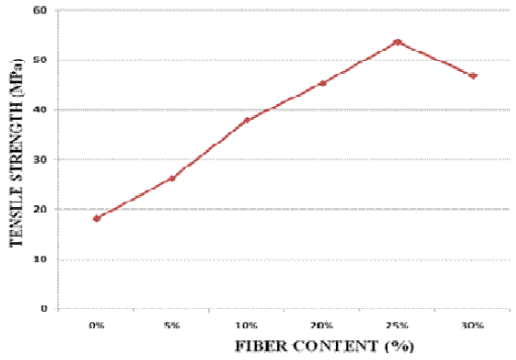

Figure 1: Effect of grit stacking on elasticity of Compounds

Impact of grit stacking on flexural quality of Composites:

Figure 2 demonstrates the impact of grit stacking on flexural quality of Wool grit Compounds substantial.

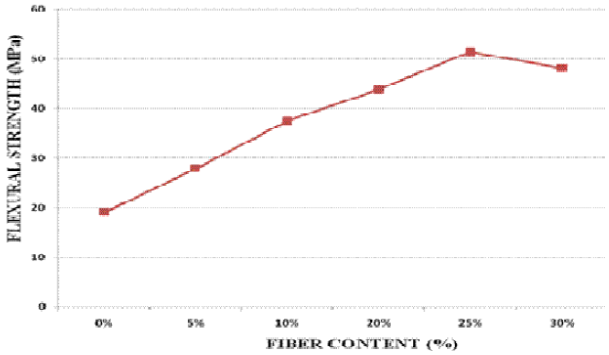

Figure 2: Consequence of grit stacking on flexural qualityof Compounds

Impact of grit stacking on superficial rigidity of Composites:

Figure 3 demonstrates the impact of grit stacking on superficial rigidity of Wool grit Compounds substantial.

Figure 3: Consequence of grit stacking on external rigidity of Compounds

III. CONCLUSION

The contemporary investigation demonstrates that the elasticity of Wool-Silicone Polymer Compounds increments to the specific degree of grit stacking and afterward begins diminishing on further grit stacking. The greatest estimation of elasticity is acquired at 25wt% of grit stacking also investigation uncovers that the flexural quality of Wool-Silicone Polymer Compounds increments to the specific degree of grit stacking and after that begins diminishing on further grit stacking. The most extreme estimation of flexural quality is acquired at 25wt% of grit stacking. Likewise demonstrates that the miniaturized scale external rigidity of Wool-Silicone Polymer stacking and after that the rigidity is almost steady.

AUTHORS PROFILE

Mr. T. Naresh Kumar, Assistant professor in Mechanical Engineering Department, Malla Reddy Engineering College(Autonomous), Maisammaguda, Hyderabad. He has 5.6 years of teaching experience. He completed M.Tech in 2013 at MITS, Madanapalle, Jawaharlal Nehru Technological University, Anantapur. He had guided 3 M.Tech projects and published 13 papers in various National and International Journals and Conferences.

Dr. M.K. Aravindan presently working as a Associate professor and Head in Department of Automobile Engineering, School of Engineering and Technology ,Jain (Deemed to be university),Bangalore. Completed Ph.D. in the area of Nano Composites at Anna University, Chennai. Perused M.E. degree in Mechanical Engineering with a specialization of Engineering Design from Bannari Amman Institute of Technology, Sathyamangalam, B.E. Degree in Mechanical Engineering from SSM College Of Engineering Komarapalyam, Diploma in Mechanical Engineering from Sri Ramakrishna Polytechnic College Coimbatore,.Fruitfully practicing the Isha Yoga and Meditation practices. Having 13.1 years of teaching experience, attended as an External expert member for Research scholars registered under various universities across Karnataka state at National law school of india university, Bangalore. One week workshop in Jain Deemed to be university,established TKCESAE collegiate club at The Kavery College of Engineering, Mecheri (Salem),conducted CSIR sponsored National Conference on Green Automobile Conceptualization Towards Sustainable Development and Organized Two Weeks Faculty Development Program Sponsored by AICTE and conducted various programs in various institutions.

A. Abraham Eben Andrews, Assistant Professor working in Mechanical Engineering Department at Hindustan Institute of Technology and Science, Chennai. Having 4 years of Teaching Experience and a year of Industrial Experience. I had conducts research in the broad area of Material Science and Metal Castings. Reviewer of two International peer Reviewed Journals in Materials. Executive member of YP CLN team in The Institution of Engineering and Technology.

Experimental Research on Abaca/Agave/ Fly ash Nano Powder Reinforced Hybrid Composites

T. Naresh Kumar, D. David and S. Shankaranarayanan

Abstract*: Regular grit are those which are made normally, for example, Abaca, Jute, Hemp, cotton, hair, fleece coir and etc. Because of numerous points of interest Ordinary grit are supplanting glass grit and carbon grit, for example, its biodegradable nature so it dumps it beyond all detectable inhibitions space after it takes retirement, and its simplicity of accessibility, low weight, and better quality in multi hub support with including Nano powder particles with it. In this examination work motorized conduct of Flyash Nano powder/Abaca/Agave grit strengthened epoxy based half and half compounds and its creation has been considered. Work has been done to examine the flexural properties,tensile quality, hardness, and effect quality of the compounds. It has been seen that effect quality is improved with the expansion in the weight portion of normal strands to certain degree. The morphology of compounds is contemplated by utilizing Scanning Electron Microscope (SEM).

***Key words*: Abaca, Agave, Flyash nanopowder, Scanning Electron Microscope.**

I. INTRODUCTION

Regular grit fortified compounds are elective ingredients for some building applications, for example, aviation applications, little wind turbine edges, and vehicle applications [1-3]. Characteristic grit show indicates prevalent properties, for example, ductile, fk=lexural and sway at that point glass grit [3-5]. The primary points of interest of common strands are of ease, light weight, simple generation and amicable to condition [6]. Then again, there are a few downsides, for example, their poor mechanical properties and high dampness assimilation [32-34]. The fortification can be manufactured (for example glass, carbon, boron and aramid) or of regular sources [35-37]. By the by, some composite segments recently fabricated with glass strands are presently created with characteristic filaments [7-9]. Applications including entryway boards, trunk liners, instrument boards, inside rooftops, bundle racks, among other inside segments, are as of now being used in European autos because of the more positive financial, natural and social parts of the vegetable filaments [10-12]. Low degree of volume part of filaments gave not just higher modulus of versatility and mechanical quality under elastic and flexural loadings yet in addition have estimations of obvious thickness, evident porosity and water ingestion [13]. The expansion of Flyash can improve the firmness by keeping up its low thickness [14-16]. The quality of short grit compounds relies upon the sort of grit network, grit length, grit direction, grit focus and the holding between the grit and grid matrix [17].

II. EXPERIMENTAL

A. Ingredients

The fundamental points of interest of normal filaments are their accessibility, biodegradable, sustainable, natural cordial, minimal effort, low thickness, high explicit properties, great warm properties and improved the vitality recuperation, low vitality utilization, nonabrasive nature and ease [18]. These strands are ease filaments with low thickness and high explicit properties which are similar to manufactured filaments. The crude ingredients utilized in this work are, Abaca grit, Agave grit , Flyash Nano power Epoxy , Hardener.

B. Methodology

Strands in this exploration it compounds are manufactured by hand layup process. Abaca and Agave were cut into the components of length and broadness of 300×200mm was utilized to set up the example. The composite example comprises of absolutely 6 woven layers. A measure amount of gum and Flyash are taken and which is get blended with hardener in the proportion of 1:1 [19]. The layers of strands were manufactured by including the required measure of epoxy tar, 17% of Abaca ,17% of Agave and 6% of Flyash Nano powder is utilized. The six 6 layers of various strands (Abaca and Agave) are created utilizing hand layup process. The epoxy pitch connected is conveyed to the whole surface by methods for roller [20-24]. The air holes framed between the layers during the preparing were delicately crushed out, the handled wet composite were then squeezed hard and abundance sap is evacuated. At that point it is dried by keeping it in environmental conditions for 1 day to get the ideal examples as appeared in figure 1.

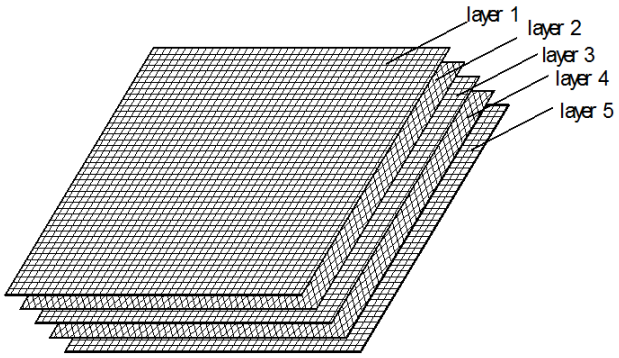

Figure 1 Multiaxial layers of Abaca and Agave

After composite ingredients dried totally, undesirable surfaces are to be evacuated utilizing optional tasks and furthermore cut the ingredients according to the required ASTM models [25-27].

C. Characterization

Malleable example

Elasticity of the example is dictated via conveying tractable test on UTM pursued by ASTM Standards. The standard utilized for elasticity id ASTM D3039. It has been manufactured by the ASTM Standards [28-29].

Sort of test: Tensile quality

Standard: ASTM D3039

Figure 2: Specimens for Tensile Test

Flexural specimen

Flexural quality of the example is dictated via conveying elastic test on UTM pursued by ASTM Standards. Threepoint twisting trial of composite example is done in ASTM D 790 test standard. A uniaxial burden was connected through both the end [30]. Sort of test: 3-point Flexural Test

Standard:ASTMD 790

Figure 3: Specimens for Flexural Test

Effect example

The vitality consumed by the material is found by charpy testing pursued by ASTM Standard of ASTM E23-15b [31] as appeared in figure.

Figure 4: Specimen for Impact Test compounds

III. RESULTS AND DISCUSSION

Pliable test

It is discovered that rigidity of woven Abaca/Agave fortified with Epoxy/Flyash Resin are given horrible outcomes.

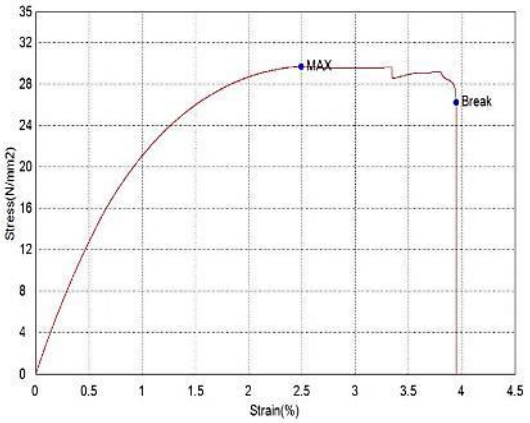

Fig 5 : Stress Vs strain diagrams for Tensile test (Specimen 1)

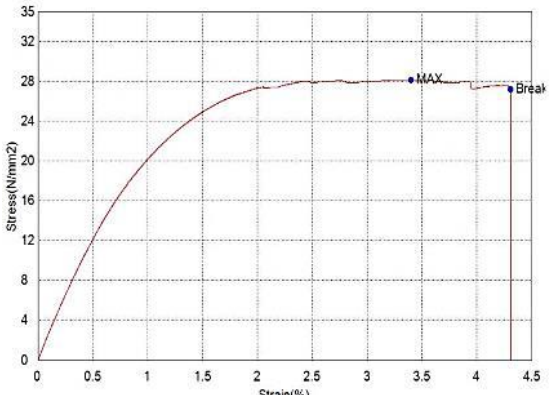

Fig 6: Stress Vs strain diagrams for Tensile test (Specimen 2)

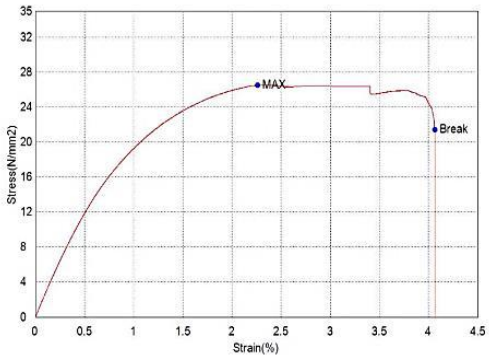

Fig 7 : Stress Vs strain diagrams for Tensile test (Specimen 3)

Flexural test

Figure demonstrates the subtleties of flexural results for three number of examples. From the beneath diagram of pressure versus strain it is seen that normal flexural worry of material is 64 N/mm2.

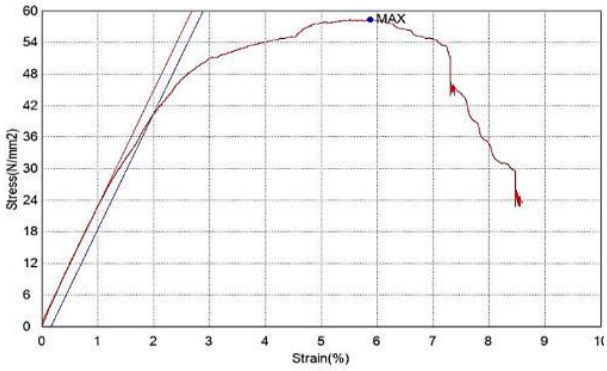

Fig 8 : Stress Vs strain diagrams for Flexural test (Specimen 1)

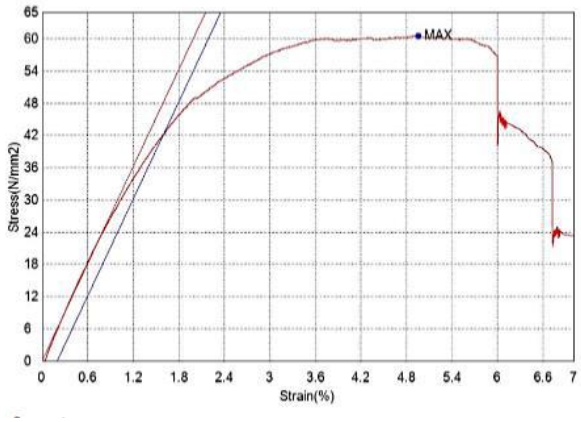

Fig 9 : Stress Vs strain diagrams for Flexural test (Specimen 2)

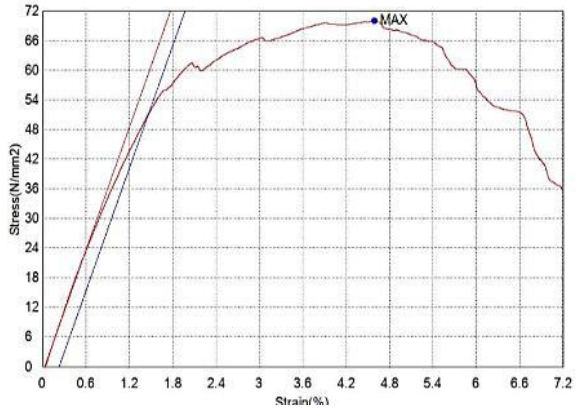

Fig 10 : Stress Vs strain diagrams for Flexural test (Specimen 3)

Effect test Effect test is led to investigations the vitality consumed by the example for unexpected connected burden. The effect test is finished by charpy effect test machine. From the table 1 it is seen that normal effect quality of composite material is 136.44 KJ/m2.

Table 1 Impact Strength of compounds

Specimen	Impact strength(KJ/m^2)
1	141.23
2	98.47
3	171.32

5.6. SEM Analysis

The accompanying Figure 11. demonstrates test's surface geography of Abaca/Agave strengthened with Flyash nanopowder/epoxy tar after creation. The SEM test demonstrates the different of mechanical properties through stage dissemination data. Figure demonstrates that period of Abaca/Agave/Flyash nanopowder/epoxy fortified epoxy composite. It is seen that because of hand layup process, Flyash and epoxy pitch are taken uneven surfaces which may diminish elastic and flexural properties similarly however it is demonstrated that this uneven surfaces of Flyash and sap may build sway quality of material.

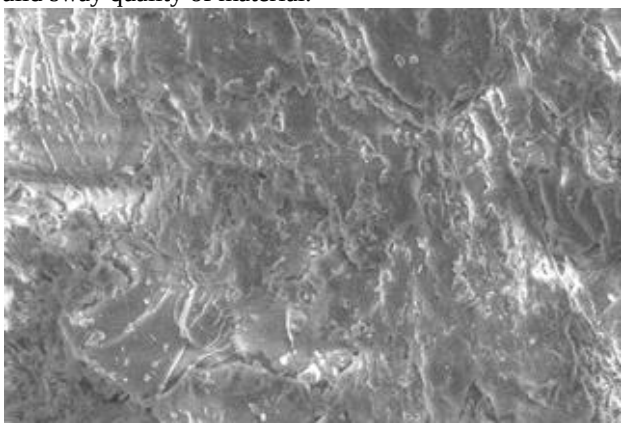

Figure 11: SEM Images of Abaca/Agave/Flyash Nano Powder Reinforced Hybrid Compounds

IV. CONCLUSION

Common grit strengthened compounds structure one such class of ingredients which gangs predominant mechanical properties as well as bio-degradable in nature. Normal grit fortified compounds can be a potential applicant where they can supplant the convential material arrangement of wind industry. Be that as it may, it is absurd to totally supplant the engineered strands by common filaments just, so as to show signs of improvement properties, it is fundamental to utilize some measure of Nanopowder, for example, Flyash to improve its mechanical properties with low thickness. From this exploration it is discovered that including 6% of Flyash Nanopowder in Epoxy which improves the effect quality of material upto 137.66 KJ/m^2, Tensile quality upto 28 N/mm^2, and flexural quality 63 N/mm^2 with keeping up low material thickness.

Experimental Research of Silane Treatment on Bamboo and Aramid Hybrid Composites

T. Naresh Kumar, D. Logendran, P. Karthick, A Arun Raja, A. Abraham Eben Andrews

Abstract*: The first and most significant target was to make composite exploiting aramid grit alongside common grit by surface change and acquire combination that has aggressive possessions by diminishing its aramid content as it is costly and its utilization causes carcinogenic though characteristic strands are eco-accommodating just as copiously accessible and its least expensive as well.

Keywords*: Bio-degradable, Nano-Bio Interface, Bio compounds.

I. INTRODUCTION

Bio compounds are compound materials, that is, materials shaped by a network (tar) and a support of common strands (normally got from plants or cellulose) [1-3]. Bio compounds are the blend of regular strands (bio grits, for example, wood filaments (hardwood and softwood) or non - wood strands with polymer frameworks from both of the inexhaustible and nonrenewable assets [4-6].

Bio compounds regularly impersonate the structures of the living materials associated with the procedure, notwithstanding the reinforcing properties of the framework that was utilized, yet at the same time giving biocompatibility, for example in making frameworks in bone tissue building [7-10]. The level of biodegradability in bio - put together polymers depends with respect to their structure and their administration condition [11-13].

Compounds are those materials that contain at least two unmistakable constituent stages, on a scale bigger than the nuclear [14-17]. The term 'Bio compounds' alludes to those compounds that can be utilized in bioengineering. The constituents of the compound hold their personalities in the compound [18-21]. Specifically, they don't break down or generally consolidate totally into one another in spite of the fact that they demonstration in show. In compounds, properties, for example, the versatile modulus can be altogether not quite the same as those of the constituents alone, yet are extensively adjusted by the constituent structures and substance [22-25].

From a basic perspective, compounds are anisotropic in nature. Further, investigation into organic inorganic interfaces centers around the plan, blend, and portrayal of novel amalgams that circuit natural and inorganic materials [26-29]. The combination of "delicate" natural and natural atomic congregations with "hard" inorganic nano-structures is of uncommon intrigue as a result of the chance to join typically dissimilar substance and physical properties inside a solitary framework [30-33].

Soluble base treated alongside Silane preserved and unprocessed filaments crossover compound was readied and every one of the kinds of physical and concoction properties examined [44-50]. Compound change utilizing Silane as a coupling operator shows better improvement in properties of both Bamboo/Aramid Hybrid compound just as in Aramid Compound moreover. All the Silane treated compound demonstrated preferred execution over untreated compound [34].

Execution properties of compound having different application in substantial and non material. Silane has an additional bit of leeway both physical and synthetic properties improvement.Diverse grit adjustment procedures can be exploited to recover its mechanical just as synthetic possessions [35] Different regular strands which are bio degradable and plentifully accessible can be make use of as fortification material with man made filaments with diverse breeds of thermoset and thermoplastic saps [51-54]. Composite framed can be used for basic applications, for making guard of vehicles and internal framing of vehicles and dashboards [36-38].

IV. CONCLUSION

Biocompounds offer open doors for ecological increases, diminished vitality utilization, protection and sound retention properties. These days, Use of Biocompounds in structure ingredients offers a few points of interest, for example, shabby, lightweight, natural neighborly, bio - inexhaustible, and increasingly solid. In any case, they have a few weaknesses also, for example, dampness ingestion and photochemical corruption in view of the UV contaminations. Moreover, biocompounds offer open doors for natural additions, decreased vitality utilization, protection and sound ingestion possessions biocompounds, their focal points, restrictions, their worldwide generation, and their monetary. Moreover, this paper displayed at this juncture is extremely valuable accumulation of the cutting edge papers comprises a precious springboard to making biocompound advancements of tomorrow.

AUTHORS PROFILE

Mr. T. Naresh Kumar, Assistant professor in Mechanical Engineering Department, Malla Reddy Engineering College(Autonomous), Maisammaguda, Hyderabad. He has 5.6 years of teaching experience. He completed M.Tech in 2013 at MITS, Madanapalle, Jawaharlal Nehru Technological University, Anantapur. He had guided 3 M.Tech projects and published 13 papers in various National and International Journals and Conferences.

D. Logendran perused M.E. degree in Mechanical Engineering with a specialization of Engineering Design from Bannari Amman Institute of Technology, Sathyamangalam. Having 13 years of teaching experience. Presently working as Lecturer in Department of Engineering, Faculty of Engineering Science and Technology, The Maldives National University, Rahdhebai Higun, Machangolhi, Male-20371, Maldives

P. Karthick, Assistant Professor working in Mechanical Engineering Department at Hindustan Institute of Technology and Science, Chennai. Having 4 years of Teaching Experience and a year of Industrial Experience.

A Arun Raja, Assistant Professor working in Mechanical Engineering Department at Hindustan Institute of Technology and Science, Chennai. Having 4 years of Teaching Experience and a year of Industrial Experience. I had conducts research in the broad area of Material Science and Metal Castings.

A. Abraham Eben Andrews, Assistant Professor working in Mechanical Engineering Department at Hindustan Institute of Technology and Science, Chennai. Having 4 years of Teaching Experience and a year of Industrial Experience. I had conducts research in the broad area of Material Science and Metal Castings. Reviewer of two International peer Reviewed Journals in Materials. Executive member of YP CLN team in The Institution of Engineering and Technology.

Effect of Chemical Treatment on Alpaca Fleece Reinforced Polymer Composites

T. Naresh Kumar, D. Logendran, A. Abraham Eben Andrews, A Arun Raja, P. Karthick

Abstract*: Fiber which is a fortification reinforced additionally manufactured characteristic investigations demonstrate solitary counterfeit strands like glass, carbon and so on., are utilized in fiber supported plastics. despite the fact that have extraordinary explicit quality, their grounds of utilization are self-same constrained inferable from their characteristic more expensive rate of creation. In this association, partner degree examination has been distributed to frame utilization of Alpaca fleece a fiber plentifully available in Bharat. Regular filaments don't appear to be just strong and lightweight however moreover generally the most reduced. Alpaca fleece compounds are created and their mechanical possessions remain assessed. Mechanical properties of Alpaca fleece /polymer and contrasted and glass fiber/amino..

***Keywords*: Alpaca fleece ; Polymer; Chemical treatment.**

I. INTRODUCTION

Compound ingredients are generally grouped by kind of support, for example, concrete and framework mixtures are for the most part economically delivered composites in which gum is utilized as grid with various strengthening materials [1-4]. The distinctive sort of fiber is characteristic (plant, creature) aimed at various application [5-8]. Bond framework composites are comprised of concrete and with total and essentially utilized in structure applications [9]. Characteristic strands have numerous striking favorable circumstances over engineered filaments [10-12]. Regular filaments are to a great extent partitioned into three classes relying upon their beginning: for example, simple accessibility, sustainability of crude materials, minimal effort, light weight and high explicit quality, and solidness. It is normal that sooner rather than later supplant manufactured any rate particular existence [13-15].

II. EXPERIMENTAL

Basic Treatment

A beaker measuring utencil is taken and 2% KmNO4 is included and 98% of refined aquatic is included and an answer is ended. After sufficient drying of the strands in ordinary concealing for 180 min, the filaments are taken and absorbed the readied KmNO4 arrangement [16-18].

Test arrangement

Revised Manuscript Received on August 30, 2019

P. Karthick., Department of Mechanical Engineering, Hindustan Institute of Technology and Science, Chennai, Tamil Nadu 603103, India.

The examples remained readied utilizing the strands and amino, which are dealt with distinctively in the preparing. The molds are gutted and dehydrated earlier smearing amino [19-23]. Beeswax remained utilized as the discharging operator [45,46]. On account of glass fiber/amino manufacture, the amino blend is laid consistently over the shape utilizing a brush [22-24]. At that point a coating of the slashed element tangle is connected ended the coating of amino [25-28]. Presently the shape is shut and compacted for a relieving time of 24 h. For ALPACA FLEECE /amino creation, the ALPACA FLEECE strands were laid consistently over the shape before applying any discharging specialist or amino. At that point the packed type of ALPACA FLEECE is expelled from the form [29-32].

Mechanical Testing

Afterward manufacture the assessment examples remained exposed to different mechanical assessments according to ASTM benchmarks [47]. The mechanical assessments that are ductile test, sway test, flexural test, wear test [33-35]

Flexural Test

Flexural test was led to ponder the conduct and capacity of substantial below bowing burden [48]. The heap was connected to the example until it is absolutely break. The flexural assessment was directed for three distinct sorts of external medicines of grit compounds [36-38].

Effect Test (Izod Method)

Effect is a solitary opinion assessment that estimates a materials protection from effect from a fluctuation weight [39-41]. Effect is characterized as the active vitality expected to start break and proceed with the crack up to the example is wrecked [49-51]. This test can be utilized as a snappy and simple superiority control check to decide whether a material meets explicit effect properties or to look at materials for general strength [42-44].

III. RESULT AND DISSUSSION

The created ALPACA FLEECE grit fortified combinations was exposed to different tests to assess their mechanical possessions. All examples were set up under the determinations of ASTM standard.

Ductile Property

Rigidity of the compound was determined via greatest burden to which the factual can endure.

It is generally an all inclusive testing machine stacked with an example amongst two grasps that remain moreover balanced physically or consequently to spread over power to the example. Substantial to be tried must be sliced to a particular shape in order to fit the grasps, most normally as a canine bone shape when level sheet is being tried. When the fiber surface was altered with a fluid KmNO4 arrangement elasticity of the compound seemed to improve observably. The rigidity increments coming about because of the pre-impregnation procedure brought about an improvement of the mechanical interlocking be that as it may an expansion in the elasticity was watched.

Table 2. Load Vs fiber length

TREATMENT	LENGTH OF FIBER IN (mm)			
	5	7	9	11
AK	770 N	940 N	710 N	650 N
AC	990 N	660 N	670 N	1044 N
UT	1100 N	750 N	650 N	1040 N
BZ	830 N	940 N	590 N	950 N

Flexural Property

The flexural quality of the ALPACA FLEECE /amino fiber compounds contrived an element of the diverse fortitude outward medications are appeared in Table. 3

Table 3. Load Vs Fiber length

TREATMENT	FIBER IN LENGTH (mm)			
	5	7	9	11
AK	71 N	31 N	69 N	33 N
AC	57 N	53 N	34 N	44 N
UT	63 N	64 N	65 N	44 N

Effect Property

Effect is a solitary point test that estimates a ingredients protection since effect from a undulation weight. Effect is characterized as the dynamic vitality expected to start break and proceed with the crack awaiting the example is wrecked.

Table 4. Impact strength Vs fiber length

TREATMENT	FIBER IN LENGTH (mm)			
	5	7	9	11
AK	20 J	28 J	14 J	14 J
AC	22 J	22 J	17 J	22 J
UT	17 J	18 J	21 J	15 J
BZ	23 J	16 J	15 J	14 J

Scanning electron microscope analysis

Toward get the SEM pictures masterminded models remained cutted and presented to sizzle covering in solicitation to obtain the conductive shallow and besides to keep up a vital good ways from the dashing of electron bars despite the fact that getting the surface nuances. The SEM micrograph of the mutt compound tests presented to tractable stacking are shown in fig.5 from the photos it will in general be seen that split of the fiber and system due to the associated tractable weight are clearly watched and tests presented to flexural stacking are presented in fig.6 demonstrated that the fiber take out and voids on the sap in the model.

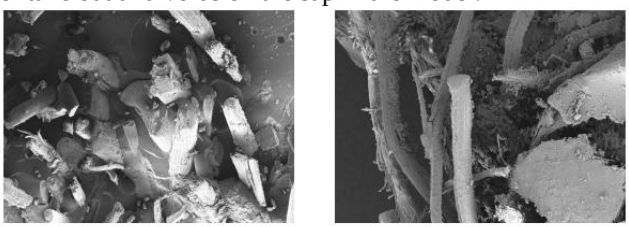

Fig.1 SEM micrographs of the composite samples subjected to tensile loading

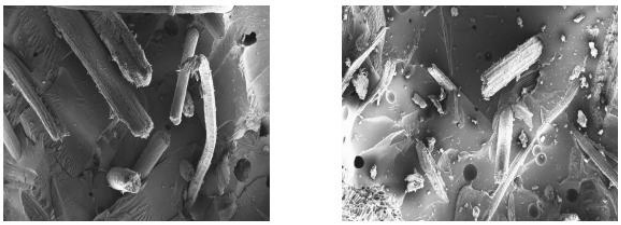

Fig. 2 SEM micrographs of the composite samples subjected to flexural loading

IV. CONCLUSION

Trials were led to portray the surfaces of preserved and unprocessed strands and to explore malleable possessions, flexural possessions and effect possessions in characteristic fiber compounds.Flexural quality of the soluble treated 9 mm fiber length was acquired great outcome because of better mechanical interlocking among fiber and grid. Effect quality of the antacid treated (7, 9 mm) fiber length was acquired same outcomes because of better mechanical dovetailing among grit and lattice.

AUTHORS PROFILE

Mr. T. Naresh Kumar, Assistant professor in Mechanical Engineering Department, Malla Reddy Engineering College(Autonomous), Maisammaguda, Hyderabad. He has 5.6 years of teaching experience. He completed M.Tech in 2013 at MITS, Madanapalle, Jawaharlal Nehru Technological University, Anantapur. He had guided 3 M.Tech projects and published 13 papers in various National and International Journals and Conferences.

D. Logendran perused M.E. degree in Mechanical Engineering with a specialization of Engineering Design from Bannari Amman Institute of Technology, Sathyamangalam. Having 13 years of teaching experience. Presently working as Lecturer in Department of Engineering, Faculty of Engineering Science and Technology, The Maldives National University, Rahdhebai Higun, Machangolhi, Male-20371, Maldives

A. Abraham Eben Andrews, Assistant Professor working in Mechanical Engineering Department at Hindustan Institute of Technology and Science, Chennai. Having 4 years of Teaching Experience and a year of Industrial Experience. I had conducts research in the broad area of Material Science and Metal Castings. Reviewer of two International peer Reviewed Journals in Materials. Executive member of YP CLN team in The Institution of Engineering and Technology.

A Arun Raja, Assistant Professor working in Mechanical Engineering Department at Hindustan Institute of Technology and Science, Chennai. Having 4 years of Teaching Experience and a year of Industrial Experience. I had conducts research in the broad area of Material Science and Metal Castings.

P. Karthick, Assistant Professor working in Mechanical Engineering Department at Hindustan Institute of Technology and Science, Chennai. Having 4 years of Teaching Experience and a year of Industrial Experience.

Experimental Research on Natural Fiber Reinforced Polymer Composite Material Composites

D. Logendran, T. Naresh Kumar and A. Abraham Eben Andrews

Abstract: ***In this examination, common strands like Abaca, Coir and Flax , Abaca and Coir (half breed) , Flax and Coir (cross breed) and Flax and Abaca (crossover) are manufactured with bio epoxy tar utilizing forming technique. In this paper the ideal blending of fortitude and sap is accomplished by utilizing Taguchi strategy. In this effort, flexural unbending nature and rigidity of Abaca besides Coir (half and half), Flax and Coir (hybridand Flax and Abaca (cross breed) composite at dry and wet conditions were considered. Hardness test remained directed utilizing rigidity testing machine. In this effort small scale edifice of the examples are examined by the Skim through Electron Hand-held microscope.***

Key words: Natural strands, Bio epoxy tar, Experimental Research, Taguchi technique.

I. INTRODUCTION

These days, the common strands, for example, Abaca, Coir and Flax can possibly be utilized by means of a substitution for glass or other conventional fortification ingredients in aggregates [33-35]. Different focal points incorporate low thickness, high durability, tantamount explicit quality properties, decrease in apparatus wear, simplicity of partition, diminished vitality of manufacture [1-3]. Composites are materials that involve solid burden conveying physical drive in more fragile substantial. Walls gives quality and inflexibility, supporting basic burden [4-6]. The lattice, or cover (natural or in-natural) keeps up the position and direction of the fortification for example, firmness, sway opposition, adaptability, and modulus [7-9]. What's more, they are accessible in huge sums, and are inexhaustible and biodegradable [32,36]. Other attractive properties incorporate minimal effort, low thickness. Employments of these filaments fulfill both financial and natural interests. The outcomes demonstrated that the most elevated mechanical properties were seen when Flax and Abaca (half breed) strands were fused [10-12]. It is surely known currently that in cooperation the quality and firmness of fortitude amalgams rely upon fiber focus, fiber viewpoint proportions, fiber-network grip, just as powdered particles of fiber direction and scattering [37]. The present commitment reports use of untreated Abaca, Coir and Flax filaments as strengthening fillers for bio epoxy tar as framework just because [12-14]. The Flax and Abaca (cross breed) Abaca and Coir (half and half) and Flax and Coir (crossover) fiber-strengthened polymer composites were readied utilizing hand shaping technique. The impacts of filaments gratified on mechanical properties.

II. EXPERIMENTAL

The network quantifiable utilized cutting-edge this examination remained bio epoxy sap Provided by Lab synthetic concoctions, Chennai. Flax, Coir & Abaca strands must remained utilized customarily in great superiority riggings in India [15-17].

A. Manufacturing process

1) Compound Treatment

The strands are pulverized. At that point the strands are scrubbed ordinarily in unsoiled consecutively river and dehydrated. A schooner measuring utencil is reserved and 6% NaOH is included and 80% of refined aquatic is included and an answer is ended. After satisfactory dehydrating of the filaments in ordinary concealing for 180 min, the strands are engaged and absorbed the readied NaOH arrangement [18]. Splashing is completed for various time interims relying on the quality of fiber required. In this investigation, the filaments are absorbed the answer for 180 min.

2) Favorable circumstances of compound behavior

Compound action by NaOH expels dampness gratified beginning the filaments along these lines expanding its quality. Additionally, synthetic treatment improves the flexural inflexibility of the strands [19-21].

E. Symmetrical cluster of analyses

By assessing the exhibition of the item in a few natural conditions, there would be a reasonable information to ascertain this present reality difference. The old style trial structure technique are excessively mind boggling, tedious and difficult to utilize. An enormous number of examinations must be completed when the quantity of procedure parameters are more. To tackle this issue, taguchi technique utilizes an uncommon structure of symmetrical clusters to ponder the whole parameter space with the base number of examinations [29].

B. Dampness Fascination Test Process

Flexural examples according to ASTM gauges remained censored after the manufactured plate. The compound examples toward remain utilized on behalf of dampness ingestion trial stood paramount dried in an airborne. At that point these adapted complex examples were drenched in refined aquatic at 30 ◦C for around 120 hrs. Next to normal interims, the examples were expelled from aquatic and cleaned with channel tabloid to evacuate shallow aquatic and pondered by means of advanced parity of 0.01mg goals. The examples remained inundated in aquatic to allow the prolongation of sorption until immersion farthest point stood come to. The assessing be located thru inside 30 s, so as to keep away from the mistake because of dissipation. The test was completed by ASTM D570 to discover the puffiness of example [22-24]. Following 120 hrs, the test examples stayed over again removed from the water shower and gauged..

C. Tensile Test

Eelasticity of the mixtures (with and without dampness) was estimated with a general testing apparatus as per the ASTM D638 strategy [25-27].

D. Taguchi Quality Loss Function

An alternate technique for estimating quality is key to Taguchi's way to deal with structure. Misfortune capacity estimates quality. The misfortune capacity builds up a monetary proportion of the client disappointment with the items execution as it strays from the objective worth. In this way, both normal execution and variety are basic proportions of value [28]. Choosing an item plan or an assembling procedure that is inhumane toward uncontrolled wellsprings of variety improves quality.

To get a superior gauge of the general significance of every one of the huge factor, non-huge variables are expelled On the off chance that the F-measurements for any factor is short of what one, at that point pool the 'SS' of that factor into the mistake term.

In the event that the quantity of elements isn't around one-half or less the quantity of sections in the table, pool the variables with the littlest F – Statistic until the no of components remaining is roughly one-portion of the no of segments [30].

particularly when more factors are included. This is known as pooling.

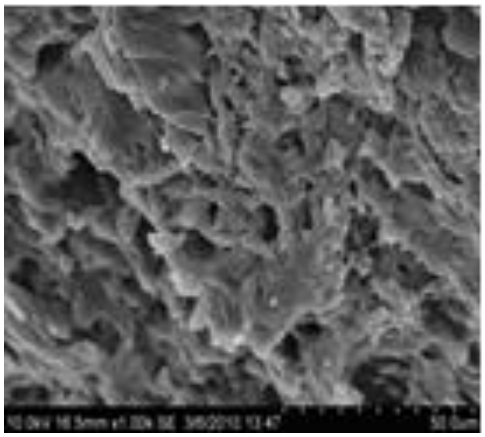

Figure 5 SEM of Flax and Coir (hybrid) without Dampness

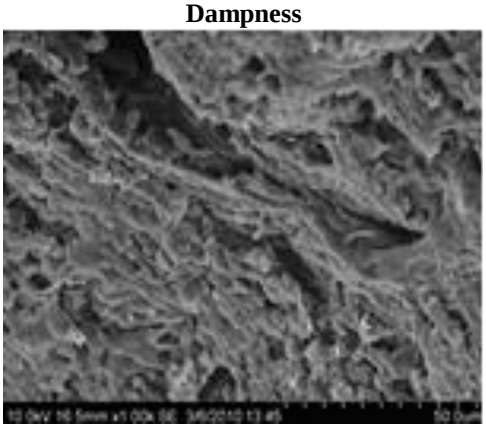

Figure 6 SEM of Flax and Abaca (hybrid) without Dampness

III. RESULTS AND DISCUSSION

The half and half composites indicated relatively better execution, the micrographs taken for the cracked Abaca, Coir, Flax and crossover composites. Abaca and Coir (crossover) and Flax and Coir (half and half) fiber composites, on tractable stacking condition, demonstrated a weak like disappointment (less in % of stretching, fig 7 and 8). Curved splits and their quick spread could be watched. Less fiber haul out is watched and this could be purpose behind the decrease in the elasticity. The nature is legitimized, where more rate prolongation could be watched for the Abaca and Flax (half and half) (high in % of lengthening, Fig 9) fiber composites which display malleable nature of break because of the nearness of Abaca filaments. The half and half composites indicated nearly better execution, the micrographs taken for the broke Abaca, Coir, Flax and cross breed composites. Abaca fiber composites, on tractable stacking condition, demonstrated a weak like disappointment. Curved splits and their quick engendering could be watched. Less fiber haul out is watched and this could be explanation behind the decrease in the elasticity. The tractable break micrograph for the fiber based composites. Plastic misshapening and more fiber haul out could be watched. This nature is legitimized, where more rate lengthening could be watched for the half breed fiber composites. Half breed fiber composites show incomplete weak nature of break because of the nearness of Abaca filaments.

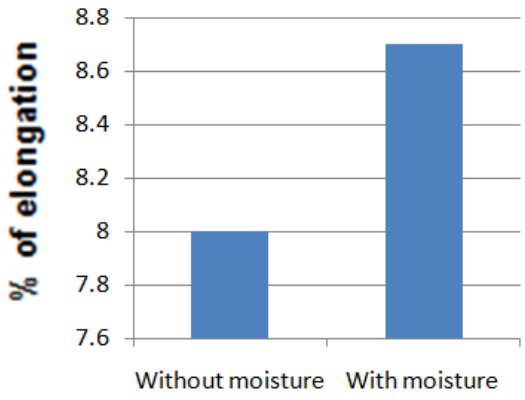

Figure 7. Comparison of Abaca and Coir (hybrid) In with &without dampness

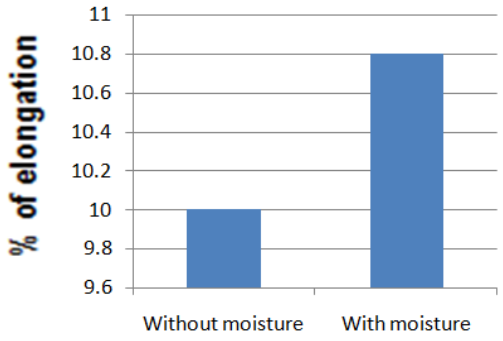

Figure 8. Comparison of Flax and Coir (hybrid) In with &without dampness

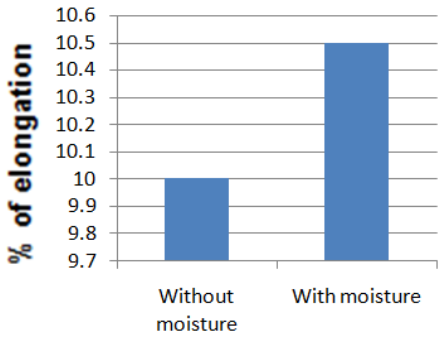

Figure 9. Comparison of Abaca and Flax (hybrid) In with &without dampness

IV. CONCLUSION

In the wake of deciding the material properties of regular fiber fortified epoxy composite utilizing six distinctive device materials and geometrics by utilizing tractable test and hardness test can be drawn:

The half breed composites indicated similarly better execution, the micrographs taken for the broke Abaca, Coir, Flax and mixture composites. Abaca fiber composites, on elastic stacking condition, demonstrated a weak like disappointment. Curved splits and their quick spread could be

watched. Less fiber haul out is watched and this could be purpose behind the decrease in the rigidity. The tractable break micrograph for the fiber based composites. Plastic misshapening and more fiber haul out could be watched. This nature is supported, where more rate stretching could be watched for the half and half fiber composites. Half and half fiber composites show halfway fragile nature of break because of the nearness of Abaca strands. At last this paper presumed that a standout amongst the best materials is Abaca and Flax (half breed) can be utilized for both interior obsession and outer obsession for break bone on human body contrasted with different materials.

AUTHORS PROFILE

D. Logendran. Perused M.E. degree in Mechanical Engineering with a specialization of Engineering Design from Bannari Amman Institute of Technology, Sathyamangalam. Having 13 years of teaching experience. Presently working as Lecturer in Department of Engineering, Faculty of Engineering Science and Technology, The Maldives National University, Rahdhebai Higun, Machangolhi, Male-20371, Maldives

Mr. T. Naresh Kumar, Assistant professor in Mechanical Engineering Department, Malla Reddy Engineering College(Autonomous), Maisammaguda, Hyderabad. He has 5.6 years of teaching experience. He completed M.Tech in 2013 at MITS, Madanapalle, Jawaharlal Nehru Technological University, Anantapur. He had guided 3 M.Tech projects and published 13 papers in various National and International Journals and Conferences.

A. Abraham Eben Andrews, Assistant Professor working in Mechanical Engineering Department at Hindustan Institute of Technology and Science, Chennai. Having 4 years of Teaching Experience and a year of Industrial Experience. I had conducts research in the broad area of Material Science and Metal Castings. Reviewer of two International peer Reviewed Journals in Materials. Executive member of YP CLN team in The Institution of Engineering and Technology.

Effect of Chemical Treatment on Ramie / Rattan /Silicone Polymer Composites

T. Naresh Kumar, D. Logendran, A Arun Raja, P. Karthick, A. Abraham Eben Andrews

Abstract*: During the most recent couple of years, regular strands have gotten considerably more consideration than any time in recent memory from the examination network everywhere throughout the world. These characteristic filaments offer various favorable circumstances over conventional engineered strands. Stagnant mechanical possessions of arbitrarily situated personally blended Ramie (Boehmeria nivea) and Rattan (Malay rotan) fiber fortified polymer composites, for example, flexural, Impact, hardness quality, water retention properties and so on, were examined as an element of fiber stacking according to ASTM measures. At first Silicone gum arranged was exposed to assessment of its ideal mechanical properties. At that point strengthening of the tar with Ramie (Boehmeria nivea) and Rattan (Malay rotan) fiber was practiced in three unique structures: molecule measure by utilizing advanced gum. Contemporary effort uncovers that mechanical possessions, for example, flexural, solidity, aquatic retention and so on of the Silicone pitch increments to significant degree when strengthened by the fortitude.

***Keywords*: Ramie (Boehmeria nivea); Rattan (Malay rotan) ; Silicone resin.**

I. INTRODUCTION

One part is frequently a solid fiber, while another segment (regularly called a grid) is regularly a pitch, for example, polyester or Silicone that ties the strands composed & condenses the material hardened and unbending [45,466]. These days, Bio compounds must remained the topic of broad exploration, explicitly in development and building industry because of their numerous favorable circumstances, for example, lower weight, and lower assembling costs[47-51]. Green Building is a development that has increased worldwide consideration in the course of recent years. Green structures are intended to be ecologically mindful, financially reasonable, and solid spots to live and effort. Solitary of the principle materials that are right now utilized in green structures is Bio compound [52]. Bio compounds might be ordered, as for their solicitations in structure manufacturing into two fundamental gatherings: basic and non-structural bio compounds. An auxiliary Bio compound can be characterized as unique that is expected to convey a heap being used [53, 54]. Basic bio compounds can go comprehensively in execution, from superior to low execution materials.

II. MATERIALS AND METHODS

1. Ramie (Boehmeria nivea)
2. Rattan (Malay rotan)
3. Silicone reinforment

Fiber treatment

Basic Treatment

Antacid treatment utilized substance action of regular filaments after rummage-sale to fortify thermoplastics and thermosets. A glass measuring glass is occupied and NaOH is included and refined aquatic is included and an answer is ended. Splashing is done for various time interims relying on the quality of fiber required. In this examination, the strands are absorbed the answer for 180 min.

Form plan for example arrangement

The element of the mixture fiber strengthened compound had 3 mm thickness. The form remained comprised of strengthen. The obligatory supplies aimed at the shape that remained utilized to the straightforwardness plastic aimed at the base coating and insertion outline.

2.5% Ramie and 2.5% Rattan

5% Ramie and 5% Rattan

7.5% Ramie and 7.5% Rattan

Mechanical testing

Subsequently manufacture the assessment examples remained exposed to different mechanical tests according to ASTM gauges. The mechanical assessments are ductile test, sway test, flexural test, attire test.

III. RESULTS AND DISCUSSION

Flexural test

Flexural test was directed to think about the conduct and capacity of substantial under twisting burden. The heap was connected to the example while waiting for it is thoroughly interruption.

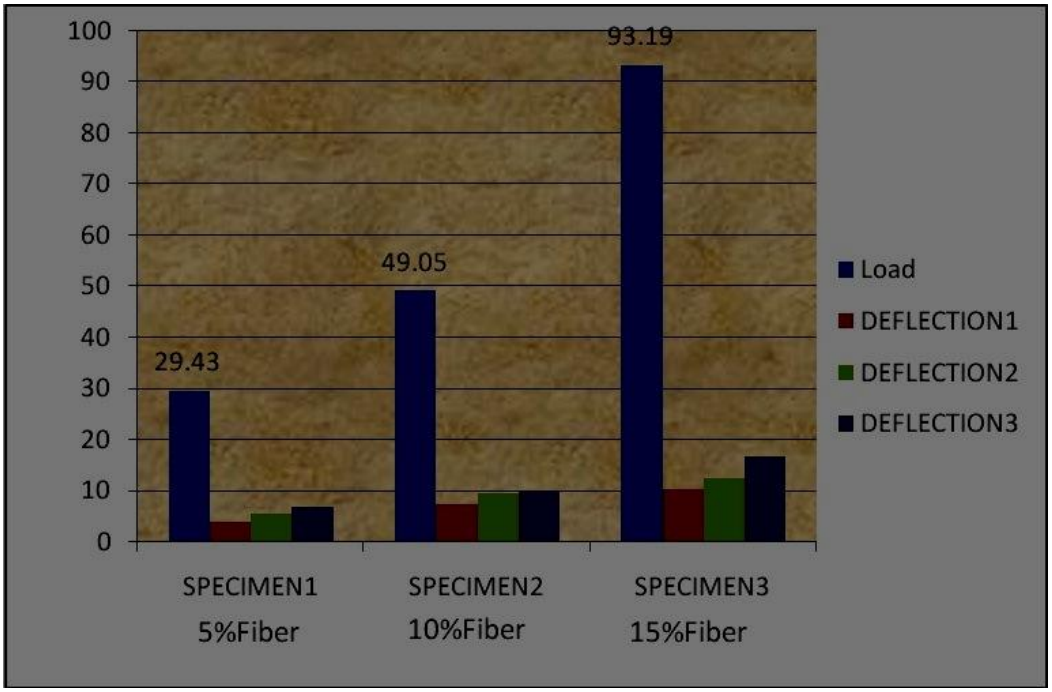

Figure 1 Flexural Load Vs Deflection Graph

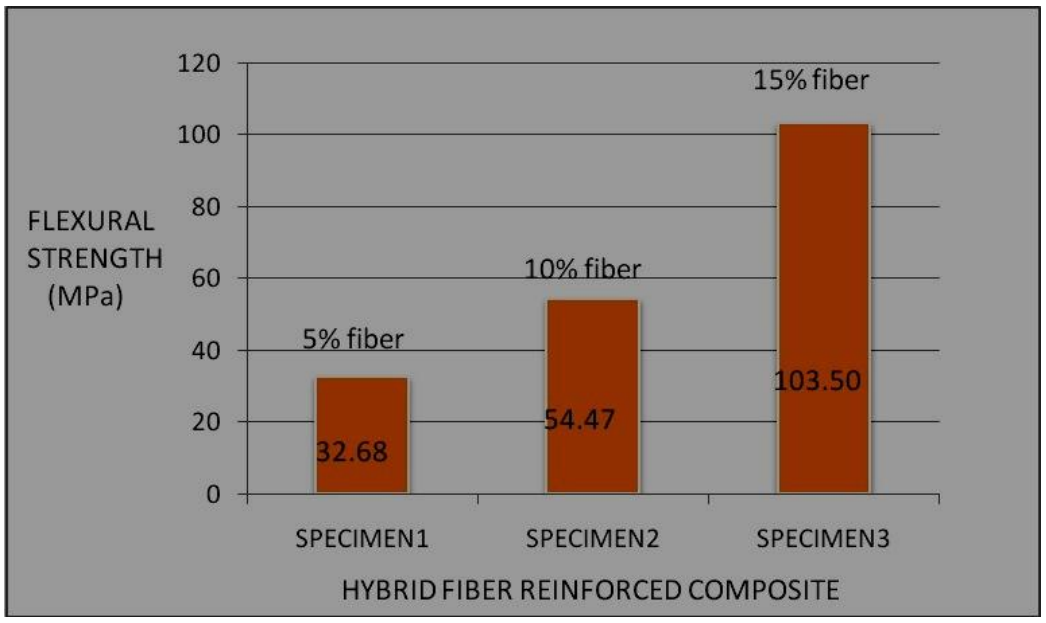

Figure 2 Flexural Strength Graph

Impact Test

Effect is a solitary argument assessment that estimates a ingredients protection effect from a fluctuation weight. This test can be exploited as snappy and simple check to decide whether a substantial sees explicit effect possessions or to think about ingredients for all-purpose durability.

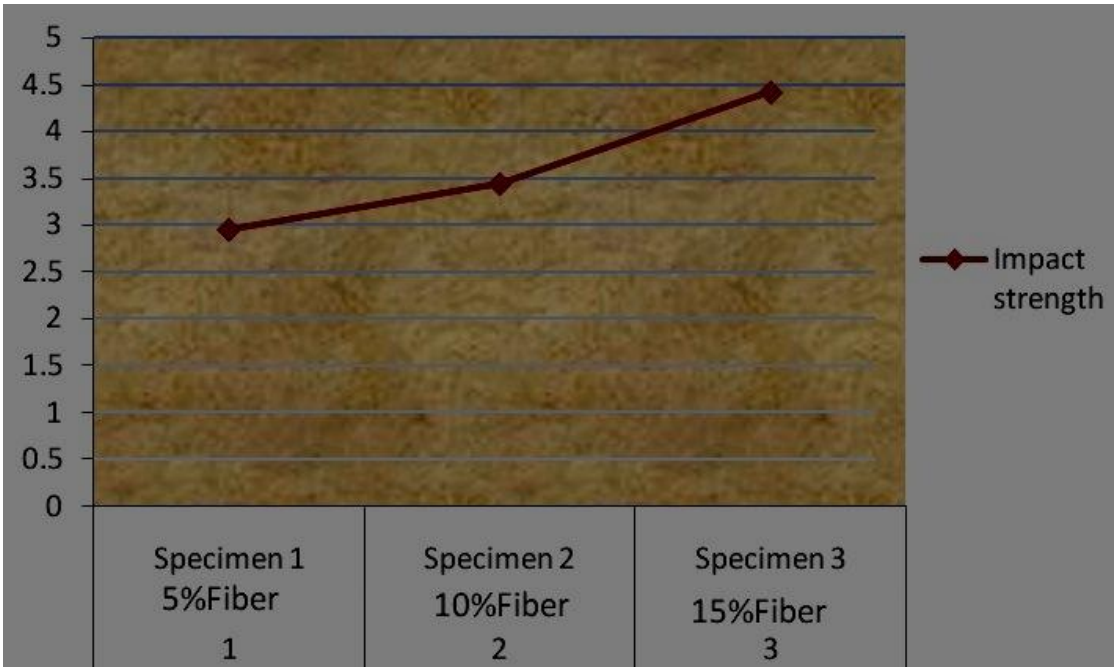

Figure 3 Impact Strength Graph

Aquatic absorption test

Aquatic retention test the compound example is exposed towards the estimation of in what way ample aquatic, the example will ingest.

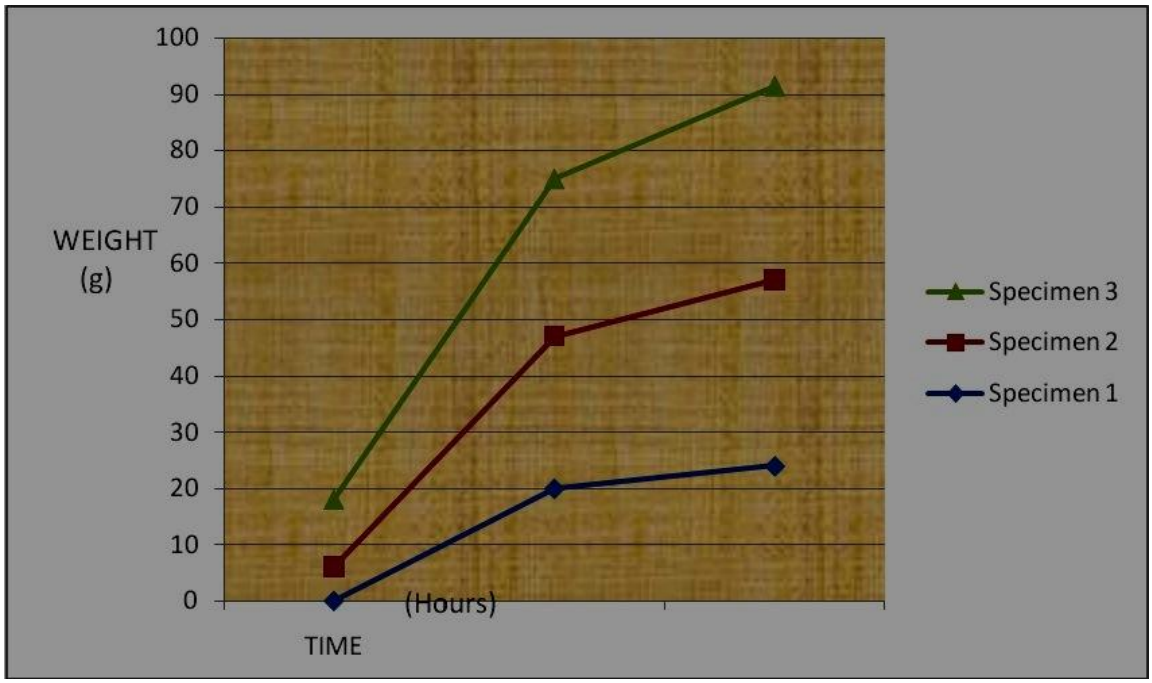

Figure 4 Time Vs Weight Graph

Rigidity test

In this stone well rigidity test the compound example is exposed to decide the stability number.

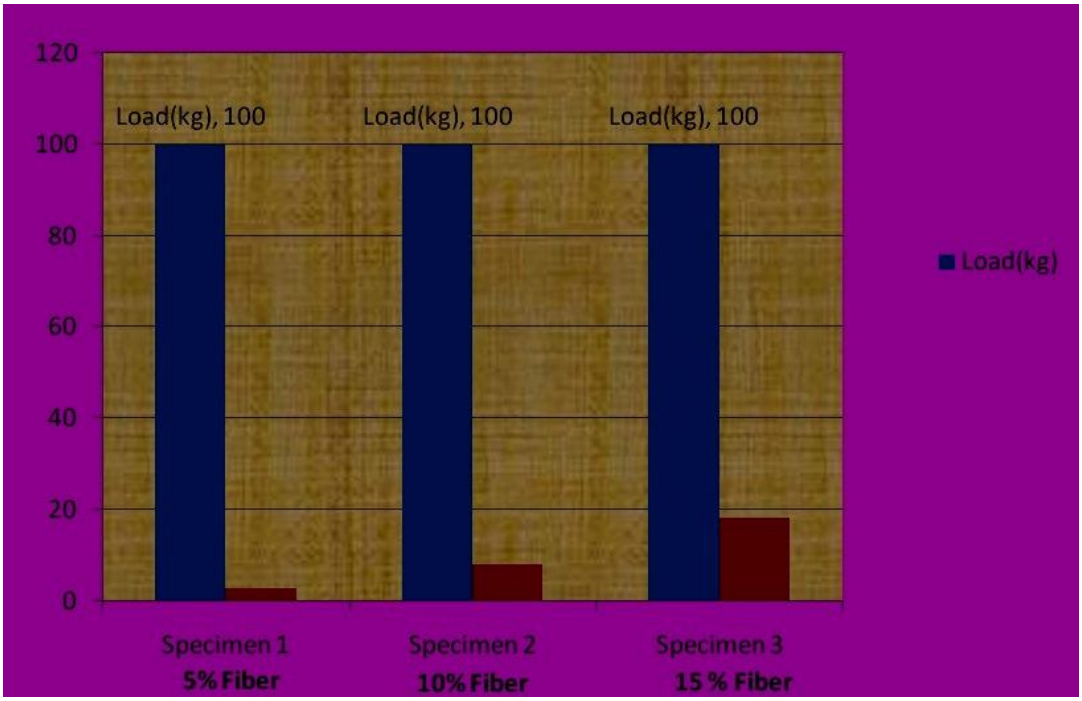

Figure 5 Load Vs Hardness Number

IV. CONCLUSION

In this effort, half breed filaments Ramie (Boehmeria nivea) Rattan (Malay rotan) have been portrayed for their properties. Half and half filaments have great length, quality, consistency, fineness, and brilliant dampness ingestion. In this examination the plausibility of applying half and half filaments, to be specific Hemp strands as an elective crude material for fiber-fortified composite (FRC) is researched. Crossover fiber stretches healthier outcome in flexural quality although looking at than other fiber. Trial examination of mechanical conduct of Hybrid fiber fortified Silicone fusions prompts the accompanying ends: This work demonstrates that effective creation of a half and half fiber strengthened Silicone composites with various extents is conceivable by straightforward hand lay-up strategy. It is noted that the mechanical assets of the mixtures, intended for example, aquatic ingestion, flexural quality, solidity quality and so forth of the amalgams are additionally incredibly impacted designed for various dimensions part of grit and irregular fiber fortified compound quantifiable.

AUTHORS PROFILE

Mr. T. Naresh Kumar, Assistant professor in Mechanical Engineering Department, Malla Reddy Engineering College(Autonomous), Maisammaguda, Hyderabad. He has 5.6 years of teaching experience. He completed M.Tech in 2013 at MITS, Madanapalle, Jawaharlal Nehru Technological University, Anantapur. He had guided 3 M.Tech projects and published 13 papers in various National and International Journals and Conferences.

D. Logendran perused M.E. degree in Mechanical Engineering with a specialization of Engineering Design from Bannari Amman Institute of Technology, Sathyamangalam. Having 13 years of teaching experience. Presently working as Lecturer in Department of Engineering, Faculty of Engineering Science and Technology, The Maldives National University, Rahdhebai Higun, Machangolhi, Male-20371, Maldives

A Arun Raja, Assistant Professor working in Mechanical Engineering Department at Hindustan Institute of Technology and Science, Chennai. Having 4 years of Teaching Experience and a year of Industrial Experience. I had conducts research in the broad area of Material Science and Metal Castings.

P. Karthick, Assistant Professor working in Mechanical Engineering Department at Hindustan Institute of Technology and Science, Chennai. Having 4 years of Teaching Experience and a year of Industrial Experience.

A. Abraham Eben Andrews, Assistant Professor working in Mechanical Engineering Department at Hindustan Institute of Technology and Science, Chennai. Having 4 years of Teaching Experience and a year of Industrial Experience. I had conducts research in the broad area of Material Science and Metal Castings. Reviewer of two International peer Reviewed Journals in Materials. Executive member of YP CLN team in The Institution of Engineering and Technology.

Machining Characteristics of Natural Fiber Particle Reinforced Polymer Composite Material using Artificial Neural Network

T. Naresh Kumar, B. Murali and J. Arulmani

Abstract*: *The point of research is improvement of biocomposite materials dependent on biopolymers and characteristic filaments has been made through creation of Natural fiber powdered material (Abaca, Mudar and Hemp strengthened polymer composite material by utilizing bio epoxy tar. The present work centers around the forecast of push power and torque of the normal fiber fortified polymer composite materials and the qualities, contrasted and the Artificial Neural Network.

Key words*: *Abaca, Mudar, Hemp, Bio Resin, ANN, Machining Parameters

I. INTRODUCTION

As of late, the characteristic filaments have pulled in generous significance as potential basic material. The appealing in addition to purpose of normal fiber is regarding modern use which has made its accessibility all the more requesting [1]. Keeping this in view the present work has been embraced to build up a polymer network composite (epoxy tar) utilizing regular strands as fortification and to ponder its mechanical properties and execution [2]. India is a nation which to a great extent relies upon farming. Homestead items comprise the different joints and bones of the foundation of the nation's economy out of which regular fiber has been a waste item which remains to a great extent undiscovered [3]. As of late the regular fiber epoxy composites has pulled in generous significance as a potential basic material [4]. The alluring highlights of regular strands like jute, sisal, coir and banana have been their minimal effort, light loads, high explicit modulus, recharge capacity and biodegradability [5]. Fiber fortified composites are being utilized broadly today, owing their utilization to better mechanical properties like high quality than weight proportion, high solidness to weight proportion and plan adaptability [6-7]. Expanded utilization of composites has implied there is interest for joining of a portion of the parts together [8]. Cement holding is the strategy utilized frequently for joining most composites, yet it has its detriments. Glue holding requires surface readiness of the materials before they can be joined [9]. Warmth and weight might be required for relieving purposes during cement holding. Glues are synthetic compounds used to consolidate composites [10-11]. Contingent upon the glue picked, the fix time of composites may be low or high [12]. Because of the synthetics utilized, security and wellbeing may be in danger. Reinforced joints are hard to assess for deficiencies or as a rule [13-14].

II. MATERIALS AND METHODS

The example utilized in this examination is a round and hollow bar of 60×40 mm made of regular fiber fortified composite material. The composite is made of common filaments.

The materials utilized in this undertaking are:

- Abaca and Hemp (half and half) molecule fiber strengthened composite
- Mudar and Abaca (half and half) molecule fiber strengthened composite
- Mudar and Hemp (half and half) molecule fiber strengthened composite.

A. Preparation of Composite Cylindrical Rod

A form of sixty metric straight unit length and forty metric direct unit distance across was made misuse GI sheet shape. partner OHP Sheet was taken and a purifying operator was connected over it and fitted with the inward part of the form and permitted to dry [15]. A glass measuring utencil and a glass pole or a stirrer were taken and clean well with running water and a short time later with warmth water. At that point, determined measure of bio manufactured pitch and hardner was superimposed and in this way the blend was mixed for almost 10-15 min. Mixing was done to shape an unvaried blend of natural compound and quickening agent particles. a while later, determined measure of filaments was superimposed and in this way the blending strategy was proceeding [16]. At that point, the blend was filled the shape and smashed tenderly for uniform settlement. The form was permitted to cement for almost 24 h [17].

Revised Manuscript Received on July 09, 2019.

B. Machining of Composite Specimens

In the wake of acquiring the composite tube shaped pole with required measurements, the machining (boring procedure) of composite examples is appropriated abuse MAXMILL CNC machining focus misuse High Speed Steel (HSS) bit bits. The boring technique was circulated misuse HSS bend drills with consistent unadulterated arithmetic. The level of the machining parameters used in this examination zone unit given as Table 1. Drill device estimating instrument was wont to live pushed power and torsion severally all through the penetrating procedures [18]. the consequences of machining parameters on push power, torsion and delamination of composite materials were comprehended by sizable sum (27) of machining tests [19].

Table 1. Assignment of the levels to the factors

Drill Level	size, d (mm)	Velocity, N (m/min)	Feed rate, f (mm/rev)
1	3	600	0.1
2	4	900	0.2
3	5	1200	0.3

C. Factorial Design

A 3^3 full factorial structure with an aggregate of 27 exploratory runs were done. The push power and torque were the reaction factors recorded for each run. The impact of the machining parameters is another significant angle to be considered. It very well may be seen that the slicing speeds from 20 to 60 m/min are typically utilized, while feed rate esteems lower than 0.3 mm/rev are visit. Cutting rate is definitely not a restricting component when boring polymeric composites, especially with hard metals and in this way, the utilization of cutting velocities underneath 60 m/min might be clarified by the most extreme rotational speed of customary machining devices, since drill distances across over 10 mm are infrequently detailed [20]. Another explanation behind continuing cutting rates underneath 60 m/min may live in the way that higher slicing rate esteems lead to higher cutting temperature, which thusly may cause the conditioning of the framework [21-22]. The utilization of feed rates beneath 0.3 mm/rev might be related with the delamination harm caused when this parameter is expanded.

D. Experimental Setup

Various boring examinations were completed on a CNC machining focus (Maxmill) utilizing HSS contort drills for the machining of NFRP composites. A two-part drill apparatus dynamometer was utilized to record the push power and torque. Traditional fast steel bend drills were utilized as much as established tungsten carbide drills. Device geometry is a significant angle to be considered in penetrating of fiber-fortified plastics, especially when the nature of the machined gap is basic.

III. Discussion

In this examination work ANN has been utilized as a device to anticipate the test results. In ANN, feed forward back propogation was utilized to anticipate the qualities. The information parameters are speed, feed and instrument distance across. By methods for utilizing these parameters the yield parameters, for example, push power and torque has been anticipated. The system has been prepared by differing the neurons and the layers. Two-third of the exploratory qualities are utilized for 33% of the qualities are anticipated dependent on the preparation and both the outcomes from trial and Artificial Neural Network are great in understanding as appeared Table. 2-7. Factual qualities and of mixture of Abaca and Hemp, half and half of Abaca and Mudar and cross breed of Hemp and Mudar are appeared Table 8-10 and Scatter Index of above said crossover materials appeared from this correlation of exploratory and ANN results cross breed of Abaca and Mudar machining properties is superior to other two mixture materials.

Conclusion

When all is said in done, the push and torque parameters will for the most part rely upon the assembling conditions utilized, for example, feed, cutting pace, apparatus geometry, machine instrument and cutting device unbending nature. A bigger push power happens for bigger width drills and higher feed rates. As it were, feed rate and drill distance across are perceived as the most noteworthy elements influencing the push power. Destroyed drill might be one of the significant explanations behind the intense increment in the push power just as for the presence of bigger push powers when utilizing multifacet drill than those when utilizing turn drill at high cutting velocity. In any case, we found that the expansion in torque was a lot littler than that in push power, with the expanding cutting rate. The normal torque showing up when utilizing a multifacet drill was bigger than that utilizing the wind drill at low penetrating velocity and the normal torque when utilizing a multifacet drill was littler than that when utilizing turn drill at high boring pace.

Characterization of Roselle & Kevlar hybrid Composites

A. Raveendra, Raghuram Pradhan, Ashok M R, D. Muruganandam, J.Jayapriya

Abstract: ***This paper center essentially around the ongoing patterns and advancements in Bio compounds as connected to the therapeutic and building industry, refering to certain models. Present research is Alkali treated along with Silane treated and untreated fibres hybrid composite was prepared and all the types of physical and chemical properties studied. All the Silane treated composite shown enhanced concert than untreated composite. Performance possessions of composite devising various tenders in textile& non textile. Silane has an added advantage both physical and chemical properties enhancement.***

Keywords: Silane Treatment; Roselle; Kevlar; Hybrid Composites; Structural Bio compounds.

I. INTRODUCTION

customary polymer compounds are non-biodegradable and dirty the earth [1-3]. There is an expanding development of researchers and architects who are committed to limiting the ecological effect of polymer compound creation [4-6]. Natural impressions must be lessened at each phase of the existence cycle of the polymer compound [7-9]. Utilizing common filaments with polymers dependent on sustainable assets will enable numerous natural issues to be unraveled [10-15]. In this day and age, there is an expanding request towards part materials that are sturdy, dependable, lightweight, and with mechanical properties that are fundamentally superior to those of the customary materials. In the meantime it is best if these materials are eco-accommodating and bio-degradable [16-18]. Bio compound substantial has seemed of rewarding the vast common of the above environments. At last, the welfares of employing bio compound substantial, its eco-accommodating wildlife and its imminent in the trade have been demonstrated with lucidity [19-21]. Fig 1 and 2 explain the composites preparation and characterization with treated and untreated fibers.

IV. CONCLUSION

From the Experimental Research of Silane Treatment on said Composites and the results shown in Fig 3 to 7 the following conclusion has been drawn:

- Alkali treated along with Silane treated and untreated fibres hybrid composite was prepared and all the types of physical and chemical properties studied.
- All the Silane treated composite shown enhanced concert than untreated composite.
- Performance possessions of composite devising various tenders in textile& non textile.
- Silane has an added advantage both physical and chemical properties enhancement.

Experimental Research of Wire Cut EDM for SR & MRR using Taguchi Method

A. Raveendra

Abstract: ***The present research work is to examine & advance the latent procedure factors affecting the MRR, SR and Electrode Attire despite the fact machining of Nickel composites utilizing WEDM progression. This exertion includes investigation of the connection amid the different information route considerations like Pulse-on time(Ton), Pulse off time(Toff), Pulse Peak Current(IP), Wire substantial, Work piece material & procedure factors. In light of the picked information parameters and execution estimates L-16 symmetrical exhibit is chosen to streamline the most appropriate qualities for machining for nickel amalgams by WEDM…***

Keywords: Surface Quality; EDM; Taguchi Method;MRR.

I. INTRODUCTION

Wire Cut Electric Discharge Machining process with a slight wire as a cathode changes electrical vitality to warm vitality for cutting materials, WEDM is considered as an interesting reception of the customary EDM process, which utilizes a cathode to instate the starting procedure [1]. The assortments of crop rejoinders with route strictures were numerically confirmed by utilizing non-direct deterioration examination [2]. The models were checked for their ampleness. Consequence of affirmation tests demonstrated that the set up scientific models can foresee the yield reactions with sensible exactness [3]. Be that as it may, WEDM uses a constantly voyaging wire anode made of slender copper, metal or tungsten of breadth 0.05-0.30 mm, which is equipped for accomplishing extremely little corner radii [4-6]. The wire is kept in strain utilizing a mechanical tensioning gadget diminishing the inclination of creating wrong parts [5-7]. During the WEDM procedure, the material is dissolved in front of the wire and there is no immediate contact between the work piece and the wire, wiping out the mechanical worries during machining [8, 9].

II. EXPERIMENTAL PROCEDURE

Examinations have been performed so as to explore the impacts of at least one elements of the procedure parameters superficially finish of the wire cut machined surface. Fig 1 to 8 shows the EDM machine which comprises the input variables and taguchi design and analysis and their process parameters.

4	112	50	210	0.33
5	112	55	220	0.39
6	112	60	230	0.45
7	114	50	210	1.04
8	114	55	220	0.88
9	114	60	230	0.94

IV. CONCLUSION

The target of the contemporary effort is to research the impacts of the different Wirecut EDM progression factors on the machining eminence & the ideal arrangements of procedure factors consequently the nature of machined fragments can be enhanced. Analyses are led on the pieces changing restrictions. The materials utilized for machining are Aluminum combination. Streamlining is finished utilizing Minitab programming..

Abstract: *The joining of dissimilar 6 mm thick aluminum plates for 2014-T6 and 6061-T6 was performed using the technique of friction stir welding(FSW).By using statistical approach optimized parameters for weld process have been obtained for joints. The process aimed at studying the effects of welding parameters on microstructure, tensile-strength and plate hardness. The concept of hexagonal tools was used to examine the effect of rotational speed and weld speed on micro structure and tensile property. The effect of welding speed on microstructures, the distribution of hardness and the tensile properties of weld joints are studied. By changing the process parameters more efficient and low defective weld joints are formed. The most prevalent factor is the fraction between both the shoulder of the tool and the diameter of the pin. It is evident from micro structural study that nugget region was dominated by advancing side material. At 6061 HAZ the hardness is found to be minimal, where weld joints are failed during the tensile studies at the ends of the HAZ.*

Keywords: **Friction stir welding, Dissimilar alloys, Al alloy 2014T6 and 6061T6, taguchi optimization method**

1. Introduction

1.1 Basic introduction regarding FSW

"Friction Stir Welding is a technique invented by Thomas for joining of novel material, in 1991, the welding center, TWI"[1]. "FSW has become one of the most important solid-state joining processes in recent years, and it consumes considerably less energy. Especially given the advantages they offer in design and manufacture over existing mechanical joining methods. Although a number of welding methods for airframe structures have been established, friction stir welding is an important candidate technique that is distinctive in being a low-energy, solid-state process"[2]. "FSW is a method of hot-shear joining in which a non-consumable, rotating device plunges through a rigidly clamped piece of work and travels along the joint to be welded" [3]. "The rotating tool is a cylindrical shape consisting of a shoulder and a pin; the profiled pin may be threaded or unthreaded while the length may be lower than the shoulder-extruding weld depth. The FSW process starts by plunging the tool into the joint until the shoulder is in contact with the work piece surface. The rubbing motion of the tool shoulder produces heat as the tool is moving along the joint. Shoulder is responsible for heat generation and the containment of the plasticized material in the weld region, while pin combines the material of the components to be welded, forming a joint" [4].

1.2. Working theory

The FSW mainly have four essential stages: The rotating tool reaches the surface of the metal work piece during the penetration or plunging process and pierce into the metal producing the primary heat. The residential method involves achieving the operating temperature needed to start the welding before a steady downward force between the tool and the work piece is achieved, which generates the energy of friction between them. This cycle goes on till the pressure force between both the FSW instrument and the surface of the metal working component slowly decreases, indicating that the temperature required to start welding has been reached. Complex thermo-mechanical operation includes the welding point. The constant frictional energy produces high temperatures at the joining of the plates which soften the material. As the tool goes forward in the direction of welding the material of both the joining work pieces are combines with each other with the help of the pin. The last step is the returning process. When rotating tool gets to the end of the joining line of the work pieces it retracts vertically. "The friction

stir welding process is very effective method for mechanical improvement of semi solid metal Al alloy"[10]. The operational principles of the FSW process are shown in below figure

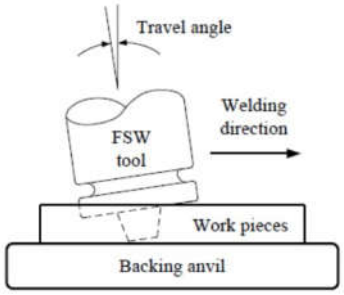

Figure 1.

2. Literature Review

- "Liu Hui performed 2219 aluminum alloy underwater friction stir welding to improve the weld properties. During normal friction stir welding, which is significantly involved in reducing the hardness, coarsened grain was achieved. Due to the precipitates dissolved in the matrix, high-density dislocations and refined grain structures were formed in submersed friction stir joint. This leads to improved welding properties, such as hardness and tensile strength"[6].
- "Basil Darras addressed AZ31 magnesium alloy friction stir processing under natural and submerged conditions and its inherence to tensile properties, grain structure, power consumption and thermal fields. For FSP in the air, average grain size of 18.9 μm, 15.9 μm, and 13.3 μm was achieved, submerged respectively in hot water and cold water. In cold water conditions more grain refining was achieved"[7].
- "Huijie Zhang demonstrated that 2219-T6 aluminum alloys had a submerged friction stir welding. In this, the most important parameters are rotational and welding speeds which affect the tensile strength of the welded sample. The ultimate tensile strength of 360 MPa in optimized condition was obtained via SFSW. This value of SFSW tensile strength is 6 per cent higher than the normal FSW"[6].

3. Experiment Materials And Methods

3.1. Materials

The friction stir welding technique can be successfully welded to a range of materials, including low - melting metals and higher melting metals. A broad variety of materials are able to weld by using FSW, including Al, Al alloys, Fe alloys, Cu alloys, brass, Mg alloys, Ti alloys, Ni alloys, Ag and Au. FSW does not only combine related metals but also dissimilar metals.

Al-2014-T6: 2014 can be used as a high-strength casting material for different uses. It contains a fairly high volume of copper, and is thus less resistant to corrosion. Adequate anti-corrosion treatment when exposed in a corrosive environment is required.

Al-6061-T6: This type of alloy has outstanding strength and resistance to corrosion, and is used as a material of the structures. 6061 has improved strength by adding small amounts of Cu. Although its corrosion resistance is somewhat lower, it has an excellent casting property and is therefore used for rivet materials and small car components. If the hardness is 254N / mm2 or higher and deflection is not a issue in design, the advantage of the allowable stress equal to that of SS400 steel is. 6063 is low in strength but has an excellent extrusion property. So it is used as a material of structure that does not have to be as strong as 6061.

3.2. Tool design:

During the improvement of the FSW process it was realized that the tool design is crucial to the production of sound welds. The working tool is one of the most critical components of FSW operation. The tool consists of different design specifications according to work types, which material to be plate or sheet thickness. The tool contains shoulder and profile pin. The shoulder takes place at the base of the pin profile and pin pace penetrates only through the working materials. The tool shoulder purpose is to monitor the material flow and during operation the pin deforms the grain size of the working material.

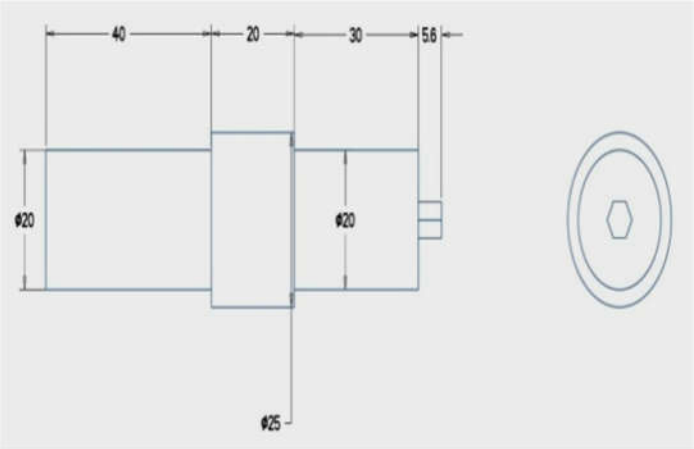

Figure 2 fsw tool design

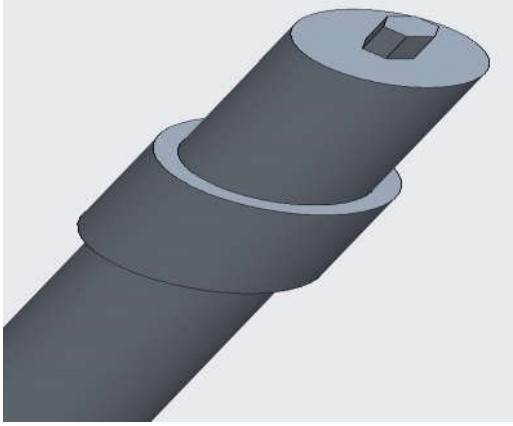

Figure 3 fsw tool design

3.3. Taguchi methodology

"Genichi Taguchi developed mathematical methods known as taguchi methods, and these methods are one among very effective DOE methods of experimental research. The quality of manufactured products can be used to enhance by using these technique and also these methods are recently applied to biotechnology, marketing and advertisement engineering. He first applied his methods was Toyoto. Robustness of the product, pioneered by Taguchi, uses experimental design to study the response surfaces associated with both the product means and variances to select suitable factor settings so that variance and bias are both small at the same time. Designing a quality product requires knowledge in making the response variable immune to unmanageable variation in the production system or client's requirements of using the item"[5]. In this study, there are 18 DOF's due to three independent parameters around three points, so that A L9 orthogonal array is used

4. Experimental Procedure

4.1. Workpieces

The FSW study is important in order to incorporate the welding of Al material into a broad range of industrial applications and to improve the use of environmentally sustainable production processes. Two dissimilar AA6061T6 and AA2014T6 Al plates with thickness about 6mm was butt weld by FSW along the joint line shown in Figure for the following experiments. The samples were cut lengthwise to 140 mm and width to 100 mm.

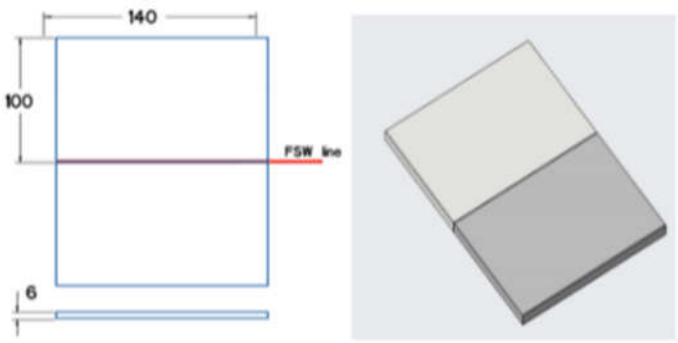

Figure: 4 butt-weld along line

The physical and mechanical property of the work pieces plays a major part in most areas like weldability and selection of the tool materials. Tables 1-6 outline the physical and mechanical properties of the aluminum sheets used in experiments. Table 3,6 shows the chemical compositions of 2014 and 6061 Al alloys. Vertical milling machine is used to do the welding process.

In this study HSS material is used for welding tool, because HSS has high resistance thermal fatigue. The shoulder surface is flat with diameter is 20mm and the shape of the pin is -hexagonal with height of 5.7mm. The complete toll design is shown in the fig

Figure:5 hexagonal tool design as shown in figure 2,3

Table 7 outlines the weld parameters of this study. Due to its higher mechanical strength AA2014 plates were kept on the tool forwarding side and positioned the tool pin at centre of the weld line.The aluminum plate sets are fixed to machine firmly, using the parameters shown in the table 7 tests are made using different weld speed and tool rotation speed.

TABLE-7 below table shows Weld parameters used

Trail no.	Tool Rotation speed(rpm)	Tilt angle (°)	Weld Speed mm/min

For the study of micro-structure of the welded samples of different aluminum alloys they undergo series of grinding process and finally to a disk polishing machine where specimens finished their final stage of grinding, then on grinding surface Keller's reagent was used and cleaned with water for microstructure study. Optical microscopeused to evaluate the microstructure characterization.

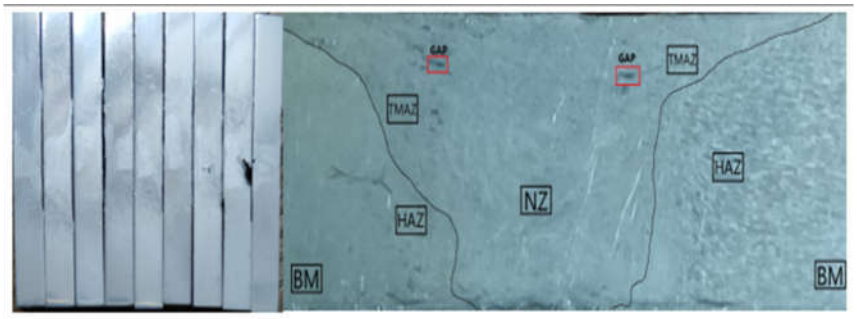

Figure:6 figure shows different zones in weld joint

The weld samples are made as per the ASTM E8 standards for tensile studies, and tensile tests are performed at a strain rate of 0.5mm/min. Micro hardness was performed at a load of 100gf with a dwelling time of 10secs and a distance of 0.25 mm through the weld.

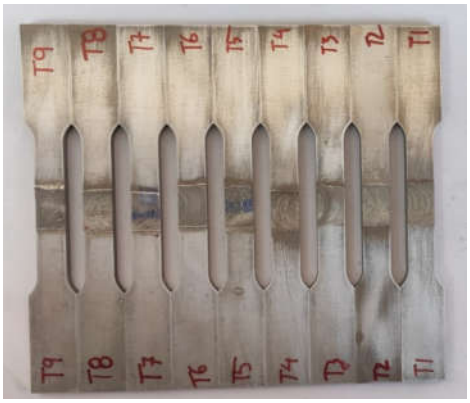

Figure:7 figure shows samples for tensile test

5. Result and Discussion

5.1. Microstructure

Below fig.6 shows the welded different material microstructure of various areas. Even if the weld passes through significant number of heat cycle, the main materials microstructure does not change significantly. The thermal cycle, on the other hand, HAZ is significantly influenced, that is visible from the microstructure. But, plastic deformation does not happen in the HAZ. Because of less heat produced and the plastic deformation in the process there is considerable growth in grain boundaries in the TMAZ area. It is also evident in the microstructure that the recrystallized zone (welded nugget) is separated by a distinct grain boundary from the deformed TMAZ areas. "The stirred zone is the dynamically recrystallized area, in which the material has undergone severe plastic deformation resulting in fine equiaxed grains"[8]. The word stirred zone is widely used in friction stir processing where the material is processed in appropriate volume. "Further to the weld nugget microstructure (Figure 6), it is obvious that the grains are highly refined, that may boost welding strength" [9]

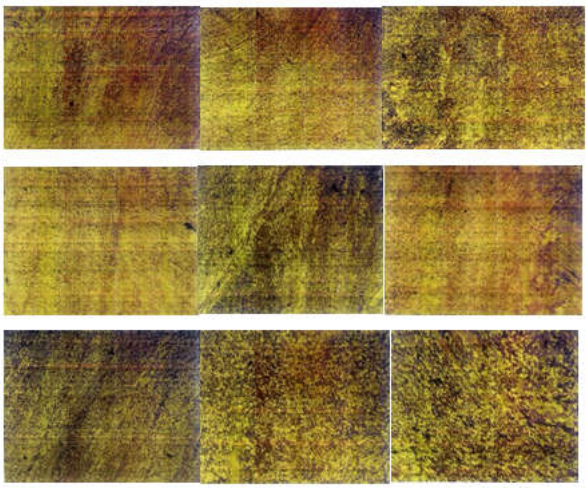

Figure:8 figure shows the microstructure results of the 9 test specimens

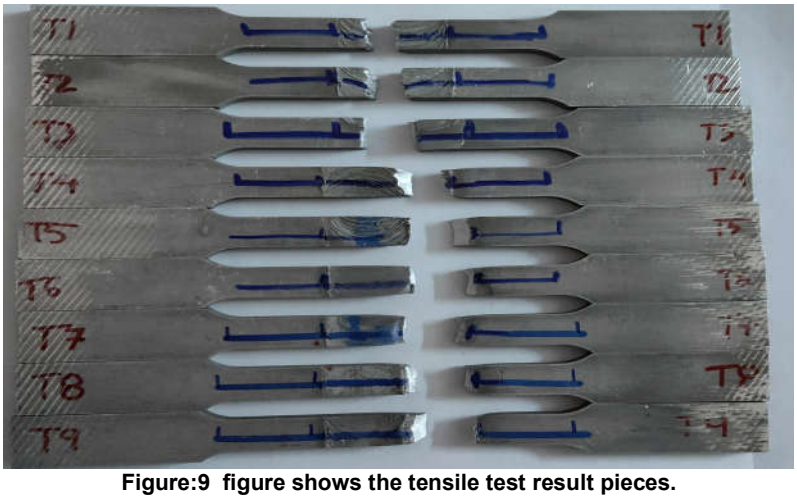
5.2. Tensile test

Using hexagonal pin, the highest weld strength was 184N / mm2 and 187 N / mm2. The fracture occurred at 6061 HAZ side as shown in fig 9. The welded specimen displays lower force as the tool rotating at low speed. Joint efficiency has been achieved by 80%. The welded specimens exhibit high strength when the weld speed with lower tool tilt angle is high.



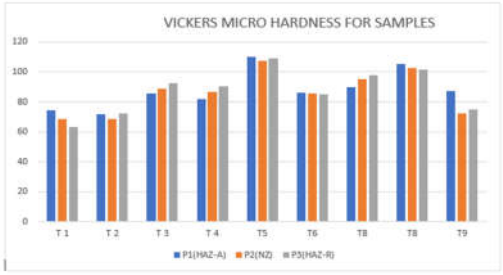


Figure:9 figure shows the tensile test result pieces.

Table:8 table noted the tensile test values

Test specimen number	Tensile strength values (N/mm^2)
1	166.605
2	145.095
3	155.983
4	187.934
5	164.137
6	179.392
7	184.612
8	179..274
9	174.460

5.3. Hardness

Tests are conducted for Vickers hardness around diverse weld spacing zones of (1 mm). Hardness aggregate of 105.15 HV is obtained by this welding for hexagonal pin. At weld nugget area the durability is slightly lesser than AA2014; while, the durability is significantly greater than AA6061 material and thermo mechanically affected zone.

Graph: 1graph represents the hardness values in bar chart

Table: 9 hardness values of the table

Sample-no.	Hardness Values
T1	63.0, 74.5, 68.3 HV0.2
T2	72.2, 71.5, 68.8 HV0.2
T3	92.3, 85.4, 88.9 HV0.2
T4	90.3, 82.1, 86.8 HV0.2
T5	109.1, 110.3, 107.4 HV0.2
T6	85.1, 86.2, 85.4 HV0.2
T7	98.1, 89.7, 95.4 HV0.2
T8	101.7, 105.4, 102.8 HV0.2
T9	74.8, 51.3, 66.1 HV0.2

6. Conclusion

The Taguchi approach was used in this analysis to obtain optimized process parameters of AA2014T6 and AA6061T6 for FSW. In 2014T6 and 6061T6 aluminium alloys, the influence of rotating tool speed, speed at which welding is carried out and inclination angle of tool on the joint excellence was established. The tensile strength was found to be raised with the raise in speed from 900 - 1400 rpm. The raise in tool forwarding speed from 20mm / min to 30mm / min has also been found to increase the hardness. Visual inspection was understood from the trial and error methods that rotation speed of 900 rpm and below surface defects were extremely prominent and poor welding joints were developed. The FSW joint, manufactured with optimized parameter of 1120 rpm rotational speed, 0 tilt angle and 25mm / min weld speed, exhibited a higher tensile strength of 187.9 N / mm2. Rotation speed of the tool was the main contributing factor to the tensile strength.

Manufacturing of Foot step power generation by using rack and pinion motion with suspension spring.

[1]Mr. S. Udaya Bhaskar, [2]A. Paul Praveen,

[1,2]Associate Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

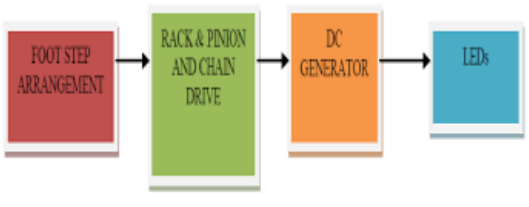
ABSTRACT:

In this project we are generating electrical power as non-conventional method by simply walking or running on the foot step by using rack pinion methods. Non-conventional energy system is very essential at this time to our nation. Non-conventional energy using foot step is converting mechanical energy into the electrical energy. This project using simple drive mechanism such as rack and pinion assemble and chain drive mechanism.For this project the conversion of the force energy in to electrical energy. The control mechanism carries the rack & pinion, D.C generator, battery and inverter control. We have discussed the various applications and further extension also. The D.C generator used in this project is Permanente Magnet D.C generator. The Generator is coupled to the fly wheel Shaft with the help of Spur Gear Mechanism.

Keywords: Footstep, Conventional Energy,Non-conventional Energy system.

1.INTRODUCTION

In this project the weight which acts on the foot step is used to generate electrical energy. When a person walks over the foot step, a force acts on the step. One can simply be amazed by knowing how much energy a person can have just by walking on the floor with normal speed. Whenever a person walks, manages to lose energy towards the floor by means excess weight to the floor. That energy may be used and converted into electrical energy. The Mechanical energy(weight)is converted into electrical energy using drive mechanism, in this case rack and pinion. Generated energy can be stored in batteries. Then the output of the battery is used to lighten the lamps in the room.



2. PROBLEM STATEMENT

Design and fabrication the model of foot step power generation. Also to fabricate the model of the same which would able to show the characteristics of the systems and working according to need.

3. OBJECTIVES

To design and develop the model of Stair case power generation. o fabricate the model which will work on the systems for required application

4. METHODOLOGY

5. LITERATURE REVIEW

[1] "PowerGeneration in Automobile Suspension System" by C.NithiyeshKumar,K.Gowtham, M.Manikandan, P.Bharathkanna, T.Manoj Kumar In this research paper author studied three methods of foot step power generation namely piezoelectric method, rack and pinion method and fuel piston method comparatively and found that the rack and pinion mechanism is more efficient with moderate cost of operation and maintenance

2] "Generation of Electrical Energy from Foot Step Using Rack and Pinion Mechanism" by Md.Azhar, ZitenderRajpurohit, Abdul Saif, NallaAbhinay, P.Sai Chandu In this research paper authors used regulated 5V power, 500mA power supply. Bridge type full wave rectifier is used to rectify the ac output of secondary of 230/12V step down transformer. A rack and pinion is a type of linear actuator including a pair of gears which convert rotational motion into linear motion. The "pinion" engages teeth on the rack. In this paper, since the power generation using foot step get its energy requirements from Non-renewable source of energy. There is no need of power from external sources (mains) and there is less pollution in this source of energy. It is very useful to the places like all roads and as well as all kind of foot step which is used to generate the non-conventional energy like electricity.

[3] "Electrical Power Generation Using Foot Step for Urban Area Energy Applications" by Joydev Ghosh, Amit Saha, Samir Basak, Supratim Sen. In this research paper authors used 80 volts and 40 mA from one coil have been generated from a prototype model as first invention. The second invention provides 95 volts and 50 mA from one coil and this generated power can be used to light LED array and to run DC fan after rectifying the AC or can charge batteries. For high efficiency in the axel of the second gear, they fitted a strong magnet vertically, so that when the gear will rotate due to human body weight the magnet also rotate. The magnet is placed in a loop type copper coil. When the magnet start rotating according to the Faraday's law of electromagnetic induction, there will be induced emf in the coil.

[4] "Power generation through step" by Vipin Kumar Yadav1, Vivek Kumar Yadav1, Rajat Kumar1, Ajay Yadav In these research paper authors used equipments with following specification: Motor Voltage:10 volt Type: D.C. Generator, RPM:1000 rpm, Gear 1-Mild Steel,No. of teeth:59(big gear),No. of teeth:36(small gear),Type: Spur Gear, No. of gear used:2 Spring 1-Load bearing capacity:60-90 kg, Mild Steel,Total displacement:5 inch, Bearing 1- Type: Ball bearing, Bearing no.N35,Shaft 1-Diameter: 15 mm- Material: Mild steel author concluded that with these method energy conversion is simple efficient and pollution free.

[5] "Power Generation Footstep" by Shiraz Afzal, Farrukh hafeez This paper is all about generating electricity when people walk on the Floor if we are able to design a power generating floor that can produce 100W on just 12 steps, then for 120 steps we can

produce 1000 Watt and if weinstall such type of 100 floors with this system then it can produce 1MegaWattAs a fact only 11% of renewable energy contributes to our primary energy. If this project is deployed, then not only we can overcome the energy crises problem but this also contributes to create a healthy global environmental change. In this project a gear system is attached with flywheel which causes to rotate the dynamo as the tile on the deck is pressed The power that is created is saved in the batteries in addition we will be able to monitor and control the amount of electricity generated When an individual passes it push the tile on the ground surface which turn the shaft beneath the tile, turn is limited by clutch bearing which is underpinned by holders. Primary shaft is rotate approx. twice by a single tile push. The movement of the prevailing shaft turn the gearbox shaft which builds it 15 times (1:15) then its movement is smoothen by the help of fly wheel which temporary store the movement, which is convey to the DC generator (it generates 12V 40 amp at 1000 rpm).

[6] “POWER GENERATION FROM STEPS” by Ramesh Raja R, Sherin Mathew This research paper attempts to show how energy can be tapped and used at a commonly used floor steps. The usage of steps in every building is increasing day by day, since even every small building has some floors. A large amount of energy is wasted when we are stepping on the floors by the dissipation of heat and friction, every time a man steps up using stairs. There is great possibility of tapping this energy and generating power by making every staircase as a power generation unit. The generated power can be stored by batteries, and it will be used for slighting the building.

[7] "Electricity Generation from Footsteps; A Regenerative Energy Resource” by Tom Jose V*, BinoyBoban*, Sijo M T* In these research paper author manufactured a model made from stainless steel, recycled car tires and recycled aluminium, also includes a lamp embedded in the pavement that lights up every time a step is converted into energy (using only 5 percent of the generated energy). The average square of pavement produces about 2.1 watts of electricity. And according to author, any one square of pavement in a high-foot traffic area can see 50,000 steps a day. Based on this data, only five units of Pavegen pavement can be enough to keep the lights on at a bus stop all night.

6. WORKING

The complete diagram of the power generation using foot step is given below. The pushing power is converted into electrical energy by proper driving arrangement. The rack & pinion, spring arrangement is fixed at the upper plate and lower plate. The spring is used to return the plate in same position by releasing the load. The gear wheel is coupled to the smaller motor shaft. The generator is used here, is permanent magnet D.C generator. This arrangement is fitted in FOOT STEPs; the complete arrangement is kept inside the floor level except the pushing arrangement. Basic Components: It consists of the following main parts:

1. MS plate

2. MS Pipes

3. Rack and pinion

4. DC motor

5. FRAME

6. LED lights Etc

7. ADVANTAGES

1. Power is generated simply by walking on the step.

2. Power also generated by running or exercising on the step and implementing this mechanism on treadmills.

3. No need input fuel for power generation.

4. This is a Non-conventional system.

5. Battery is used to store the generated power else we can use directly this generated power for conventional purposes.

8. DISADVANTAGES

1. High Initial Cost

9. APPLICATIONS

1. This can be implemented on railway stations, bus stops, air ports to generate electric power by human physical activity.

2. Also can be implemented in parking lots, electric escalators.

3. This mechanism can be implemented on gymming instruments like cardio machine for power generation and the power generation rate is high.

4. We can use this mechanism in automobile suspension system.

5. In rural areas etc.High Initial Cost

10. CONCLUSION

In concluding the words of our project, since the power generation using foot step gets its energy requirements from the non-renewable sources of energy. There is no need of power from the mains and there is less pollution in this source of energy. It is very useful to the places like all roads and as well as all kind of stair case which is used to generate the nonconventional energy like electricity. It is able to extend this project by using same arrangement and construct in the footsteps/speed breakers so as to increase the rate of power production rate.

ABSTRACT

In this paper, a gear shifting mechanism was designed and applied to make the shifting process more expeditious and less destructible for the driver. The incipient contrivance must be reliable, has a diminutive dimensions, low construction and maintenance cost. This paper aims to gear shifting process utilizing contrivances as: a manual four speed gear box, two pneumatic double acting cylinders, , an electrical motor , limit switches, buttons, , a table (holder) and power supply. According to suggested gear shifting mechanism the control unit select optimum gear shifting ratio for an automobile without operating it manually (utilizing relays). Utilizing this method leaves to the driver the exhilaration of selecting the shifting moment.

Key Words: pneumatic cylinders, Solenoid valves, gear box, gear shifting mechanism, electric motor.

INTRODUCTION

In this project, a gear shifting mechanism is designed and applied to make the shifting process more expeditious and less destructible for the driver. The incipient contrivance must be reliable, with minute dimensions, low construction and maintenance cost. This project aims to ameliorate gear shifting process utilizing contrivances as: a manual four speed gear box, two pneumatic double acting cylinders, two pneumatic two position five ways directional control valves, , an electrical motor, a belt, two pulleys, limit switches, push buttons, bulbs, a table (holder) and power supply. According to suggested gear shifting mechanism the driver can cull the transmission gear ratio without moving his hands from the steering wheel by putting the gear shifting push buttons on the steering wheel. Utilizing this method leaves to the driver the exhilaration of culling the shifting moment. This study describes in detail in an simple way to how to convert the traditional manually gear shifting mechanism to a semi-automated gear shifting mechanism. The development has concluded withal the gearbox, which became much smoother and engenders less noise. Gear shifting mechanism must be facile to utilize and workable, these authoritative ordinances are very paramount especially for minute cars utilized by special needs people. For some drivers, the gear shifting can cause some perplexing at driving specially at critical situations. A crowded road on a hill or a sudden detour makes an abundance of tension on the driver. One of the difficulties in this situation is to operate the right reduction ratio and engaging it at the

right time. This design avails the driver to increment his fixating on the road. Withal reduces the time needed to engage the required. Reduction ratio, which increases the conveyances replication, this design may be considered as an inculcative model for gear shifting mechanism. So, we pointed to the following: 1. The opportune dimensions for the main components holder keeping in mind the integration of other part for enhancement and development. 2. A manual, 4-frontal speed gear box is utilized automobile drive is culled for this design because it is more facile to modify. 3. An electrical motor is utilized to engender mechanical power in lieu of an internal combustion engine, which is arduous to be placed there. It is additionally used to make the engagement process more facile .Motor is variable speed (0 to 9000 rpm) 4. A couple of pulleys and a belt are acclimated to transmit power from the electrical motor to the gear box. 5. To eschew binding in the input shaft caused by the radial force, we utilized a bearing fine-tuned on the holder. 6. We used two pneumatic, double acting cylinders, per pair of gear shifting. 7. Two (five ways, two positions) directional control valves are habituated to transmute the compressed air direction. Every directional valve has 230V ac solenoid that converts electrical power to magnetic puissance, which magnetizes the spool inside the valve; this action transmutes the compressed air direction.

2. OBJECTIVE

The main objective of this system is to minimize the human errors in operating the gears with the avail of automatic technology. Other objectives include optimum gear ratios, reducing wear and tear of the gears, shifting the gear efficaciously, optimum performance of the gear box, optimum force exerted by the cylinders to move the shifting levers (pedals).

3. MODEL COMPONENTS

3.1 Base Frame

The base frame is a structural element that fortifies the entire gear box system. The frame carries the drive system at its lower end which comprises of the LH and RH rear bearing housings. The drive motor is mounted on the base frame.

3.2 Drive system

Drive system comprises of the single phase AC commutator motor with following designations

• Single phase AC moto

r • Commutator motor

• Power = 1/15hp=50 watt

• Speed= 0-6000 rpm (variable)

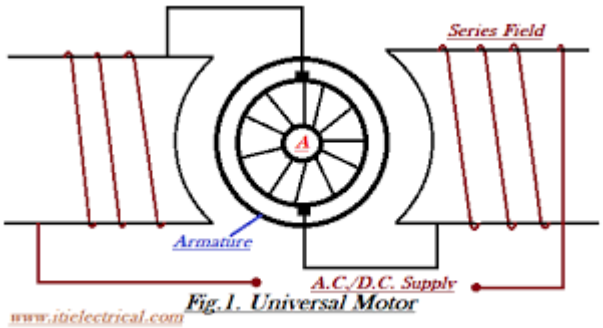

Fig -1: AC commutator Motor

3.3 Pneumatic linear actuator

The pneumatic linear actuator is an Standard cylinder SDA 20 x 15.This cylinder is an double acting cylinder that is operated by an pneumatic valve5/2 way. The valve is supplied compressed air from the compressor by

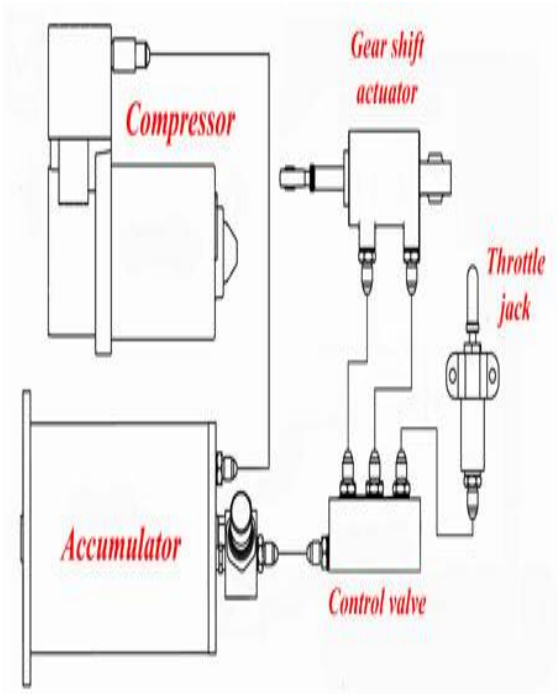
denotes of an a AGB operates filter-regulator-lubricator (FRL) unit. This linear actuator is utilized in the following positions, a. 1st gear b. 2nd gear c. 3rd gear d. 4th gear

3.4 Shifter mechanism

The shifter mechanism is an assemblage of levers actuated by the linear actuator as mentioned above. This shifter is mundanely in neutral condition; it shifts the gears at commencement of cycle and releases it at cessation of cycle

. 3.5 Position control system

The position system comprises of the following components; a. 5/2 ways, Solenoid operated, center off, and detent type b. Pneumatic cylinder DPNC connectors The details of this relay system are given in the circuit diagram of the pneumatic system



4. CONSTRUCTION DETAILS

The two solenoid valves are connected to a compressor with the avail of hoses of Ø6mm from which pressurized air is extracted. The solenoid valves are followed by two pneumatic cylinders with the avail of air hoses. The cylinders are followed by a clutch pedal. Contiguous to the clutch pedal gear box and a motor arrangement is present. The construction withal includes a proximity sensor which senses the haste of the wheel. The precise signals are sent tothe solenoid valves by the control unit through the relays. Ergo the input is speed of the wheel sensed by a sensor and the output is shifting of gearaccordingly. The puissance to the control unit is supplied from the 12V battery as well the shifting of gear monitored on an LCD. It withal consists of DC motor, ATMEGA Development board, speed regulator (expeditor), transformer etc.

5. WORKING PROCEDURE

The pneumatic circuit is as shown in fig.2,the motor is started to drive the main shaft by means of belt and pulley arrangement, initially the gear box is in neutral i.e., the output shaft is stationary condition. When the 5/2 way direction control valve -1 is operated the cylinder -1 operates the piston to move in the right hand direction thereby bringing the 3rd gear into engagement, and thus the output shaft starts to rotate thereby transmitting power from the input (motor/engine) to the output (differential). Fig -2: Electro-Pneumatic gear shifting mechanism The flow control valve in the circuit governs the pressure which is of the order of 1.5 to 2 bars, hence the governed pressure causes the gradual push provided to the piston rod which brings about gradual engagement of the gears hence, (effect of gradual clutch release for smooth engagement is not required). When the 5/2 way direction control valve -2 is operated the cylinder -2 operates towards left as the piston rod is locked for movement left , hence first the fork shifter moves towards left bringing on the neutral position and then slides further left to bring the 1st gear into engagement. Similarly the circuit works for the 2nd and 4th gear. Note: If both the valves i.e., 5/2 way direction control valve - 1&2 are operated simultaneously, the system is arranged such that neutral position will be

achieved, hence the system becomes fool proof.

6. CONCLUSION

The pneumatic gear changer was designed and checked for successful working. It was found to be running successfully under all the conditions. By the results, the suggested mechanism is realizable and workable. Using the simplest and required hardware enables to convert the old traditional gear shifting mechanism to semiautomatic one. Using of this mechanism in vehicles leads to make the driving process easier, reduces the risk of destabilizing the car, the lap/stage time, and the chance of miss shifting.

Rack and pinion motion-based Head light tilting system

[1]Dr.Zaheer Ahamed T [2]A. Paul Praveen, [3]N. Rishi Kanth

[1,2,3]Associate Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract

A regulation system of one or more supports of the domes of the headlights in a vehicle having a chassis a rear wheel at least one front steering wheel and a roll and steering mechanism operatively connected with the chassis is described. The regulation system comprises articulated connection means between the roll and steering mechanism and the supports for controlling the domes of such headlights so that they rotate such to compensate the roll rotation of the vehicle while driving.

Keyword: -Rack & pinion, Head light, front wheel steering with Ackerman's principle.

INTRODUCTION

Car safety is the avoidance of automobile accidents or the minimization of harmful effects of accidents, in particular as pertaining to human life and health. Special safety features have been built into cars for years, some for the safety of car's occupants only, and some of the safety of others. One of the choices available is Design and fabrication of steering controlled head light system. This device relates to a headlight arrangement for vehicles, and, more particularly, to a head light arrangement operably connected to the steering mechanism of the vehicle for illuminating the proposed path of travel including support brackets operable to support head light members thereon connectable to a frame portion of the vehicle, linkage means interconnecting the brackets for conjoint movement thereof, and means interconnecting one of the brackets to the connector rod of the vehicle whereupon the brackets and headlight members are moved in relation to the direction of vehicle travel. Still, more specifically, this device relates to a headlight arrangement operably connected to the steering and front wheel assembly of an automobile operable to maintain headlight members and front wheels pointed in the same direction at all times.

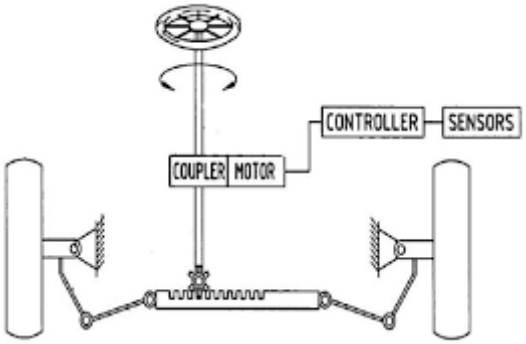
Objectives

The main objective of this system is to apply automotive vehicle.

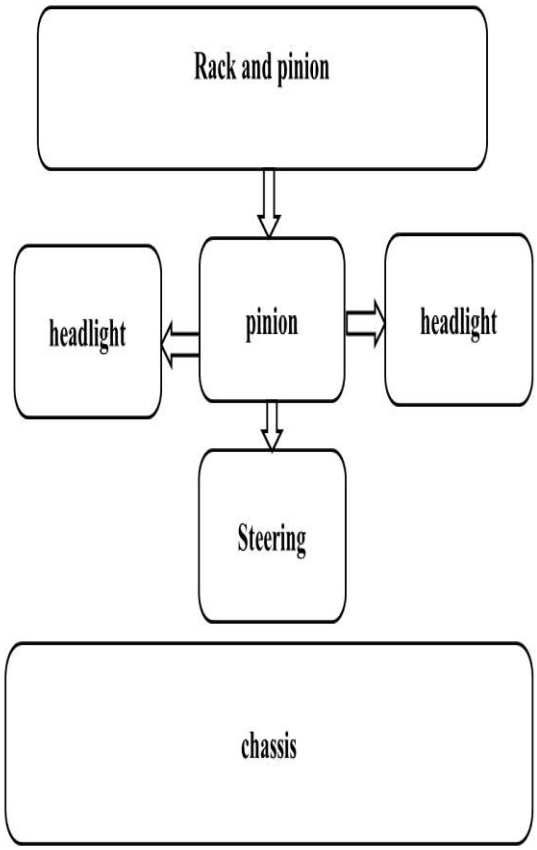
- To move the headlight along with steering on sharp turning.
- To keep the headlight beam parallel to road turning as possible as can.
- To change the place of area illuminated by headlight and direct illumination area of headlight in useful direction.
- To improve the visibility area of driver at night so that driver can judge road turning well.
- To prevent road accidents on sharp turning at night specially in hilly areas.
- To increase safety at night.

. **LITERATURE REVIEW**

The present invention relates to a vehicle front lamp light distribution control system and more particularly to a vehicle front lamp light distribution control system capable of raising visibility at the time of cornering by controlling light distribution means of the front lamp. According to1. Japanese Patent Publication No. H5-23216, 2. Japanese Patent Application Laid-Open No. H8-183385, 3. Japanese Patent Application Laid-Open No. H11-78675, and 4. Japanese Patent Application Laid-Open No. H8-192674 Laxmi et al. [1] Design &Fabrication of steering controlled headlights in automobile states, A vehicle head lamp including a fog lamp is provided with a movable reflector and by turning the movable reflector in the steering direction by an amount corresponding to a steering angle of the steering wheel, the light distribution pattern of the front lamp is changed in the direction of vehicle's turn so as to raise visibility at the time of cornering However, according to the aforementioned earlier art, the light distribution pattern of the front lamp is changed in the steering direction of the steering wheel by an amount corresponding to the steering angle when the vehicle turns on an intersection or the like, cornering destination cannot be beamed brightly enough before operating the steering wheel. Therefore, an t capable of beaming the cornering destination prior to operation of the steering wheel has been demanded. Czech Tetra and 1920s Ca dills were early implementer of such a technique, producing in the 1930s a vehicle with a central directional headlamp. The American 1948 Tucker Sera was likewise equipped with a third central headlamp connected mechanically to the steering system. The 1967 French Citroën DS and 1970 Citroën SM were equipped with an elaborate dynamic headlamp positioning system that adjusted positioning in response inputs from vehicle steering and suspension systems, though US regulations required this system to be deleted from those models when sold in the USA. Presently, studied changes are unfolding in automotive lighting technology. Automobile manufacturers - together with suppliers and representatives - currently aspire to develop the headlights of tomorrow. Freeform headlamp is one of the popular design which offers great flexibility and compactness. They suggested that the apparatus for automatically adjusting a direction of a light axis of a vehicle headlight includes a steering angle sensor detecting a steering angle of a steering wheel of a vehicle and a swivel control unit performing swivel control by which the direction of the light axis of the vehicle headlight is adjusted to the target direction in accordance with the steering angle detected by the steering angle sensor. Proposed automatic optical-axis adjusting device for automatically adjusting direction of optical axes of front lights with respect to steering angle of steering wheel An electronic control for automobile headlight utilizing a spherical sensor comprised of a metal ball surrounding by a fluid encapsulated in a spherical sensor which is connected to the spherical sensor system. The automatic optical axis adjusting device for automatically



adjusting direction of optical axis of from lights headlight control apparatus and method controls an irradiation direction of a headlight. This apparatus uses a navigation based swivel angle calculated based upon the shape of a road in a navigation based control period and a steering based swivel angle calculated based upon a steering angle in a steering based control period [2] The optical design, fabrication and the measurement of the freeform reflector headlamps are investigated by Shinde G. et al. [3] proposed the new standard for cornering light system allows not only the conventionally approved ONOFF control mode interlocked with the operation of the turn signal switch but also an automatic ON-OFF control according to the steering wheel angle. The active cornering light system (ACL system) on the new DELICA D: 5 have a dedicated ECU to control the operation of the lamps. On-dong line investigated by car light piloting system objective of the present invention is to provide a steering wheel controlled car light pointing system which automatically turns the lights of the motor car to coincide the projection of the lights with the steering direction of the motor car



WORKING

Steering system is to achieve angular motion of the front wheels to negotiate a turn. This is done through linkage and steering gear which convert the rotary motion of the steering wheel into angular motion of the front road wheels. The parts of steering system are consisting of Steering linkage and Steering gear. Steering Linkage-it depend upon the type of vehicle, wither it is a car which has independent front suspension. Steering linkage for vehicle is defining two types like as Steering Linkage for Vehicle with Rigid Axle Front Suspension and Steering Linkage for Vehicle with Independent Front System.

1 Rack and Pinion Steering Gear:

The rotary motion of the steering wheel is transmitted to the pinion of the steering gear through universal joints. The pinion is in mesh with a rack. The circular motion of the pinion is transferred into the linear rack movement which is further relayed through the ball joints and tie rods to the stub axles for the wheel to be steered. In the figure shows the schematic and actual modal of steering gear mechanism.

CONCLUSION

In the view of forgoing disadvantages inherent in the known types of road tracking headlamps now present in the prior art, the present invention provides a new movable vehicle head light construction wherein the same can be utilized for automatically aiming the head lamps in the same direction of the travel regardless of the terrain of the road. The further object of the system is, this is susceptible of a low cost of manufacturing with regard to both cost and labor and which accordingly is then susceptible of low prices of sale to the public.So there by making such movable vehicle head lamps which are economically low to available to the public

Railway track based power generation with rack and pinion mechanism

[1]Dr.Zaheer Ahamed T, [2,] Mr. S. Udaya Bhaskar, [3]A. Paul Praveen, [4]N. Rishi Kanth, Mr. Yogesh Madaria

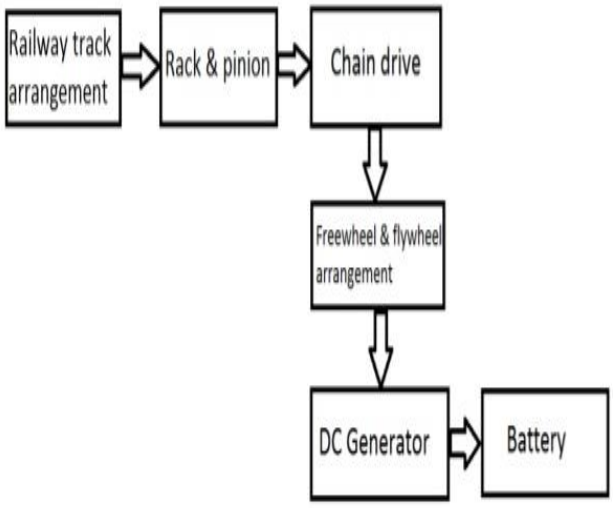
[1,2,3,4,5]Associate Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract:

This project using simple drive mechanism such as tension spring assemble and link mechanism. For this project the conversion of the force energy in to electrical energy. The control mechanism carries the rack and pinion, Dynamo generator, battery and inverter control. So this project is implemented to all railway track, the power generation is very high. The initial cost of this arrangement is low. Used energy at an increasing rate for his requirement.**The principle** of this project is conversion of mechanical energy in the form of force into electrical energy.

KEYWORDS: Energy, Energy Harvesting, Non-conventional Method, Rail Road

INTRODUCTION



Man has needed and used energy at an increasing rate for his requirement. Man required energy primarily in the form of food. He derived this by eating plants or animals, which they hunted. With further demand for energy, man began to use the wind for sailing ships and for driving windmills, and the force of falling water to turn water for sailing ships and for driving windmills, and the force of falling water to turn water wheels. Till this time, it would not be wrong to say that the sun was supplying all the energy needs of man either directly or indirectly and that man was using only renewable sources of energy. World is growing at the faster rate with regards to consumption of fuel and so the scarcity of energy as the sources producing them are depletable in nature. Around the world, there were 8,06,000 cars and light trucks on the road consuming 260 billion US gallons 980000 liters of gasoline yearly. The extensive usage of energy has resulted in an energy crisis and there is a need to develop methods of optimal utilization. Which will not only ease the crisis but also preserve the environment. Commuter rail and subway are including railway transportation which play an important role in the economy and quality everyday life. Researches show that the world has already had its enough shares of its energy resources. Fossil fuels pollute the environment , Nuclear energy requires careful handling of both raw as well as waste material. The focus now is shafting more and more towards the renewable sources of energy. which are essentially nonpolluting. In the present day scenario power has become the major need for human life. Energy is an important input in all the sectors of any countries economy. The

increasing population and decreasing conventional sources for power generation. provides a need to think on non-conventional energy resources. To facilitate policymakers and transportation into making informed decisions on operating transportation systems, it is essential that railway track-side equipment (signal lights, wireless communication monitoring devices, positive train control, etc.) are well maintained and operated. When train moves over the track, the track deflects vertically due to load exerted by the train's bogies. The vertical displacement of the track under the weight of a passing train can connected regenerative devices i.e. a vibration energy harvester. The generated power can be stored into the battery and used to power track side equipments. Railroad energy harvesting is no trivial disturbance.In our project we are using these powers for irrigation system to the near by lands and fields and for lamp lights near the track.

PROPOSED SYSTEM

When a train ease up the track, the track deflects in downward direction attributable to the load exerted by the train's bogies. additionally due the deflection of track there's a deflection of timber that is place below the track and thus the flap is occupation downward direction because the flap is occupation a downward direction the spring that is connected to flap get compress in downward direction and thus rack is additionally move in downward direction and attributable to these pinion get rotates and thus larger freewheel turned as a result of each square measure mounted on same shaft. As there's a rotation of larger freewheel then the smaller freewheel is additionally turned through chain drive. The freewheel and regulator square measure mounted on same shaft thus the regulator additionally turned. The regulator is connected to the shaft of the generator therefore if the regulator can turned then there's a rotation shaft generator and power get generated which power is keep into the battery ADVANTAGES • Power generation is solely running the vehicle on this arrangement • Power additionally generated by running or exercise on the brake. • No want fuel input • This could be a Non-conventional system • Battery is employed to store the generated power

Block diagram

ADVANTAGES

• Power generation is solely running the vehicle on this arrangement

• Power additionally generated by running or exercise on the brake.

• No want fuel input

• This could be a Non-conventional system

• Battery is employed to store the generated power

DISADVANTAGES

• Slight inclination is needed within the railway track

• Mechanical moving elements is high

• Initial value of this arrangement is high.

• Care ought to be taken for batteries

APPLICATIONS

Power generation exploitation railway track system will be employed in most of the places like

All highways road speed breaker

All Railway track

• For Irrigation system:

The battery will be connected to the relay which will work as a switch.This switch will be activated with the current coming from an op-amp.A comparator op-amp will be used which will be work as a sensing device to sense the moisture in soil.A potentiometer will used to set the minimal voltage. Two cross wires will be placed in the soil with a nominal distance.When the soil is dry,resistance in soil will be around 10k.This will trigger the op-amp to give a output with low resistive path,i.e.fromground.This will connect the coil in relay and pump will be on. And on the contrary,when moisture will be enough,conduction will take place and relay will be switched off.

• For Lamp lights near track:

Another application which we are showcasing is lamp lights near track. The energy stored in battery can be used for lights near railway track. As we are searching for of a automatic solution for every problem, hence we are using LDR sensors here to avoid manual switching. The LDR wil allow electricity to flow through it when the photovoltaic cells are inactive and the resistance are low. This happens in the absence of sunlight.So during the day time, the lights connected through the sensors are switched off due to high resistance and evetually will glow in night time. One potentiometer is used for setting a reference value of resistor and a comparator IC to compare the light with the reference and allow the leds to glow.

RESULT

• As our project is Electric power generation using railway track and according to our fabricated model we are glowing LED which indicates the power is generated this is approximately equal to 5 volts. And even we are storing energy in battery by using toggle switch. Which can be utilized to any application.

• In our project we are glowing LED instantly when the train is passing over the roller and some of energy is stored in battery at the same time. And by using toggle switch we are using the pumps for irrigation system. And over all energy generated in our model is 8volts.

• These new design leads to more generation of electricity. And also it is more optimumand reliable in usage. The compact design of the structure leads to its easy and compatible mounting wherever required. Also less number of contact pairs leads to less frictional forces developed. These will lead to non-conventional energy generation which would further be used in the nearby railway infra-structure.

• A train weighing 1,000 kg going up a height of 10 cm on a rumble strip produces approximately 0.98KW power by placing one such speed-track on a busy highway, where about 100 trains pass every minute, about one kilo watt of electricity can be produced every minute.

CONCLUSION

It is ascertained that the electric power is in nice demand, we tend to as applied scientist ought to be in discovered for brand spanking new plan of power generation. As energy will ne'er be created or destroyed, we should always rework it into the shape that we will wont to provide for railroad station instrumentation light-weight, fan, beacon etc. we will implement this method at each entry and going away purpose within the railroad station This arrangement will be employed in completely different application like in foot step or speed breaker in school, faculties and main road for generation ways in which of voltage. so the facility production rate is raised and demand at explicit space will be consummated.

FUTURE SCOPE

This arrangement is slightly changed to construct in foot step and this arrangement is mounted in • colleges, cinema theatres, • searching advanced and • several different buildings

SOLAR Grass cutting machine

[1]Mr. N Rishi Kanth, [2]Ms.N.Harini,

[1]Associate Professor,[2]Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract

In this project we studied a solar grass cutter. A solar Grass cutter is a machine that uses revolving blades to cut a grass at an even length. Even more sophisticated devices are there in every field. Power consumption becomes essential for future. Grass cutter is a very useful device which is very simple in construction. It is used to maintain and upkeep land s in gardens, schools, college's part etc. We have made some changes in the existing machine to make its application easier at reduced cost. Our main aim in pollution control is attained through this. Unskilled operation can operate easily and maintain the land very fine and uniform surface look. In our project, "solar economical grass cutter" is used to cut the different grasses or different grass for the different application.

Key Words: Solar panel, battery, Motor, Pulley system, Grass cutter, pollution.

INTRODUCTION

In large size of grass field is cut manually. The farmer used hand scissors used to cut and maintain grass uniformly. It is not easy and also very difficult to maintain uniform size. Hence, we design to make a grass cutter without any power source due to reduce the power consumption. The unskilled gardener is enough to operate the grass cutter. The grass cutter easy to operate and it consists of Rotary Blade, Roller etc. The blade removes the extra growth of the land and roller gives light pressure to the top surface of Land. It gives fine cutting done fast work done on the land and uniform speed throughout the Land. The project work was very great successful one. It is used to maintain land of our college auditorium land maintenance. The operations involved in the grass production cycle include land clearing, land forming/ land levelling, tillage, and grass establishment, harvesting and post-harvest operations. Grass establishment, harvesting and post-harvest operations. Grass establishment is necessary to eliminate the effect of weeds, pests and disease infestation and to provide suitable conditions for optimum yield. More than 3000 species of weeds had been identified all over the world. The cost of weed management is enormous; however, the opportunity cost of weed management is higher. Weed control measures must be put in place to check the growth and propagation of weeds. Chemical and manual weed control methods are viable alternatives; however, whereas environmental impact of herbicides made chemical method unsustainable, drudgery limits the size of farm of an individual in sub-Saharan Africa. Introduction of an effective mechanical weeder is expected to encourage subsistent farmers leading to increased production and hence

reducing poverty. To achieve this objective, a row grass cutter was developed in the Federal University of Technology, Akure in Nigeria. The weeder was designed, fabricated and tested and found to be very efficient. The machine consists of an abrasive nail- brush mounted on a shaft, transmission system, engine, frame and wheels. The height of cut of the machine is set above the ground level, but works effectively as a weeder. The machine is simple, cost effective and useful for small to medium scale farm holders. A Crop cutter is a machine that uses revolving blades to cut a crop at an even length. Even more sophisticated devices are there in every field. Power consumption becomes essential for future. Crop cutter is a very useful device which is very simple in construction. It is used to maintain and upkeep land s in gardens, schools, college's part etc. We have made some changes in the existing machine to make its application easier at reduced cost. Our main aim in pollution control is attained through this. Unskilled operation can operate easily and maintain the land very fine and uniform surface look. In our project, "crop cutter" is used to cut the different grasses or different crops for the different application.

2. LITERATURE REVIEW

Automated Solar Grass Cutter (February 2017) Ms. Rutuja A. Yadav, Ms. Nayana V. Chavan, Ms. Monika B. Patil, Prof. V .A. Mane According to the author a daily purpose robot which is able to cut the grass in the lawn. The system will have some automation work for guidance and other obstacle detection and the power source that is battery and a solar panel will be attached on the top of the robot because of this reduces the power problem. Automated solar grass cutter are increasingly sophisticated, are self –docking and some contain rain sensors if necessary, nearly eliminating human interaction. The system is switched to automatic mode in which the robot's infrared sensors make a compason between, cut and uncut the grass. The mower continues this process until it completes the job. The system uses 12v batteries to power the vehicle movement motors as well as the grass cutter motor. They also use a solar panel to charge the battery so that there is no need of charging it externally. The grass cutter and vehicle motors are interfaced to an 8051 family microcontroller that controls the working of all the motors. It is also interfaced to an ultrasonic sensor for object detection. The microcontroller moves the vehicle motors in the forward direction in case no obstacle is detected. If in case obstacle is detected by the sensor then the microcontroller stops the grass cutter motor so as to avoid any damage to the object/human/animal coming. [2] Solar Based Grass Cutting (January-June 2017) Ms. Bhagyashri R. Patil, Mr. Sagar S. Patil According to the author, human enlargement in many countries there are studies and trials going on the solar energy and the wind energy, so they made their new concept solar power grass cutting machine. In this concept they cut the grass on the agricultural land or small plants in lawns and gardens. The design of solar powered agricultural equipment will include direct current (DC) motor, a rechargeable battery, solar panel, a stainless-steel blade and control switch. The automatic grass cutting machine is going to perform the grass cutting operation by its own which means no manpower is essential. The purpose of the project here is to

design and build a remote-controlled grass cutter. The device consists of linear blades and it does not affected by climatic conditions. They have used many components for preparing grass cutter like DC Motor (3) for rotating the wheels and blade, wheels (4), battery, Solar panel, IR sensor, Collapsible blade. There are two main components such as transmitter and receiver. Transmitter continuously transmits the rays if any obstacle come in front of grass cutter then the rays are reflected back towards the receiver. The receiver receives the signal in the serial form from encoder but microcontroller requires parallel data for communication so receiver sends data to decoder to convert data in the parallel form and then it is passed to microcontroller.[4] Solar bases wireless grass cutter (IJSTE - International Journal of Science Technology & Engineering, May 2016) According to the author, The idea of autonomous machine used to reduce man power with efficient work has given. Mainly this project explains application of green energy. This knowledge can be used in agricultural field as a future scope. According to the author, it gives description multipurpose grass cutter which is sensor based for special purposes like in grass trimming, hedge trimming etc. utilization of sensor and design calculation are used in proposed system. According to the author, A robot was designed that operates on an on-board, solar charged battery has been designed by the French manufacturer SN Eno. The RoboMower4 the capability of steering itself across a person's lawn. This robot called the Atawa A34, uses built-in infrared sensors to avoid obstacles. This system uses wires buried beneath the surface of the ground [4]

3. BLOCK DIAGRAM DESCRIPTION

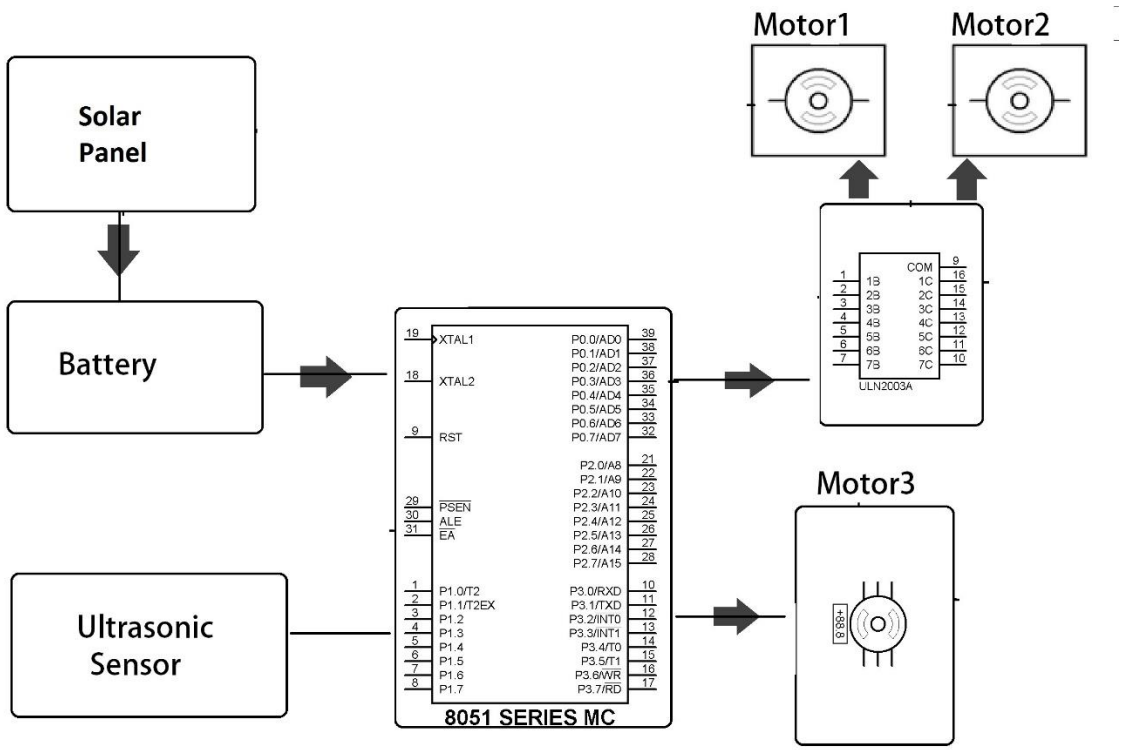

Fig-2: block diagram

3. Mechanism and working layout

The work layout shows the arrangement of3various parts of project. to the end of 3rd shaft and which is power transmit to the cutter mechanism

Fig -3: front view of grass cutter

3.1. WORKING PRINCIPLE

Coming to the working of solar powered grass cutter, it has panels mounted in a particular arrangement at an angle of 45 degree in such way that it can receive solar radiation with high intensity easily from the sun. These solar panels convert solar energy into electrical energy is stored in batteries by using a solar panel. The main function of the solar charger is to increase the current from the panels while batteries are charging, it also disconnects the solar panel from the batteries when they are fully charged and also connects to the panels when the charging in batteries is low. The motor is connected to the batteries through connecting wires. Between these two mechanical circuit breaker switches is provided. It starts and stops the working of the motor. From this motor, the power transmits ton the mechanism and this makes the blade to slide on the fixed blade and this makes to cut the grass.

3.2. SOLAR ENERGY

Solar radiation is format among the promising new source of energy. India receives annually over 60 x 1000 MWH of solar insulation with a span of 3000 – 3200 hrs in Rajasthan, Gujarat, West of Madhya Pradesh and North of Maharashtra; and 2600 – 2800 hours in the rest of the country excepting Kerala, Assam and Kashmir. Energy from the sun can be utilized in multi various ways. It can be tapped directly from solar radiation in the form of thermal, thermodynamic and photovoltaic energy and indirectly through the production of Phyto man and other related energy sources such as wind, hydropower and ocean energy all of which are the result of solar radiation on the planet Earth. The contribution of these sources in the total consumption of energy in the world is about 15%. The scope for the application of solar energy now stands greatly enhanced through intensive research and

development carried out all over world. The major areas that manifest great potential out all over world. The major areas that manifest great potential for immediate.

3.3ADVANTAGES

¬ Compact size and portable

¬ Easy to move from one place to another place

¬ Operating principle is simple.

¬ Non-skilled person also operates this machine

3.4 LIMATATIONS

¬ Large time required to remove the grass

¬ Manually operated

¬ Difficult to operate in rainy season

3.5APPLICATION

¬ For cricket ground

¬ College campus

¬ All playground

4. COST BENEFITS & ANALYSIS:

In our market, the approximate cost of an electric grass cutter is 25000/- coming to our project, we are modelling a solar powered grass cutter.

5. CONCLUSIONS

This project work has provided us an excellent opportunity and experience, to use our limited knowledge. We gained a lot of practical knowledge regarding, planning, purchasing, assembling and machining while doing this project work. We feel that the project work is a good solution to bridge the gates between institution and industries. We are proud that we have completed the work with the limited time successfully. The Crop Cutter is working with satisfactory conditions. We are able to understand the difficulties in maintaining the tolerances and also quality. We have done to our ability and skill making maximum use of available facilities. In conclusion remarks of our project work, let us add a few more lines about our impression project work. Thus, we have developed an “solar

economical grass cutter" which helps to know how to achieve low cost automation. By using more techniques, they can be modified and developed according to the applications.

Solar Powered refrigeration system

[1]Ms.N.Harini, [2]A Vijaya Krishna

[1,2]Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract

In this paper, a review has been conducted on various types of methods which are available for utilizing solar energy for refrigeration purposes. Solar refrigeration methods such as Solar Electric Method, Solar Mechanical Method and Solar Thermal Methods have been discussed. In solar thermal methods, various methods like Desiccant Refrigeration, Absorption Refrigeration and Adsorption Refrigeration has been discussed. All the methods have been assesed economically and environmentally and their operating characteristics have been compared to establish the best possible method for solar refrigeration. Also, the various available technologies for Cooling Thermal Energy Storage (CTES) have been discussed in this paper. Methods like Chilled Water Storage (CWS) and Ice Thermal Storage (ITS) have been compared and their advantages and disadvantages have been discussed. The results of the review reveal Solar Electric Method as the most promising method for solar refrigeration over the other methods. As far as CTES systems are concerned, ITS has advantage over other methods based on storage volume capability, but it has a comparatively lower COP than other available techniques. Keywords: Solar powered refrigeration, Solar Electric Method, Solar Mechanical Method, Solar Thermal Method, CTES system, Chilled Water Storage (CWS) system, ice TES systems, etc.

Introduction

A solar-powered refrigerator is a refrigerator which runs on electricity provided by solar energy. Solar-powered refrigerator are able to keep perishable goods such as meat and dairy cool in hot climates, and are used to keep much needed vaccines at their appropriate temperature to avoid spoilage. Solar-powered refrigerators may be most commonly used in the developing world to help mitigate poverty and climate change. In developed countries, plug-in refrigerators with backup generators store vaccines safely, but in developing countries, where electricity supplies can be unreliable, alternative refrigeration technologies are required. Solar fridges were introduced in the developing world to cut down on the use of kerosene or gas-poweredabsorption refrigerated coolers which are the most common alternatives. They are used for both vaccine storage and household applications in areas without reliable electrical supply because they have poor or no grid electricity at all. They burn a liter of kerosene per day therefore requiring a constant supply of fuel which is costly and smelly, and are responsible for the production of large amounts of carbon dioxide. They can also be difficult to adjust which can result in the freezing of medicine. The use of Kerosene as a fuel is

now widely discouraged for three reasons: Recurrent cost of fuel, difficulty of maintaining accurate temperature and risk of causing fires. There are three methods by which solar energy can be utilized for refrigeration purposes. They are as follows- Solar Electric Method, Solar Mechanical Method and Solar Thermal Method.

Solar Electric Method

In Solar Electric Method, the solar energy is directly converted to DC current by an array of solar cells known as Photovoltaic (PV) panel. Photovoltaic Cells are nothing but semiconductors which allow direct conversion of solar energy to direct current. A part of this current is stored by lead acid battery while the rest is utilized in driving the compressor of the refrigerator. This DC current can be either used to run a DC motor coupled to compressor or an inverter can be used to convert this DC current to AC current for running the compressor. A solar charge controller consisting of capacitor, sensors etc. may be required to stabilize and smoothen the current.

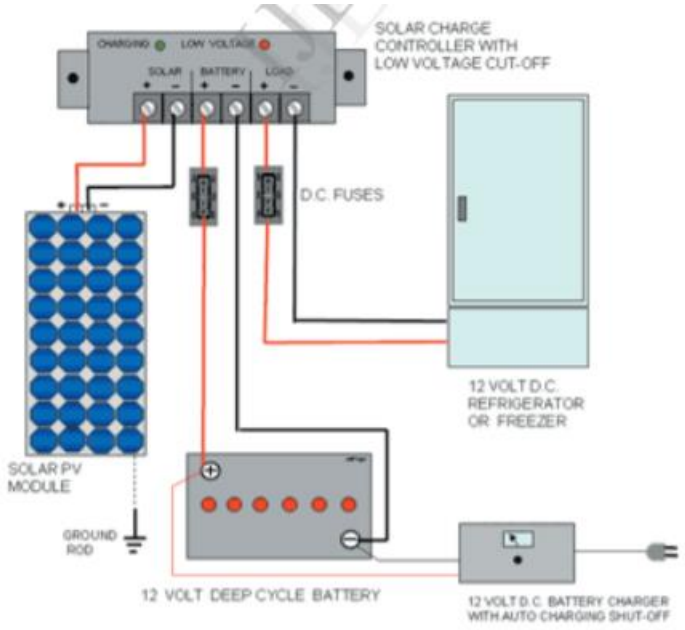

Fig. 1- A typical Solar PV system

A normal Solar PV system includes different components that should be selected according to the system type, site location and applications. The major components for solar PV system are solar charge controller, inverter, battery bank, auxiliary energy sources and loads (appliances).

• PV module – converts sunlight into DC electricity.

• Solar charge controller – regulates the voltage and current coming from the PV panels going to battery and prevents battery overcharging and prolongs the battery life.

• Inverter – converts DC output of PV panels or wind turbine into a clean AC current for AC appliances or fed back into grid line.

• Battery – stores energy for supplying to electrical appliances when there is a demand.

• Load – is electrical appliances that connected to solar PV system such as lights, radio, TV, computer, refrigerator, etc.

• Auxiliary energy sources - is diesel generator or other renewable energy sources.

Solar Mechanical Method

In Solar Mechanical Method, the mechanical power required to drive the compressor is generated by solar driven heat power cycle. Rankine cycle is the heat power cycle considered for this process. In Rankine cycle, fluid is vaporized at an elevated pressure by heat exchange with a fluid heated by solar collectors. A storage tank can be included in this process to provide some high temperature thermal storage. The vapor flows through a turbine or piston expander to produce mechanical power. The fluid exiting the expander is condensed and pumped back to the boiler pressure where it is again vaporized. The efficiency of the Rankine cycle increases with increasing temperature of the vaporized fluid entering the expander. Whereas, the efficiency of a solar collector decreases with increasing temperature of the delivered energy. High temperatures can be obtained by employing concentrating solar collectors that track the sun's position in one or two dimensions.

The disadvantages of using solar trackers are cost, weight and complexity of the system. If tracking is to be avoided, evacuated tubular, compound parabolic or advanced multi-cover flat plate collectors can be used to produce fluid temperatures ranging between 100°C – 200°C. Both intensity of solar radiation as well as difference of temperature between entering fluid and ambient govern the efficiency of solar collector. The efficiency of such a system is lower than solar electric method using non-concentrating PV modules. Solar Mechanical is advantageous only when solar trackers are used but, the use of such systems is limited to large refrigeration systems only i.e.atleast 1000 tons. (refer fig. 2)

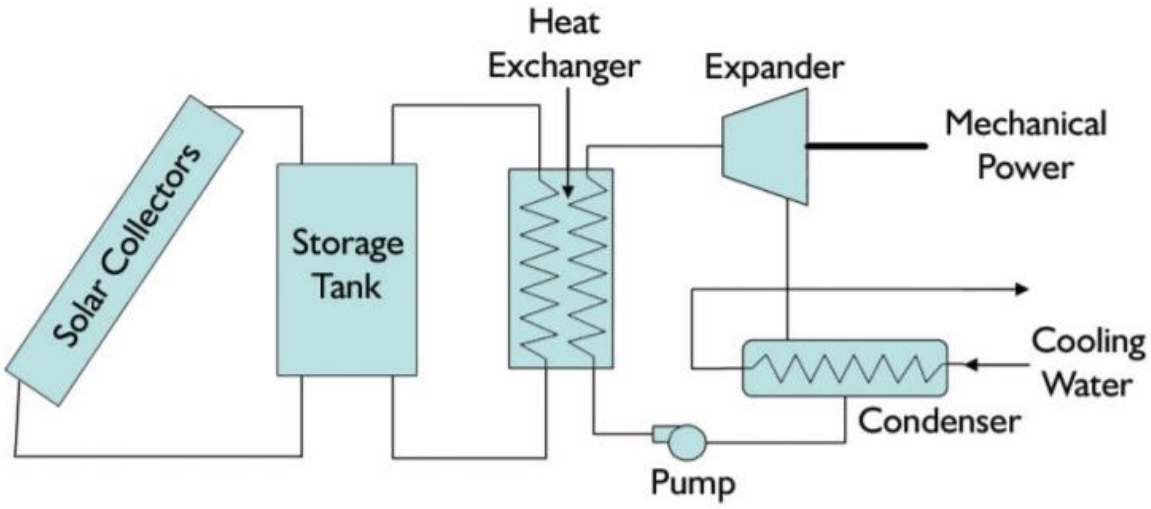

Fig.2- Solar Mechanical Method

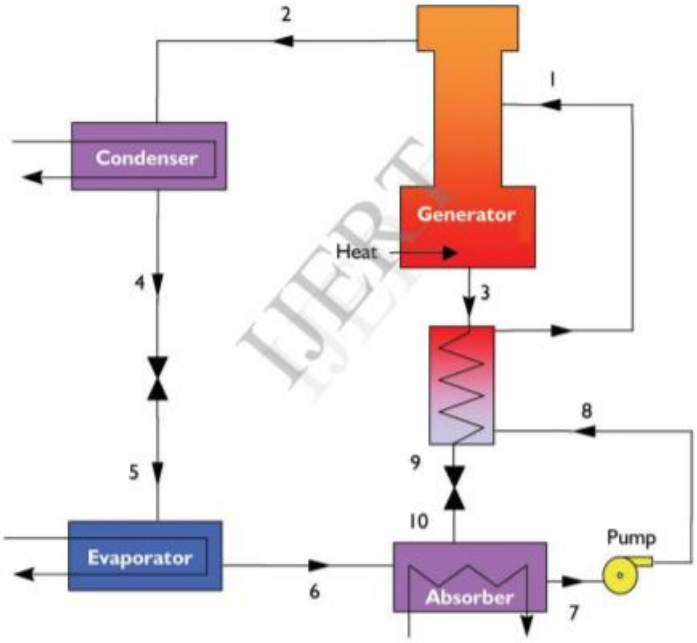
Solar Thermal Method

The main advantage of using Solar Thermal Method is that they can utilize more of the incoming sunlight than photovoltaic systems. In a conventional PV collector, 65% of the incident solar radiation is lost as heat whereas in solar collectors over 95% of the incoming solar radiation is absorbed. But all of this is absorbed energy is not converted to useful energy due to inefficiencies and losses. Collection efficiencies for commercial solar thermal collectors are generally more than double that of crystalline photovoltaic solar collectors. A typical solar thermal refrigeration system consists of four basic components - a solar collector array, a thermal storage tank, a thermal refrigeration unit and a heat exchange system to transfer energy between components and the refrigerated space. Selection of the solar array depends upon the temperature needed for refrigeration system. Generally for temperature range 60-100C, flat plate collectors, evacuated tube collectors and concentrating collectors of low concentration can be used. Concentrating collectors are avoided for residential purposes due to high cost of solar trackers. Selection of the thermal storage tank depends upon the type of storage medium and the temperatures desired. Water is mainly selected for its low environmental impact and high specific heat.



Desiccant

A desiccant system is usually an open cycle where two wheels turn in tandem – a desiccant wheel containing a material which can effectively absorb water, and a thermal wheel which heats and cools inward and outward flows. Warm, humid, outside air enters the desiccant wheel where it is dried by the desiccant material. Next, it goes to the thermal wheel which pre-cools this dry, warm air. Next, the air is cooled further by being re-humidified. When leaving, cool, conditioned air is humidified to saturation and is used to cool off the thermal wheel. After the thermal wheel, the now warm humid air

is heated further by solar heat in the regenerator. Lastly, this hot air passes through the desiccant wheel so that it can dry the desiccant material on its way out of the cycle. Pre-packaged desiccant is most commonly used to remove excessive humidity that would normally degrade or even destroy products sensitive to moisture. Some commonly used desiccants are silica gel, activated charcoal, calcium sulfate, calcium chloride, montmorillonite clay, and molecular sieves.

Absorption

An absorption refrigerator is a refrigerator that uses a heat source (e.g., solar, kerosene-fueled flame, waste heat from factories or district heating systems) to provide the energy needed to drive the cooling system. Absorption refrigerators are a popular alternative to regular compressor refrigerators where electricity is unreliable, costly, or unavailable, where noise from thecompressor is problematic, or where surplus heat is available (e.g., from turbine exhausts or industrial processes, or from solar plants). In absorption, two mainly used cycles are- LiBr (Lithium Bromide) and NH3 (Ammonia Hydrogen). The main difference between them is which substances are used as the refrigerant and absorbent. In a LiBr system, LiBr is the absorbent and water is the refrigerant. In an NH3 absorption system, water is now the absorbent and NH3 is the refrigerant. In both cases, the job of the compressor (in a conventional vapour compression system) is replaced by an absorber and a generator. Concentrated absorbent enters the absorber, which is connected to the evaporator. When refrigerant is boiled off in the evaporator (removing heat from the refrigerated space), vapour (of relatively high pressure) then moves to the LiBr/water absorber where it is absorbed. Next, the mixture moves to the generator where solar heat is supplied to boil off the refrigerant. High-pressure refrigerant vapour then travels to the condenser where heat is rejected to the surroundings to condense the refrigerant back to liquid. Liquid refrigerant goes back into the evaporator, where it can be used again to take in heat from the refrigerated space, which completes the loop.

Adsorption

In this cycle, solar heat is directed to a sealed container containing solid adsorbent saturated with refrigerant. Once this reaches the proper temperature/pressure the refrigerant desorbs and leaves this container as pressurized vapour. That is, the vapour has been compressed with thermal energy. This vapour then travels to a condenser where it turns to liquid by rejecting heat to the surroundings. Expanded, low-pressure liquid refrigerant then flows over the evaporator which pulls heat from the conditioned space to boil off the refrigerant. The refrigerant vapour can then be adsorbed again by the cool adsorbent material easily at night. Although there are similarities between absorption and adsorption refrigeration, the latter is based on the interaction between

gases and solids. The adsorption chamber of the chiller is filled with a solid material (for example zeolite, silica gel, alumina, active carbon and certain types of metal salts), which in its neutral state has adsorbed the refrigerant.

Cooling Thermal Energy Storage (CTES) System

The most important use of CTES systems is to shift the power consumption from peak to offpeak periods. For this reason these systems are also known as “off-peak cooling” systems. The performance of a TES system is described by its co-efficient of performance (COP). The COP of a system during peak and off-peak hours is defined by the chiller and compressor design. CTES systems are generally classified into three types- chilled water, ice storage and eutectic salt TES systems. Among these techniques, the Chilled Water Storage (CWS) and the Ice Thermal Storage (ITS) systems are the most promising ones in case of the normal applications. The ITS system has the

advantages of larger storage volume in comparison with two other systems. However, the COP of the ITS system is much lower than other techniques. In sensible CTES, the storage medium is usually water-based whereas in latent CTES systems, eutectic salts with phase change materials is generally preferred as storage medium. Sensible CTES systems account for most cold TES applications presently. Thermochemical TES may prove useful for cooling TES systems provided ongoing efforts to develop systems are successful. So, in short, the various advantages of using CTES system are: -

- Reduction in electricity bills by shifting the power consumption from peak to off-peak periods.

- Usually, the systems with CTES would consume less operating energy than conventional air conditioning (AC) systems due to constant and comparatively lower temperature during the nights.

- Producing off-peak electricity is cheaper as it would consume less fuel.

- Chiller efficiency is improved by shifting the electricity consumption from daytimes to nights when the ambient temperature (Ta) is considerably low.

- The significant air temperature difference across the Air Handling Unit (AHU) reduces the required air volume required for circulation. Hence, smaller AHUs, less duct working and less electrical equipment's are required.

Chilled Water Storage (CWS)

It is a famous strategy adopted in many countries to save energy by shifting power consumption from peak hours in the daytime to off-peak hours during the nighttimes by employing chilled water to store cool thermal energy. In the past, prior to the successful evolution of thermally stratified systems, many different types of CWS designs have been developed and employed. Designs of CWS were such in order to primarily avoid temperature mixing of chilled water with return water. However, they often require complex tank configurations or piping systems that are expensive and difficult to operate. The CWS systems currently in use can be classified as (a) labyrinth, (b) baffle, (c) tank series, (d) membrane tank. (refer fig.4)

Ice Thermal Storage (ITS) The most popular technique for storing cool thermal energy was the use of ice due to its high latent heat of fusion i.e.hsf = 334 kJ/kg. This method was used especially when the available space was limited. The supplied chiller in this technique must be able to produce charging temperature in the range of -60C to -30C in order to produce ice. Investigations revealed that employing the ITS system would downsize the cooling generation devices such as pipes, ducts and AHUs. This downsizing will help in lowering the primary cost of the HVAC system. The ITS storage technologies are generally categorized by their different combinations of storage media, charging or discharging mechanism. ITS systems can be commonly categorized into the following types –

- Ice Harvesters
- Ice slurry
- Encapsulated Ice
- External melt ice-on-coil storage systems
- Internal melt ice-on-coil storage systems

Ice Harvesters

This technique is a dynamic type of ITS system consisting of an open insulated storage tank and vertical plate surface positioned above the tank. A circulating pump brings the water at a temperature of 00C on the outer surface of the evaporator, which is fed internally with liquid refrigerant. Normally, thickness of the produced ice varies between 8 mm and 10 mm depending on the length of the freezing cycle. (refer fig.5)

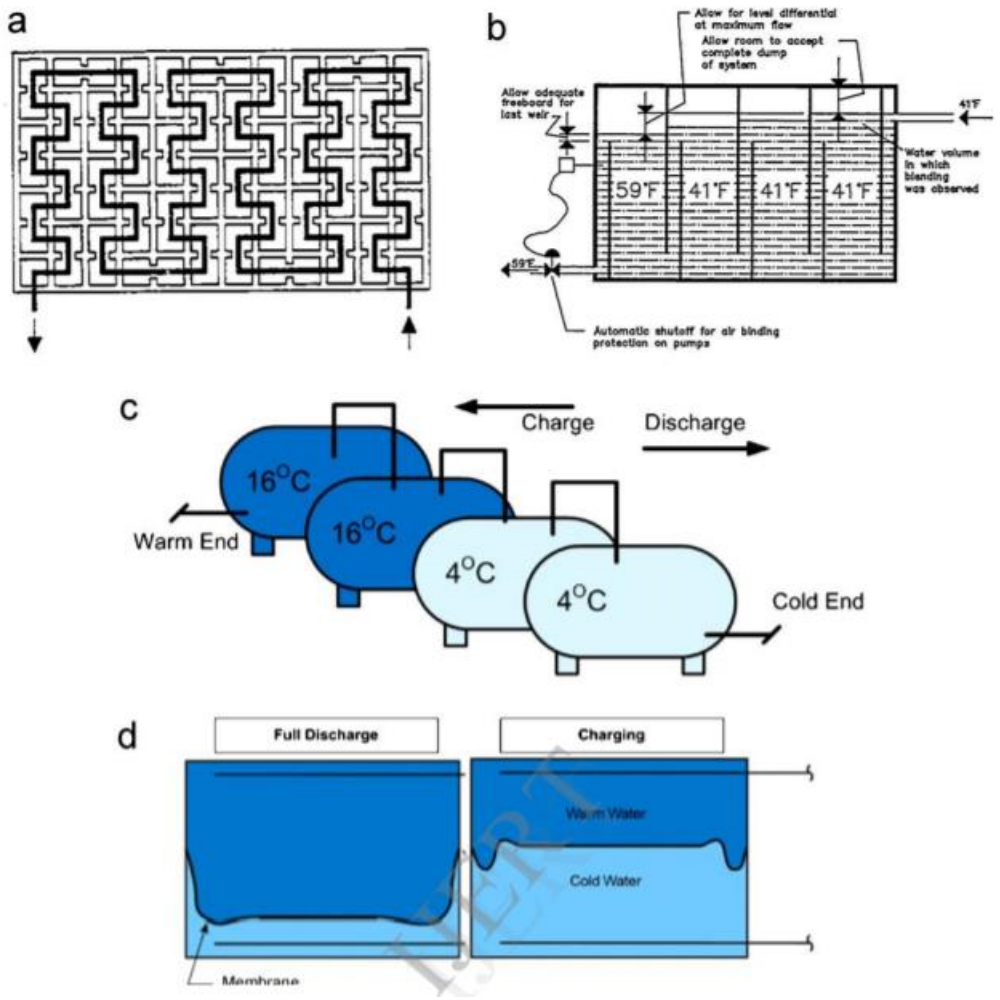


Fig.5- Schematic diagram of a typical ice harvesting ITS system

The ice would then be harvested by feeding a hot gas to the evaporator. The outer surface temperature rises to about 50C causing the ice in contact with the plates to melt and fall into the storage tank. During the discharging period, the chilled water that circulates through the storage tank further reducing the water temperature to cope with the load. Due to the system complexity, only a few manufacturers are involved with these systems, which are normally employed only in special applications.

Literature survey of work carried out by various authors

M. M. Hussain, et al. [1]: The simulation of thermal energy storage (TES) system for HVAC system has been dealt with in this paper. To store cooling capacity, TES system is integrated with conventional HVAC system. Ethylene Glycol is used as a storage medium in this system. Exergy and Energy analyses have been used to determine the thermodynamic performance of the system. Effect of various parameters such as ambient temperature, cooling load and mass of storage on the performance of the TES system has been also studied in this paper. The results of various studies and analyses conducted on TES systems revealed that the storage temperature International Journal of Engineering Research &Technology Vol. 2 Issue 2, February- 2013 ISSN: 2278-0181 www.ijert.org 10 IJERT decreases linearly with time when there is no load and follows the load profile during daytime and decreases linearly with time at the end. Also, it was found out that the storage temperature decreases slightly with increase in ambient temperature when there is no load. COP of the system was found out to decrease sharply with small increase in storage temperature. It was also discovered that for all mass flow rates of discharging fluid, the energy efficiency of the system was found out to be nearly 80%. But, the exergy efficiency of the system decreased with increase in mass flow rate of the discharging fluid and increased with increase in reference temperature.

FakehaSehar, et al. [2]: In this paper, the impact of ice storage systems on the chiller energy consumption for large and medium-sized office buildings in diverse climate zones has been investigated. The various studies indicated that the systems with ice thermal storage (ITS) have higher chiller energy consumptions than the conventional non-storage systems because of the day and night operation of the chiller. By discharging ice storage during the peak hours, the ITS were able to achieve peak energy savings by reducing or even by completely eliminating the chiller operation during the daytime. It was also noticed that climatic zones with summers having high temperatures and relative humidity (RH) increase not only the building cooling load but also the chiller energy consumption by decreasing the cooling intensity of the condenser water, for example- Miami and Las Vegas. But, climate zones with less extreme summers have lower chiller energy consumption due to lower building cooling loads and more cooling of condenser water, for example- Seattle.

Mehmet Azmi Aktacir, [3]: In this study, a PV-powered multi-purpose refrigerator system has been erected to investigate experimentally its daily and seasonal operating performances based on semi-

arid climatic conditions of Sanliurfa province in Turkey. It is one of the sunniest rural regions in the world and hence the need for refrigeration is critical. The overall results revealed that PV-refrigerator system can be reliably used in places where the local grid was unreliable and the refrigeration need is critical. On observation, the following results were observed- Low temperature of 10.6°C was reached in the refrigerator, the highest energy amount produced by PV panels was recorded between 11:00 am and 14:00 pm, amount energy consumed by the refrigerator was determined to be 347.7 Wh/day, the amount of energy stored in the battery bank was 78.2 Wh/day while the amount of electric energy produced by photovoltaic panel was 425.9 Wh/day.

Sanford A. Klein and Douglas T. Reindl, [4]: In this paper, it was stated that the energy use associated with refrigeration system operation and the environmental impacts associated with its generation and distribution often outweigh the choice of environmental friendly refrigerants. In this article, three approaches to use solar energy for refrigeration at temperatures below 0C were reviewed and their operating characteristics were compared. The COP of all the three refrigeration cycles- Solar Electric, Solar Mechanical and Absorption cycles were compared and found to be low due to various barriers like firstly, the solar refrigeration systems are complicated, costly and bulky because of the necessity to locally produce the power required for operation and secondly, the energy source for these systems i.e. solar energy is variable which requires energy storage system that further adds to the system size and cost. The PV system was International Journal of Engineering Research & Technology (IJERT) Vol. 2 Issue 2, February- 2013 ISSN: 2278-0181 www.ijert.org 11 IJERT most viable of all other systems especially for small capacity portable systems whereas the absorption systems were more feasible for large stationary refrigeration systems.

S.M. Hasnain, et al. [5]: In this paper, the incorporation of ice thermal storage with conventional air conditioning systems in Saudi office was studied. This incorporation reduced the peak electric demand, cooling plant capacity and new electric connection charges of an office building. For this study, two different scenarios were studied. The partial ice storage technique adopted for this study reduced the peak electrical load for Scenario-I and Scenario-II, by 15 and 23%, respectively. It was estimated that an ice storage system would reduce the peak cooling load between 35 and 40% in this type of Saudi buildings. The savings that resulted by downsizing the cooling plant overcame the cost of storage and the additional interface equipment. Similarly, it wass also estimated that in Saudi Arabia, the use of ice storage systems with gas turbines for inlet air cooling will increase the turbine's output by 30% and reduce its heat rate by 10% at a mere fraction of the cost of installing the additional capacity for power generation in order to meet the summer peak demand.

Todd Otanicar, et al. [6]: In this paper, a variety of solar cooling schemes have been economically and environmentally analyzed to reveal some key details regarding system choice. For solar electric cooling the system, the cost is highly dependent on the system COP when PV prices remain at the

current levels but when prices are lowered the impact of COP on cost diminishes. For solar thermal cooling, the cost of solar collection is much lower as a percentage of the overall cost, but the cost of the refrigeration system represents a larger percentage of the total cost. Additionally, the paper reveals that the costs for solar thermal cooling are not projected to decrease as much as PV cooling over the next 20 years due to the relatively stable cost of collection and storage. Solar electric cooling, even with the associated impact of refrigerants with global warming impact, have a lower projected emission value of carbon dioxide per kWhr of cooling than any of the thermal technologies due to the much larger COP values associated with solar electric cooling. One additional favorable aspect to solar electric cooling systems is the collector area foot print i.e. for solar PV systems, expected sizes in 2010 were between 24 and 48 m2 as compared to 78 and 106 m2 for solar thermal systems depending on system COP.

David MacPhee, et al. [7]: In this paper, the solidification process for an encapsulated ice TES is investigated. Using Fluent 6.3 software, a domain consisting of one capsule containing water as the PCM and with an outer shell made of PVC is simulated from an initial temperature of 275 K until completely frozen, using ethylene glycol as the heat transfer fluid (HTF). The purpose of this study is to assess how changing capsule geometry, inlet HTF temperature and flow rate affect the performance of the charging process. Using both energy and exergy analyses, efficiencies were calculated for each simulation, while varying the inlet temperature from 267 to 271 K, and choosing three flow rates, Q = 0.87 l/s, 1.74 l/s and 2.61 l/s. The results indicate that considerable cost and energy savings could be realized by utilizing a higher HTF temperature, perhaps a few degrees below the solidification temperature of the PCM. It is possible for the designers to increase flow rate to make up for the increase in charging time associated with this increase in HTF inlet temperature since, the losses associated with viscous dissipation and hence, International Journal of Engineering Research & Technology (IJERT) Vol. 2 Issue 2, February- 2013 ISSN: 2278-0181 www.ijert.org 12 IJERT pressure drop have been shown to be inconsequential compared to other modes of losses. Doing so should allow for an increase in efficiency while still maintaining a working and effective encapsulated ice TES system.

B. Rismanchia, et al. [8]: The work in this paper investigated the feasibility and potential of employing ITS systems for the cooling application of office buildings in Malaysia along with the economical and environmental benefits of utilizing these systems. This study is mainly conducted due to the vast potential that the country has, the statistical data shows that in Malaysia, AC systems are the major energy consumers in office buildings with around 57% share. However, they are not well promoted in Malaysia and their potentials are not yet well investigated. The overall results show that the full storage strategy can reduce the annual costs of the air conditioning system by up to 35% while this reduction is limited to around 8% for a load levelling strategy. By comparing the installation, maintenance and electricity costs of the conventional system with the ITS system, it was found that

for the full storage strategy it will take between 3 and 6 years for the benefits of the investment to be equal with the investment. For the load levelling strategy this period varies between 1 and 3 years. The comparison results between the conventional AC system and the ITS system indicate that a proper design could lead to lower energy consumption due to better utilization of the equipment. It shows that the load levelling strategy consumes around 4% less energy than the conventional AC systems. The annual energy saving stated that the annual CO2 emission reduction for load levelling strategy varies from 3000 to 60,000 ton for the total system capacities of 352 and 7034 kW.

David MacPhee, Ibrahim Dincer, [9]: In this paper, a performance assessment of four main types of ice storage techniques for space cooling purposes, namely ice slurry systems, ice-on-coil systems (both internal and external melt), and encapsulated ice systems is conducted. The ice making techniques are compared on the basis of energy and exergy performance criteria including charging, discharging and storage efficiencies, which make up the ice storage and retrieval process. Losses due to heat leakage and irreversibilities from entropy generation are included. A vapor-compression refrigeration cycle with R134a as the working fluid provides the cooling load, while the analysis is performed in both a full storage and partial storage process, with comparisons between these two. In the case of full storage, the energy efficiencies associated with the charging and discharging processes are well over 98% in all cases, while the exergy efficiencies ranged from 46% to 76% for the charging cycle and 18% to 24% for the discharging cycle. For the partial storage systems, all energy and exergy efficiencies were slightly less than that for full storage, due to the increasing effect wall heat leakage has on the decreased storage volume and load. The results show that energy analyses alone do not provide much useful insight into system behavior, since the vast majority of losses in all processes area result of entropy generation which results from system irreversibilities.

STUDY OF ABRASIVE JET MACHINE

[1]A Vijaya Krishna, [2]Mr. Balaji Krushna.P, Mrs. S.C. Sireesha

[1,2,3]Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract –

Abrasive Jet Machining (AJM) or Micro Blast Machining is a non-traditional machining process, wherein material removal is affected by the erosive action of a high velocity jet of a gas, carrying fine-grained abrasive particles, impacting the work surface. The process is particularly suitable to cut intricate shapes in hard and brittle materials which are sensitive to heat and have a tendency to chip easily. As Abrasive jet machining (AJM) is similar to sand blasting and effectively removes hard and brittle materials. AJM has been applied to rough working such as debarring and rough finishing. With the increase of needs for machining of ceramics, semiconductors, electronic devices and L.C.D., AJM has become a useful technique for micromachining. The experimental results of the present work are used to discuss the validity of proposed model as well as the other models. With the increase in nozzle tip distance (NTD), the top surface diameter and bottom surface diameter of hole increases as it is in general observation of abrasive jet machining process. As the pressure increases, the material removal rate (MRR) is also increased. The present study has been introduced a mathematical model and the obtained results have been compared with that obtained from the theoretical. Key Words: Abrasive Jet Machine (AJM), LCD, Nozzle Tip Distance (NTD), Material Removal Rate (MRR)

1.INTRODUCTION

Abrasive jet machining (AJM) is a non-traditional machining process that can machine material without generating heat and shock and also without formation of chips. Abrasive processes are usually expensive, but capable of tighter tolerances and better surface finish than other machining processes chances, delectability, costs and safety aspect etc. Abrasive jet machining (AJM) is a process of material removal by mechanical erosion caused by the impingement of high velocity abrasive particles carried by a suitable fluid (usually a gas or air) through a shaped nozzle on to the work piece. Common examples include Cutting, Drilling, Surface finishing, Etching, grinding, honing, and polishing. The erosion phenomenon in an AJM study may be considered in two phases. The first phase consists of transportation problem, that is, the quantity of abrasive particles flown, and the direction and velocity of impinging particles as determined by the fluid flow condition of solid-gas suspension. The second phase of the problem is the determination of the material removal rate or the erosion rate.

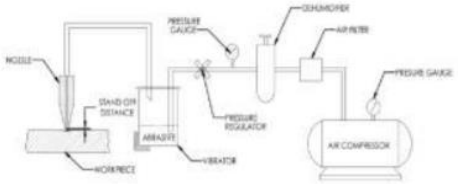

Fig -1: Schematic Layout of Abrasive Jet Machine

The erosion of a surface by impacting solid particles is a discrete and accumulative process. Hence, the models are first made on the basis of a single particle impact. The mechanism of erosion in such cases is complex, involving mechanical, chemical and material properties. The erosion is a function of several variables such as:

a) Speed and angle of impact;

b) Ductility and! or brittleness the impinging particles;

c) Elasticity of the material; of the material and

d) Shape and geometry of impinging particles;

e) Impinging particle diameter to work-material, thickness ratio;

f) Average flow stress; g) Material and density; and

h) Distance between the nozzle mouth and work piece

An AJM set-up may be of two types: one employing a vortex type mixing chamber and the other employing a vibratory mixer. In the former, abrasive particles are carried by the vortex motion of the carrier fluid, whereas in the latter type abrasive particles are forced into the path of the carrier gas by the vibrating motion of the abrasive particle container.

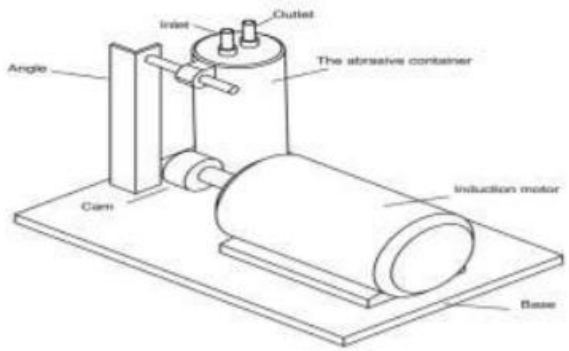

Fig -2: The vibrator assembly

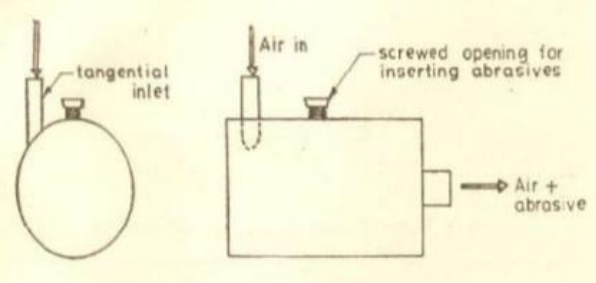

Fig -3: Vortex type mixing chamber

1.1 PROCESS PARAMETERS OF AJM

1.1.1 CARRIER GAS (MEDIUM):

(a) Carbon dioxide,

(b) Nitrogen,

(c) Air: Air is most widely used.

But oxygen never used as a carrier gas due to fire hazards.

1.1.2 ABRASIVE:

Abrasives are available in many sizes ranging from 10 micron to about 1.3 mm. the smaller sizes produce a finish cut and are suitable for polishing, cleaning and grooving. The larger sizes are more suitable for cutting and peening because of their faster cutting action.

a. Aluminium oxide suitable for cutting, grooving and debarring operations.

b. Silicon carbide used for similar operation but for harder material

c. Sodium bicarbonate is useful for light duty work like cleaning, cutting and debarring for soft materials.

d. Dolomite also is suitable for fine etching or polishing work only.

e. Glass beads can be used for polishing surface to a matte finish and debarring work.

1.1.3 VELOCITY OF ABRASIVE:

The jet velocity is a function of nozzle pressure & design. The range of jet velocity is 150-300 m/min.

1.1.4 WORK MATERIAL:

It is recommended for processing of hard, brittle, and glass sheets material.

1.1.5 NOZZLE:

AJM nozzles generally made of WC or Sapphire to resist abrasive wear due to the high velocity abrasive stream. The nozzle has either a right angled or straight edge shape.

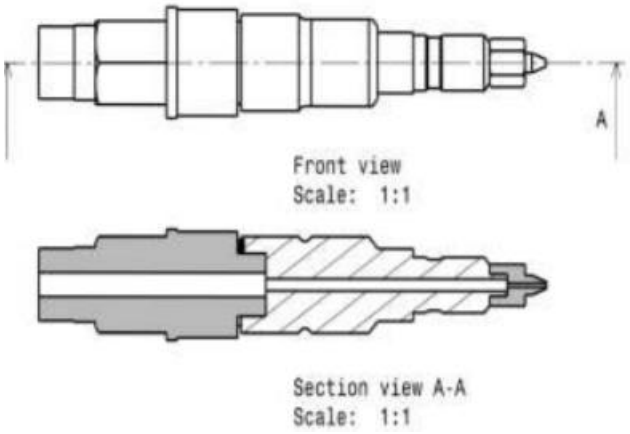

Fig -4: Nozzle

1.1.6 NOZZLE TIP DISTANCE (NTD):

It is the distance between the nozzle tip & work material. It is also called as Standoff Distance (SOD).

1.3 COMPONENTS OF AJM

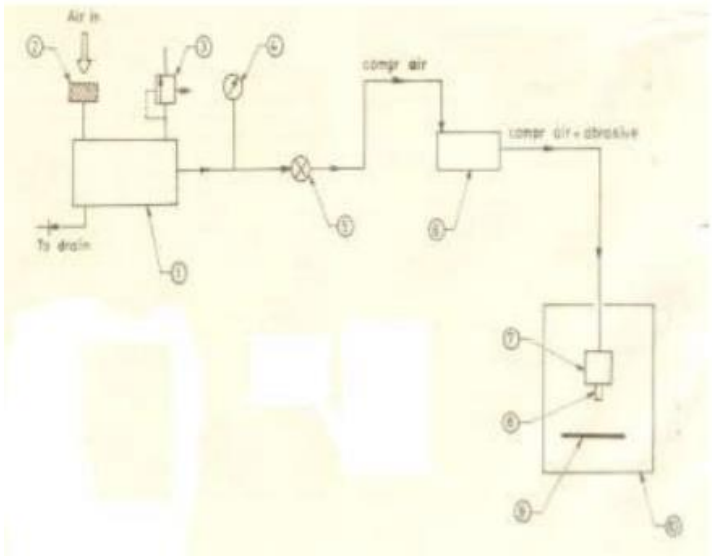

Fig -6: Components of AJM

a) Compressor

b) Air filter cum drier

c) Relief Valve

d) Pressure Gauge

e) Opening Valve

f) Mixing Chamber

g) Nozzle Holder

h) Nozzle

i) Work piece

j) Working Chamber

1.4 PROCESS

Glass was used as a test specimen, was cut into square and rectangular shape for machining on AJM. Specimens were cleaned using air jet and weighed on a sensitive scale, accurate to 0.001 gm. The compressed air from the compressor enters the mixing chamber partly prefilled with fine grain abrasive particles. The vibratory motion of the air created in the mixing chamber carries the abrasive particles to the nozzle through which it is directed on to the workpiece. The nozzle and the work-piece are enclosed in a working chamber with a Perspex sheet on one side for viewing the operation. The abrasive particles used were SiC, Al2O3, Sodium Bicarbonate (grain size 60 microns and 120 microns).The nozzle material was stainless steel and the nozzles used were of different diameters. This type of set-up has the advantage of simplicity in design, fabrication and operation. The equipment cost is much less except the compressor. The machine work-piece was then removed, cleaned and weighed again to determine the amount of material removed from the work piece. The size of hole at the top surface and bottom surface was measured and the results were tabulated.

1.5 ADVANTAGES

a) Ability to cut intricate holes shape in materials of any hardness and brittleness.

b) Ability to cut fragile and heat sensitive material without damage.

c) No change in microstructure as no heat is generated in the process.

d) The process is characterized by lower consumption and capital investment.

e) There is no contact between the tool and work-piece.

f) Good surface finish of 10 to 50 microns is possible with the process using finer abrasive.

g) Cutting action is cool because the carrier gas serves as a coolant.

1.6 DISADVANTAGES

a) Material removal rate is low about 15 mm3 / min.

b) The parts manufactured by this process have to be cleaned.

c) Embedding of the abrasive in the work-piece surface may occur while machining softer material.

d) The abrasive material may accumulate at nozzle and fail the process if moisture is present in the air.

e) It cannot be used to drill blind holes.

f) Nozzle wear rate is high and abrasive particles may get embedded in the work surface.

1.7 APPLICATIONS OF AJM

a) Machining of hard and brittle materials like ceramics, quartz, glass, sapphire, mica etc.

b) Fine drilling and micro-welding.

c) Machining of semi-conductors.

d) Production of intricate profiles on hard and brittle materials.

e) Cleaning and finishing of plastic compounds. Ex. Nylon, Teflon.

2. WORKING PRINCIPLE OF AJM

Fine particles are accelerated in gas stream. The particles are directed towards the focus of machining. As the particle impacts the surface, it causes a small fracture, and the gas stream carries both the abrasive particles and the fractured (wear) particles away.

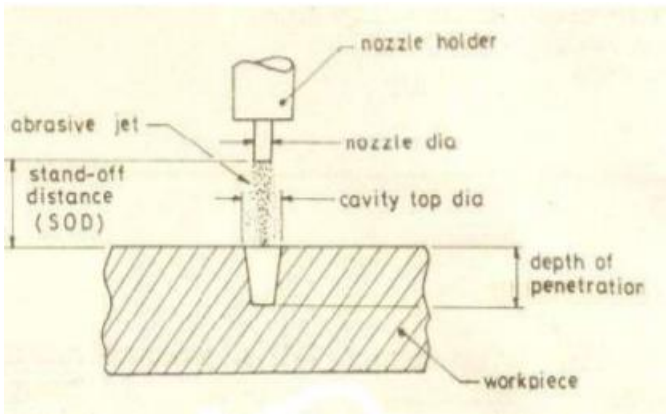

Fig -6: Working principle of AJM

Abrasive jet machining (AJM), also known as abrasive micro blasting, pencil blasting and micro-abrasive blasting. “Abrasive blasting machining process that uses abrasives propelled by a high velocity gas to erode material from the work piece.” The working principle of Abrasive jet machining (AJM) is similar to sand blasting in which AJM effectively removes hard and brittle materials. AJM has been applied to rough working such as debarring and rough finishing. Common uses include cutting heat-sensitive, brittle, thin, or hard materials. Specifically it is used to cut intricate shapes or form specific edge shapes. A machining operation is basically a material removal process, where material is removed in the form of chips. In a machining operation, the output parameter is achieved by controlling various input parameters. Drilling of glass sheets with different thicknesses have been carried out by Abrasive Jet Machining process (AJM) in order to determine its machinability under different controlling parameters of the AJM process.

2.1 EXPERIMENTAL SET-UP

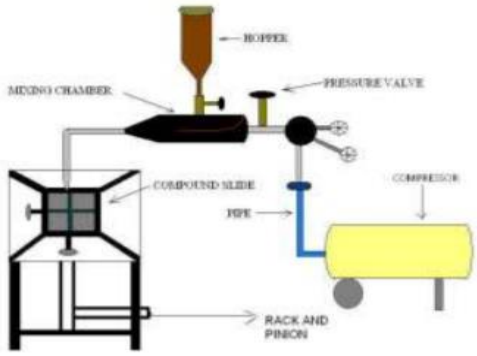

Fig -7: Schematic Diagram of Experimental Set-Up

The compressed air from the compressor enters the mixing chamber partly prefilled with fine grain abrasive particles. The vortex motion of the air created in the mixing chamber carries the abrasive particles to the nozzle through which it is directed on to the work-piece. The nozzle and the workpiece are enclosed in a working chamber with a Perspex sheet on one side for viewing the operation. The nozzle and mixing chamber are shown below.

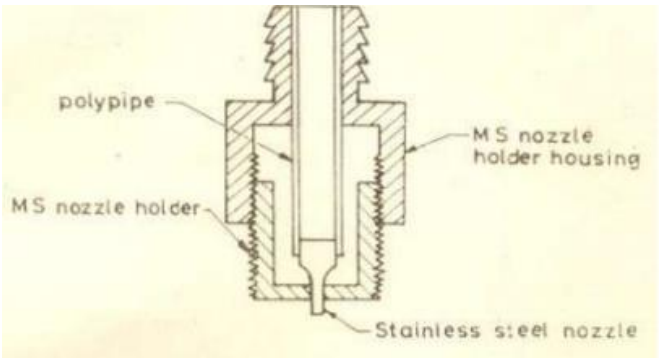

Fig -8: Nozzle Assembly

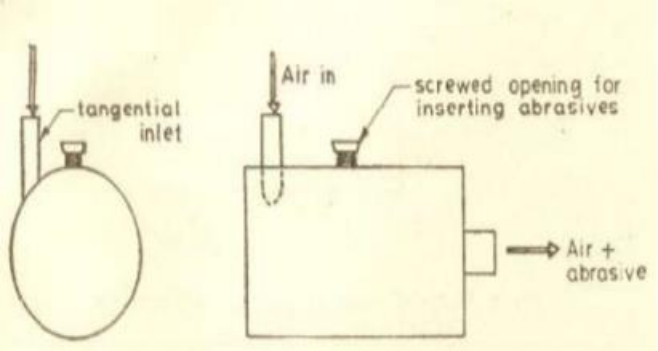

Fig -9: Vortex

Type Mixing Chamber The abrasive particles used were SiC (grain size 60 microns and 120 microns). The nozzle material was stainless steel and the nozzles used were of diameters 1.83 mm and 1.63 mm. This type of set-up has the advantage of simplicity in design, fabrication and operation. The equipment cost is much less except the compressor. The mixture ratio is controlled by the inclination of the mixing chamber. The mixture ratio is defined as: Where mp is the mass flow rate of the abrasive particles and ma the mass flow rate of air.

3. CONCLUSION

It is very clear that AJM is greater Non-conventional machining process which is used as a multipurpose system. It is also a most effective among various affordable systems. This system is eco-friendly. Even some of the companies in India like ABB, L & T and ESSAR are already using this system with CNC programming. This system is also use as Water Jet Machining (WJM) in which abrasives such as garnet, diamond or powders can be mixed into the water to make slurry with better cutting properties than straight water. Further development in WJM is called Hydrodynamic Jet Machining (HJM) which combines the principle of Water Jet Machining and Abrasive Jet Machining process. AJM is also used as Abrasive Flow Machining (AFM), Ultrasonic Machining (USM).

Thermo electric refrigerater

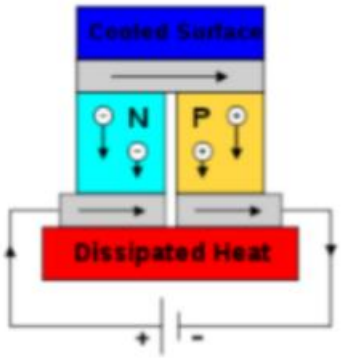
[1]D.S.CH.Mouli, [2]Sri Deepthi Immaneni

[1,2]Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract

The global increasing demand for refrigeration in field of refrigeration air-conditioning, food preservation, vaccine storages, medical services, and cooling of electronic devices, led to production of more electricity and consequently more release of CO2 all over the world which it is contributing factor of global warming on climate change. Thermoelectric refrigeration is new alternative because it can convert waste electricity into useful cooling, is expected to play an important role in meeting today's energy challenges. Therefore, thermoelectric refrigeration is greatly needed, particularly for developing countries where long life and low maintenance are needed. The objectives of this study is design and develop a working thermoelectric refrigerator interior cooling volume of 18L that utilizes the Peltier effect to refrigerate and maintain a temperature from 33 °C to 22 °C. The design requirements are to cool this volume to temperature within a time period of 1 hr and to obtain COP in the range of 0.2 to 0.6. The design requirement, options available and the final design of thermoelectric refrigerator for application are presented.

Key Words: Carbon dioxide, thermoelectric refrigerator, interior cooling volume, time period, COP etc.



1.INTRODUCTION

Refrigeration means removal of heat from a substance or space in order to bring it to a temperature lower than those of the natural surroundings. Thermoelectric cooling is a way to remove thermal energy from a medium, device or component by applying a voltage of constant polarity to a junction between dissimilar electrical conductors or semiconductors. Thermoelectric Refrigeration provides cooling effect by using thermoelectric effect i.e. Peltier effect rather than the more prevalent conventional methods like those using the 'vapor compression cycle' or the 'gas compression cycle'. Thermoelectric Refrigeration finds applications in electronic systems and computers to cool sensitive components such as power amplifiers and microprocessors. TER can also be used in a satellite or space application to control the extreme temperatures that occur in components on the sunlit side and to warm the components on the dark side. In scientific applications like digital cameras and charge-coupled devices (CCDs) TER are used to minimize thermal noise, thereby optimizing the sensitivity and image contrast. The coefficient of performance (COP) of compression refrigerators decreases with the decrease in its capacity. Therefore, when it is necessary to design a low-capacity refrigerator,

TER is always preferable. Also, better control over the space temperature is the major advantage of the TER. Hence, TER is good option for food preservation applications & cooling of pharmaceutical products.

1.1 PRINCIPLE

Peltier Effect: It states that when electric current is maintained in a circuit of material consisting of two dissimilar conductors, one junction becomes cold and the another junction becomes hot.

1.2 MATERIAL REVIEW

Thermoelectric module is made of two different semiconducting materials, which generate thermoelectric cooling effect (Peltier effect) when a voltage of similar polarity & in appropriate direction applied through the connected junction. Two heat sinks & fans are attached to hot and cold sides of thermoelectric module in order to enhance heat transfer and system performance. There exists an optimum current & optimum voltage for maximum coefficient of performance (COP) for a specific module and fixed hot/cold side temperatures.

a good thermoelectric material should have high Seebeck coefficient, high electrical conductivity, and low thermal conductivity. Commonly used thermoelectric materials are Bismuth Telluride (Bi2Te3), Lead Telluride (PbTe), Silicon Germanium (SiGe) and Cobalt Antimony (CoSb3), among which Bi2Te3 is the most commonly used one. These materials usually process a ZT value (figure of merit at temperature) less than one. From 1960s to 1990s,developments in materials in the view of increasing ZT value was modest, but after the mid-1990s, by using nano structural engineering thermoelectric material efficiency is greatly improved. Thermoelectric materials such as primary bulk thermoelectric materials like skutterudites, clathrates and half-Heusler alloys, which are principally produced through doping method are developed but not exploited for commercial use. [10]

The best commercial thermoelectric materials currently have ZT values around 1.0. The highest ZT value in research is about 3. Other best reported thermoelectric materials have figure-of-merit values of 1.2-2.2 at temperature range of 320-5200C. It is estimated that thermoelectric coolers with ZT value of 1.0 operate at only 10% of Carnot efficiency. Some 30% of Carnot efficiency could be

reached by a device with a ZT value of 4. However, increasing ZT to 4 has remained a formidable challenge. Bell also mentioned that if the average ZT reaches 2, domestic and commercial solidstate heating, ventilating and air-cooling systems using thermoelectric material would become practical. [10]

2. LITERATURE REVIEW

Jincan Chena et al.,[1]:- According to non-equilibrium thermodynamics ,cycle models of single-stage and two-stage semiconductor thermoelectric refrigeration were experimentally investigated. By using the three important parameters which governs performance of thermoelectric refrigerator i.e.coefficient of performance (COP), the rate of refrigeration, and the power input, development of general expressions performances of the two-stage thermoelectric refrigeration system took placed. It was concluded that performance of thermoelectric refrigerator depends on temperature ratio of heat sink to cooled space. When this ratio is small, the maximum value of COP of a two-stage thermoelectric refrigeration system is larger than COP of a single-stage thermoelectric refrigeration system; however maximum rate of refrigeration is smaller than that of a singlestage thermoelectric refrigeration system. Hence it is convenient to use single stage thermoelectric refrigerator when ratio is small. When temperature ratio is large two stage thermoelectric refrigerator is observed to be superior than single stage by both parameters i.e. maximum value of COP and maximum rate of refrigeration.

X.C. Xuan et al., [2]:- In this paper Two stage thermoelectric refrigerator was investigated with two design configurations. Two configurations were pyramid style and cuboid style as shown in respective figures. In pyramid style configuration top side is being coldest as current is unidirectional. In cuboid style configuration current can be alternated causing top and bottom side to be switched between heating and cooling mode. To obtain optimization methods other multi stage designs can be used. The point of maximum cooling capacity and maximum COP both were taken into consideration while investigation for optimization for the two-stage TE coolers. It was concluded that value lies between 2.5-3 for both parameters that is optimum limit of ratio of number of thermo electric modules of two stages in pyramid style TE cooler and optimum limit of ratio of electric current between stages of cuboid style TE cooler. Maximum temperature difference of pyramid-style cooler is greater than single stage cooler.

Jun Luo et al., [3]:- Using finite time Thermodynamics theory performance of a thermoelectric refrigeration system, with multielements was analysed. To improve and maximise the cooling load and coefficient of performance (COP) optimisation of the ratio of the heat transfer surface area of the high temperature side to the total heat transfer surface area of the heat exchangers was done. The analysis of number of parameters which affects optimum performance of Thermoelectric system was done , parameters were number of thermoelectric refrigerating elements, the Seeback coefficients,

internal heat conductance, the heat source temperature and internal electrical resistance. As well as the analysis of other parameters like influences of total heat transfer surface area and working electrical current on the optimum performance was done. They concluded that the cooling load and coefficient of performance (COP) of TE system is greatly influenced by total heat transfer surface area and working electrical current. These results can be used for designing and manufacturing of practical Thermoelectric refrigerators.

D. Astrain et al.,[4]:- In this paper a device using phase change material based on Thermosyphon principle was developed. This device was used and tested as a heat dissipater for hot side of TE cooler. Performance of TE cooler with this device was compared with TE cooler with conventional heat dissipater made up of fins. It was concluded that with the help of developed phase changing device it is possible to reduce thermal resistance between hot side of TE cooler and atmosphere up to 23.8% at 293 K ambient temperature and 51.4% at 308 K ambient temperature, compared to commercial finned heat sink . Decrease in thermal resistance ultimately causes heat to dissipate more effectively from heat sink of TE cooler, therefore improving the COP of TE cooler. At the same values of temperatures it was observed that COP increases by 26% and 35% respectively.

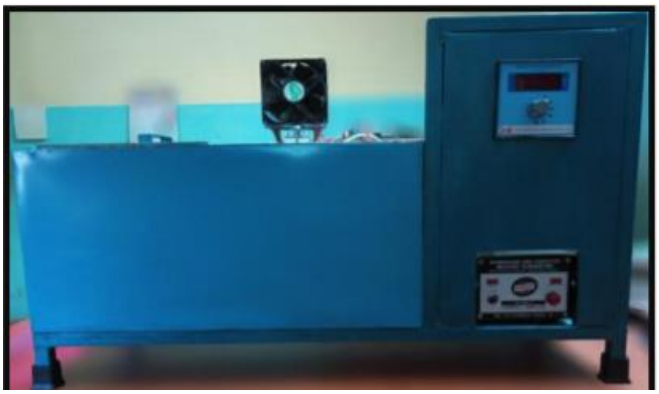
Yuzhuo Pan, et al, [5]:- Author of this paper designed and analyzed an Irreversible multi-couple thermoelectric refrigerator, which operates between two reservoirs maintained at constant temperature. Effect of other factors like external and internal irreversibility of thermoelectric refrigerator on performance was also studied. They have specified many important parameters which affects coefficient of performance (COP) of system. Results of obtained from experiments leads to knowledge of information about performance characteristics of real multicouple thermoelectric refrigerator. This information may be used to manufacture and design thermoelectric refrigerator which will perform at its optimum level.

Hongxia Xi.et al, [6]:- In this paper Author done survey on solar based driven Thermo electric technology. A brief history of development of solar based driven Thermo electric technology was presented. It's today's status and drawbacks present in current Technologies were reviewed. Applications, future scope, advantages over conventional technology where also discussed. In this paper they have discussed about two main modes, that are solar based thermoelectric power generation and refrigeration. Current status of both Technologies was described. Problems related to this technology and there possible solutions were presented. Ultimately these Technologies with some more development may lead to solve demand of Environment protection and energy conservation.

SuwitJugsujinda et al, [7]:- In this paper they have fabricated thermoelectric refrigerator using thermoelectric cooler. Thermoelectric refrigerator (25 × 25 × 35 cm3) and thermoelectric cooler (4 × 4 cm2). This system was applied to 40 W electric power without any cooling fan as heat dissipater at

heat sink. They have measured temperature of this system at ten different points. It was concluded that these experiments results into temperature of cold side of thermoelectric cooler to be decreased from 30°C to -4.2°C for 1 hour and decreased to -7.4°C for 24 hours with heat plate temperature being 50 °C. Temperature of cold side of thermoelectric refrigerator decreased from 30°C to 20°C for 1 hour and decreased further in 24 hours. 3 and 2.5 are the maximum value of coefficient of performance (COP) of thermoelectric cooler and thermoelectric refrigerator respectively. S.A.Omer et al, [8]:- This paper presents some results of thermoelectric refrigeration system using phase change materials (PCM) integrated with thermosyphones. They investigated two models of thermoelectric refrigeration system, one with conventional finned devices as heat dissipater and other with phase change material (PCM) as heat dissipater. After results they have concluded that coefficient of performance (COP) and effectiveness of thermoelectric refrigeration system with Phase Change Material (PCM) is higher than conventional one. They have also compared thermoelectric refrigeration system of two kinds, one is using phase change materials (PCM) without thermal diode and other integrated with thermal diode (Thermosyphones). Results shows that thermosyphones used prevent leakage of heat during power off. Overall they have concluded system can be work with the help of renewable energies like solar energy producing electricity. It is suited for medicine and food storage.

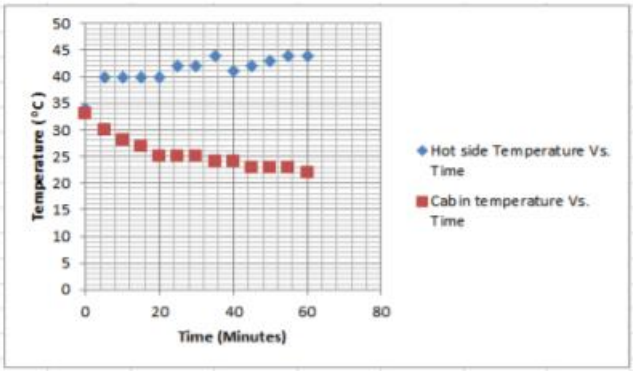
3. CONSTRUCTION



The cabin of volume 21 lit. is fabricated using galvanized sheets and polyurethane foam(puff). The inner surface of the cabin is insulated completely using puff (3.8mm) so as to isolate the cooling cabin from the atmosphere. The thermoelectric module is sandwiched between two CPU heat sinks of different sizes using thermal paste to set a single unit. Thermal paste plays a vital role in conduction of heat from Peltier module to the aluminum heat sinks. One such unit is made. These units are placed in the cut slots with the smaller CPU heat sink facing the interior of the cooling cabin and the larger CPU heat sink on the outside of the cabin to establish greater heat rejection. Additionally, fans are fitted on the inner and outer side of the heat sinks. Electrical connections are made and power is supplied from a 12V battery eliminator. K type thermocouples are placed inside the cabin and outside the heat sink to record the temperatures. Separate control panel containing dc eliminator switches and temperature indicator is made for taking readings.

4. WORKING

Experiments are conducted to analyses the COP. The power supply from the battery eliminator is given to system and readings of temperatures at different places are taken by placing the thermocouples near modules, at center and outside the heat sink for every 10 minutes of time. The readings are tabulated and check for least temperatures occur in cabin and maximum temperatures occur at the outside heat sink. After that the power is switch OFF and checks for the storage times of



the cabin and readings are taken. The tabulated values are plotted as temperature vs time for power ON and OFF conditions.

5. EXPERIMENTAL SETUP

6. RESULT AND DISCUSSION

Sr. No.	Parameter	Values
1	Maximum temperature difference in ºC	22
2	Time taken in minutes	60
3	$(COP)_{theoretical}$	0.4855
4	$(COP)_{actual}$	0.3143

From result table and graphs, it can be concluded that as time goes on increasing, the temperture inside the cabin falls down gradually. At the same time, hot side temperature remains constant (near about 40°C).

7. CONCLUSIONS

1. The Coefficient of performance of the system for TEC1- 12706 is calculated from the average of readings. It is observed that COP of Thermoelectric refrigeration using TEC1-12706 is lesser than COP of VCRS.

2. Solar power can be used as power source to the system as it is a renewable source of energy. This immensely decreases the working cost of the refrigerator and burden on the earth.

3. Liquid cooling at hot side can be used to increase the refrigeration effect.

4. Waste heat can be recovered using ducts for heating purpose.

5. Number of Peltier modules or multistage Peltier modules can be used to increase the cooling effect.

VENDING MACHINE

[1]S. Udaya Bhaskar, [2]Mr. Sandeep Mulabagal

[1] Associate Professor ,[2]Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract –

This paper presents different beverage machines each includes unique operation like vend beverage when user will insert coin or design of vending machine depends on FSM etc. Vending Machine is a system which can vend or offer different products normally installed in supermarkets like household goods, railroad lines, offices, institutes and various other public region. Dispense different products is an automated process, without man power easy to save precious time of human normally seen in fast moving cities because of fast paced life. This paper compares different aspects or response like space, time, speed, power dissipation of a vending machine that is automated product to create our day to day life more suitable and to cover market viability. Key Words: Vending Machine, FSM, Human Machine Interaction, Xilinx ISE and Cadence, etc.

1.INTRODUCTION

Vending Machine (VM) is a machine which can automatically vend different products according to user demand. Vending machine is a machine which uses digital and mechanical energy or mechanisms uses actuators etc. in order to dispense items like medicines, food products, passes or licenses to users automatically means without man power on payment into slot. In most cases vending machines receive two sets of instalment, Credit/Debit Cards and Cash. Credit/Debit Card attributes require to be seized for sales along credit cards. Coffee vending machines can be installed anywhere such as bus station, office, residential region, construction, etc. Accordingly, humankind who likes to drink coffee or tea can buy a cup of coffee or tea anywhere and anytime from them.

2. SURVEY ON DIFFERENT VENDING MACHINES

A great flavoring drink permits workers, guest and customers a bit of gratification in a overdone day. All foods, beverages and constituents offered for disposal through vending machines will be constructed, handled and developed in creations.

2.1 Influential Factors of Vending Machine to Enhance the Interaction Performance

General VM buy activity. The entire operation carried 5 steps, namely starting buy, selecting, filtering, instalment and closure. The selected particular performance solutions in each step were clarified and costumers' tasks in each selection were examined.

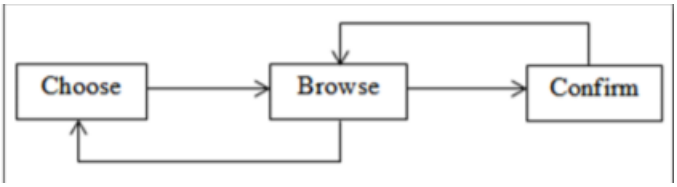

Fig. 1 : Concept of model

Vending machine interface action is mostly divided into four important steps of click, browse, confirm and return. Click, browse and confirm are the three important steps as the main important action. Phase return is considered as an coincidental performance, that is, return demands are constructed when the costumer handles incorrectly. Return is splited into two kinds: return to the previous step and return to the start sheet. Choose - browse - (return) – establish the correctness that can be deliberated into the less time for T=a+b+c as stated by to buying operation. Buy time is being enlarged when the return performance appears. Then the total time for the buy action can be decided as T0=a+b+c+d. They hypothesize that increase the time of buy are 2 return actions: 1. The first time to considering for the return button. 2. Returning to the start sheet, click on the return button and halting on each sheet before this one. The concept of model is shown in above figure. It market viability with improving intellectual benefits or regulation, shortens buy time and stay away from performance defeats.

2.2 Comparison of different attributes in FSM based Vending Machine

They speak about two different set of rules for a vending machine as delineated below and then detecting out the changing speed, timing restraint, power, space demand andusability of logic present in stratixfpga family in order to observe out more well organized and synthesizable that is covert HDL into actual component machine as for this vending machine specification. Vending machine characteristics to be executed is related as below:

1The machine withdraws multiples of Rs10 only.

2. The machine can disburse:

Water:Rs 20 (Wi)

Snacks: Rs 20 (Si)

Soft Drink: Rs30 (Ci)

3. It has a Cancel key or tab (Cc)

4. Only one input may be operate at a time

5. A system can be disbursed in one complete clock cycle

6. If more than Rs 30 is put, the money is automatically that is without physical interaction the extra money come back means returned

7. If no inputs are active lively, the state system remains in same state that is in the current state

. 8. Outputs: All construct a pulse that operates the deliver contraption:

Ro: Return out (all money in the system)

Wo: Water out, Co: Soft drink out

So: Snacks out,

out10: Rs 10 out

Originally the system was in its set initial position or condition which called state A for the design reason. Given an input of Rs 10 the system design moved in its 2nd condition which was state B involved with this point the vending system is griping Rs 10 in its balance and the user has 2 selections either to reject the vending operation with the input of Cc that is cancel which is available on the system or set in another Rs 10 note in the system and go on to the next condition which is state D. Now at this period vending system assembled Rs 20 accordingly user is qualified to select options between water or snacks both of which are of Rs 20 and then go back to its inceptive condition besides beat Cc (cancel) key to finish the operation or besides set in another Rs 10 note in the machine to vend the soft drink which prices Rs 30 so by now the user has extended state G, another Rs 10 note will be directly discarded and signal out10 goes high radiating off the additional Rs 10 out of the system from this condition user can prefer any one of the three outcomes to vend from the vending system that is soft drink (Co), water bottle (Wo) or snacks (So) or one can comparable Cc (cancel) and all money will be get back by forcing Ro signal. Total number of conditions utilized is from A to H that is 8 conditions constructing it a little redundant. Next the same vending system with same characteristics with a little more expert or skillful way so as to reserve some space and condition demand and then observe out the wanted system is well organized or not than the foregoing space proceeding system in phrases of different essential features of a design cycle. Differentiating two dissimilar algorithms, the key difference is under timing restriction permitting positive setup time and negative hold time. One design finding one more additional condition it is better organized in terms of timing restriction and space.

2.3 Smart Coffee Vending Machine

A smart vending system accommodates a sensor and actuator network which made up of a gateway, arising from a person's surroundings sensors, and controllers. A gateway suits an overpass between the network and an implementation managing on a smartphone that is mobile along Bluetooth. The gateway presented with some missives associated to the arising from person's surroundings

conditions (for example, cleaning status) of the system from the sensors. Those missives are sent to the supplication. In inclusion, the gateway sends command missives involving the customer's predilection on the taste of coffee to the controllers. On an approach of the verification of abstraction, they establish two magnetic sensors and three controllers. The vending system and the apparatuses established in the vending system. The magnetic sensors are established interior the system: one is connected to the substances mixer and the other is connected to the body of the system. The sensor on the body is joined to a sensor interface which conveys resolute data to the gateway. The sensors react like a switch. If the mixer is isolated from the body, an unsecured happening occurs. Otherwise, a secured happening occurs. The remoteness of the mixer is examined to be the cleaning status of the system. The substances mixer is a tool in which water, coffee, sugar and powered coffee creamer are motley to create a cup of coffee. As a much of remnant of thosesubstances are connected to the internal exterior of the blender, the blender should be cleaned from time to time. The blender has to be disconnected from the system while it has been washed. Accordingly, it is supposed that the blender is wash if it is isolated from the system. By the supposition, the role of the sensors examines whether the system is washed or not for a definite time interval. With the details of data collected from the sensors, the gateway computes the constituting wave of cleaning for a particular time and regulates whether the system is clean or not. The gateway conveys these detailed data to a smart phone application when the supplication links to the gateway. The controllers adjust and manage the quantity of coffee, sugar and powered coffee creamer depending on whether to customer's predilection on the taste of coffee. The customer's predilection is collected from a smartphone supplication through the gateway. Each controller handles the gyration of a motor which regulates the quantity of each substance. The quantity of the gyration is handled in three steps: less, normal, and much. Smart vending system which can automatically that means without man power and without physical contact with that object evaluate its own under cover situated arising from person's surrounding conditions and handle the quantity of coffee, sugar, and powered coffee creamer to create a cup of coffee depending on whether to customer's predilection on the taste of coffee. A sensor and actuator network which made up of a gateway, magnetic sensors, and controllers and a smartphone supplication depended on Android. The network and the supplication interchange some data through Bluetooth.

2.4 Automatic Beverages Vending Machine and it's performance on Cadence and Xilinx 13.1

The popular behavior of any vending favors the as a result of steps with available make different depended on the end user demands. The systems generally work, when some money is set in a time period. Then, a key or tab requires to be forced or a bar dragged. If the exact amount value is loaded into the time period of the system, the selected object will be dribbled to a flat container, where it can be drawn out by the person creating the buy. Selection: User creates a selection of product. Waiting for money placing: When user puts money or cash, money token allows the quantity of cash or money placed into the vending system. Product Delivery: If accurate quantity of cash value is placed the

product will be dropped and if there is any assess will quantity that will be get back to user. Service: The vending system will request for service if the product is not able to be used in the system.

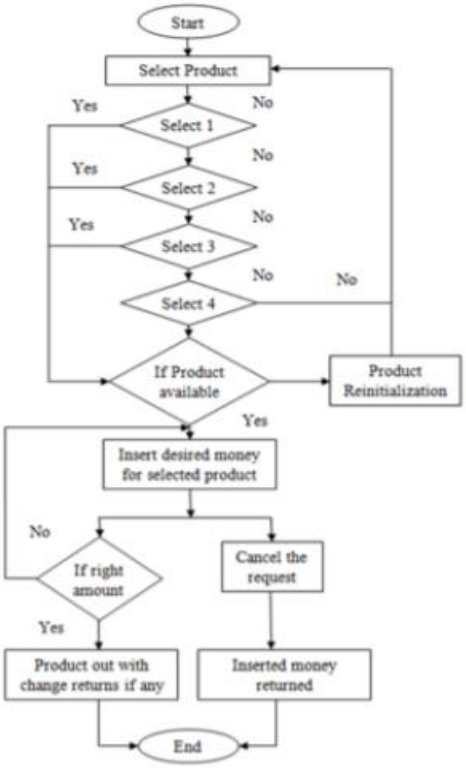

Fig. 2 : Flowchart for Vending machine

This same design they executed or contrivance on xlinix 13.1 and cadence so ultimately they judge regarding these execution, operating cadence permits optimized or improving efficiency related to space, power and delay.

2.5 Vending Mahine based on the short message payment

The vending system is predominantly collected of 3 parts: vending system correlated interact with system (containing vending system interface plate, monolithic integrated circuit and GPRS module), GPRS communication networks which are containing mobile diverting middle of GPRS base station controller, GPRS service support node as well as GPRS backbone networks etc. and the control center. The vending system communication interface module is predominantly collected with of monolithic integrated circuit and GPRS module and so on.

The monolithic integrated circuit obtains vending system's condition or position information via the Multi drop bus (MDB) protocol, reserves it to the burn and then sealants the user datagram protocol (UDP) data packet depending on whether to the user datagram protocol (UDP) agreement's message data, seals the IP data newspaper in addition to the IP highest part, and then seals the point to point protocol (PPP) frame depending on whether to the point to point protocol (PPP) frame's form,

broadcast it to the managing main center through the GPRS module by the IP protocol, assembles communication between monolithic integrated circuit and GPRS module via PPP. The user first sends the information data to the guest facility managing center and then the buying or selling from user center sends back the information frame to the user and the vending system GSM module. The user inputs the information data frame on the vending system and then the automatic managing vending system handles the information data frame to send the managing instructions automatically. The information data frame which the GSM module accepts is transferred to the buying and selling action of user center to assemble the last information data processing. The short message payment by acquiring M68HC11 and MC35 and construct it have the task of the short message shopping and assemble it simple to use and handle.

3. EXAMPLE OF IMPLEMENTATION OF VENDING MACHINE USING XILINX 14.2

Vending system that sells soda canes that costs are a 20 each. Additionally system has only 3 types of coins: 10, 20 and 50. System purpose is to design a state machine with different conditions that regulates when to disburses a cane, how to get back the change. In this design cane pay no attention to the volume of the storage, which means, it will suppose that there will ever be cane in the vending system. Also, suppose that only one operation could be created in every “clock cycle” or position. Understanding the possibilities : There are quite few options:

1) invading no money

2) placing 10 reproduced by another 10 => acquiring the can

3) placing 10 reproduced by 20 => accepting modification => acquiring a cane

4) placing 10 reproduced by 50 => accepting modification => getting a cane

5) placing 20 and acquiring the cane

6) placing 50 => accepting change => acquiring a cane.

State Diagram:

Fig. 3 : State Diagram

Explaining the states:

1) put_money: this is the first condition after idle condition; here the user sets in the coins.

2) in_5: If the user place 50, the system proceed to this condition. Pay attention that the machine gives back a 20 change without disbursing the cane yet.

3) change_1: after providing a 20 change for the user who paid 50 they require to get back another 10 change. Here, in this condition they do absolutely that. Again, note that the cane still has not been disbursed yet.

4) in_1, in_3, in_6: acquire to those conditions be controlled on the sum of money that been entered by the user.

5) soda_out: disbursing out the soda cane.

Simulation Result:

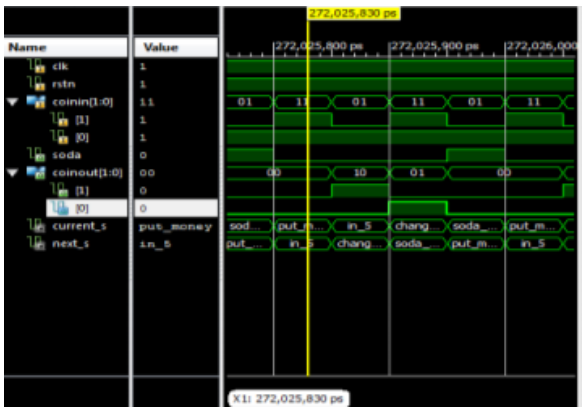

Fig. 4: Waveforms gives detailed information about system

4. CONCLUSIONS

Compared different vending machines and all are designed with different aspects like area, power and delay because of time, switching speed, etc. In smart coffee vending machine is more optimized system with customer preferences. Because according to customer choice they can also select amount to prepare coffee or tea. This is optimized system with some aspects which are power, area and time. Also explain with one example of dispensing soda according to inserted coin to cover market feasibility.

WIND ENERGY VEHICLE

[1]S. Udaya Bhaskar, [2]Ms. S.C.Sireesha

[1] Associate Professor ,[2]Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract-

Due to scarcity of fossil fuel in future and its detrimental effect on the environment, an alternative energy has to be discovered. Wind power is clean and sustainable natural resources that has yet to be fully utilized in the automotive industry. Also, the sun is probably the most important source of renewable energy available today. The hybrid system has been designed and installed to generate power which combines wind turbine and solar panel. The hybrid model system is renewable energy system, which helps conserve energy by reducing the use of fuel in vehicle. Hence developing a new method for the economical evaluation of Hybrid Systems for electricity production. Keywords- Scarcity, fossil fuel, environment, alternative energy, natural resources, renewable energy.

1. INTRODUCTION

Here the hybrid car is specially designed so that the energy limitation can be easily overcome y using the hybrid technology. As the battery running are beneficial for the society and more often this type of technology is fruitful for the environment. so to overcome the energy limitation we have installed wind with solar energy and that is called the regeneration of A. Reducing Carbon Dioxide Emissions The most effective way to reduce carbon dioxide (CO2) emissions is to reduce fossil fuel consumption. Many strategies for reducing CO2 emissions from energy are crosscutting and apply to homes, businesses, industry, and transportation.

B. SOLAR ENERGY

Solar energy is radiant light and heat from the Sun harnessed using a range of ever-evolving technologies such as solar heating, photovoltaic's, solar thermal energy, solar architecture and artificial photosynthesis. The large magnitude of solar energy available makes it a highly appealing source of electricity.

C.WIND ENERGY

Wind power is the use of air flow through wind turbines to mechanically power generators for electricity. Wind power, as an alternative to burning fossil fuels, is plentiful, renewable, widely distributed, clean, produces no greenhouse gas emissions during operation, and uses little land.

2. FIELD OF INVENTION

The fixed wind powered electricity generation systems in use, till now are dependent on wind direction and the force of the wind. But the wind is not available at all places and all time throughout the year. Therefore, there exists an immense need of a system for generating electricity from wind induced by moving vehicles which is available throughout the year at various places and with sufficient force of wind. Also solar powered electric vehicle is there but need to install it as an auxiliary fuel for fuel vehicle. Therefore, need of inventing a hybrid renewable energy source as an auxiliary source for fuel vehicle. Therefore, this invention provides a solution to the problem for generating electricity in this manner.

3. OBJECTIVES

1. The main object of the present invention is to provide a method and a system for generating electricity using easily available wind induced by moving vehicles and solar energy in transit or in operation.

2. The other objective is to provide a solution for reducing pollution created by fuel vehicle by use of freely available renewable energy source i.e. solar and wind energy.

4. METHODOLOGY

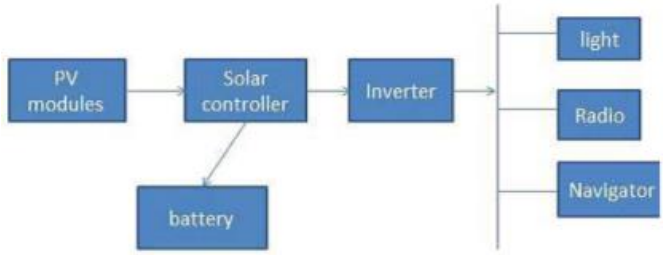
This paper deals with how energy can be stored by moving or standstill vehicle which has a fuel kit using wind and solar energy.

5. WORKING

Here first of all the vehicle that is presently running on battery say for ola electric vehicle can be modified by installing various new circuits. The solar panel will charge the battery on the day time. The circuit attached to the battery will protect the battery from damages the sunlight intensity is more in the summer the solar panel passes more amount of voltage than required by the battery and this leads to the battery damage so forstabilizing the voltage the circuit will be installed between the solar and the battery. As there is no one in the electric car we can install the carborator fan and the fan will be attached to the generator and the vehicle is in moving position even in the night time when the solar panel will not work the battery will be charged through the wind energy that is from the fan with dynamo attached and the battery will be charged. Clips are attached so that the user can change power source for charging the battery from solar to wind when required. And in another part the sensor based circuit is also installed this circuit will connected to the motors of the vehicle in the night time or at that when the driver forgets to apply brake in the traffic portion or when

driver fall asleep while driving in the night time this sensor circuit will continuously bypass the invisible rays and the rays will detect the in front object of the vehicle if suddenly in front objects say for any vehicle has applied brake and the driver forgets to apply brake this sensor will automatically will calculate the distance and the both objects comes closer then the sensor will pass command to the circuit and the brakes will be applied automatically. This system can save lot of life even it can avoid accidents. For increasing the loading capacity of the motor the gear section that is the gear box is also installed that will increase the loading capacity of the motor without consuming more voltage and power from the battery.

Chart -1: CIRCUIT DIAGRAM

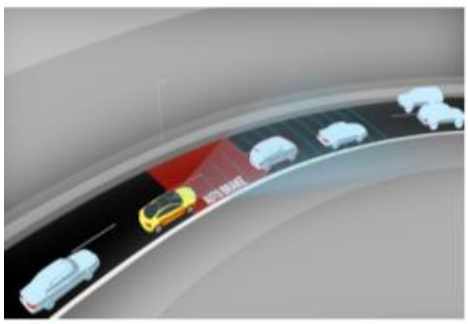


A. CONVERSION OF WIND ENERGY INTO ELECTIC ENERGY:

In this prototype the wind capturing device is a fan. Fan is mounted on the front side of the chesis with the truncated cone in front of it. Fan will get rotated by the wind blown by the blower which will get directed toward the fan due to cone where in actual it will be the wind around the vehicle when vehicle is in running condition. Rotating fan will convert the captured kinetic energy of wind into mechanical energy .The centre shat motor which is connected to battery will convert this mechanical energy into electric energy which is going to stored in the battery. Fig shows below the energy stored by prototype from wind energy.

B. **CONVERSION OF SOLAR ENERGY INTO ELECTRIC ENERGY:**

Solar panel is situated on the top of battery in the prototype. Where in actual vehicle it will be mounted on the upper body of chess is of four wheeler. While the vehicle in running position or stand still and have a sufficient solar energy the solar panel will trap that energy and due to the



photovoltaic effect of solar panel, it will convert this solar energy into electric energy which will get stored into the battery.

6. AUTOMOTIVE TRACKING SENSORS

The sensors used to track objects and monitors, the movement of the host vehicle as well as the movement of the surrounding objects to predict collisions are known as 'tracking sensors'. In automotive applications, cost of the sensor is a major factor.

7. ADVANTAGES

1. Zero Carbon emission

2. Accidents are avoided due to automatic braking

3. Use of brushed motor

4. Vehicle speed has been increased

5. Can run in the city as well as on highways.

8. DIS-ADVANTAGES:

1. Limited vehicle speed

2. Limited distance covered

3. Takes more time to charge the battery.

4. Only can be used in city.

9. CONCLUSIONS

After making the final completion of project it is found that project is in working condition. It is found that prototype captured the solar energy through solar panel and wind energy through fan induced on it. There are huge potential for producing electricity from renewable sources. This paper gives a clear idea that vehicle powered with the help of solar energy and wind energy is more effective than fuel vehicle.

WIND MILL BASED WATER PUMPER

[1]Mr. P.Praveen Babu, [2]Ms. S.C.Sireesha

[1,2]Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract –

The main source of energy has been coal, oil, natural gas, nuclear energy, wood and coal. However, all these sources are limited and are the main cause of pollution and this has led to development and more focus on sustainable energy supply with minimum pollution effects. Hence research and analysis has shown that wind energy, solar energy and biomass are the most prominent solutions to the above problems because they are eco-friendly and readily available in nature. Wind energy can be generated using windmills that provide mechanical energy that is used directly on machinery e.g. water pump and grinder; or wind turbines that provide electrical energy. The main objective of our project was to design a windmill and therefore our scope will be limited to a windmill for water pumping water. Windmills are classified into two main types based on the axis about which they rotate. Horizontal axis has the main rotor shaft running horizontally and if the rotor must be oriented in the direction of the wind, a wind vane is coupled with a servomotor. Vertical axis has the main rotor shaft running vertically. The rotor assembly can have two or more blades depending on the desired solidity. In our design, we used a horizontal axis windmill with 3 blades, tensile strength 31 N/mm², density 0.855 g/cm3, length of blade 30 inch (2.5 feet) and strength of blade is 4500- 6000 psi. Key Words: natural resources, renewable energy, wind pumps, insufficient fuels, aerodynamic blade.

1.INTRODUCTION

Energy today has become ultimate need of world. Today every application which has been develop in the world require energy supply for its functioning but population of the world is increasing causes tremendous pressure on the energy and mineral resources leading to their exploitation. More ever the greenhouse gases are increasing due to exploitation of these resources. So we need to focus an alternative solution for this problem. Light, wind, Biomass, water etc. are some of the alternative for this problem. Wind is one of the most clean and highly abundant resources in nature.

1.1 Definition

Wind This is air in motion and it is a natural resource that is freely available in space and moves at varying speeds depending on the geographical location Wind energy Wind energy originates from solar energy where the sun heats the atmosphere unevenly causing some parts to be warmer than others. The warmer patches of air rise and other air patches blow in to replace them. Thus alternating air flow which results in wind. Windmill Windmills are machines that are used to harness the kinetic

energy of the wind which blows over the blades rotor assembly causing it to rotate on a shaft. The resulting shaft power is then used to provide mechanical work for pumping water.

1.2 Objective

- Lifting the water without using electricity and fossil fuel.
- Setup must be non-polluting and less noise operation.
- Setup cost should be less and maintenance free, one time investment is preferable.
- It must produce some amount of power.
- Installation must be easy and cheap.
- Fuel must be cheap, clean and renewable.
- Solution for the above problem must be eco friendly

2. MATERIAL SELECTION

There are various materials available for design of blade such as wood, fiber, steel, aluminum, carbon fiber, polypropylene plastic. Out of which we have used polypropylene plastic (pp) type material for our design because of following reasons: Polypropylene blade performance and also to decrease process temperatures by adding special particles like nano, fillers.etc in order to replace the current thermo sets by utilizing the benefits associated with the thermoplastics like emission free, process-ability, recyclability, and weld-ability. Polypropylene materials offer higher strength to weight properties than thermo sets, therefore leading to lighter aero foils which can lead to cheaper transport costs and reduced turret weights.

3. MANUFACTURING

3.1 DESIGN OF BLADE

Aerodynamic performance is fundamental for efficient rotor design. Aerodynamic lift is the force responsible for the power yield generated by the turbine and it is therefore essential to maximize this force using appropriate design. A resistant drag force which opposes the motion of the blade is also generated by friction which must be minimized. Turbines operate for long periods at ground level where insect and dust particulate build up is problematic. This build up known as fouling can have detrimental effects on the lift generated. Provision is therefore made for the reduced sensitivity to fouling of wind turbine specific aero foil designs. The structural requirements of turbine blades signify that aero foils with a high thickness to chord ratio be used in the root region. Such aero foils are rarely used in the aerospace industry. Thick aero foil sections generally have a lower lift to drag

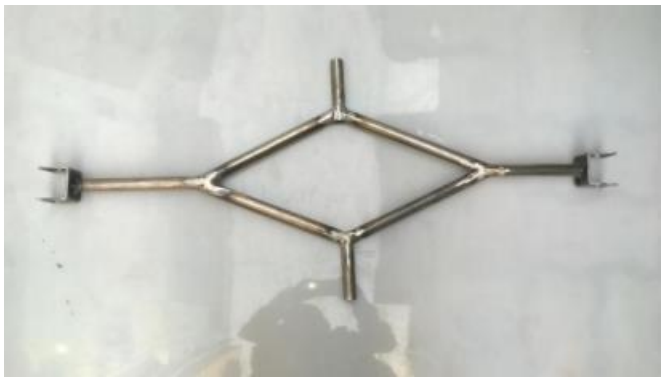
ratio. Special consideration is thereforemade for increasing the lift of thick aero foil sections for use in wind turbine blade designs.

3.2 CRANK SHAFT

Another most important component for the smooth functioning of prototype is crankshaft. Crankshaft should poses high strength, rigidity and toughness due to these requirement they are manufactured by casting and forging production techniques. Crankshaft is component connected between the turbine blade and connecting rod. With the rotation of turbine blade, certain mechanical motion is obtained which is transmitted to the crankshaft leading to rotary motion of connecting rod with piston in the pumping assembly.

3.2.1 DESIGN OF CRANKSHAFT

The size of crankshaft was too large so we have fabricated it to the required size for our project. Above table shows the original size & required size.



3.3 CONNECTING ROD

Connecting rod is long slender component between crankshaft and piston assembly via sew-saw mechanism. Mechanical motion obtained from the crankshaft for the reciprocation of piston rod in pumping assembly is transmitted via connecting rod. Connecting rod should have high ultimate tensile stress, resistance for the bending, fatigue stresses so it should be manufactured by casting and forging production techniques

3.4 SEW-SAW MECHANISM

Sew-saw mechanism is the basic principle for reciprocation of piston in pumping assembly is achieved by sew-saw mechanism. Blade rotate further leading to the rotary motion of crankshaft. This rotary motion is further transmitted in the form of transverse motion for the reciprocation of piston rod in pumping assembly.

3.5 PUMP

There are two types of pumps;

1. Volumetric (Positive displacement pump)

2. Centrifugal (Roto-dynamic pump)

Out of which we have used positive displacement pump. Positive Displacement Pump are further categorized as

- Rotary lobe pump
- Progressive cavity pump
- Rotary gear pump
- Piston pump
- Diaphragm pump
- Screw Pump
- Gear pump
- Hydraulic pump

Hence for better displacement and sufficient water discharge we have used “Piston Pump (single acting reciprocating pump)” Piston pumps are generally connected to a surface-mounted motor and used to pump water from shallow wells, surface water sources, and pressurized storage tanks, or

through long pipes. The suction head is limited to 6 meters. They are not tolerant to silt, sand, or abrasive particles because the piston seals are easily damaged. Filters may be used to remove the dirt

4. WORKING

To conduct trail, we have done set up of wind operated water pump. Windmill blades made up of polypropylene (pp) plastic. Turbine is fixed on crank shaft. Crank shaft is mounted on supporting stand. To permit relative angular motion crank shaft is mounted between bearings. One end of connecting rod is connected to crank shaft and other end connected to sew-saw mechanism by using connecting pin. A piston rod of pump is connected to one end of sew-saw mechanism. All these assembly mounted on structure insucha manner so that we should get the desired motion of piston rod. When wind is imparted on blade kinetic energy of wind is converted into mechanical energy as an angular motion of crank shaft. This angular motion of crank shaft is converted into transverse motion by sew-saw mechanism. Transverse motion is given to piston of pump so that piston will move in transverse direction. When crankshaft rotates the piston will moves in upward and downward direction inside the cylinder. When piston moves from bottom dead centre to top dead centre of cylinder, vacuum is created due to which water is sucked inside cylinder. When piston moves from top dead centre to bottom dead centre pressure of water increased above atmospheric pressure at the end water is discharged through pipe. Due to pump is single acting reciprocating pump thus there is alternate flow of water in the delivery pipe. The shaft power can be used to generate electricity by using alternator, which is mounted on crankshaft.

6. CONCLUSION

The goal of project is accomplished from the requires analysis and fabrication of prototype that is utilization of wind power to pumping water and generate electricity. Most preferable and suitable material from the design consideration point of view satisfying all the optimum condition and requirement is found to be Polypropylene Plastic. From result we have seen the efficiency of aerodynamic shape blade.

WIND WATER PUMPING

[1]Mr. N Rishi Kanth, [2]Mr. S. Udaya Bhaskar, [3]Yogesh Madaria

[1,2,3]Associate Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract:

In our project wind energy is used to rotate the wind blades. This blade coupled to the shaft. At the end of shaft, the flywheel is placed. The eccentric arrangement is provided in the flywheel. When the blade rotates automatically fly wheel also rotates. Due to the eccentric arrangement the rotation motion of the flywheel is converted into linear motion. This reciprocating motion is given to the handle of the pumping system. The up down motion of the handle is given to the piston, where the water is sucked using pressure variation from lower ground. Finally the water is supplied to the outlet. Wind blade provides the continuous motion which helps to supply the water continuously .Since time immemorial, the main source of energy has been coal, oil, natural ga s, nuclear energy, wood and coal. However, all these sources are limited and are the main cause of pollution and this has led to development and more focus on sustainable energy supply with minimum pollution effects. Hence research and analysis has shown that wind energy, solar energy and biomass are the most prominent solutions to the above problems because they are eco -friendly and readily available in nature. Keyword: Fly wheel, Reciprocating pump, Blade, and etc….

INTRODUCTION

Energy from the air can be utilized in multi various ways. It can be tapped directly from air in the form of electrical energy. The contribution of these sources in the total consumption of energy in the world is about 15%. The scope for application of air energy now stands inherently enhanced through intensive research and development carried out all over the world. Air can be directly utilized for the purpose of cooking and drying. By the same time, it can be also used for boiling of water, air heating and refrigeration. Furthermore, wind energy can be utilized for driving motors for pollution free riding at this time, where air pollution plays a major problem for environmentalist

II. EXPERIMENTAL PROCEDURE

The experimental analysis of this project started with a detailed study of various mechanisms that could be used in this project and their practical applications. Since this project involves the effective utilization of energy derived when a nature air the design aspects may not actually coincide with the requirements for the fabrication and practical applications. Hence, the method of Reverse Engineering was adopted in this project. As per this method the tower was first fabricated based on the requirements with standard parts keeping in mind various safety precautions. Testing and then the

basic designing of the parts followed this. If any of the parts was found to possess strength lesser than the required, it was replaced by a standard part of greater strength. The wind energy is converted into mechanical energy. Initially this project had a nature air area and tower with a fly wheel leaf reciprocating pump arrangement .Also the rotation of the flywheel was not found to be satisfactory, reducing the efficiency of the leaf. This flywheel and leaf has a velocity ratio of 1:1. Leaf is attached to the flywheel. Windmills generally consist of two basic types with the classification being based on the orientation of the axis of the rotor. The main classifications are discussed below:

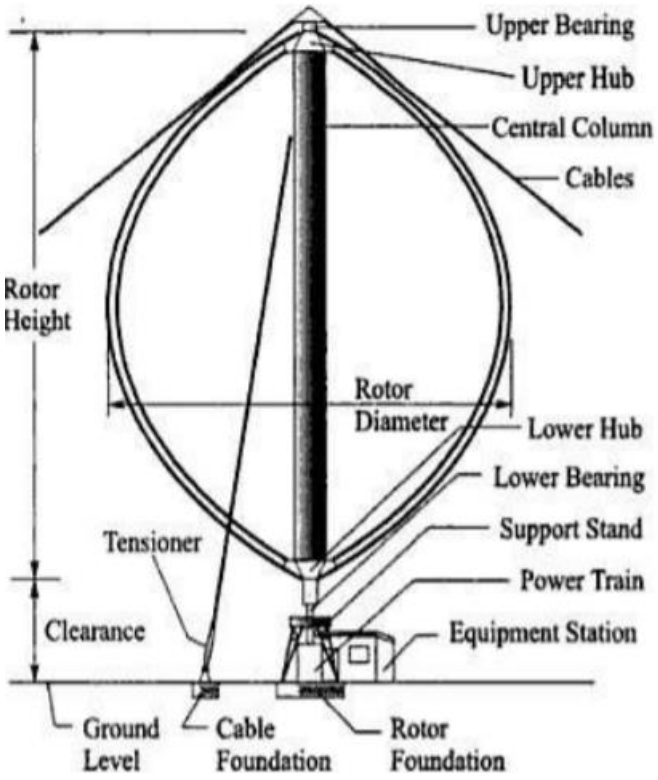

Figure.1. Wind Mill with Pump

2.1 Vertical Axis Wind Turbine (VAWT)

This has blades which are arranged on the vertical axis and are rotated by wind and therefore it doesn't require a yaw mechanis m since it can harness wind from any direction. It does not rely on the direction of the wind to generate power as in the case of the horizontal axis. They usually operate closer to the ground which has an advantage of allowing for placement or replacement of heavy equipment. However this is a disadvantage as winds are lower near ground level hence less power output. 2.2 There are two main types of the VAWT namely: Savonius It operates like a water wheel which uses drag forces. It has a simple design and is therefore relatively simple and cheaper to build. It is mostly used in situations that do not require large amounts of power. However, it is less powerful than most HAWT because it uses drag to rotate itself and has a higher power to weight ratio. The total amount of turning torque of the mechanism relies on the drag force on each blade. Darrius It uses

blades similar to those used in the horizontal axis wind turbine (HAWT). It has two or more curved blades that depend on wind in order to revolve around a central column. It functions by generating a lift using the rotating motion of the blades. The wind acting on the blade creates a rearward momentum change which propels the blade in the direction of rotation. This cannot occur unless the blades are already rotating and therefore they require a separate means of starting i.e. they are not self-starting. Figure.2. Vertical Axis Wind Turbine

2.3 Horizontal Axis Wind Turbine (HAWT)

It has blades that are similar in design to aircraft propellers where air flow over the air foil shaped blades produces a lifting force that turns the rotor. They should be placed on towers to ensure maximum use of the winds at higher levels. For large scale types, they have an active yaw mechanism with wind direction sensors and motors that will rotate the nacelle. In both upwind and downwind the rotors should be perpendicular to the direction of wind and if the rotor is held in a fixed position, only 21% of the wind energy will be captured (Wortman, 1983).For upwind type, the rotor rotation is accomplished by using a vane to measure the direction of the wind and then the information is communicated to the yaw drive. The yaw drive then drives the rotor so that the turbine is facing the direction of wind for maximum harness. They don't suffer from wind shade phenomenon as the wind is tapped early enough before obstruction by the tower. For downwind types, they don't use a yaw drive because the wind itself orients the turbine. The blades are situated on the downwind side and therefore capture the wind and rotate following its direction. These designs are prone to "wind shade" a process in which the wind flow is obstructed by an object e.g. the tower thus reducing amount of wind and therefore a reduction in the power output.

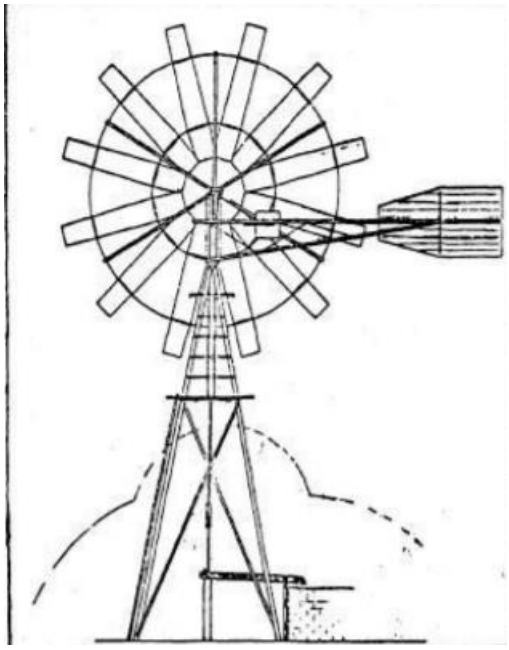

Figure.3. Wind Mill

III. DES CRIPTION

3.1 Field of the Invention

The present invention relates generally to the recovery of water from an underground source through the use of a reciprocating pump system. The present invention relates more specifically to an improved water pumping system adapted to be driven by a windmill that utilizes an air lift fluid pump for generating a flow of water to the surface.

3.2 Description of the Related

Art Water pumping windmills may be found on farms and ranches worldwide and provide critical water supply for domestic and livestock use, especially in areas where electrical and fuel driven pumps are not practical. The type of technology associated with these windmill water pumps has enjoyed continuous use since the late 19th Century and may be generally illustrated by U.S. Pat. No. 1,632,188 assigned to the Dempster Mill Manufacturing Company (1927). This type of windmill pumps water by means of a positive displacement, reciprocating pump, submerged below the static water level of a drilled well. The pump is conventionally connected and supported by a water discharge pipe which leads to the surface and a reservoir for the water. The pump is driven by a reciprocating rod, typically made of wood or fiberglass, which reaches down from the windmill's transmission to the pump through the discharge pipe. It is typical in reciprocating water pumps of this type to utilize a barrel or cylinder within which a piston is moved in a reciprocating motion by the pump rod. Both the piston and the bottom of the pump barrel incorporate check valves that allow water to flow only in the upper direction. The check valve at the bottom of the cylinder is commonly called the foot valve, while the valve in the piston is commonly called the lift valve. When the piston is lifted by the pump rod attached to the surface windmill, the lift valve closes and the piston lifts the entire column of water above it until water overflows out of the discharge pipe at the surface. At the same time a slight suction is formed under the piston causing the foot valve to open and water to flow in under thepiston. During the next half of the cycle the piston moves down causing the foot valve to close and the lift valve to open such that water flows through the piston into a position to be lifted during the next half cycle. Water flow valves, such as those described above, must be periodically replaced. The lift valve, which is typically made of leather or rubber, eventually wears due to particles of sand or earth in the water. Other check valves involved with the system also have finite useful lives and must be replaced on a regular basis. Replacement typically involves the removal of the pump rod, discharge pipe and pump by lifting the entire assembly up from the drilled well in order to access the valves. Such replacement efforts involve considerable labour and expense and greatly affect the down time of the windmill pumping system. Obviously, many efforts have been made in the past to replace the windmill pumping system powered by electrical motors and internal combustion engines. The present concern relates only to such efforts that have sought to improve upon wind driven pumping

systems. One effort in the past is described in U.S. Pat. No. 3,367,281 issued to Gray on Feb. 6, 1968 entitled apparatus for pumping water from wells using wind power. The Gray patent discloses a water pumping device in which compressed air is generated by a windmill, stored in a tank, controlled through a pressure regulator, and delivered to a displacement type water pump. This invention, although not overly complex, is not directly adaptable to the typical windmill structure. The Gray disclosure describes a down stroke of a windmill pump rod as the compression stroke which does not lend itself well to application in conjunction with typical windmills that are designed to apply force and power on the upstroke of the pump rod. The pump rod conventionally made of wood would likely snap if used to compress air on the down stroke. The Gray invention also utilizes solenoid valves that are electrically controlled to effectuate the air compression cycle. Such electrically controlled valves are typically not practical in remote windmill locations. Finally, the Gray invention further requires the use of an air hold-up means and a pressure regulator. U.S. Pat. Nos. 4,385,871 and 4,358,250 provide further examples of inventions generally related to the conversion of wind energy into compressed air for the purpose of water pumping. These earlier efforts, however, also do not address an appropriate adaptation of the air compressing mechanis m to the typical windmill structure or to the utilization of the same in conjunction with an air injection type water pump. **IV. S ELECTION OF SITE TO WORKING**

The viability of a windmill is greatly affected by its location. The site must have sufficient wind power to move the windmill and also be away from obstructions that might cause turbulence. The speed of wind for a given location is not constant and thus the climatic condition of the site should be examined for over on a year and recorded on a wind map which is then used to analyze the suitability of the sit. To avoid distractions, most windmills are located on hilly areas or the rigs are tall enough to ensure the rotor is far above the obstacles. The site of our windmill had been identified and there was no need for selection of another site. However, we did an analysis on the site to determine its suitability and the findings were as follows. The location of the windmill is strategically away from tall buildings and tree.

V. CONCLUS ION

The total torque output of the windmill is 106.4572 Nm and this is sufficient to sustain the desired flow rate of (0.1736 X 10-3) m3 per second with a maximum head of 30m, and also to overcome other barriers to 5motion e.g., friction. The number of blades used is 24 with a total surface area of 0.5585 m2 and this gives a solidity of 0.8, the minimum (optimum) value of solidity for a windmill and therefore ensures conformity with the standard specifications. Gears and bearings are subject to very high heat losses due to friction and this will be greatly minimized by application of oil and grease and therefore greatly improving the efficiency. All materials used are locally available and at a low cost making the model economically viable.

FABRICATION OF RICE PLANTING MACHINE OPERATED MANUALLY

[1]Mr. P.Praveen Babu, [2]Ms. S.C.Sireesha

[1,2]Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

ABSTRACT

Agriculture is the most important sector of Indian economy. Rice being the major crop cultivated in India, a huge amount of work force is engaged in rice production. The common practice of rice cultivation is manual transplanting of seedlings. Besides being costly, cumbersome and time consuming it is very labour-intensive task. To mechanize the transplanting system several attempts has been made to design and fabricate transplanting machines. Due to high price of an automated paddy transplanter it becomes impossible for a small scale farmer to purchase a non-subsidized automated paddy transplanter. An attempt has been made to fabricate a manual paddy transplanter which is effective as well as cheap. Selection of an efficient power transmission system and a suitable mechanism to drive the planting claw is given due considerations in its design. The objective of this project is to design a paddy transplanting mechanism to transplant rice seedlings by small scale farmers in the country.

Keyword: - saplings, Tray, Rocker arm, wheels, paddy transplanter

1. INTRODUCTION

Rice being the important food crop covers about one fourth of the total cropped area and cater food to half of the Indian population. In India, average rice production per hectare is 2.2 tonne. Rice is the staple food of more than half of the world. It constitutes 20% of the total daily nutrition need of an average person. More than 3.5 billion people depend on rice for their daily demands. A Rice Transplanter is an agricultural machine used for transplanting saplings to the field. .This is very important as it reduces the time taken to transplantsaplings (when compared to manual transplanting), thus allowing more time for harvesting. Hence, paddy transplanter is one type of transplanter which plants paddy saplings to the field. The main objective to develop a mechanism for transplanting rice seedlings is:

- To increase the efficiency of traditional rice planting method without sacrificing its basic purpose
- To achieve higher productivity, yield and reduce health risk.
- To develop an alternate source of income for rural youth through custom services.
- To develop an instrument, which will be cheap to buy, repair and maintain.
- To reduce the labour cost.

Rice transplanting requires considerably less time and labour than manual transplanting (1–2 ha/person/day versus 0.07 ha/person/day). It also save from Tedious Farming Work Struggle, the tedious working of planting paddy by hand.

1.1 Literature Review

1) Design & Development of Rice Planter Machine, D hanesh D Patil ,Dr. Mangesh R Phate, ISSN 2347-6710, Vol. 5, Issue 7, July 2016. They used 4 row, 3 row and 2 row rice transplanter on the basis of their study of various parameters they concluded that the 3 row rice transplanter was the best among all transplanting methods. So ,Due to higher costing for 3 row rice transplanter, we are manufacturing 2 row rice transplanter.

2) Design Analysis and Fabrication of Manual Rice Transplanter , Satish Kumbhar, Sangram Khot, ISSN 2347-6710, Vol. 6, Issue 3, March 2017. The cost is cheap than motor and hand cranked mechanical rice transplanter. The four bar mechanism gives the each operating and maintenance with less parts which reduces the weight. Therefore we are using four bar mechanism for giving a simple and easy operation of rice transplanter machine.

3) Ergonomic Evaluation of Manually Operated Six-Row Paddy Tramsplanter, Rajvir Yadav, Mital Patel, ISSN 147- 157, 2007 The height at which push-pull forces were applied was the most important variable in affecting the force output. They concluded that the foot placement, handle height and body postures all affected the push-pull strength. Further reported that the posture of workers while performing some tasks is another factor that can influence energy requirements. Transplanting in bending posture required the highest energy than any other posture. The body posture during the push and pull force is important factor while transplanting.

4) Impact of SRI Technology on Rice Cultivation and Cost of Cultivation, Ramapuram Jayapal Reddy, Dr. N. Sandhya Shenoy,ISSN 2250-3153, Volume 3, August 2013. They conducted an economic analysis of traditional SRI rice cultivation practices in Mahbubnagar district of andrapradesh. It was concluded that the SRI (system of rice intensification)method of cultivation is advantageous to the paddy farmers as compared to traditional method. By studying the SRI system, we came to know the proper area for planting.

1.2 Construction and working

Rice transplanters have seedling trays where mat-type nurseries of seedlings are laid. The tray shifts seedlings like a carriage of typewriters as pick-up forks get seedlings from the tray and put into the ground. The pick-up forks act like human fingers by taking the seedlings from the tray and pushing them into the earth.This machine is operated on wheel so no use of extra arrangement to run the

mechanism. Four bar mechanism helps the machine to operate more comfortable and easier and with low noise, Low noise designed transplanting arms can help to judge transplanting condition timely. The machine is with compact structure and small volume and can operate in the field easily.

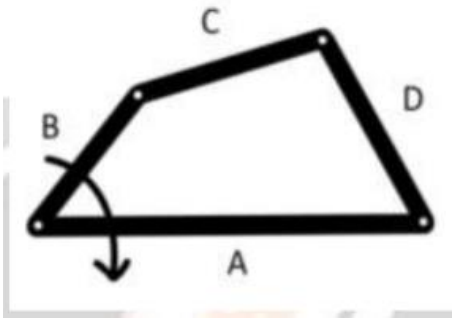

Fig1: “Four Bar Linkages”

In the Rice Transplant Machine , we are using “Four bar mechanism” to carryout the work. A Four bar mechanism consists

ofFixed Link- fixed part in linkage

Crank-can rotate full 360 Degrees

Coupler Rocker

Arm-can rotate through limited range angle

Connecting rod-connects the crank and lever

Components of rice transplanter -The manually operated rice transplanter machine consist of the following main components:

Sprockets

Chains

Tray

Shaft

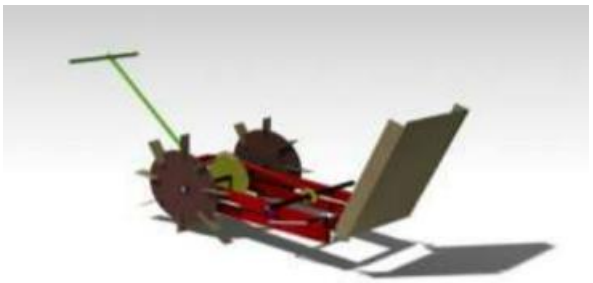
Fork

Rocker Arm

Connecting rod

Bearing

Wheels



Working-

Paddy seedlings are kept in tray and allowed to flow down under gravity. The fork which is attached to shaft picks up the seedlings from the tray and keeps it in a horizontal position on the skid. The motion of the wheel and shaft is given by hand using chain and sprocket mechanism.

Fig2 : "Working Mechanism"

Here, simple four bar is used to plant paddy seedlings in the field. In this mechanism fixed Link has no motion in the mechanism, Crank will be having rotatory motion. Coupler is transmitting motion to the rocker arm. The extended portion of coupler is used to pick up the seedling from the tray which is called as the fork. Due to rotation of crank the fork will do oscillatory motion in up and down direction. Fork follows a curved path when going to downward direction. At certain point of the path the fork will grab the seedling from the tray and plant it in the soil while traveling in downward direction. After that the fork will reach its highest position and the process continuous until the rotation is stopped. Rocker arm carries out oscillatory motion with a limited range of angles.

2. CONCLUSION

Since the farm land is of the average size in the area thus a mechanized paddy transplanter would highly aid in the rice transplantation. It will also decrease the high dependence of farmers upon labourers for transplantation. Transplanting through the manual rice transplanter have got seven advantages like less water for raising the mat type seedlings, less area for raising seedlings. It saves

the costly seed by 50%. The cost for uprooting of the seedlings is zero. Due to the machine transplanting, the raw-to-raw distance is fixed.

FABRICATION OF SOLAR CAR

[1]S. Udaya Bhaskar, [2]Ms. S.C.Sireesha

[1] Associate Professor ,[2]Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract:

The primary goal of this venture was to structure and create the Electric Solar Vehicle which is intended for singleseated vehicle fuelled by 2 kW BLDC centre engine (motor). Electric sun oriented vehicle is fabricated to improve a safe and Eco-friendly transportation. In the current scenario, due to increase in population and usage of vehicles, the consumption of fossil fuels like petrol and diesel are keep on increasing. Due to this, the availability of fossil fuel will reduce in turn to increase in demand and cost and it will be exhausted in future. Because of this, it is necessary to find the alternate fuel to operate the vehicles. In the non renewable energy sources, Solar energy is one which is freely available. Daylight is viewed as a wellspring of vitality which can be utilized for many applications. Sun based vitality is being utilized to create power through daylight. The fundamental segment to fabricate a sunlight based vehicle with a sun based board solar panel and a battery to store the electrical vitality. The sun based cells gather a bit of the sun's vitality and store it into the batteries of the solar based vehicle. After the vitality is stored in the batteries, it is accessible for use and the engine and controller is made to drive the vehicle. There are two arrangements of batteries; one of which will get the electrical vitality from the solar board to drive the engine and another will be utilized as helper control source which will give expected capacity to other electrical gadgets being utilized in the vehicle. After that the engine controller changes the measure of vitality that streams to the engine to compare to the throttle. The engine utilizes that vitality to drive the wheels.
Keywords: BLDC Motor and controller, Batteries, Solar panel, Seamless pipes, Steering set, Tyres and brake set.

INTRODUCTION

The idea of fabricating sunlight-based vehicle is from Imperial Society of Innovative Engineers (ISIE) which arranges the electric sun-based vehicle title ESVC which is an Asia's biggest sun-oriented vehicle title. According to this, a solitary situated sun-based vehicle is designed and fabricated with a BLDC motor, power source (battery) and additionally sun-based board. The reason for this venture is Eco-accommodating and safe to ride. A sunlight-based vehicle is essentially controlled by direct sun-oriented vitality. 48 V 100 amps Li-ion battery is used to run the 48 V 2000 W BLDC motor which transmits power to drive the vehicle. The vehicle is fabricated for hustling on the dashing track, so least load of the vehicle gives most extreme effectiveness. Seamless Pipes (AISI 106-B Grade) is used

in the vehicle. The structure of the vehicle is displayed with the end goal since vehicle is fit for the track and to take corners in the most effortless way.

II. LITERATURE REVIEW

Imperial Society of Innovative Engineers [1] are well known Society of India for organizing Motorsports events, live projects based industrial training and research and publication. ISIE – India provides a platform to the students and professionals for the development and enhancement of their technical as well as managerial skills. A platform especially for engineering students is developed where they can easily face real-time engineering problems and find the best solution, especially in the sector of Electric and Hybrid. Sharma et al. discussed that the future of vehicles seems to be with the combination of various energy sources. This sort of growth in vehicles to look for the benefits from the best quality of each energy source and it is particularly useful in urban driving vehicles. Cities of India one of the major mediums of transportation like buses, lorries and auto rickshaws, which produce a huge amount of air contamination as well as greenhouse gases like CO2. At present, transportation charges increase due to the usage of costly non-renewable fuel [2]. Singhalet al. discussed thatthe renewable energy is essential for today's world as the non-renewable sources that are going to get exhausted shattered in near future [3]. The solar vehicle is one of the replacement of the nonrenewable sources of energy. The basic principle of Electric Solar Vehicle (ESV) is to use energy that is accumulated in a battery during and after charging it from a solar panel. The batteries are in charged conditions are used to drive the motor which serves here as an engine and runs the vehicle in reverse or forward direction. Wamborikar et al. detailed that energy from the sources for generating electricity, running automobile vehicles etc. But the main drawbacks of these fossil fuels are that they are not environmental friendly and they are exhaustible [4]. To deal with these problems of fossil fuels, it is necessary to look at the non-conventional sources of energy. Because of this, an Electrical motor vehicle that runs on solar energy is designed. Vishal improved that the solar car is to create an eco-friendly vehicle with the help of solar energy [5]. Initially solar panels are used as a source of power to charge the batteries in addition to that self power generation system and thermo-electrical power generation system are also used as an alternate source to charge the batteries. These systems help to run the vehicle during the absence of solar power.

III. COMPONENTS USED IN SOLAR CAR

A. Wheels & Tyres: There are different types of tires accessible in the market and the determination is made based on the traction of the tires.

Design and Fabrication of a Solar Car

Minimized structure of the tire is likewise considered while doing the choice. Slicks give better grip than a treaded tire. Activa Aviator tires are chosen since they have increasingly more surface region and better footing. Wheel specifications: Wheel diameter and tread width are 12 inch and 4 inch respectively.

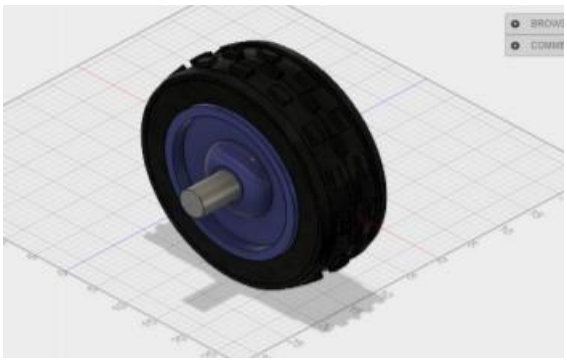

Figure 1 Designed Tyre using software

B. Brake:

Brakeis the most essential element in any vehicles. It makes use of to stop the vehicle and to control the movement of the vehicle. Mostly, either disc brakes or drum brakes are used. A brake disc normally made of cast iron or ceramic is associated with the wheel or the axle. To stop the wheel, friction material used as brake pad is constrained mechanically, hydraulically against the two sides of the disc. Friction makes the disc slow or stops the wheel. After a long overview in market and concentrating different parameters, a disc brake from Activa aviator is placed over drum for its better cooling efficiency because of uncovered contact surface, simple assembly, uniform wear in disc, better anti fading character, less weight and occupies less space. The dimensions of the disc are 200 mm external diameter and 10 mm thickness. There are two kinds of calliper accessible. One is a fixed type and the other is a float type. Fixed type of calliper is utilized in the disc in both back and front wheels to stop the vehicle. Fixed calliper has a good performance but it is costlier than the floating type calliper. The calliper has a piston diameter of 30 mm. Activa Aviator calliper and DOT 3 brake oil are used in the vehicle. Its cost is less and has a great performance.

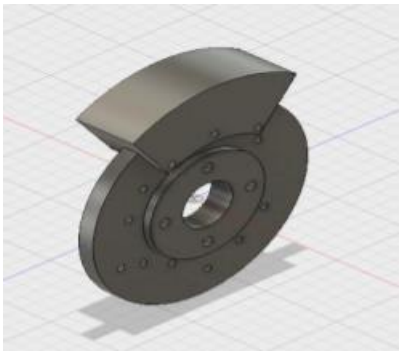

Figure 2 Brake disc and caliper

C. Suspension (Double Wishbone type):

Mounting In vehicles, a independent type double wishbone (upper and lower A-arm) suspension is used. It has two wishbone shaped arms to locate the wheel. Every wishbone or arm has two mounting joints, one is mount with the chassis and the other is mount with the knuckle joint. The shock-absorber and coil spring mount to the wishbones to control vertical up and down movements.

Figure 3: Suspension

D. Steering System:

Steering is the component used to turn the vehicle while cornering. The fundamental aim of steering is to guarantee that the wheels are pointing in the ideal directions. This is normally accomplished by a progression of linkages, tierods, pivots and gears. The control of vehicle is done by the steering system. It gives directional changes to the moving vehicle. To fulfil this condition, the inner wheel must turn through a more prominent angle than the outer one; if not tire wear is greatly increased. While taking a turn, each wheel must move on an arc and these arcs ought to have a common centre. In the steering system, the rack and pinion mechanism is used. For perfect

steering, all the four wheels revolve around an instantaneous centre. For this reason inner wheel needs to turn more than the outer wheel. To accomplish this condition, Ackermann steering mechanism is utilized. It comprises of a four bar chain having turning pairs. The stub axles are connected together by two short track arms and a tie rod. In this solar based vehicle, four bar linkage mechanism is used. Purpose for this is to take sharp turns on the track rapidly. So by using this system driver has the straight forward to control wheels on time. Steering ratio of 9:1 is used which implies on pivoting steer wheel at 9° which turns the wheels by 1°.

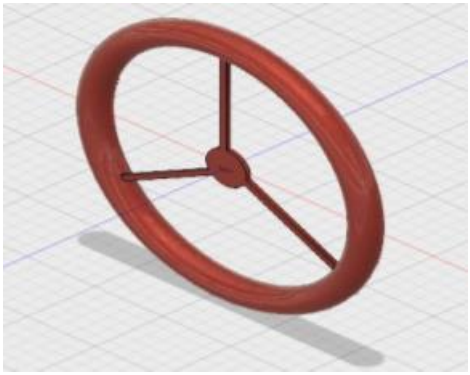

Figure 4 Steering wheel

E. Transmission (Drive chain)

The power train is used to transmit the power of the engine to the wheels and tyres. At the point when a vehicle keeps running on a track, it encounters an obstruction drive from outside the vehicle. It is known as a running resistance of the vehicle on a track. On the off chance, a driver needs to keep its speed consistent and needs equivalent capacity of power. Running resistance yet needs more power for increasing speed resistance. All endeavours are made to make the power transmission as an effective and reliable as could be expected under the circumstances.

IV. METHODOLOGY

At the point when the electrically operated throttle pedal is throttled, the controller controls and transmits required current and voltage to the engine. The required measure of current is from batteries which are charged from sunlight by solar panels. The solar panels get sun's radiation and charges the batteries. The solar panel comprises of photovoltaic cells which observes heat from daylight i.e. sunlight and changes over it as current. The engine shaft rotates and make the drive shaft rotates. The drive shaft rotates the wheel and vehicle moves. There is no emission and it is an Ecofriendly vehicle. When the vehicle is needed to stop, brake pedal is pressed which is associated as an arrangement with master cylinder and thus related with the calliper to stop the vehicle. The calliper impels the brake pad and it will stop the disc to rotate which is connected with the wheels

of the vehicle. Forward and reverse switch is utilized to run the vehicle in forward and reverse movement. The kill switches are making use of to stop the vehicle ordinarily or if there should be arise and an occurrence of any crisis. It stops the general supply of current to the engine.

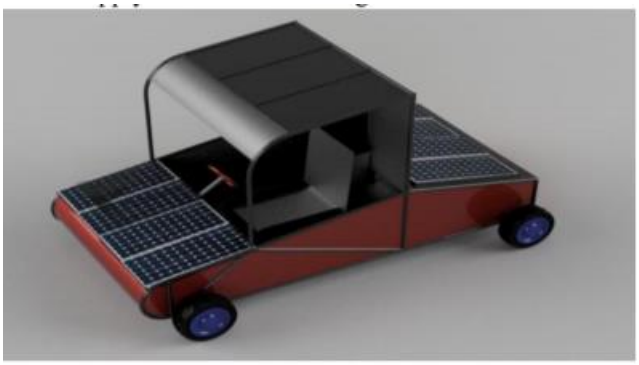

Figure 5 3-D Diagram of Solar car

Figure 6 Solar car

V. CONCLUSION

a. Solar vehicle is made with a single seat to run in the race track. b. The vehicle efficiency is high as the weight of the vehicle is very less. c. Solar vehicle can be available at low running and maintenance cost and it requires only more initial cost. d. High safety measures are considered while fabricating. e. Solar vehicles are used to make pollution free environment.

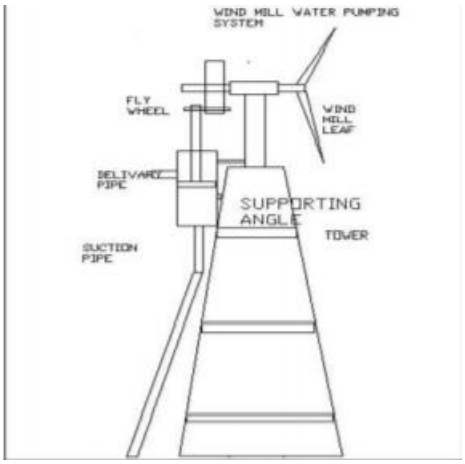
FABRICATION OF SOLAR SEED SPRAYER

[1]S. Udaya Bhaskar, [2]Mr. Sandeep Mulabagal

[1] Associate Professor ,[2]Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100



Abstract-.

Today's era is marching towards the rapid growth of all sectors including the agricultural sector. To meet the future food demands, the farmers have to implement the new techniques which will not affect the soil texture but will increase the overall crop production. In this project, a=-n attempt has been made for the "Design and fabrication of solar seed sprayer machine". In this technique seeds in a hopper get sprayed by means of fan or blower directly to land without human effort. By this process the seed is feed to land at the time of plough. The main benefit of using this method is to reduce the time of seed to the land and reduced human effort. Usually, the manpower is needed for sowing a seeds by using this machine there is no need for human power. This system does not require any additional power source to run the fan, because here solar panel is employed as a power source. Key Words: Agricultural sector, Power source, Solar seed sprayer machine

INTRODUCTION

Agriculture has been the backbone of the Indian economy and it will continue to remain so for a long time. The government of India appointed a commission to assess the feasibility of increasing the crop productivity under prevailing Indian ecological conditions. In order to develop the standard of living of small farmers we should make the machines with low cost. Then only small farmers can implement the recent modern machines for farming purposes. The basic objective of sowing operation is to put the seed and fertilizer in rows at desired depth and spacing, cover the seeds with soil and provide proper compaction over the seed. The recommended row to row spacing, seed rate, seed to seed spacing and depth of seed - 089IJlacement vary from crop to crop and for different agricultural and climatic conditions to achieve optimum yields and an efficient sowing machine should attempt to fulfill these requirements. In addition, saving in cost of operation time, labor and energy are other advantages to be derived from use of improved machinery for such operations. A traditional method of seed sowing has many disadvantages. Our proposed "Solar seed sprayer machine" is used to sowing seed easily. In this project an attempt has been made to provide the low cost sowing machine and also it reduces the human effort. A. Problem Statement Seed sowing machine is a device which helps in the sowing of seeds in a desired position hence assisting the farmers in saving time and money. The basic objective of sowing operation is to put the seed and seed in rows at desired depth and seed to seed spacing, cover the seeds with soil and provide proper compaction over the seed.

Hence, there is a greater need for multiple cropping on the farms and this in turn requires efficient and high capacity machine

B. OBJECTIVES

1.To investigation of various types of seed sowing and spraying machine

2.Todevelopment of solar powered seed sowing and seed spraying machine.

3.Totesting of development of solar powered seed sowing and seed spraying machine in actual agricultural farm.

4.To extend the concept of Solar PVTechnology on “Solar Sprayers” as “Energy Alternate Devices”.

II. LITERATURE REVIEW

Our country faces the total loss of 33% of its economy from Weeds. The Losses are due to some of the following reasons, total loss of 26% from Crop Diseases, total loss of 20% from Insects and Worms, total loss of 6% from Rats. Has been Surveyed. Shrinking farm lands, acute labor shortage, decreasing income per acre of cultivation, and economic frustration are some of the key factors hurting a farmer's confidence in continuing farming. Weeding control is done by: mechanical weeding, thermal weeding: flaming, biological control, chemical control, and by farming pattern. It has always been a problem to successfully and completely remove weeds and other innocuous plants. Invariably, weeds always grow where they are not wanted. This work involved the design and construction of mechanical weeder, after discovering that tools such as cutlass and hoes require high drudgery,time consuming and high labour force. As a solution to these problems, mechanical weeder was designed and constructed. The mechanical weeder was made of two implements attachment i.e. the primary cutting edge which is in front to loose soil above and the secondary cutting edge which is behind to do cutting and lifting of weeds. The overall machine field efficiency was 98.67%. The Single Wheel Weeder being manufactured is the equipment, which is used for very special purpose when the weeding is required at narrow places or between rows. The blade is thin but very sturdy and

tough besides, it is very safe to use and offers zero threat of hurting to the user, Other than the wheel, there is nothing mechanical in this single wheel weeder but, it works wonderfully under the condition where it is put into. This hassle free equipment requires no special maintenance. It is necessary to design the weeder which minimize the human effort and provide efficient work output.

A. Scope

1.Maintain row spacing.

2.Proper utilization of seeds can be done with less loss.

3.Achive automation in agriculture field.

III. METHODOLOGY

First, we will design the Seed Sowing & Spray Pump system suitable to various agriculture application. we need to analyze Seed Sowing & Spray Pump system taking into consideration the applications and operational conditions. Then we will analyse the design in ANSYS for static and dynamic conditions. Theoretical: Theoretically we will compare basic and operational parameter of existing system with propose system.

IV Working Mechanism:

The Solar panel (specification: 10W, 12A, 10*12inch) will be placed at the top in the device and is supported by the frame, it is placed such that it comes right above the head of the farmer, providing him shade, like a cap. The frame will be designed such that, the panel along with the frame can be tilted/rotated to position the solar panel normal/perpendicular to the sun rays depending upon the position of the sun, in order to trap greater solar energy and increase the power generation. The panel traps the solar energy, converts it into electricity, which is then stored in a Battery (specification: 12V dc) placed at the bottom in the device on the frame. The battery provides the necessary electricity for the operation of the device. To control the supply of electricity to each part, Toggle switches are used. A Tank (specification: plastic, light weight of 10lts capacity) will be attached at the top of the frame. It is used to carry seeds or liquid viz. pesticides, fertilizers etc. Tank has 2 outlets. One of the outlets is connected to the outlet of blower; the other outlet is connected to the hose pipe. The battery runs the Motor (specification: dc, 2000rpm, high torque) placed at the center. The shaft of the motor drives the Air Blower (Specification: Diameter 9inch, Aluminum), which blows the air out at high speed through a hosepipe. To this hosepipe, the outlet of the tank is attached. Hence a partial vacuum is created at the tank outlet and the seeds or liquid fall down in the hosepipe and are sprayed by the action of the blower. A spray nozzle is fitted at the end of the hosepipe to spray the seeds/liquids uniformly. The rate of spraying the seeds or liquids is controlled by using control valves. A cap is inserted at the inlet of the blower to allow the entry on air only through this restricted opening. A pipe

is inserted in the cap and the other end of the pipe with a filter to avoid entry of dust into the blower is inserted inside the tank. From the outlet of the tank, another long pipe is drawn out, which will work as inlet for the vacuum cleaner. As the blower is operated, due to high suction pressure at the inlet of the blower, the dust particles 5 are sucked inside the tank. The filter prevents the dust particles from entering the blower and gets collected in the tank. The tank can be emptied later. A hollow shaft for grass cutter is supported by the frame. At the end of the handle, there is a 45deg. bend, to which a high rpm motor is attached. The electric wire connecting the motor and the battery passes through this hollow shaft. The shaft of the motor drives the Blades (specification: Nylon wire) which is used for grass cutting action.

V. Conclusion:

This project work has provided us an excellent opportunity and experience, to use our limited knowledge. We gained a lot of practical knowledge regarding planning, designing, purchasing, assembling and machining while doing this project work. We feel that the project work is a good solution to bridge the gates between institution and industries. 6 We are proud that we have completed the work with the limited time successfully. We are able to understand the difficulties in maintaining the tolerances and also quality. We have done to our ability and skill making maximum use of available facilities. Thus, we have developed a "Fabrication of Solar Seed Sprayer" which helps to know how to achieve great farm yield with simple mechanisms. The application of this machine is very high when compared to the cost of the machine. By using more such techniques, cutting costs, employing indigenous technologies, these devices can bring a revolution in the modernization of Indian farming.

Future scope:

The solar panel can be fitted with 4 light sensors. Thus depending upon the position of the sun, the panel will be tilted, such that the sun rays are incident normally (at 90deg) to the solar panel. With this the device would be even capable of trapping the solar energy at times when the intensity of the sun light is less (Example: Early morning, evening, during raining season etc.)

FUEL THEFT PREVENTION IN MOTORCYCLES USING SOLENOID VALVE

[1]D.S.CH.Mouli, [2]Sri Deepthi Immaneni

[1,2]Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract-

Fuel is one of the most widely-used sources of energy in the world today. Most fuels are natural substances such as petrol fuel, diesel, and natural gas, which are either extracted straight from the earth or produced by refining substances such as petroleum. Such important non-renewable fuels are pilfered by the people at different stages of fuel delivery process. In this paper, a Antipilferage and Antiadulteration System (AAS) has been developed to prevent the fuel from pilferage and adulteration. Increase in the incidence of fuel tankers pilfering and even adulterating liquid/fuel materials has prompted fuel companies to track and monitor the transport vehicles. The main intention of the AAS is to ensure the fuel safety. An experimental analysis is carried out using solenoid valve, flow sensor, electromagnet lock and GPS with the open source IoT platform. After these sensors get fitted in the fuel tanker, it monitors and controls the pilferage of fuel with the help of lids/valves during filling or emptying at the fuel stations. Electromagnetic lock helps in preventing adulteration. GPS will enroute the vehicles' path. All of this data is uploaded to the dashboard display using IoT technology. This solution will allow owners and managers of fuel companies to make informed business decisions, remote monitor tankers and prevent theft of fuel and goods.

Keywords – AAS, Pilferage, Adulteration, Electromagnetic lock, IoT, GPS, Solenoid valve, Fuel

I. INTRODUCTION

The energy produced by burning fuel has many applications, such as powering vehicles, ships, and airplanes as well as providing electricity for homes and buildings. The developments of automobiles have a significant role in modern civilization over the past few decades. Most of the vehicles like cars, motorcycles, buses, trucks etc. run by traditional transport fuels such as gasoline, octane, diesel etc. Furthermore, the fuel price over the past few years is increasing which may effect on the modern life. The vehicle may lose fuel in many ways such as leakage, cracking of fuel tank and fuel theft/pilferage. It may hamper both safety of life and economic loss. Fuel pilferage is a huge problem for many individuals as well as business owners with fleet of vehicle. So, the fuel loss or theft from the vehicle is an important issue in many countries in the world. Although there are many alarming issues, in this work, preference is given to the unanticipated issue of fuel theft from the transport vehicles. Most of the transport users are counting a loss of huge number of currencies because of this unusual fuel loss. This unexpected fuel loss has a great impact on the economy of a country. It is very alarming and undesirable issue for developing countries. Petrol and diesel theft is an international

problem [3]. Fuel theft has become a big problem for fleets around the world, and it is a real threat to the fleet's overall budget, as it can have a significant impact on the company's bottom line. Automation is mandatory to handle all type of systems. It is made possible by embedded design which is a combination of both computer and mechanical system, often with real-time computing constraints. In today's world, it is common to control most of the devices, by automation since it optimizes by reducing the size and cost of the product and increase the reliability and performance. Embedded systems are based on Microcontroller and their applications range from portable devices to large installations and it also extends to large complex systems. [2]

EXISTING SYSTEM

Rubayat Islam has described the automatic prevention of fuel theft using Ultrasonic sensor. It determines the fuel flow rate by measuring the distance of fuel level with respect to time. When the fuel flow rate or fuel consumption rate oversteps or falls behind the usual rate, then the sensor was activated which then sends a signal. After receiving the signal the GSM module sends a message to a specific number instantly by indicating that something is unusual so that one can immediately go into inspection.t1 is considered as the time taken for transmission of sound wave and t2 as the time taken for reflection of sound wave. So the average time taken as, t = (t1 + t2)/2. The velocity of sound in air is considered constant and that is taken approximately 332 m/s. The distance of the fuel surface from the ultrasonic sensor is calculated as, S= v*t. Ultrasonic sensor responses effectively within the range of 0.3~3meffectively. As some ripple occurs in liquid, the value given by the sensor fluctuates a little. So, one of the limitations of this approach is that this cannot be used for fuel reservoir fully filled with fuel. At least there should be some gap or level difference so that ultrasonic sensor cannot touch the liquid as the sensor is non-contact type. Proper calibration was needed to get reliable value from ultrasonic sensor.[4]

Naomi Somer Lepcha focused on the enhancement of the vehicle alarm security system via SMS. The system will manipulate a mobile phone to send SMS. Even though the SMS can be sent using the features available in the mobile, the objective was to activate the SMS sending by the mobile phone using external program connected physically to the mobile phone. Antitheft security system utilizes an embedded system designed with GSM to monitor and safeguard a car. In attempt of theft, the system sends text message to the car owner and at the same time starts up an alarm from the buzzer installed within the system. The safety of vehicles fuel is extremely essential for public so this went to notice due to the alarming rate at which vehicles fuel are being stolen in our country and with this design the vehicle can also be monitored irrespective of where it is parked , provided there is a GSM network coverage. So this model (theft detector) uses very few electronic components and looks very small and compact and can be mounted on vehicles easily. An interfacing mobile is connected to the microcontroller. When a person attempts fuel theft then the microcontroller commands the GSM

modem to send a text message as an alert to the vehicle owner and further an alarm is raised by the buzzer installed within the system. In this system the microcontroller AT89S52 is interfaced with SIM 900A modem to decode the message.[5]

P. Senthil Raja focused in the aspect to facilitate and enhance the vehicle's features such as speed, mileage and volumetric level of fuel by providing it with the detection of level and restrict illicit activities using sensor. It is implemented using Vehicle Area Network (VAN) and embedded design. The owner of the vehicle immediately receive a message when the fuel tank is opened by the operator or by a fuel traded and also the height of the fuel tank when opening and closing of the tank. The system uses Wireless based communication for monitoring the vehicle's position. A message is sent along with vehicle position and fuel level in the tank. This enables in identifying the level of fuel at different times whenever the tank is opened. Hence the larceners results rather than the fuel or to the vehicle theft by chance in the situation and provide the overall protection. The message are provided to the owner in relation to the fuel level in the vehicle in periodic manner and also avoids the other way to fuel theft of fuel tank fault detection system. The numeric lock system is to open authentication for the fuel in the vehicle fuel tank. The wireless technology will enable the vehicle owner, the vehicle with the mobile phone to monitor anywhere, anytime.[6]

Tatsuo Nakagawa et al (2013) describe a non-contact method for measuring liquid level by an opaque container is proposed. A millimeter-wave Doppler sensor is to detect by a target container developed, and measures the liquid level on the basis of the absorption of millimeter waves in the liquid. The feasibility of this method for clearly an air-liquid interface detecting hidden in an opaque container is confirmed experimentally. The non-linearity error of the measured liquid level within 0.5 mm. A capacitive sensor semi cylindrical mounted to a liquid container can measure liquid level, without coming into contact with the liquid, has, but its accuracy is not high, because the capacity of the distance between the container and the sensor is highly dependent. Optical sensors such as CCD cameras can measure fluid without the liquid with the image processing. However, to capture an image of the surface of the liquid, the container should be transparent, or the optical sensors should be introduced into the container. By the use of ultrasonic sensors, level can be calculated from the area between the sensor and the liquid surface. However, these sensors cannot be used for sealed containers. The principle of measurement is based on the absorption properties of a millimeter wave to a target liquid.

PROPOSED SYSTEM

The input block consists of electromagnet lock (i.e.) the inlet door indicator, Solenoid valve to control the flow of fuel, Flow sensor to measure the flow rate of the fuel. Also has an emergency switch that is used in case of erroneous situations. Arduino Mega 2560 is the controller which takes the inputs

and produces the digitized outputs. GPS is to track the vehicles path from source to destination. Node Mcu is in contact with open source IoT platform.

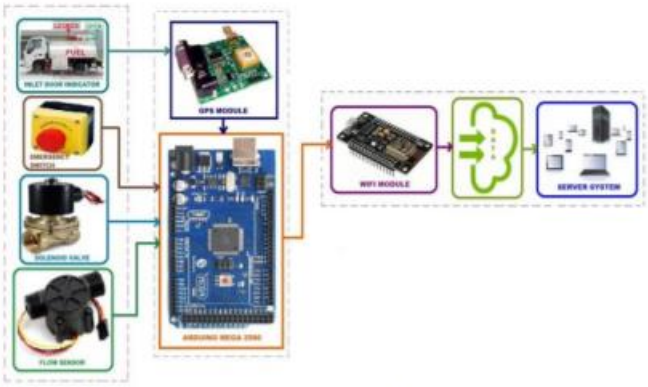

Figure 1: Block Diagram of Antipilferage and Antiadulteration System (AAS)

Figure 1: Block Diagram of Antipilferage and Antiadulteration System (AAS)

3.1 Working of AAS –

Initially the vehicle starts from its source i.e. fuel filling station .The vehicle moves towards the destination, once the tanker fuel is filled. Installation of physical parameters such as magnetic door lock, Emergency switch, Flow sensor, Solenoid value, GPS and controller with WIFI module should be fitted to the vehicle. Importantly, in case of emergency situations like fire accident or vehicle breakdown, intimation must be sent to the nearest service station. As the vehicles enroute path is monitored by GPS, this will intimate if the vehicle deviates from the desired path. As there is a magnetic door lock fitted to the tanker, this prevents from adulteration and pilferage. If there are any chances of occurring, then alert can be sent to the police station. Finally when the vehicle reaches the destination, the fuel gets deposited.

Figure 2: Working Principle of AAS

3.2. Use Case –

Initially, the tanker will fill the fuel from fuel filling station which is the source. The electromagnet lock is fitted at the inlet valve. Once the fuel is filled to the tanker, the valve gets locked. This lock can also be controlled via dashboard. As soon as the tanker reaches the destination, Solenoid valve is used to control the fuel flow. Followed by flow sensor which determines the flow rate of the fuel.

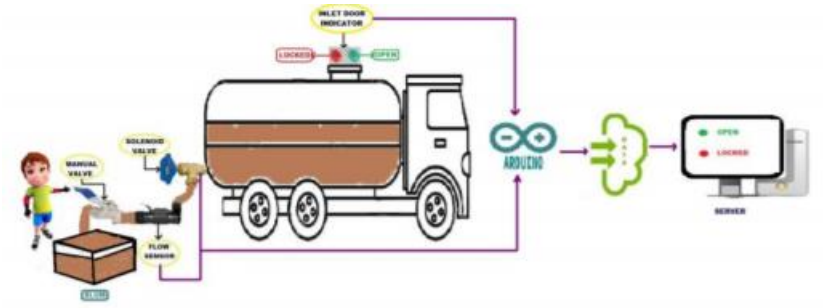

Figure 3: At fuel filling station

In this proposed system Phase I is designed to get the OTP entered into system which is to be verified and indicated their reserved seat with a LED indication. During this process the Controller get the OTP and its corresponding reserved seat number from the cloud-storage and is stored in the controller. When the booking is done the details are send to the cloud data base which stores it till the date of commence. After the due date the data is discarded. During boarding the data is verified by the system, when the passenger enter the data and the booking is confirmed.

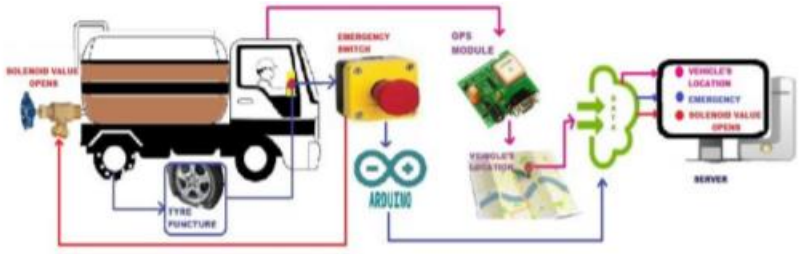

Figure 4: In case of emergency

IV. RESULTS

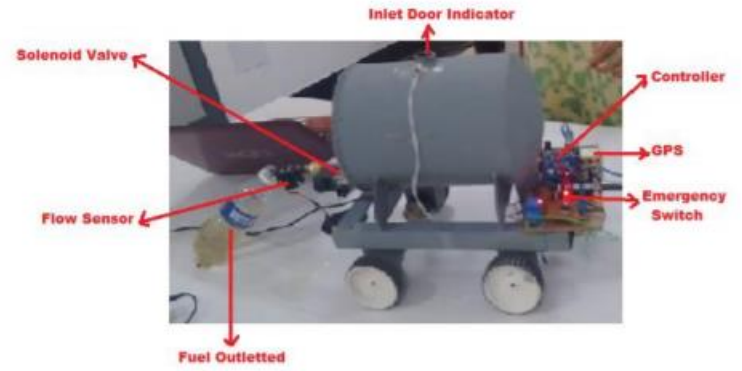

Figure 5 shows the working model of the AAS with the sensors, valves and GPS module.

The electromagnetic lock is fitted in the inlet valve, which can be controlled from the control room. Figure 6 shows the status of the inlet valve/ door on the display of the system in the control room.

Figure 6: Door status displayed on the system

The solenoid valve connected at the outlet of the fuel tank is used to control the fuel flow rate, which operated manually/ from the control room. Figure 7 shows the solenoid valve control.

Figure 7: Solenoid valve control

When the solenoid valve is open, the fuel from the tank is flow out. The valve can be opened manually in the case of emergency or in the intention of theft. To know this, the flow rate of the fuel is displayed on the system in the control room. The person from the control room can continuously monitor the flow rate and know the status.

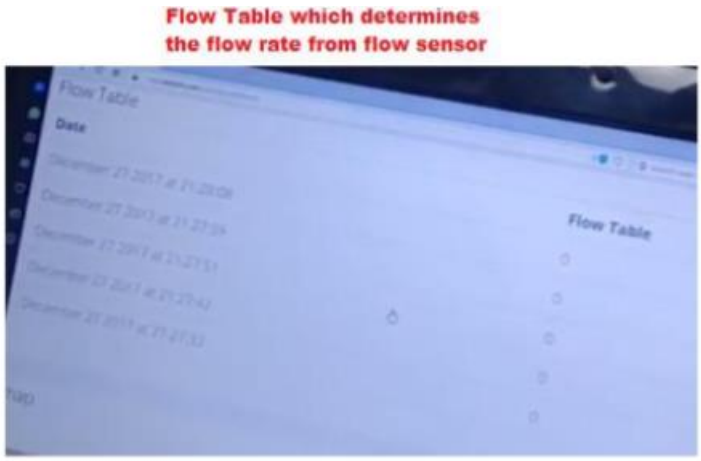

Figure 8 shows the flow rate table displayed in the control room.

Figure 8: Flow rate displayed on the system

The GPS module fitted in the tanker vehicle makes the person in the control room to track the location of the vehicle at any time. Figure 9 shows the vehicle tracking at the control room.

Figure 9: Tanker Vehicle tracking by GPS

V.CONCLUSION

The embedded devices in the environment for monitoring, enables self-protection (i.e., smart environment) to the environment. By deploying sensor devices in the environment, the environment might be brought into real life i.e. it can interact with human through the network. The proposed AAS is one of such embedded devices designed with electromagnetic lock, solenoid valves, flow sensor and GPS module. The AAS prevents the fuel pilferage and fuel adulteration. The flow rate sensed by the flow sensor at the outlet valve controlled by the solenoid valve makes the person at the control room to know the theft of fuel if the outlet valve is opened manually. The inlet valve of the fuel tanker is electromagnetically lock which avoids the adulteration of fuel. The GPS module is used to track the tanker vehicle at any instance of time from the control room.

IMPLEMENTATION OF ARTIFICIAL EYE FOR INTELLIGENT LINE FOLLOWING ROBOT APPLICATIONS

[1]Mr. Balaji Krushna.P, [2]A Vijaya Krishna

[1,2]Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract:

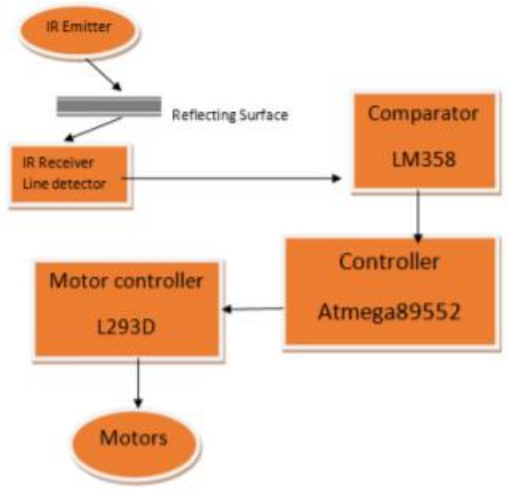
Implementation of new idea and new technology are the valuable gift to the recent generation. Utilization of new technology has shrunk the world and brought very easy within our reach. The expansion and growth of the ideas and concepts, are directly linked to the economic growth as well as development of the country. This paper presents microcontroller-based line following robot. Successful implementation on control is depend upon the logic utilization and with proper knowledge on the specific design model. Basically, a line following robot can easily follow the line as per instructions loaded in the controller.

Keywords: Microcontroller, LM358 comparator, IR sensor, DC motor, robot.

INTRODUCTION

Embedded system normally includes many advance technologies like interfacing, microcontroller hardware and automatic control and software and all different sensors working knowledge. Project based learning in the subject of embedded system which will help the students learning due to their interest and motivation Line follower robot where one can easily understand the hardware circuits and software implementation as well as the large applied to the system. Now a days in many institutions there is a competition between students as a robot racing , robot war and many more. During recent years robots are placed in hospitals as it can save time, also save the manpower, work any hostile environment and conditions with good efficiency [1]. 8051 is very good microcontroller which is used for controlling the robot to follow the exact line position [2]. Robot is intelligent programmed to follow the desired path to perform a task in military, construction, manufacturing units [3],[4]. Now a day‟s android apps are there to control button, voice and line and make very user friendly [5]. Now a day‟s to encourage students and for educational tool as to increase the confidence and ability to take innovative ideas to implement low-cost line follower robots are also available in the market [6]. Robots are also used for different services like drug delivery [7], to increase transportation line follower robot is highly essential [8] even it‟s advantages are more in industry revolution 4.0. Obstacle detection is also an important application of a robot [9]. Carrying cartage in a specific direction is also one application of line follower robot [10]. Importance of Microcontroller is

much more in all kind of field [11]. In this paper we describe the proposed procedure in section II, hardware and proto type implementation in section III and IV,



II. PROCEDURE FOR PROPOSED SYSTEM

A. Motor controller

To control current in the motor, the motor driver IC act like a current amplifier. L293D can have the capabilities to rotate the motor either forward or reverse direction or one can say clockwise and anticlockwise direction. Even it receives low current but it provides adequate amount to the DC motor.

B. Comparator

Comparator is used to compare with the threshold voltage accordingly it will act on the system. infrared sensor basically if anything comes in between transmitter and receiver then it immediately gives the output. Basically, comparator sends the desired signals to the controller, so that controller can take the exact action based on the received signal.

C. DC Motor

For proper movement of the robot two DC motors has been implemented and a castor wheel is attached.The reason behind caster wheel to make the easy movement of the robot. Motor driver IC will control the two DC motors. To control the overall line follower robot system ,here we used At89552 microcontroller is used. Also 10 volts DC supply can be provided by battery. As the proper block diagram is shown in figure 1. Basically we are using five IR sensors named as S1,S2,S3,S,S5. Out of this five S5 which will detect the path. In the back side we have implemented S1 to S4 four sensors out of that S1 and S4 used for angle or turn and whole thing can be controlled by microcontroller. Figure 2 shows the logic flow diagram of the line follower robot . As per this the „C" programming can be implemented.

III. POSIBILE ROBOT DIRECTION

Here we control the robot with specific mentioned line. Normally in manufacturing plant pick and placement or we can say pick and drop capabilities are used. To follow a specific location and keep them on required or desired location/place. For this a specific path to be taken for consideration for smooth performance. Using a feedback mechanism in control system there will be no chance of wrong movement. When there will be any sensed signal goes to the controller then it immediately gives to the motor driver IC for appropriate speed and voltage. A programming instruction is given to the robot so that as per the instructions it can turn right or left or move forward.

IV. PROTOTYPE IMPLEMENTATION

Before prototype implementation software verification is important. Because before implementing it should be properly run by the simulation, which is very important to find the silly fault in the coding or idea implementation. For this we are using proteus software and after proper implementation of motor driving direction, one can easily implement or drive further in hardware. Figure 9 indicates the proteus analysis of the output. Figure 10 and figure 11 as proto type implementation and final touch of the model.

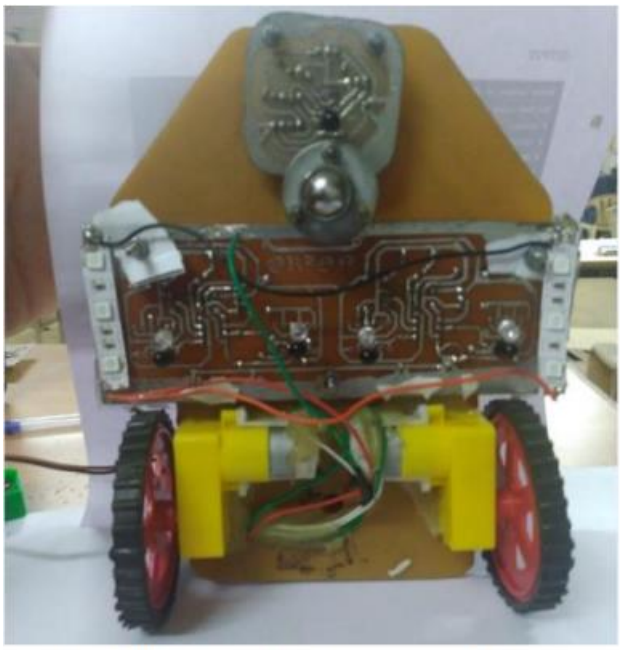


Fig. 10. Back side of the prototype Model

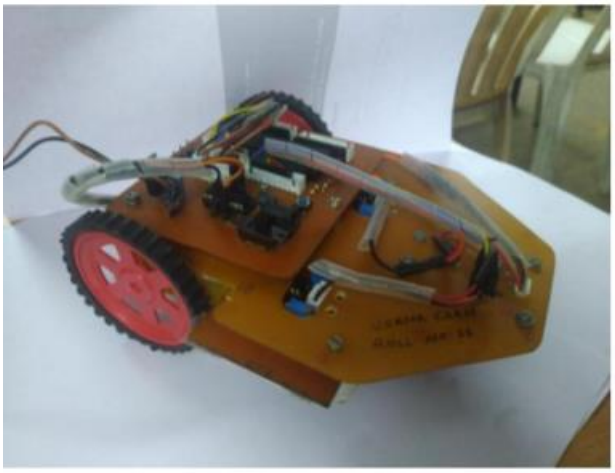

Fig. 11. Prototype implementation.

V. USEFUL APPLICATION

There will be automatic movement of the robot, once properly instruction set to the controller. Secondly if the prototype model will be successful then one can use real time implementation by assigning to the robot as some work and can sit as with no matter about that work. Microcontroller based model is also cost effective and due to it‟s simplicity it may be very good guidance in the shop floor in the market complex.

VI. RESULT AND DISCUSSION

The line or path following robot can implemented successfully. It runs over a specific path with the help of sensors and specific logic used in the controller. Initially it will take some time for PCB designing, printing and hardware debugging.

1) Big size robot can change the role play of worker like supplying material to the architectural high rise construction building.

2) The role also may change in hospital like supplying medicines to all the patients within the proper time. Even smarter robot can send the emails within the office and can also deliver the news paper, magazines, foods to the office workers in time.

VII. CONCLUSION

Now a day's health care systems greatly depend upon different robotic machinery for the cost and best accuracy point of view. The programming and interfacing was the master key during final stage and also successfully complete of this work. For perfect performance one should check the battery activities in the designed circuit properly.

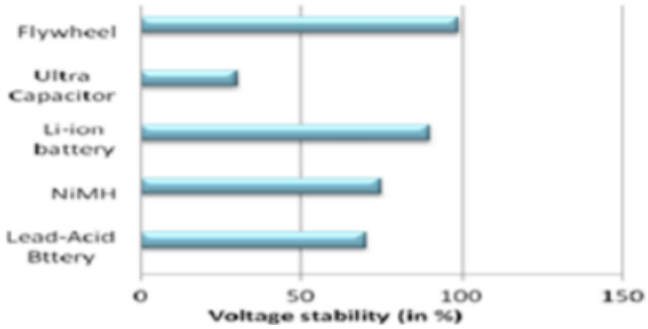
KINETIC ENERGY RECOVERY SYSTEM IN BICYCLE

[1]Ms.N.Harini, [2]A Vijaya Krishna

[1,2]Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

ABSTRACT

Kinetic Energy Recovery System (KERS) is a system for recovering the moving vehicle's kinetic energy under braking and also to convert the usual loss in kinetic energy into gain in kinetic energy. When riding a bicycle, a great amount of kinetic energy is lost while braking, making start up fairly strenuous. In this context the mechanical kinetic energy recovery system is used by means of a flywheel to store the energy which is normally lost during braking, and reuse it to help propel the rider when starting. The rider can charge the flywheel when slowing or descending a hill and boost the bike when accelerating.



Keywords - Kinetic energy, bicycle, flywheel, energy recovery system.

1.INTRODUCTION

KERS is a collection of parts which takes some of the kinetic energy of a vehicle under deceleration, stores this energy and then releases this stored energy back into the drive train of the vehicle, providing boost to the vehicle. Kinetic energy recovery system store energy when the vehicle is braking and return it, when accelerating. During breaking, energy is wasted because kinetic energy is mostly converted into heat energy or sometimes sound energy that is dissipated into the environment. Vehicle with KERS are able to harness some of kinetic energy and in doing so will assist in braking. By a proper mechanism, this stored energy is converted back into kinetic energy giving the vehicle extra boost of power.

2. KINETIC ENERGY RECOVERY SYSTEM

A type of Regenerative braking is called KERS. KERS is an automotive system for recovering a moving vehicle's kinetic energy under braking. The recovered energy is stored in a reservoir (for example a flywheel or a battery or super capacitor) for later use under acceleration. Electrical systems use a motor-generator incorporated in the car's transmission which converts mechanical energy into electrical energy and vice versa. Once the energy has been harnessed, it is stored in a battery and released when required.

2.1 Types of Kinetic Energy Recovery System

There are different types of devices and forms in which the Kinetic energy lost while braking can be stored. They are:

1) Mechanical KERS

2) Electric KERS

3) Hydraulic KERS

4) Hydro-electrical KERS

Fig 1: Voltage Stability Graph

3. DESIGN REQUIREMENTS

There are many requirements that need to be met to produce a product that is both feasible and optimal. There are also some constraints, both geometric and engineering that also need to be satisfied. The following list describes these requirements and constraints:

3.1 Store energy while braking

This is the main requirement and the overall objective of the device and must be suitable to meet the rider's needs.

3.2 Return energy to start up

Once the energy is stored in the device, it is necessary to have a simple way to release this energy back to the user in positive way. This can be accomplished with an innovative chain drive system.

3.3 Must fit on a bicycle

This is one of the most difficult constraints to achieve and most important because we are dealing with such confined spacing. The objective is to fit the flywheel and accessories in the bicycle.

3.4 Lightweight

The importance of having a light weight design is driven by the rider's desire to have a bicycle that is more manoeuvrable and more portable. This is also a direct trade off with how much energy can be stored in the flywheel.

3.5 Inexpensive and affordable

This product must be able to make a profit and be desirable.

3.6 Safe to user and environmentally friendly

Safety is always a very important aspect whenever there is a consumer product.

3.7 Economical

The product economical and the products for this design must be cheaply available.

3.8 Reliable

It is important to have a product that is reliable and this requirement will affect the normal bicycling process and must be easy to use.

3.9 Manufacturability

In order to make anything economical, it needs to be manufacturability, hence the important of having a product that can be made easily and cheaply.

3.10 Aesthetically pleasing

This is not a requirement that needs to be taken heavily, but the design should always have nice look about it, because looks will persuade the rider.

3.11 Modular

Having a device that can be adapted to existing bicycles is essential to be added to the existing ones so that it's easier to adopt. This also can reduce other types of manufacturing costs.

3.12 Should not hinder normal riding

To have a successful accessory for a bicycle, the ride should not feel a noticeable change in the riding performance or in the normal riding motion. A device that impedes the normal riding experience would be considered undesirable.

4. COMPONENT USED

4.1 Fly wheel:

The flywheel has to be bored centrally in order to place a ball bearing so that flywheel can rotate over the axle. Also flywheel has to be selected so that the selected weight does not affect the bicycle physics and riding performance of the rider.

(a) Cast iron flywheel weighing 4.2kg.

(b) Radius of the flywheel is 122mm with thickness of 16mm.

(c) Maximum torque of 69NM @ 3500 rpm.

4.2 Clutch:

A clutch has to be provided so as to control the power delivery and release from the flywheel. This can be achieved by providing a clutch plate that is linearly moved to and fro by applying a lever mechanism incorporated with a spring assembly for providing return mechanism. Linear clutch movements have to be made possible. For this purpose, two cylindrical rods can be used. One end of each rod was variably cut. This variable length is female part of another. One part of this is fixed near the frame side. This can be achieved by welding the part. Another part is made rotator. This part can be rotated by applying force on it from lever via cable. This moves only partially over fixed one and firstly this is hold in position by a spring arrangement. (a) Clutch plate of 10cm radius and thickness of 6mm is used.

4.3 Axle:

The axle has to be made so as to carry the flywheel and clutch units. The flywheel can be inserted after bearing is added to it and if variable diameter is provided on axle within mid-point the flywheel can be made to be inserted from one end and it automatically locks in the middle of the axle over which it rotates. Also the clutch units sequentially clutch plate and the fixed and moving rods along

with its mechanism can be mounted over the axle. An axel of 168mm length and 16mm diameter is used.

4.4 Sprocket:

Two sprockets have to be used. The gear ratio is to be taken in to account here. One sprocket with higher number of teeth (52 teeth) is to be selected and other having lesser number of teeth (13teeth). The larger sprocket is to be placed at the rear wheel end and smaller sprocket at the axle end. This is to ensure that we can provide larger flywheel rotations so that energy storage increases. The gear ratio of 1:4 is maintained.

4.5 Bearing:

The bearing will rest inside the flange and will be covered in oil. The purpose of the bearing is to take the torque load from the flange and not to transmit it to the end piece to allow for a successful clutch actuation. The bearing used for the bicycle belongs to 6200 series and they are single row, deep groove and Conrad type. Basic load rating is 2150lbs and is 1080lbs, basic load factor is 13.2, and limiting speed is 17000 rpm, bearing weight (approx.) 0.14lbs.

4.6 Steel pipe and U-clamp:

It is easy Steel pipe is produced by cold forming flat rolled steel into tubular shapes and electric-resistance welded into solid wall tubing. Controls during the cold forming to square or rectangular shapes prevent irregularities in structure or loss of physical properties across the weld area. Since it begins as a flat rolled product, the finished tube has a uniform wall thickness and equal strength throughout. to machine and fabricate, using all common machining and fabricating operations. It can be bent or drawn, flattened or flared, expanded or swaged, drilled or punched easily. It is easily mechanically joined or welded using all the commonly used practices. Because of ease of fabrication, and a surface suitable for painting or plating, Structural Steel Square and Rectangular tube has almost unlimited applications.

4.7 Roller chain:

All chains are classified according to pitch (the distance between centers of adjacent bearing pins), roller diameter and width between inner plates. Collectively, these dimensions are known as the gearing dimensions as they determine the form and width of the sprocket teeth.

5. FRAME MODIFICATION

The frame modification is the first part of the fabrication that has to be done. The frame has to be modified by adding steel tube of length 1m. The frame should have enough strength so as to carry the flywheel and the additional forces that comes to play. The modification should not hinder normal riding of the bicycle. Also the modified frame should have enough space in order to accommodate flywheel and clutch assemblies. The clutch lever is arranged to operate the clutch operation during the engaging and disengaging the flywheel rotation. The larger sprocket is fitted to the rear wheel to transmit the power to the flywheel and again recover it back. Chain of 1.2m length is used to transmit the power. This is shown in figure below.

(a) Frame width of 138mm.

(b) 3/4inch steel tube of 1m is used, weighing 0.7kg each.

(c) Radius of the wheel is 30cm.

6. KERS BICYCLE WORKING

A crank wheel connected to the rear wheels always rotates the clutch plate, connected in the flywheel axle. This is being achieved by using chain transmission at a specified gear ratio, crank to clutch sprocket helps us to increase the overall speed of flywheel. Now at a time when a speed reduction is required, clutch is applied which makes the contact between the clutch and flywheel. Then the flywheel starts rotating, also the speed of bicycle is decreased. Thus a regenerative braking system is achieved. On course energy is stored in flywheel. In case the brake has to be applied fully then after flywheel rotations clutch is disengaged and the brake is applied. Now when we again rides the bicycle during which we would apply clutches at this time as rear wheel rotation is lesser compared to fly wheel the energy gets transmitted from the flywheel to the wheels. Now also we can reduce the overall pedaling power required in course of overrides by having clutch fully engaged. Also situation arises such as traffic jam, down climbing a hill where we do not intend to apply brake fully. For such cases we can apply our smart braking system which would allow us to decelerate and allow us to boost acceleration after this during normal riding and distance that can be covered by pedaling can also improve. During normal rides situations may arise we need to reduce the speed without braking fully such as traffic jams, taking, turns etc. we can store the energy that would normally be wasted due to speed reduction by the application of clutch. When the clutch is engaged that time due to initial engage the flywheel rotation consumes energy which would result in speed reduction thus a braking effect. After some instances the energy is being stored in the flywheel this can be reused by the engage of clutch plate and energy transfer from the flywheel occurs whenever the rotation is high

enough to rotate rear wheel. Thus if sudden braking is applied then we can disengage the flywheel connections so that flywheel energy is not wasted and going to take ride the speed of rear wheel is null and hence engage would help in returning the energy from the flywheel to rear wheel. While riding downhill we always use braking for allowing slowdown. This is the best case where we can store maximum amount of energy in our flywheel. The flywheel can be engaged for full downhill ride and after all for some distance we need not ride the bicycle which would be done by the flywheel. This is the main advantage area of KERS bicycle.

7. WEIGHT AND PERFORMANCE

Normally energy stored in the flywheel is directly proportional to the weight and radius. Hence increase in weight proves to improve the performance. But as we know that the maximum safe weight that can be used is limited due to frame properties and rider compatibility. And also after some extent the radius can't be increased and the energy storage thus seems to be limited to some particular extend. This is also because of the fact that the total running speed is being reduced due to weight. Energy storage capacity increases with increase in weight but limitation seems to be the speed driving the flywheel. And performance of system is directly linked with the energy stored. Thus a graph can be plotted between performance and weight. Optimum value lies between 4 and 8 kg.

8. CONCLUSION

KERS system used in the vehicles satisfies the purpose of saving a part of the energy lost during braking. Also it can be operated at high temperature range and are efficient as compared to conventional braking system. KERS system has a wide scope for further development and the energy savings. The use of more efficient systems could lead to huge savings in the economy of any country. Here we are concluding that the topic KERS got a wide scope in engineering field to minimize the energy loss. As now a day's energy conservation is very necessary thing. Here we implemented KERS system in a bicycle with an engaging and disengaging clutch mechanism for gaining much more efficiency. As many mating parts is present large amount of friction loss is found in this system which can be improved. Boost is reduced because of friction

Motorized Grass cutting machine

[1]Mr. N Rishi Kanth, [2]Ms.N.Harini,

[1]Associate Professor,[2]Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract

The automating lawn cutter is a fully automated grass cutting robotic vehicle powered by solar energy that also avoids obstacles and is capable of fully automated grass cutting without the need of any human interaction. The grass cutter and vehicle motors are interfaced to an 8051-family microcontroller that controls the working of all the motors. It is also interfaced to an ultrasonic sensor for object detection. The microcontroller moves the vehicle motors in forward direction in case no obstacle is detected. On obstacle detection the ultrasonic sensor monitors it and the microcontroller thus stops the grass cuter motor to avoid any damage to the object/human/animal whatever it is. Microcontroller then turns the robotic as long as it gets clear of the object and then moves the grass cutter in forward direction again.

Keywords: micro controller, lawn cutter, ultrasonic sensor, solar panel, motor drivers

I.INTRODUCTION

Grass cutter machines have become very popular today. Most common machines are used for soft grass furnishing. This project aims at developing the Grass cutter operation and construction. The main parts of the Grass cutting machines are DC motor of 75HP capacity, relay switch for controlling motor, Battery for charging it through solar panel. It is placed in a suitable machine structure. The motor have 18000 rpm and it is connected to the electric supply by the use of a roll of wire. The motor rpm increased by the help of gears. Motor controlled by an electric switch for easy operation. The tempered blades are attached in this machine. The raw materials mainly used are GI sheet, motor, switch, wheel, wire, aluminium sheet, square pipe, paint, insulating material and other standard item like nuts, bolts and reverts. The machines required for manufacturing includes welding machine, grinding machine etc. Working principle of the grass cutter is providing a high-speed rotation to the blade, which helps to cut the grass. The blade will get kinetic energy while increasing the rpm. The cutting edges are very smooth and accurate. Also Electric Grass Cutting Machines are much easier to be used in garden, lawn and grass fields. In order to enhance the beauty of home- lawns and gardens, Grass cutting machines are the best available option in the industry. With the help of a lawn mower which is a machine with revolving blades to help us cutting lawns at even length, people can easily maintain and beautify their lawns and gardens without any hassle. Now-a-days, there are plenty of options starting from the simplest push along mower to the most advanced electric grass cutting

machine. According to world energy report, we get around 80% of our energy from conventional fossil fuels like oil (36%), natural gas (21%) and coal (23%). It is well known that the time is not so far when all these sources will be completely exhausted. So, alternative sources should be used to avoid energy crisis in the nearby future. So introduce solar energy for the machine process to work. A solar panel is a large flat rectangle, typically somewhere between the size of a radiator and the size of a door, made up of many individual solar energy collectors called solar cells covered with a protective sheet of glass. The cells, each of which is about the size of an adult's palm, are usually octagonal and coloured bluish black. Just like the cells in a battery, the cells in a solar panel are designed to generate electricity; but where a battery's cells make electricity from chemicals, a solar panel's cells generate power by capturing sunlight instead. They are sometimes called photovoltaic cells because they use sunlight ("photo" comes from the Greek word for light) to make electricity (the word "voltaic" is a reference to electricity pioneer Alessandro Volta). As small engines became more powerful, a new type of lawn mower that could cut larger and longer swaths of grass became more popular. Instead of cutting grass like scissors cut paper as a reel mower does, the rotary mower spins a horizontal blade around fast enough to cut the grass as it hits it. The blade sits within a casing called a deck, which keeps the grass and other objects from flying in all directions when struck. Typically, the deck rides on four wheels, with a motor sitting on top of it and a bag attached to it to collect the cut grass. The basic version of a rotary mower has a handlebar attached to it that the operator stands

behind and pushes to make it move forward. Self-propelled versions have a transmission that turns the wheels using the power of the motor.

Solar Energy:

Solar energy is very large, inexhaustible source of energy. The power from the sun interrupted by earth is approximately 1.8/10MW, which are many thousands of times larger than the present consumption rate on the earth of all energy sources. The quantum of energy India's land area receive from sun is equivalent to 15,000 time sits consumption requirement (500 billion kWh) as projected for 2004. In addition to its size, solar energy has two other factors in its favor. Firstly, unlike fossil fuels and nuclear power, it is an environmentally clean source of energy. Secondly, it is free and available in adequate quantities in almost all parts of the world people live. But there are some problems associated with its. The real challenge in utilizing solar energy is of and economic concern. One has to strive for the development of cheaper methods of collection and storage so that large initial investments required at present in most applications are reduced, solar energy in India. A large amount of solar radiation fall on India and for most of the country very few days are without sunshine. India lies within the latitude of 7 N to and 37 N with annual average intensity of solar radiation as 500 to 600 cal/cm/day with more such insulations available in arid and semi-arid regions. Average solar radiation falling on India in arid and semiarid regions is 7.5 K w h/m/day. Solar energy 5× 10 K w

h/year potential to meet basic energy needs of teeming millions who live in rural India. Solar energy is an important, clean, cheap and abundantly available renewable energy. The sun radiates heat and light. The heat, light received from the sun supports the environment on the earth through the following well known natural effects

. - Temperature balance on the earth.

- Photo-synthesis by biological plants production of oxygen and organic materials, production of organic chemicals and bio-mass.

- Wind due to unequal heating of water, land surfaces.

- Heating of ocean water: ocean thermal energy (OTEC).

- Waves in ocean: ocean wave energy.

- Tides in ocean:

ocean tidal energy (due to gravitational forces) The sun produces enormous amount of energy of heat and light through sustained nuclear fusion reactions. The solar energy received on the earth in the form of radiation is used for heating and producing an electrical energy. Among the non-conventional sources of energy solar energy is the most promising. Hence our project is based on the solar energy conversion to mechanical energy to run a grass cutter.

II. LITERATURE SURVEY

The self- powered design objective is to come up with a mower that is portable, durable, easy to operate and maintain. It also aims to design a self-powered mower of electrical source; a cordless electric lawn mower. The heart of the machine is a battery-powered dc electric motor. It is also useful method for our lawn mower. It is similar to our lawn cutter using display[3].

For designing of Automatic Lawn Cutter, we referred various literature, papers etc. The review of previous method used to give below: In this lawn mower uses an solar based energy source, which is easier to use, more advantageous comparing to other energy source especially for gas based source of power. This is useful to our project [4].

In this hydrogen-based lawn mower, the advantage of powering a lawn mower by hydrogen rather than by gasoline is mainly ecological. We not used this for our lawn cutter because it is very old method and many overcome produced from this type lawn cutter [6].

III. BLOCK DIAGRAM

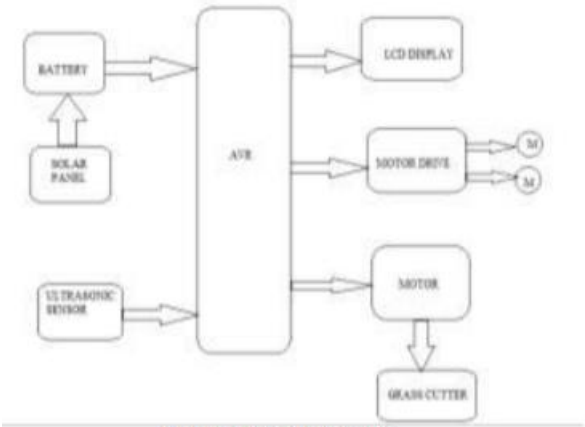

Fig. 3.1: Block diagram

Block Diagram Explanation:

Solar panel receives solar energy from the sun and it converts solar energy into electrical energy by photovoltaic principle. Electrical energy is then stored in the battery. The battery used here is rechargeable battery, the vehicle can be powered on either by using solar energy or by using external power supply. Here 12v supply is converted into 6v which is enough to power on and working of our lawn cutter. Ultrasonic sensor is the eyes of lawn cutter. It is a Tran's receiver, it will detect the obstacles present in front of it by receiving echo signals and take deviation until obstacles is cleared. The grass cutter and vehicle motors are interfaced to a microcontroller that controls the working of all the motors. That is when the obstacle is present the blade should stop rotate and after the obstacle clears the blade should rotate again. It should also take right deviation when obstacles is present so to take right deviation motor 1 should be made forward direction and motor 2 should be made reverse direction. 2*16 LCD display is used, initially it will display initialization message when we power on the vehicle soon after it will display protect title. Once it receives the signal from RF transmitter then vehicle starts moving in forward direction at that time the distance between sensor and obstacle is calculated and that value is displayed using LCD display.

The RF module as the name suggests operates at radio frequency. The corresponding frequency range varies 30khz and 300Ghz. The digital data is represented as variation in the amplitude of carrier wave, this kind of modulation is known as amplitude shift keying. The transmitter or receiver pair operated at a frequency of 434Mhz. an RF transmitter receiver serial data and transmits it wireless through RF through its antenna connected at pin number 4. The transmission occurs at the rate of 1Kbps-10Kbps. The transmitted data is receive by an RF receiver operating at the same frequency as that of the transmitter. The RF module is often used along with a pair of encoder/decoder; the encoder is used for encoding parallel data for transmission feed, while reception is decoded by a decoder.

Transformer – steps down high voltage AC mains to low voltage AC. Rectifier- converts AC to DC but the DC output is varying. Smoothing- smoothness the DC from varying greatly to a small ripple. Regulator- eliminates ripple by setting DC output to a fixed voltage

IV. RESULTS

We are successfully completed this project that is automatic lawn cutter. The robotic vehicle will mow in forward direction automatically to cut the grass uniformly and also calculate the distance of obstacle. If any obstacle is present, it takes deviation towards right direction. After the obstacle is cleared the vehicle moves forward direction automatically to cut the grass.

V. CONCLUSION

This lawn mower will meet the challenge of environmental production and low cost of operation since there is no cost for fueling. A lawn mower has been developed for the use of residences and establishments that have lawns where tractor driven mowers could not be used. The machine's capacity is adequate for its purpose. The machine has proved to be a possible replacement for the gasoline powered lawn mowers. We are developed "Automatic Lawn Cutter" by using keypad and LCD display and for this we are using battery hence it works Automatically.

VI. FUTURE SCOPE

In future we can implement lawn cutter by specifying the area that is to be mown and also the height of grass as per the requirement.

MULTI-PURPOSE MACHINE

[1]Mr. N Rishi Kanth, [2]B Indrakanth

[1]Associate Professor,[2]Assistant Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract –

This Thesis deals with development and fabrication of "MULTI PURPOSE MACHINE". This machine is designed for the purpose of multi operations i.e. drilling, hacksaw cutting and shaping operations. This machine performs multipurpose operations at the same time with required speed and this machine is automatic which is controlled or operated by motor which is run with help of current. This machine is based on the Scotch Yoke Mechanism. This model of the multi operational machine may be used in industries and domestic operations, which can perform mechanical operations like drilling, cutting and shaping of a thin metallic as well as wooden model or body.

Keywords - Multipurpose Machine, Scotch Yoke Mechanism

I. INTRODUCTION

Multi-purpose machine as a research area is motivated by questions that arise in industrial manufacturing, production planning, and computer control. Consider a large automotive garage with specialized shops. A car may require the following work: replace exhaust system, align wheels, and tune up. These three tasks may be carried out in any order. However, since the exhaust system, alignment, and tune-up shops are in different buildings, it is impossible to perform two tasks for a car simultaneously. When there are many cars requiring services at the three shops, it is desirable to construct a service schedule that takes the least amount of total time.

1.1 SCOTCH YOKE MECHANISM

The Scotch yoke is a mechanism for converting the linear motion of a slider into rotational motion or vice-versa. The piston or other reciprocating part is directly coupled to a sliding yoke with a slot that engages a pin on the rotating part. The shape of the motion of the piston is a pure sine wave over time given a constant rotational speed.

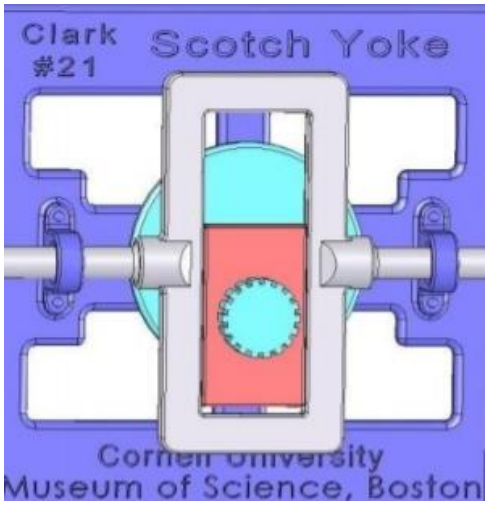

Figure 1: scotch yoke mechanism representation

1.2 CONSTRUCTION

The scotch yoke mechanism is constructed with iron bars. Here the crank is made of some length and the yoke is also made using the same material. It is noted that the minimum length of the yoke should be double the length of the crank. The crank and yoke is connected with a pin. Iron bars are welded to both sides of the yoke to get the reciprocating motion. The yoke with the iron bars is fixed on the display board with the help of c clamp. Now the crank is welded to the end of the shaft of the motor. Now the pin on the crank is connected to the yoke. The pin used to connect yoke and crank is a bolt.

1.3 WORKING PRINCIPLE

When the power is supplied to the 12v Dc motor, shaft and crank attached to the shaft start rotating. As the crank rotates the pin slides inside the yoke and also moves the yoke forward. When the crank rotates through in clockwise direction the yoke will get a displacement in the forward direction. The maximum displacement will be equal to the length of the crank. When the crank completes the next of rotation the yoke comes back to its initial position. For the next of rotation, yoke moves in the backward direction. When the crank completes a full rotation, the yoke moves back to the initial position. For a complete rotation of crank the yoke moves through a length equal to double the length of the crank. The displacement of the yoke can be controlled by varying the length of the crank.

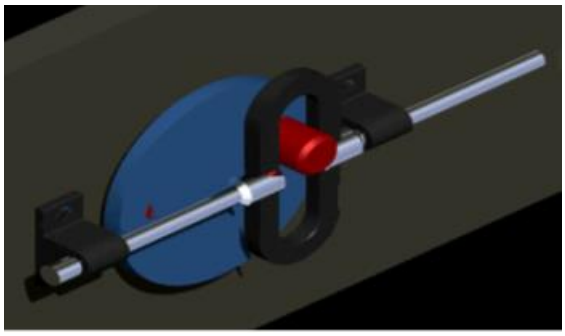

Figure 2: working of the mechanism

1.4 RADIAL ARM DRILL PRESS

A radial arm drill press is a large geared head drill press in which the head can be moved along an arm that radiates from the machine's column. As it is possible to swing the arm relative to the machine's base, a radial arm drill press is able to operate over a large area without having to reposition the workpiece. This saves considerable time because it is much faster to reposition the drill head than it is to unclamp, move, and then re-clamp the workpiece to the table. The size of work that can be handled may be considerable, as the arm can swing out of the way of the table, allowing an overhead crane or derrick to place a bulky workpiece on the table or base. A vise may be used with a radial arm drill press, but more often the workpiece is secured directly to the table or base, or is held in a fixture. Power spindle feed is nearly universal with these machines and coolant systems are common. Larger size machines often have power feed motors for elevating or moving the arm. The biggest radial arm drill presses are able to drill holes as large as four inches (101.6 millimetres) diameter in solid steel or cast iron. Radial arm drills are specified by the diameter of the column and the length of the arm. The length of the arm is usually the same as the maximum throat distance. The Radial Arm Drill pictured in this article is a 9-inch column x 3-foot arm. The maximum throat distance of this drill would be approximately 36", giving a swing of 72" (6 feet).

Figure 3: Radial arm drill press

1.5 HACKSAW

Hand-held hacksaws consist of a metal arch with a handle, usually a pistol grip, with pins for attaching a narrow disposable blade. Ascrew or other mechanism is used to put the thin blade under tension.The blade can be mounted with the teeth acing toward or away from the handle,resulting in

cutting action on either the push or pull stroke. On the push stroke, the arch willflex slightly, decreasing the tension on the blade, often resulting in an increased tendency of the blade to buckle and crack. Cutting on the pull stroke increases the blade tension and willresult in greater control of the cut and longer blade life A hacksaw is a fine-tooth saw with a blade under tension in a frame, used for cuttingmaterials Such as metal. Hand-held hacksaws consist of a metal frame with a handle, and pins for attaching a narrow disposable blade. A screw or other mechanism is used to put thethin blade under tension. A power hacksaw (or electric hacksaw) is a type of hacksaw that is powered by electric motor. Most power hacksaws are stationary machines but some portablemodels do exist. Stationary models usually have a mechanism to lift up the saw blade on thereturn stroke and some have a coolant pump to prevent the saw blade from overheating.

Figure 4: hacksaw

II. LITERATURE SURVEY

We have done a survey regarding cutting, shaping and drilling machines, from that we came to know that these machines can perform only single operation at a time so that we found a problem in that machine that we cannot perform all three operation in single machine. From this survey only we got an idea to develop a multi-purpose machine. In this survey we had met with few machines and the operators who operate those machines. The machines are namely cutting machine, shaping machine and drilling machine. By seeing those three different machines, we noticed that they occur a huge space for their working. And those three machines are operated with skilled workers. We have done a survey with those workers who operate those machines. From their words we came to know that these three different machines need three different types DC motors of different volts for their working. And they said these machines also need high maintenance and manpower. From the data details which we gathered from the people who deals with this drilling machine, shaping machine and cutting machine we came to a point that the operation of these three different machines are usually carried out individually and it requires three different motors for their functioning. Theseoperations are also required of skilled operators and more man power.

Figure 5: shaping machine:

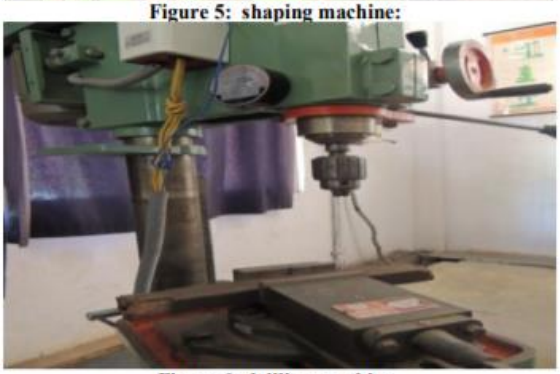

Figure 6: drilling machine

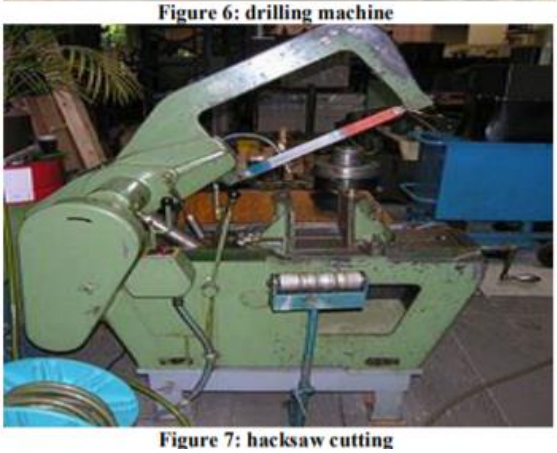

Figure 7: hacksaw cutting

The above three figures (Fig 5, Fig 6, Fig 7) shows shaping machine, drilling machine and cutting machine respectively. To make the working operations easier we planned to assemble these three different machines in to a single machine. This assembled machine can be called as a multipurpose machine, in which we can do all three operations like cutting, drilling and shaping at a same time from a single DC motor. The use of multipurpose machine makes the work easier and reduces the manpower. It can also be automated and the speed can be regulated.

III. PROBLEM DEFINITION

3.1 PROBLEM STATEMENT:

To design and development of MULTI PURPOSE MACHINE, a structured which is designed for the purpose of MULTI-OPERATIONs i.e., DRILLING, CUTTING & SHAPING.

3.2 PROBLEM IDENTIFICATION:

This machine perform multipurpose operation at same time with required speed & this machine is automatic which is controlled or operated by motor which is run with the help of current. This machine is based on the Scotch Yoke mechanism. This model of the multi-purpose machine may be used in industries and domestic operation which can perform mechanical operation like drilling, cutting & shaping of a thin metallic as well as wooden model or body.

IV. METHOD OF DEVELOPING MULTI PURPOSE MACHINE

4.1 CONCEPT 1

In the very first concept the use of crank and slot mechanism which was not effective as it doesn't give complete rotation and the length of the stroke is also less, which won't be much enough to cut or shape when a work piece of higher dimensions are used. Thus use of crank and slot mechanism was not useful for this machine so we denied the use of it.

4.2 CONCEPT 2

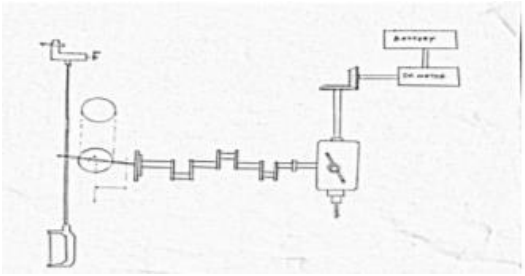

Figure 8: concept 2 In

the second concept we changed the crank and slot mechanism to Scotch Yoke Mechanism, which gives complete rotation and sufficient stroke length to preform our operation, and we have used crank shaft to transmitte power D.C motor to shaper and cutting machine.

4.3 CONCEPT 3

In the third concept we changed crank shaft to simple shaft again, as the crank shaft does not give proper allignment and creates more vibration to the system. Use of simple shaft has helped us to reduce the vibration of the complete device to its half.

4.4 BLOCK DIAGRAM

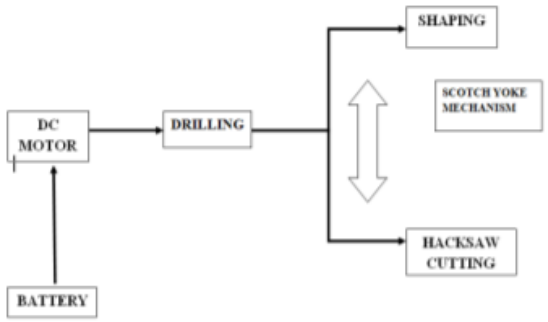

Figure 9: block diagram of multi-purpose machine

From the block diagram we can see that a DC motor is connected to a battery, with the help of this battery the DC motor is rotated. The bevel gear which is attached to the motor also starts rotating. And when the bevel gear rotates the drilling machine which is connected to it starts to work. From the drilling machine a shaft is connected to the cam mechanism which is used to reciprocate the cutting and shaping machine. V.

2D DIAGRAM OF MULTIPURPOSE MACHINE

2D computer graphics is the computer-based generation of digital images—mostly from two-dimensional models (such as 2D geometric models, text, and digital images) and by techniques specific to them. The word may stand for the branch of computer science that comprises such techniques, or for the models themselves. 2D computer graphics are mainly used in applications that were originally developed upon traditional printing and drawing technologies such astypography, cartography, technical drawing, advertising, etc. In those applications, the two-dimensional image is not just a representation of a real-world object, but an independent artifact with added semantic value; two-dimensional models are therefore preferred, because they give more direct control of the image than 3D computer graphics (whose approach is more akin to photography than to typography). In many domains, such as desktop publishing, engineering, and business, a description of a document based on 2D computer graphics techniques can be much smaller than the corresponding digital image—often by a factor of 1/1000 or more. This representation is also more flexible since it can be rendered at different resolutions to suit different output devices. For these reasons, documents and illustrations are often stored or transmitted as 2D graphic files. 2D computer graphics started in the 1950s, based on vector graphics devices. These were largely supplanted by raster-based devices in the following decades. The PostScript language and the X Window System protocol were landmark developments in the field.

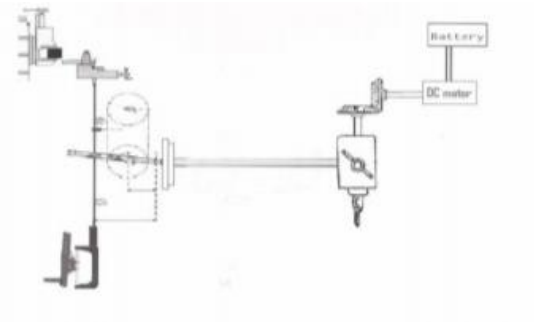

Figure 10: 2D view

5.1 3D DESIGN OF MULTIPURPOSE MACHINE

3D modeling is the process of developing a mathematical representation of any threedimensional surface of object (either inanimate or living) via specialized software. The product is called a 3D model. It can be displayed as a two-dimensional image through a process called 3D rendering or used in a computer simulation of physical phenomena. The model can also be physically created using 3D printing devices. Models may be created automatically or manually. The manual modeling process of preparing geometric data for 3D computer graphics is similar to plastic arts such as sculpting. New concepts in 3D modeling have started to emerge such as curve-controlled modeling that emphasizes the modeling of the movement of a 3D object instead of the traditional modeling of the static shape. 3D modeling software is a class of 3D computer graphics software used to produce 3D models. Individual programs of this class are called modelling applications or modellers.

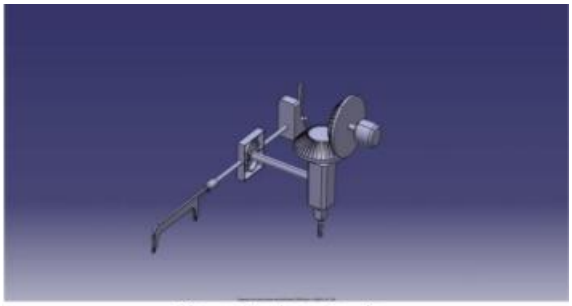

Figure 11: Angular view

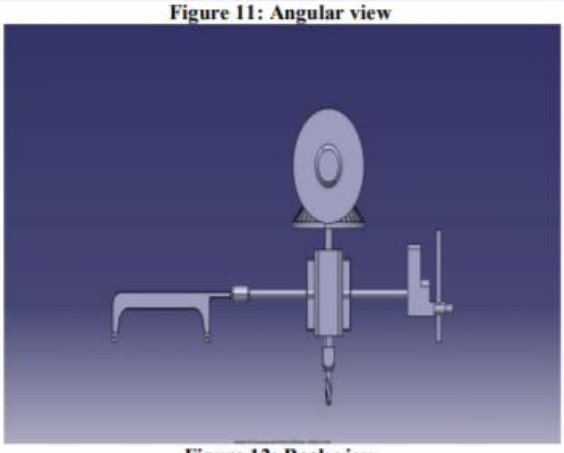

Figure 12: Back view

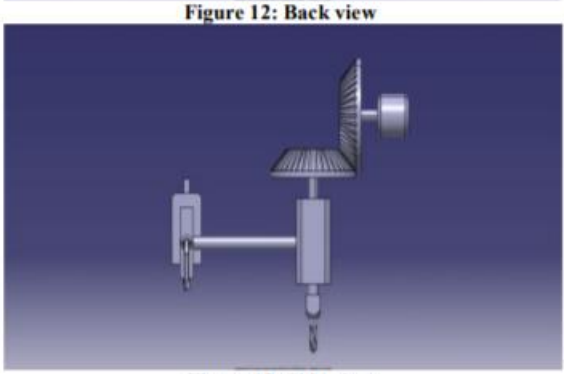

Figure 13: Side view

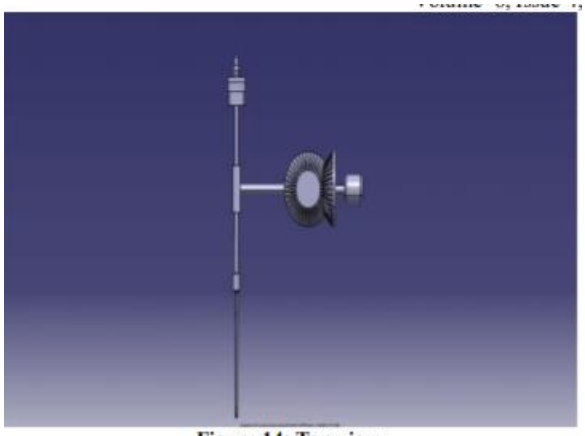

Figure 14: Top view

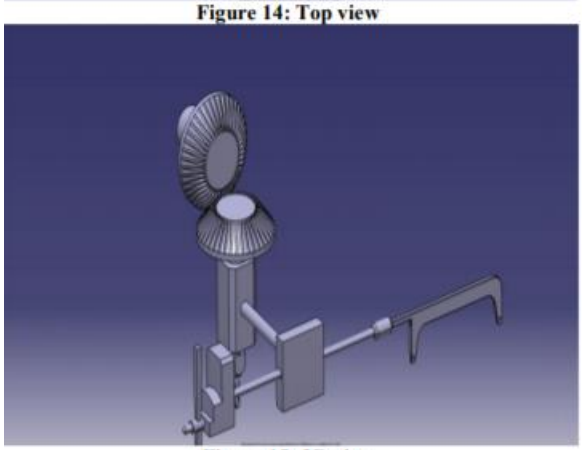

Figure 15: 3D view

Fabrication is a value added process that involves the construction of machines and structures from various raw materials. A fab shop will bid on a job, usually based on the engineering drawings, and if awarded the contract will build the product. Large fab shops will employ a multitude of value added processes in one plant or facility. These large fab shops offer additional value to their customers by limiting the need for purchasing personnel to locate multiple vendors for different services. The raw material has to be cut to size. This is done with a variety of tools. The most common way to cut material is by Shearing (metalworking); Special band saws designed for cutting metal have hardened blades and a feed mechanism for even cutting. Abrasive cut-off saws, also known as chop saws, are similar to miter saws but with a steel cutting abrasive disk. Cutting torches can cut very large sections of steel with little effort. Burn tables are CNC cutting torches, usually natural gas powered. Plasma and laser cutting tables, and Water jet cutters, are also common. Plate steel is loaded on a table and the parts are cut out as programmed. The support table is made of a grid of bars that can be replaced. Some very expensive burn tables also include CNC punch capability, with a carousel of different punches and taps. Fabrication of structural steel by plasma and laser cutting introduces robots to move the cutting head in three dimensions around the material to be cut. Machining is a trade, in and of itself, although Fab shops will generally entail a limited machining capability including; metal lathes, mills, magnetic based drills along with other portable metal working tools After the weldment has

cooled it is generally sand blasted, primed and painted. Any additional manufacturing specified by the customer is then completed. The finished product is then inspected and shipped.

Figure 16: Unassembled bevel gear arrangement for drilling process

Figure 17: Bevel gear arrangement and drilling machine

Figure 18: Slot during welding

CONCLUSION

Multi operations are performed at same time. our machine is used in return stroke mechanism also. All operations are performed in single motor. Size is compact therefore it requires less space. It is time saving. Less man power is required.Low manufacturing and maintenance cost. The operations which are discussed like cutting, shaping and drilling are usually carried individually and it requires

three different motors for their functioning. These operations are also required of skilled operators and more man power. The machine which we designed here can perform multi operations i.e.; drilling, hacksaw cutting and shaping operations simultaneously at same time with a single motor.Use of simple shaft has helped us to reduce the vibration of the complete device to its half.

PNEUMATIC AUTO FEED DRILLING MACHINE

[1]Mr. N Rishi Kanth, [2]Mr. S. Udaya Bhaskar

[1,2]Associate Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract:

Today most of the industries are trying to make improvement in their production processes as well as relevant machinery to improve the productivity along with the automation. Drilling, taping, boring etc. are such operations which are most frequently used in small and large scale industries. Most of the industries uses the conventional method says hand tapping, drilling, boring. This conventional method is very time consuming process, less accurate and includes higher labour cost, and ultimately leads to less productivity. So there is a scope to develop the machine for various operation which would overcome all the problems faced by the conventional process. So we are going to develop the portable pneumatics machine which will make the use of compressed air for it operation less human involvement as which is used in hand tapping, drilling, boring. Key words: Pneumatic gun, Universal, Drilling

INTRODUCTION

We had chosen the user defined project (UDP) for our final year project. We are decided our topic to develop the automatic multi-operational portable machine say like tapping, drilling, grinding, reaming, and other relative operation. This will make use of compressed air (pneumatic mechanism) for its operation. We will trying to develop the portable machine which will easily handle and cover a maximum working area from one station and make it more flexible to working easily. As a small industries the machine and operation method use for drilling, tapping and other similar process is not economically and eco friendly. As we know that drilling machine use the electricity as there power source these machine have many limitation like it is not flexible and not moveable, consume more floor area and main problem is that it need continuous electricity which increase the cost of production. The tapping operations are performed by use of convention tap or hand tap. during operation it is necessary with a hand tap to periodically reverse rotation to break the chip formed during the cutting process, thus preventing effect called crowding that may cause defect. In convention method, main problem causes during the tapping operation for big job industries and complex job these causes are created defect on tap tool, increasing operational lead time, inaccuracy of thread geometry, more production cost and more labour cost.

II. WORKING PROCEDURE

Pneumatic multi-operation machine makes use of compressed air obtained from compressor passes through pressure regulator & then passes through pneumatic gun. In pneumatic gun air exerts a axial

spinning force on the spindle located inside the tool head which causes the drill tool to rotate inside the work piece with required RPM.

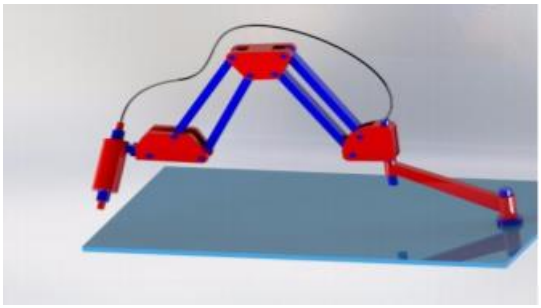

Fig. 1: Concept Design

III. METHODOLOGY

A. Step 1: Part collection After some survey from market finally we bought pneumatic gun, pressure regulator, pipes, wheels for table & adaptor at the reasonable price.

Fig 2: Pneumatic Gun

Fig 3: Pressure Regulator

fig 3: Connecting pipe

B. Step 2: Define Joints We defined joints which are used for relative motion of arms & also to rotate gun in 360 degree. We designed mainly three types of joints such as ball joints, pin joints & rotational top head. We can switch to an automation by using servo motor in the defined joints for future scope.

Fig 4: Joints

C. Step 3: Design arms or linkages We made arms or linkages having material of mild steel with help of fabricator. We can use telescopic arms to extend the work envelope of pneumatic drilling machine for future scope.

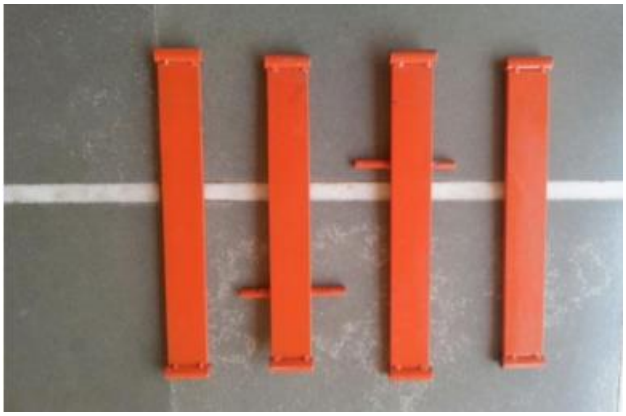

Fig 5: Arms or linkages

D. Step 4: Fabrication of table We made supporting table to sustain the load of pneumatic drilling machine by mounting it on the table. We provide wheels to the table to provide the portability to the machine.

Fig 6: Supporting table

E. Step 5: Assembling of component After collection & designing of all parts we go for the final assemble to give the final touch to our machine. Finally we assembled all the components in the one single unit and made universal drilling machine to justify our project title "DESIGN & DEVELOPMENT OF UNIVERSAL PNEUMATIC DRILLNG MACHINE".

Fig 7: Partial Assembling

Fig 8: Final assembly

F. Step 6: Fabrication of table We did some experiment by drilling the material as wood, aluminium & cast iron using the appropriate tool & air pressure. The experiments in the image shows the drilling of the workpiece. The other operation such as tapping, boring, grinding, thread cutting can also Performed by our machine.

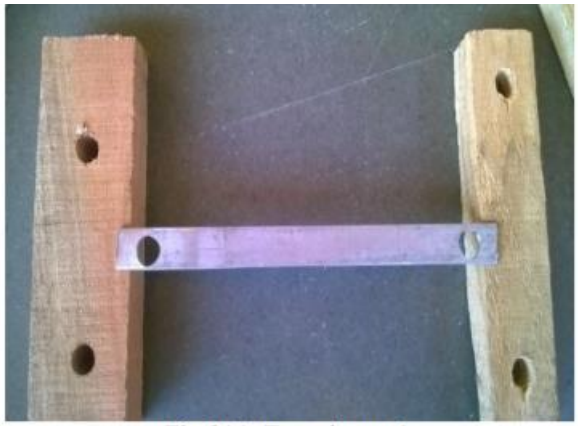

Fig 9(a): Experiment 1

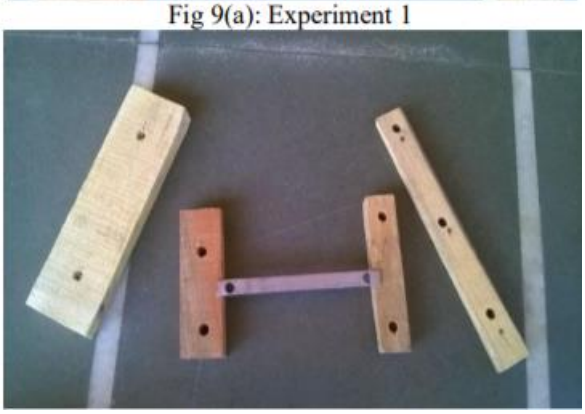

Fig 9(b): Experiment 2

V.FUTURE SCOPE

a use servo motor in our machine to provide the automation by giving auto feed.

- We can use telescoping arm to increase the working envelope of the machine to reach in any direction easily.
- We can use hydraulic system or hydraulic lubrication to operate the machine in smooth manner without including the less fatigue of man power.

VI. CONCLUSION & SUMMARY

- Due to the various problems faced by conventional operation processes such as Poor thread finish, more time consumption, frequent tool breakage and many more. So, we have decided to design the machine which will make use of compressed air as a power source.
- Above is the Future model of pneumatic machine on which the tapping ,drilling, boring etc operation is achieved by Pneumatic system and it eliminates all the problem faced by conventional operation process.
- This pneumatic multi-operation Machine is to be presented for increasing their productivity as well as quality of job. It also gives the detailed description of machine mechanism and their different main

parts of machine. In this we are defining different process parameters like spindle speed (rpm), cutting feed rate, cutting force, torque and power for their efficient working of operation.

Quick Lifting Jack with Gear Arrangement

[1]Mr. N Rishi Kanth, [2]Mr. S. Udaya Bhaskar

[1,2]Associate Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract

This project work titled **"**FABRICATION OF QUICK LIFTING JACK WITH GEAR ARRANGEMENT**"** has been conceived having studied the difficulty in lifting the any type of light vehicles. Our survey in the regard in several automobile garages, revealed the facts that mostly some difficult methods were adopted in lifting the vehicles for reconditioning. Now the project has mainly concentrated on this difficulty, and hence a suitable device has been designed. Such that the vehicle can be lifted from the floor land without application of any impact force. The fabrication part of it has been considered with almost case for its simplicity and economy, such that this can be accommodated as one of the essential tools on automobile garages.

Keywords: frame, Handle, lifting rod.

INTRODUCTION

This device the quick lifting jack with gear arrangement for automobile garages has been developed to later the needs of small and medium automobile garages, who are normally man powered with very minimum of skilled labors. In most of the garages the vehicles are lifted by using screw jack. This needs high man power and skilled labours. In order to avoid all such disadvantages. This, motorized hydraulic jack has been designed in such a way that it can be used to lift the vehicle very smoothly without any impact force. The operation is made be simple that even an unskilled labour can handled, by just demonstrating the working of the motorized hydraulic jack once.

Literature Review

Screw type mechanical jacks were very common for jeeps and trucks of World War II vintage. For example, the World War II jeeps (Willys MB and Ford GPW) were issued the "Jack, Automobile, Screw type, Capacity 1 1/2 ton", Ordnance part number 41-J-66. This jacks, and similar jacks for trucks, were activated by using the lug wrench as a handle for the jack's ratchet action of the jack. The 41-J-66 jack was carried in the jeep's tool compartment. Screw type jack's continued in use for small capacity requirements due to low cost of production raise or lower it. A control tab is marked up/down and its position determines the direction of movement and almost no maintenance. The virtues of using a screw as a machine, essentially an inclined plane wound round a cylinder, was first

demonstrated by Archimedes in 200BC with his device used for pumping water. There is evidence of the use of screws in the Ancient Roman world but it was the great Leonardo ad Vinci, in the late 1400s, who first demonstrated the use of a screw jack for lifting loads. Leonardo‟s design used a threaded worm gear, supported on bearings, that rotated by the turning of a worm shaft to drive a lifting screw to move the load - instantly recognizable as the principle we use today. We can't be sure of the intended application of his invention, but it seems to have been relegated to the history books, along with the helicopter and tank, for almost four centuries. It is not until the late 1800s that we have evidence of the product being developed further. With the industrial revolution of the late 18th and 19th centuries came the first use of screws in machine tools, via English inventors such as John Wilkinson and Henry Medley The most notable inventor in mechanical engineering from the early 1800s was undoubtedly the mechanical genius Joseph Whitworth, who recognized the need for precision had become as important in industry as the provision of power. While he would eventually have over 60 British patents with titles ranging from knitting machines to rifles, it was Whitworth's work on screw cutting machines, accurate measuring instruments and standards covering the angle and pitch of screw threads that would most influence our industry today. Whitworth's tools had become internationally famous for their precision and quality and dominated the market from the 1850s. Inspired young engineers began to put Whitworth's machine tools to new uses. During the early 1880s in Coaticook, a small town near Quebec, a 24- year-old inventor named Frank Henry Sleeper designed a lifting jack. Like ad Vinci's jack, it was a technological innovation because it was based on the principle of the ball bearing for supporting a load and transferred rotary motion, through gearing and a screw, into linear motion for moving the load. The device was efficient, reliable and easy to operate. It was used in the construction of bridges, but mostly by the railroad industry, where it was able to lift locomotives and railway cars. Local Coati cook industrialist, Arthur Osmoses Norton, spotted the potential for Sleeper's design and in 1886 hired the young man and purchased the patent. The Norton‟ jack was born. Over the coming years the famous "Norton" jacks were manufactured at plants in Boston, Coati cook and Moline, Illinois. Meanwhile, in Alleghany County near Pittsburgh in 1883, an enterprising Mississippi river boat captain named Josiah Barrett had an idea for a ratchet jack that would pull barges together to form a „tow‟. The idea was based on the familiar lever and fulcrum principle and he needed someone to manufacture it.

That person was Samuel Duff, proprietor of a local machine shop, together, they created the Duff Manufacturing Company, which by 1890 had developed new applications for the original "Barrett Jack" and extended the product line to seven models in varying capacities. Over the next 30 years the Duff Manufacturing Company became the largest manufacturer of lifting jacks in the world, developing many new types of jack for various applications including its own version of the ball bearing screw jack [3].

It was only natural that in 1928, The Duff Manufacturing Company Inc. merged with A.O. Norton to create the Duff-Norton Manufacturing Company. Both companies had offered manually operated screw jacks but the first new product manufactured under the joint venture was the air motor-operated power jack that appeared in 1929. With the aid of the relatively new portable compressor technology, users now could move and position loads without manual effort. The jack, used predominantly in the railway industry, incorporated an air motor manufactured by The Chicago Pneumatic Tool.

MAIN COMPONENTS

- FRAME
- BEVEL GEARS
- HANDLE
- LIFTING ROD
- BEARING

WORKING PRINCIPLE

The quick lift jack is a device used for lifting heavy loads by the application of much smaller force. The working principle of a quick lift jack may be explained with the help of Fig. Consider a two bevel gears arrangement.

Quick lift jacks and much other technological advancement such as automobile brakes and dental chairs work. Handle is used to rotates the bevel gear arrangements. Jack arrangement i.e. lifting rod will be fixed to bevel gear. Clockwise rotation of handle, jack will rotates upward motion and anti clockwise rotation of handle, jack will rotates downward motion.

ADVANTAGES

•Quicklift ofvehicles.
•Lowmanpowerusing.
•Low-cost automation.
•Maintenance cost is verylow.
•Easytoinstall
• Less in weight

APPLICATIONS

• Implementation in automobiles.
• Lifting four-wheeler vehicles.
• Implementing in industries for lifting machines

Conclusion

In this research, a novel design for a lifting jack driven by a quick-return crank mechanismand gear drive has been designed and fabricated. The design equations for gear selection, gear driveratios and mechanism forces have been derived from its geometry. Kinematic analysis has beenperformed. A design example has been given for illustrating the design process. The detailedworking diagram has been explicitly explained equally. To verify the feasibility and accuracy, aprototype has been made, and then an experiment has been conducted. The proposed mechanism iscapable of increasing capacity; reducing input effort; saving cost of operation and requires simplemaintenance compared to conventional lever lift mechanisms of lifting jacks. The experimentalresult shows that Very little effort (5.280N minimum and 102.76N maximum) and torque (0.597Nmand 51.38Nm maximum) is required to lift a load using the modified screw jack compared with theclassical method which requires effort of 127.4N and torque of 135.04Nm. Also, the time requiredto lift a car using the modified method is lesser (2.025s) compared to the time required to lift sameweight of car using the traditional method (4.094s). Conclusively, the modified design provides agood alternative to the lever lift mechanism as other existing conventional lifting jacks require moreeffort, capacity, power generating sources and maintenance cost. The proposed quick lifting jackprototype was made up of a gear drive and a quick-return crank mechanism.

RF Based farmer friendly Agricultural Robot with motorized shovel control System with automatic seed dispensing system

[1]A. Paul Praveen, [2]Dr.Zaheer Ahamed T

[1,2]Associate Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

ABSTRACT:

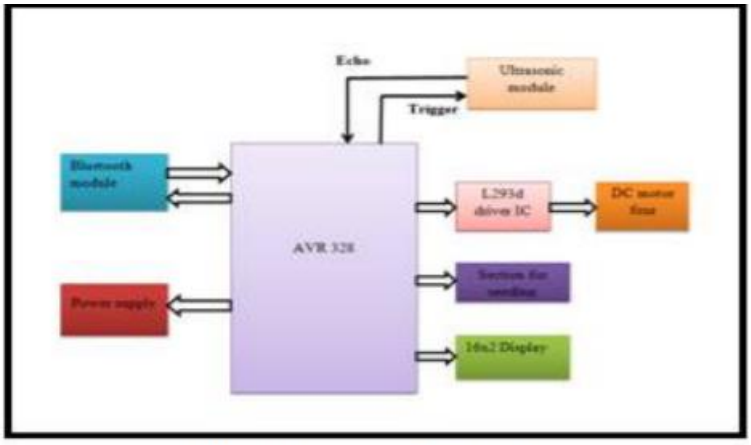
This paper strives to develop a robot capable of performing operations like automatic ploughing, seed dispensing. It also provides manual control when required and keeps tabs on the humidity with the help of humidity sensors. The main component here is the AVR Atmega microcontroller that supervises the entire process. Initially the robot tills the entire field and proceeds to ploughing, simultaneously dispensing seeds side by side. The device used for navigation is an ultrasonic sensor which continuously sends data to the microcontroller. On the field the robot operates on automated mode, but outside the field is strictly operated in manual mode. For manual control the robot uses the Bluetooth pairing app as control device and helps in the navigation of the robot outside the field. The field is fitted with humidity sensors placed at various spots that continuously monitor the environment for humidity levels. It checks these levels with the set point for humidity and alerts the farmer. The alerting mechanism is GSM module that sends a text message to the farmer informing him about the breach in set point. The farmer then responds via SMS to either switch on the water sprinklers or ignore the alert. The water sprinklers, if on, bring down the humidity level thus providing an ideal growing environment to crop.

KEYWORDS: Movement, Agricultural robot, Arduino, Robot Architecture.

1.INTRODUCTION The project implements different parts of seed sewing machine which will be useful for the cultivation business to move towards automation. The farming business has dependably been the establishment of India's supported development. As the number of inhabitants in India keeps on developing, the interest for deliver develops also. Subsequently, there is a more prominent requirement for different editing on the ranches and this along these lines requires effective and high-limit machines. Motorization of the Agricultural business in India is still in a phase of earliest stages because of the absence of learning and the inaccessibility of cutting edge instruments and hardware. In conventional methodologies seed sowing is done by conveying physically, opening wrinkles by a furrow and dropping seeds by hand. The system is utilized for sensing, monitoring, controlling and for communication purpose. The System block diagram shown in fig 1.Different sensors are used to detect the various parameters of the soil like moisture. Depending upon the sensors output the Microcontroller will take the necessary action. The moisture sensor output will help to determine

whether to irrigate the land or not depending upon the moisture content. Along with moisture sensor the temperature sensor output can also be taken into consideration while irrigating the land. If the moisture content of soil is very low and the temperature is very high then there is need of irrigation for plants, but the time for which irrigation will be provided is different for different temperature range.

II. Proposed system



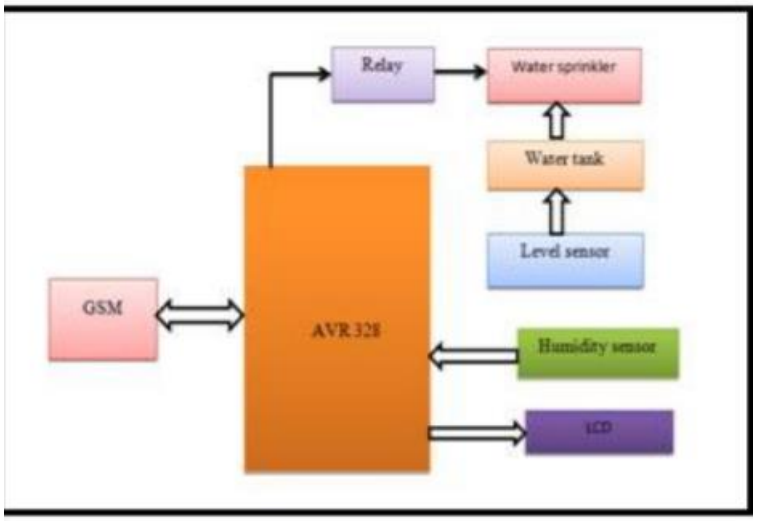


Fig.1.Block diagram of Robot Section

A. Block Diagram Explanation:

2.1 Field Section

1) AVR Microcontroller:

The AVR has Harvard Architecture where program and data memory are separately placed with an 8-bit RISC single chip microcontroller. It is the heart of the agricultural robot here. It is one of the first microcontroller families to use on-chip flash memory for program storage while other controllers used programmable ROM, EPROM or EEPROM. RISC-Reduced Instruction Set Computing, this is a CPU designed strategy based on the insight that simplified instruction can provide higher performance. AVR is most appropriate for battery powered appliances. The main advantages of using this ATmega32 are its 8-bit high performance with low power consumption and that it is based on enhanced RISC architecture with 131 powerful instructions of which most of the instructions execute in one machine cycle.

2) Ultrasonic Sensor:

This is the HC-SR04 ultrasonic ranging sensor. This economical sensor provides 2cm to 400cm of non-contact measurement functionality with a ranging accuracy that can reach up to 3mm. Each HC-SR04 module includes an ultrasonic transmitter, a receiver and a control circuit. There are only four pins that you need to worry about on the HCSR04: VCC (Power), Trig (Trigger), Echo (Receive), and GND (Ground).

3) Motor Driver IC (L293D):

L293D is a dual H-bridge motor driver, i.e. by using one IC we can control two DC Motors in both clock wise and counter clockwise directions. The L293D can provide bidirectional drive currents of up to 600-mA at voltages from 4.5 V to 36 V. IC is designed to drive inductive loads such as dc motors, bipolar stepping motors, relays and solenoids as well as other high-current or high-voltage loads in positive-supply Applications. The main purpose is for driving purpose.

4) DC motor:

A DC motor is any of a class of rotary electrical machines that converts direct current electrical energy into mechanical energy. The most common types rely on the forces produced by magnetic fields. Nearly all types of DC motors have some internal mechanism, either electromechanical or electronic; to periodically change the direction of current flow in part of the motor. The universal motor can operate on direct current but is a lightweight motor used for portable power tools and appliances.

5) Relay: The electromechanical relay is an output device which comes in whole host of shapes size and design and has many uses and application in electronic circuits. In this project the relay switch has a coil which is driven by the npn transistor. The coil of the relay switch gets energized due to the

collector current of the transistor according to that switch gets on and off to control the water sprinkler.

6) Humidity Sensor: Humidity is defined as the presence of water in air. The amount of water vapour in air can affect human comfort as well as many manufacturing processes in industries. The presence of water vapour influences various physical, chemical and biological processes. In agriculture, measurement of humidity is important for plantation protection, dew prevention, soil moisture monitoring etc.

7) Bluetooth Module

Here Bluetooth is used as a basic universal Remote control for Bluetooth enabled serial devices such as Bluetooth modules connected to the microcontroller. It is a short-range wireless networking technology and is used to link (or pair) two devices, such as smart phones and headsets, cameras and printer Ms, and keyboards and computers, it is sometimes called a cable-replacement technology. Both devices must support Bluetooth in order to be paired, if they do, though paring the paring is designed to happen automatically, with little to no user interaction. The Bluetooth module used here is a HC-05 based on SPP support. HC-05 module is an easy to use Bluetooth SPP (Serial Port Protocol) module, designed for transparent wireless serial connection setup. In our idea we have made use of blue tooth Control App available on Android as controlling software more like a remote control for the manual operation of the robot.

2.2 Seeding Section

The robot has to plant the seeds after every 10cm; it will have to stop after every 10cm. This can be done by turning off the dc motors. Once the robot stops the mechanism attached to the robot will be used for planting the seeds. This mechanism consists of a funnel containing the respective seeds which will be clamped to a hinge attached to motor. There is a plate below the funnel with an indentation in the corner. Note that there is no space between the funnel and the disc below so the seeds would not slip out. Also the disc is smooth to avoid friction between funnel and disc.

IV.CONCLISION

The main focus of this system is its Automatic way of sowing the seeds. The seeds are been sowed in a proper sequence which results in proper germination of seeds. This automatic way of sowing seeds using a robot reduces the labour requirement. Here the wastage of seeds is also been reduced to a greater extent. This system has been developed for the sowing of seeds in an automatic way. Here with the help of a robot the seeds are been dispensed in the soil in a proper sequence hereby reducing the wastage of seeds. This robot will help the farmers to do the farming process efficiently.

SEEDING MACHINE

[1]Mr. N Rishi Kanth, [2]Mr. S. Udaya Bhaskar

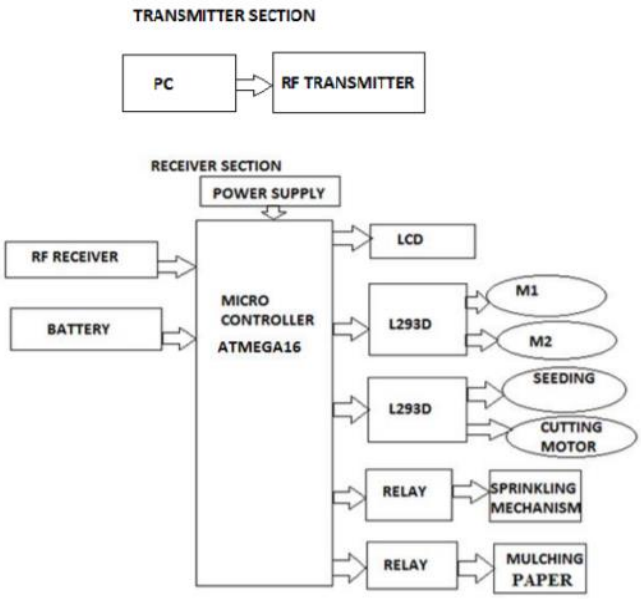
[1,2]Associate Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

ABSTRACT:

The paper aims on the design, development and the fabrication of the robot which can dig the soil, put the seeds, leveler to close the mud and sprayer to spray water, these whole systems of the robot work with the battery and the solar power. More than 40% of the population in the world chooses agriculture as the primary occupation, in recent years the development of the autonomous vehicles in the agriculture has experienced increased interest. The vehicle is controlled by Relay switch through Bluetooth technology using mobile. The idea of applying robotics technology in agriculture is very new. In agriculture, the opportunities for robot-enhanced productivity are immense - and the robots are appearing on farms in various guises and in increasing numbers. We can expect the robots performing agricultural operations autonomously such as ploughing, seed sowing, mud closing and water spraying. **KEYWORDS**: ATMEGA16 Microcontroller, L293D, Relay, Battery, RF Module, LCD, Motors, LED, Solar panel.

1.INTRODUCTION

This project work described here is quite useful in the agricultural fields. The project aims on the design Agricultural Robot for Spraying water, seeding, Mulching and cutting operation". More than 42% of the total population in the world has chosen agriculture as their primary occupation. In recent years, the development of autonomous vehicles in agriculture has experienced increased interest. This development has led many researchers to start developing more rational and adaptable vehicles. In the field of agricultural autonomous vehicles, a concept is being developed to investigate if multiple small autonomous machines would be more efficient than traditional large tractors and human force. These vehicles should be capable of working 24 hours a day all year round, in most weather conditions and have the intelligence embedded within them to behave sensibly in a semi-natural environment over long periods of time, unattended, while carrying out a useful task. There are a number of field operations that can be executed by autonomous vehicles, giving more benefits than conventional machines. The idea of applying robotics technology in agriculture is very new. In agriculture, the opportunities for robot-enhanced productivity are immense - and the robots are appearing on farms in various guises and in increasing numbers. We can expect the robots performing agricultural operations autonomously such as ploughing, seed sowing, mud closing and water spraying. Watching the farms day & night for an effective report, allowing farmers to reduce the environmental impact, increase precision and efficiency, and manage individual plants in novel ways. The applications of



instrumental robotics are spreading every day to cover further domains, as the opportunity of replacing human operators provides effective solutions with return on investment. This is especially important when the duties, that need be performed, are potentially harmful for the safety or the health of the workers, or when more conservative issues are granted by robotics. Heavy chemicals or drugs dispensers, manure or fertilizers spreaders, etc. are activities more and more concerned by the deployment of unmanned options.

2. LITERATURE SURVEY

In agriculture the use of robots enhances the productivity and reduces the human effort and cost. The automation of various agricultural activities by robots are envisioned. It has been described that the present robot can perform better and can automate more than one work simultaneously. This robot can be effectively used by the farmers. In future this robot can be enhanced with some more cognitive capabilitiesand also to take appropriate actions even in the absence of the farmers. It can be induced with human interaction and also learning from experience, given by Blackmore, S.(2007). “A systems view of agricultural robotics”.[4]. Central to this idea was the proposal of theimplementation of the PFDS and PADS, and their strong interaction. The PFDS is primarily used for relaying spatial accuracy information for machinery navigation, while the PADS are used to communicate the agronomy information about, and requirements of, the crop, given by R. Eaton, R. Eaton, J. Katupitiya, S D Pathirana (2008), “Autonomous farming: Modeling and control of agricultural machinery in a unified framework”,[5].

3. PROPOSED SYSTEM

In the field of agriculture, various operation are performed. For example, grass cutting, cultivation, seed sowing, water sprinkling, mud closing. workers should require strength and skill for the working. Fig. shows the platform of an agricultural robot designed on the basis of the design concept of open architecture. Robot structure is divided in to threesection, first is embedded section second is battery section and last one is water tank. A portable PC or smartphone, motor controllers and other control components are placed in the front cabin and a camera is fixed in front of it for capturing the front images. The rear cabin can be used for storage boxes to store some materials such as seeds, water and fertilizers. The driving devices include DC motors and wheels. According to the needs of operations and control, the driven method of the platform can be chosen.

3.1 Elements of block diagram are as follows:

1 Grass cutting operation:

A grass cutter is a machine utilizing one or more revolving blades to cut a grass surface to an even height. The height of the cut grass may be fixed by the design of the mower, but generally is adjustable by the operator, typically by a single master lever, or by a lever or nut and bolt on each of the machine's wheels. The blades may be powered by muscle, with wheels mechanically connected to the cutting blades so that when the mower is pushed forward, the blades spin, or the machine may have a battery-powered or plug-in DC motor.

2 Seed sowing operation:

A sheet metal hopper box is used for Seed storage. We have provided 3 holes to the main wheel shaft, where the Storage box is placed above it. The main wheels are powered by DC motor which is regulated by a Relay switch and is controlled by a remote controller. As the motor is switched on, the wheels tend to rotate and rotation of shaft makes the seeds fall on the cultivated filed.

3 Mud closing and leveling operation:

A Sheet metal Plate is used as mud closer and leveler. The sliding mechanism is used for leveler up & down movement. The Leveler is powered by a DC motor which is regulated by Relay switch and controlled by a remote controller. As the leveling plate moves downward to the ground level, the mud is closed in the sowed soil.

4 Cultivating operation:

A DC Motor coupled with the screw rod is used. The power for motor is regulated by relay switch. The screw rod rotates and the nut welded to the cultivator slides between the screws of the screw rod. As the cultivator is lowered down, soil is digged up to 1.5 inches. The direction of motor rotation can be controlled by remote controller for up and down movement of the cultivator.

5 Water spraying operation:

A water container is used for water storage. A water pump is used for pumping water to the water sprayer. The water flows to the sprayer through pipe. The power for pump is regulated by a toggle switch

4. ADVANTAGES

- Reduce the workload on the farmer and as it is easier to operate.
- The former need not spry in the hot sun, he can operate the device while standing in a cooler place.
- By the development of these robots' lot of manual labour will also be decreased and the farmer life will save from chemicals

5. APPLICATIONS

- Agricultural robotics is the use of automation in bio systems such as agriculture, forestry, and fisheries.
- It is replacing the conventional techniques to perform the same tasks, with efficiency.
- Applying automation to agriculture has helped create several advancements to the industry while helping farmers save money and time.

6.Result:

7. CONCLUSION

The robot for agricultural purpose an robot is a concept for the near the performance and cost of the product once optimized, will prove to be work through in the agricultural spraying operations. We

have been successful in developing a robot whose construction is enough to withstand the challenges of the field. We are sure that once this concept is presented in a manner suitable to Indian market, it will differently help in bringing down the 15% molality rate found in the Indian formers associated with the agricultural spraying operation

SHOCK ABSORBER

[1]A. Paul Praveen, [2]Mr. S. Udaya Bhaskar

[1,2]Associate Professor, Department of Mechanical Engineering, Malla Reddy Engineering College (Autonomous), Maisammaguda, Gundlapochampally Village, Secunderabad, Telangana State – 500100

Abstract –

Shock absorber is a mechanical device designed to smooth out or damp shock impulse, and dissipate kinetic energy. In a vehicle, it reduces the effect of traveling over rough ground, leading to improved ride quality, and increase in comfort due to substantially reduced amplitude of disturbances. In this work suspension system is designed and a 3D model is created using CATIA V5 R21. The model is also changed by changing the thickness of the spring. Structural analysis and modal analysis are done on the shock absorber by varying different spring materials. Spring materials are Spring Steel, Phosphor bronze, Beryllium Copper and Titanium alloy. To validate the strength of the model, the structural analysis on the helical spring was done. The analysis is done by considering loads, bike weight, and single, double riding. Modal analysis is done to determine the displacements for different frequencies for number of modes. Finally comparison is done for different materials to verify best material for spring in Shock absorber. Modeling is done in CATIA and analysis is done in ANSYS.

Keywords: Static, Transient Dynamic, Buckling, CATIA V5 R21, ANSYS.

I.INTRODUCTION

A shock absorber or damper is a mechanical device designed to smooth out or damp shock impulse, and dissipate kinetic energy. Pneumatic and hydraulic shock absorbers commonly take the form of a cylinder with a sliding piston inside. The cylinder is filled with a fluid (such as hydraulic fluid) or air. This fluid-filled piston/cylinder combination is a dashpot. The shock absorbers duty is to absorb or dissipate energy. These are an important part of automobile suspensions, aircraft landing gear, and the supports for many industrial machines. Large shock absorbers have also been used in structural engineering to reduce the susceptibility of structures to earthquake damage and resonance. A transverse mounted shock absorber, called a yaw damper, helps keep railcars from swaying excessively from side to side and are important in commuter railroads and rapid transit systems because they prevent railcars from damage station platforms. In a vehicle, it reduces the effect of traveling over rough ground, leading to improved ride quality, and increase comfort due to substantially reduced amplitude of disturbances. Without shock absorbers, the vehicle would have a bouncing ride, as energy is stored in the spring and then released to the vehicle, possibly exceeding the allowed range of suspension movement. Control of excessive suspension movement without

shock absorption requires stiffer (higher rate) springs, which would in turn give a harsh ride. Shock absorbers allow the use of soft (lower rate) springs while controlling the rate of suspension movement in response to bumps. Damp the motion of the upspring weight up and down on the springiness of the tire. Since the tire is not as soft as the springs, effective wheel bounce damping may require stiffer shocks than would be ideal for the vehicle motion alone. Spring-based shock absorbers commonly use coil springs or leaf springs, though torsion bars can be used in tensional shocks as well. Ideal springs alone, however, are not shock absorbers as springsonly store and do not dissipate or absorb energy. Vehicles typically employ springs and torsion bars as well as hydraulic shock absorbers. In this combination, "shock absorber" is reserved specifically for the hydraulic piston that absorbs and dissipates vibration.

There are a number of different methods of converting an impact /collision into relatively smooth cushioned contact.

- Metal Spring
- Rubber Buffer
- Hydraulic Dashpot
- Collapsing safety Shock Absorbers
- Pneumatic Cylinders
- Self-compensating Hydraulic

3.2 DESIGN OF BOTTOM MOUNT

Draw a circle with 160mm diameter and 150mm diameter, thickness 20mm, rectangle length 80 mm

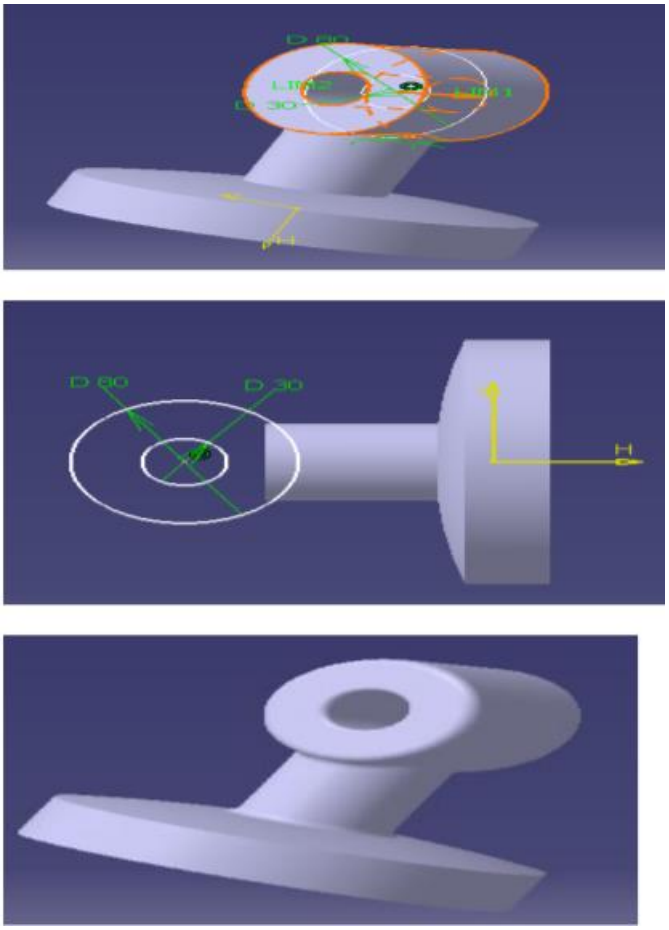

Fig.3.2. Design of bottom mounts

3.3 Design of oil Pad D

raw a circle of 80 mm diameter, length of 180 mm, the helix of pitch 15 mm, a circle of 20 mm diameter, depth 150mm.

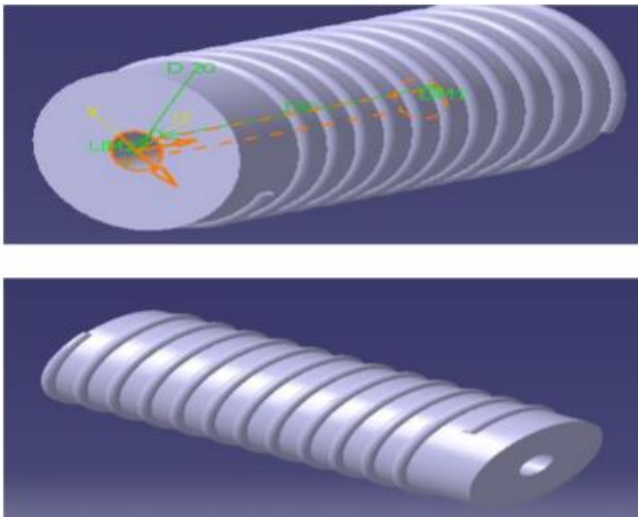

Fig.3.3. Design of oil Pad

3.4 Design of Rod Draw a circle of 20 mm diameter, 300 mm length, a pitch of 50 mm and height of 400 mm

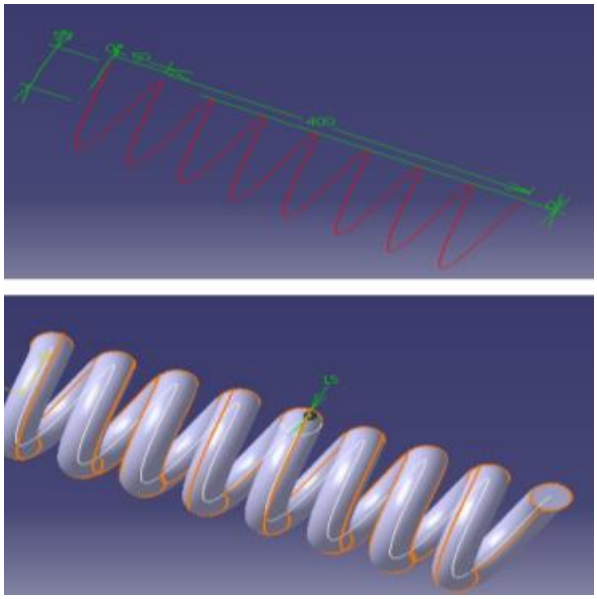

Fig.3.4. Design of oil Pad

3.4 Assembly Module

- In the Assembly module of CATIA insert all the existing such as upper mount, lower mount, strip rod, spring and oil Pad.

- Assemble it step by step by using different tools like coincide, offset, and contact constrain, Manipulation, Smart Move and Etc…. As shown in below.

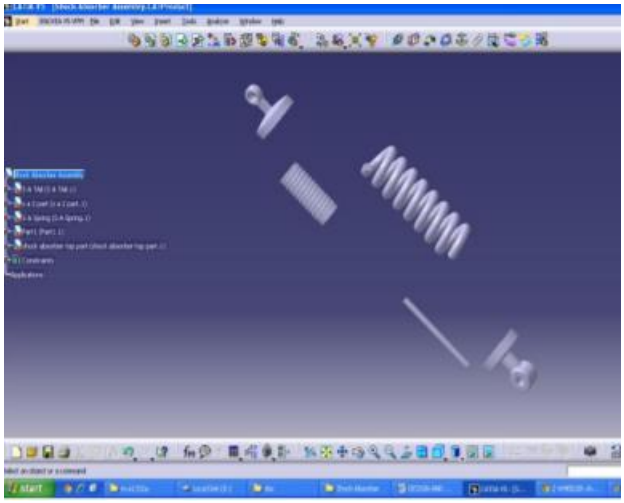

Fig.3.5 different engineering materials present in CATIA V5 R21.

IV.INTRODUCTION TO ANSYS

Finite Element Analysis is a numerical method of deconstructing a complex system into very small pieces (of user-designated size) called elements. The software Implements equations that govern the behavior of these elements and solves them all; creating a comprehensive explanation of how the system acts as a whole. These results then can be presented in tabulated or graphical forms.

4.1. STEPS IN FINITE ELEMENT ANALYSIS:

STEP 1:

First the domain is represented as finite elements. This is called descritization of domain. Mesh generation programs called processors, help in dividing the structure.

STEP 2:

Formulate the properties of each element in stress analysis. It means determining the nodal loads associated with all element deformation stress that is allowed.

STEP 3:

Assemble elements to obtain the finite element model of the structure.

STEP 4:

Apply the known loads, nodal forces in stress analysis. In stress analysis the support of the structure has to be specified.

STEP 5:

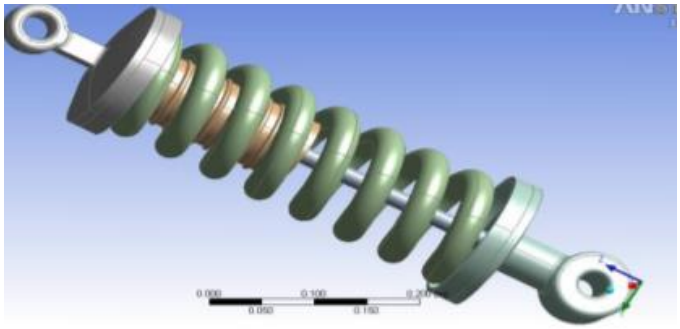
Solve simultaneous line algebraic equations to determine nodal displacements in the stress analysis.

STEP 6:

Postprocessors help the user to sort the output and display in the graphical output form. A typical finite element model is comprised of nodes, degrees of freedom, elements material properties, externally applied loads and analysis type. The finite element method is a numerical analysis technique for obtaining approximate solutions to a wide range of engineering problems.

4.2. ASSUMPTIONS IN FEA

The four primary assumptions, which must be considered in any Finite element based solution, be itstructural, electromagnetic, fluid flow or manufacturing simulation is:



1. Geometry

2. Material properties

3. Mesh

4. Boundary conditions

• Import the model in to the geometry section of the ANSYS work bench as shown below.

V. RESULTS AND DISCUSSION

In this project the helical spring of a shock absorber by using 3D parametric software CATIA. And also the analysis was performed by using ANSYS is a general purpose finite element analysis (FEA) software package. To validate the strength of the model, the structural analysis on the helical spring was done by varying different spring materials like steel, titanium alloy, copper alloy and Phosphor bronze Modal analysis is done to determine the displacements for different frequencies for Number of modes. The maximum displacements and stress intensities of the respective materials are given below. To validate the strength of our design, we have done structural Analysis.

Implementation of Low Power Optimizing Chien Search Usage in the BCH Decoder

D. Manaswi, Vijaya Durga Ravva, Swapna Thouti

Abstract—In this a new power-saving chien search (CS) structure is proposed for parallel Bose-Chaudhuri-Hocquenghem (BCH) Decoder .The CS assumes a huge hobby in distinguishing the regions of blunder in illness based absolutely decoding, but brings about an vast misuse of entire calculation control utilization. in this proposed engineering, the manner in the direction of looking for the parallel portrayal of the lattice is decayed in degrees. The preliminary step is gotten to each cycle, however the subsequent boom is actuated without a doubt while the initial step is strong, this can result in top notch energy sparing. proper right here a probable improvement is displayed in a segment procedure to keep away from a diffusion within the postponement of the easy way. Exploratory aftereffects of the proposed two-broaden shape for the BCH (8752, 8192, forty) code that spares half of electricity usage contrasted with a commonplace structure of the show.

Keywords:Bose–Chaudhuri – Hocquenghem (BCH) codes, Chien search (CS), low power, two-step approach.

I. INTRODUCTION

Interchanges and potential frameworks for incredible mistake alternate codes are implemented to get well the adulterated code phrases, Bose-chaudhuri-Hocquenghem (BCH) code [1],

[2] is the most usually done due to its great blunder treatment execution and moderate system multifaceted nature is one of the mathematical signs and symptoms. Twofold BCH code is a strong nation stockpiling such in advance [3], [4] and optical fiber correspondence frameworks [5], the majority of the applications and the endless hobby for excessive through placed disentangling has been walking ever larger

blunder treatment ability of numerous systems.first-class the great computational restriction of high thru placed and strong mistake adjustment is inescapable, alongside the ones lines, seems to be increasingly huge strength sparing shape of the BCH translating. through and large, a BCH decoder to address the bits T on the pinnacle of the three essential squares, to be specific, the sickness recall (SC), the essential factor-state of affairs illuminating (KES) has, and Chien are looking for (CS) [1], [2]. Getting a code phrase for a given R (x) Compute issues SC 2T and KES (X) using the issues of the blunder locator polynomial Λ. At extended remaining, the blunder is E (X) Λ assets (X) CS dictated thru the calculation is predicated upon on the locating. In a parallel BCH decoder, CS vital purpose pressure of intensity utilization and whole strength utilization [6] and can take in to a half of. numerous examinations have exhibited the capability to lower the strength utilization of CS proposed systems. Early give up of the techniques delivered in [6] and [7] After locating a blunder in the beyond to take out excess calculations. A further blunder counter is augmented even as a mistake is determined, and the counter KES drawbacks determined in the CS is killed suits. BCH decoder dealing with few mistakes proper off the bat in the execution of the normal and a hit treatment, but, when the electricity sparing little inconsequential mistake revision capability. [8], is a little by little feasible technique all together polynomial decrease (POR) whilst the error became observed inside the blunder locator polynomial of the proposed alternate. Locator polynomial request every in turn, errors are distinguished by the usage of using the decay and in the long run finally ends up 0. POR [8] right now, grade by grade close down hardware related to a polynomial trouble makes it outlandish for the CS. POR for sequential BCH decoders are fruitful, be that as it can, in mild of the truth that it's far hard to apply the device of complicated polynomial replace parallel format. similarly increasingly more, most of the people of the past energy sparing calculations, which encompass early surrender, [6], [7] and the POR [8], contingent upon the scenario of the errors. for example, if shortcomings toward the give up of the time period of the code, as because of intensity investment price range is noteworthy that inside the begin of errors. in this concise, we have were given any other approach, that is parallel to the CS proposed tiers of disintegration. on the manner to method each one of the preliminary step, however the preliminary step to get to the subsequent stage may be actuated really at the equal time as a miles much less victory. The proposed two-improve technique [9] this is adroitly comparative. the 2-boom method, while all is stated in finished, prompt a variety in the number one manner deferral and postponement, the misfortunes may be illuminated truly by means of making use of a powerful pipelined engineering. under no circumstances like beyond designs [6] - [8], paying little respect to the error, the place of the proposed improvement of the energy utilization may be spared. superior correspondence framework for conveying the sign from the supply to the aim purchaser with the resource of a correspondence channel is executed to move information. all of the code words encoded, encoder, which produces numerous code phrase. Even as it turns into a code for the actual affiliation of statistics encoded. memories of errors and statistics debasement is a vital

Revised Manuscript Received on August 05, 2019.

D. Manaswi, Assisatnt Professor of ECE Vishnu institute of technology, Bhimavaram, Andhra Pradesh,India.

Dr.Vijaya Durga Ravva,Assistant Professor, Department of ECE, Vignan's Foundation for science,Technology and Research, Guntur,Andhra Pradesh,India.

Dr. Swapna Thouti, Professor, Department of ECE MallaReddy Engineering College (A), Telangana, India.

trouble in the channels. Disarranges which have an impact on at least one of the reminiscence cells of radiation-actuated sensitive mistakes, for instance, were regarded to exchange their characteristics. wonderful kinds of disappointments reason lasting damage, for instance, the tool will in no way all over again deliver the right facts. In case of disability to assure that the facts is not ruined, mistake modification codes (ECCs) are broadly carried out in reminiscences [1]. To function some extra equality bits to check each reminiscence ECCs word in order that blunders are identified and remedied. The proposed framework is largely solid channel .Parity portrays the greater bits of memory for its capability to decrease information debasement. There are extraordinary charges offered via way of the ECC encoding and interpreting hardware. multiple channel to transport the information to be encoded and decoded as take a look at from it moreover impacts the circuit get rid of. In maximum instances, in moderate of the fact that a massive wide type of the method of the encoding, disentangling rate is substantially greater unpredictable and ECC [1] .traditionally single mistake, twofold blunder region (SEC-DED) codes used to at ease memories are limited [3]. Be that as it is able to, the records sign mistake have turn out to be decided and amended within the proposed framework for multi-byte. This perspective in reality due to the fact the postponement within the exhibition of RS code pix in the quantity of bits of reminiscence modules and gadgets whilst the suits can be exceptionally desirable for the channel, a tool that may be adjusted disappointments. fact be knowledgeable, the principle motive is generally used to make certain the RS codes A code word for a selected polynomial coefficient of the polynomial, the generator polynomial g (x). Reed-Solomon blunder remedying codes (RS codes) to transmit a large show off of ability mistakes developing from mistake to reestablish information from a plate and records correspondence frameworks carried out for functionality. There are varieties of errors even as the bits spilling out of 1 problem to a few exclusive, they may be prone to change in view of the erratic impedance. change the dominion of the obstruction sign. From 1 to zero or 0 to greater bits of statistics consistent with unit of hetero 1.Reed Solomon code method that the cycle has transformed right right into a regular non-paired rectangular code. Repetitive encoder flag and message signs and symptoms and signs are included into the object utilizing the generator polynomial. Decoder mistake region and energy are determined the usage of a similar generator polynomial. At that factor the revision is carried out to the were given code. Reed-Solomon coding, similarly to statistics stockpiling and healing frameworks (commotion channel damage) ahead blunder adjustment of a type applied for statistics transmission.

II. WRITING SURVEY

An big wide variety of mistakes, for the reason that they may cope with the mistake redress depicted in this paper essentially memory devices, the memory is implemented for the programs important to the more element motive decodable codes. Be that as it could, the exhibition of the reminiscence they need to have a first-rate effect the deciphering time. specialised measures, in reminiscence gadgets turn out to be big

additionally, more and more great mistake revision codes are required. Euclidean geometry to defeat the troubles on this paper as they utilize more and more modern-day codes. the ones codes can cope with numerous mistakes, but greater frequently than not requires complicated decoders. Sequentially with the lion's percentage cause unraveling hardware can be performed in a number one, however it calls for big stretches of interpreting. reminiscence, that could be a considerable parameter for the doorway to the framework can collect the time. Increment the scale of the code, so most of the expansion in the hour of interpreting the disentangling rationale (completed sequentially), N cycles required. EG-LDPC code, the code word is carried out on this approach (Euclidean geometry - Low Density Parity test), there may be a dominant detail One Step tremendous judgment Decodable code. It uses the calculation to test the code. There may be not some issue to test the calculation, however code word is associated with a numerical incentive to be transmitted. The collector at that issue receives the code phrase towards the finish of the numerical dispositions related to the blunder id is an exam of some numerical charge.There. The approach is something however hard to actualize utilising modern-day-day device. This technique is more opportunity for translating. certainly because the power utilization and the requirement for the district are immoderate. One degree is to understand the inadequacies of most of sequentially MLDD sequential tool makes use of accurate judgment decoder. [2] In this text, the author of the uproarious channel (Additive White Gaussian Noise) within the sight of PSK and FSK balance techniques Reed Solomon code (RSC) of the bit blunder charge (BER) on execution research clarifies. in this paper, 32-FSK (recurrence bypass keying), PSK (diploma flow keying) law coded correspondence framework is performed for the reenactment. however the usage of Monte Carlo reenactment and be counted quantity of the tempo of BER MATLAB/SIMULINK is finished the usage of the device. The outcomes are indicated using BERTOOL. so as to analyze the exhibition of the rectangular length is consistent, we've got got taken an alternate code charges. next to getting acclimated with the arrangement and tendencies of forward blunder adjustment codes, mistake discovery and rectification codes depicted in this area are contrasted with a few. Hamming code - a Hamming encoder bits of equality bits are embedded into the message. The equality bits and equality bits of information to decide the numerous blends to pressure a hard and fast

equality. The blends are everyday equality check decoder. The equality bits are set by means of way of the decoder. The aggregate of what might be in comparison to the error region is resolved. okay, that precise piece of information this is being flipped. Hamming code in a comparable mistake code. in the occasion that any of the endeavored trade of twofold mistakes can be incredible.

• Berger code - Unidirectional Berger code blunder region

code. it may surely grow to be aware of a mistake in either '1' flipped '0' or 'zero' flipped '1', but it implies a comparable code. '1' are supposed to differentiate mistakes with a "zero", what is probably as compared to the message, at that aspect the message is sent with the aid of way of the quantity of 0s and flipped over. The introduction of the '0' plan '1', a blunder message, what is probably in assessment to the quantity of 1s and sent alongside the message, virtually as at the same time as it flipped. As indicated via the decoder to get the paired 0s or 1s appears at the amount of a similar plan. Lopsidedness between the 2 shows a blunder. it's far relied upon to be implemented in which the error is unidirectional.

• a huge code word within the code has continuously been a steady weight, regular weight code. It way that a legitimate code expression of a tough and fast style of 1s. on this way, any range demonstrates a blunder. numerous mistakes can counteract each one-of-a-type as a essential but possible method for encoding it.

• Code of Ann M - An encoder message out in a M-M significant sort of 1s of each a n bit code is mapped to a phrase. A M-1s within the code message bits which can be utilized to change the quantity of bits delivered to the amount of greater M. It contains of all the M bits of the message in any 1s '1' will. it is likewise a fulfillment as an extended manner due to the fact the code of coding charge.

• Erase Code - to delete the blunder implies which you realise earlier of time from the past revel in of its location. Deletion code is to have the choice to cope with such errors. it's miles as of now observed out that this form of code isn't always required inside the decoder circuit deficiency locator. In reality to

right a blunder inside the decoder is decided via estimating the eraser.

• low-thickness equality check code - the low thickness equality take a look at code is a straight away square code. The message square is modified proper right into a code restrict thru duplicating the exchange community. The name alludes to the low thickness and coffee thickness alternate network. this means the amount of 1s inside the alternate community much less. it is a first-rate deal of coding gain, however the encoder and decoder

configuration is involved, the terrific code is careworn. Predominantly implemented for digital Video Broadcasting.

• speedy code - it's miles a convolutional code.

Convolutional encoding, encoding regular. it is characterised with the resource of the (n, ok, l) n the quantity of bits contribution to the fast code, good enough and l is the amount of yield bits is the reminiscence of the encoder. Translating takes region in tiers. The number one degree can be a hard and touchy translating mission unraveling. that is an excellent blunder rectifying capability, because of this that there may be no coding addition. The precept drawback is that it has a low coding fee and excessive dormancy. Henceforth it isn't suitable for a few programs. satellite correspondence idleness because of separation, yet furthermore the least inside the more dormancy is excessively high. therefore it's far at the entire applied in satellite television for pc correspondence.

• Reed Solomon code - Reed Solomon code of a nonbinary rectangular direct cyclic code succession. Repetitive encoder flag and message symptoms are included into the item making use of the generator polynomial. Decoder mistake place and stress are decided using a similar generator polynomial. At that component the adjustment is applied to the had been given code. Reed Solomon code and fast codes, LDPC coding growth within reason low. Be that as it could, it is a completely excessive fee and low multifaceted nature of coding. ultimately it's miles much less luxurious for some, packages, on the side of ability and transmission.

III. REED-SOLOMON CODES

A Reed-Solomon (RS) code depicted in a paper in 1960, Reed Solomon blunder adjusting code is a rst [9]. for the reason that that point they are CD-ROM, far flung correspondences, place interchanges, DSL, DVD, superior tv software. RS encoding of the statistics is usually direct, but the disentangling of the Nineteen Sixties and different massive e ciency stepped forward via

Berlekamp, tedious [2, 5, 6, 8]. RS absolutely over the most contemporary-day couple of years, it has have end up out to be viable with the resource of using the immoderate-transmission functionality data to check. Gatherings of bits instead of each piece in turn, that it's far a motion from the Hamming code of RS ERS. we're the gatherings of digits call "(the symbols" or Co cients ") is. inside the event that a digit is sans blunder in the general public of its bits are with out mistake because it were. as an example, if a eight-piece character in a variety of, and a similar mistake in three bits of pantomime we're primary is harmed.

at the off hazard that we need to deliver a adequate digit plaintext message, RS will ship n = precise sufficient + 2s digits, and guarantee that the proper message may be reproduced at the opposite give up if there are much less than s undermined digits. A case of

generally applied parameters: okay = 223, s = sixteen, n = k+2s = 255, allowing to address 16 undermined digits out of each 255 digit parcel. even as all is stated in carried out, the quantity of bits in a digit and the parameters n and s are tuned

to streamline on your software. A CD-ROM can cope with a burst of as much as 4000 continuous mistakes.

IV. PROPOSED -STEP CS ARCHITECTURE& RESULTS

in the proposed engineering paraell CS is decayed int steps.The p-parallel CS appears at p blunder positions simultaneously, every genuinely definitely one of which creates a double grid of one x m talking to a Galois concern (GF) detail via registering

$$Y(\alpha^{wp+i}) = \sum_{j=1}^{t} \mathrm{FFM}_{ij} = \sum_{j=1}^{t} \Omega_j A_{ij} = [\Omega_1\ \Omega_2 \cdots \Omega_t] \begin{bmatrix} A_{i1} \\ A_{i2} \\ \vdots \\ A_{it} \end{bmatrix} \quad (5)$$

wherein I extending from 1 to p. The CS will appears at and comes to a selection the nearness of a mistake while Y (αwp+i) is 1, wherein αwp+i is a foundation of the blunder locator polynomial.The precept concept originates from the manner that the nonattendance of errors is ensured if a few bits ofY (αwp+i) aren't equivalent to the ones of 0(m−1:1)1(zero).within the GF of measurement m, the multiplicative character detail, αzero or α2m−1, is characterised as 1, i.E., 0(m−1:1)1(zero), all the extra correctly For the scenario of GF(24), for instance, no nearness of errors is ensured if Y (αwp+i)(three:2) _= 0. Like this -increase method is applied for early detection.This wil brings about amazing power sparing.

duplicate effects:

CS low energy, contingent upon the dimensions of the world of improvement of the proposed diploma numerous setups, and blunders adjustment ability of the flat trouble contrasted with commonplace development. on the working recurrence of 2 hundred MHz for all of the CS obstructs with a one hundred thirty-nm CMOS innovation is, and similarly possibly blunder model [7], [8] acquired recreations control utilization. all of the more honestly, V errors BCH (n, exact sufficient, t) flag, the ordinary piece of a separation among neighboring mistakes n/V model, all the code word had been given is from a similar mistake takes vicinity on the identical time as the reference is adulterated.

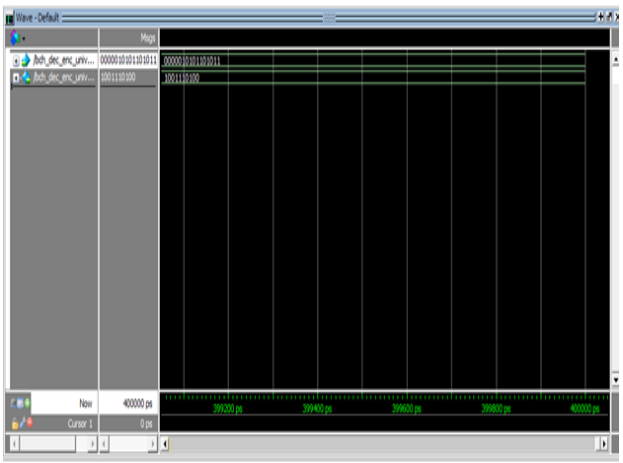

Fig: Chien search based BCH codes

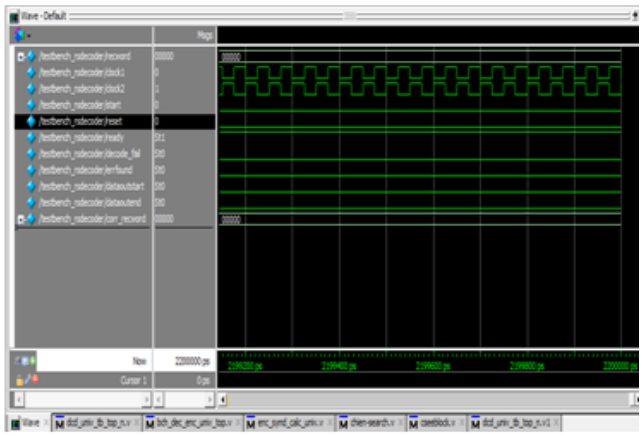

Fig: Chien search for RS decoder

SEC-RS code testbench waveforms shown in below two figures

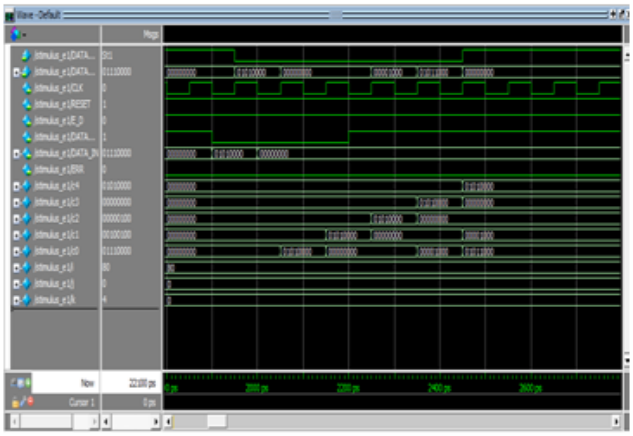

Fig. The size of the field in the first step of the bit width of 4 and shows the effect of energy saving ratio.

For cheap examination, most of the people of the BCH codes to illustrate the pace of zero.ninety 3 is mounted and appeared in Fig 8. Set the flat aspect. four, the proposed increment in the length of the arena of development seems to be plenty increasingly more massive due to the development, and few bits are good sufficient in electricity funding price range increment. for example, BCH for the proposed -develop shape (8752, 8192, 40) GF (214) forty nine.three% power, investment rate range over the code FFM fractional beginning of the initial 4 MSBs may be prepared. except, Figs. five and 6 stage blunder exchange trouble and delineate the way it impacts the effectiveness of depth sparing. the quantity component builds, the power investment price range and the flat factor of view percent in the direction of 1/2 than the power sparing share of eight. it is blunder remedy capability is freely installed to be immersed at the same time as. In figs. 3-6, we gauge a stability amongst energy funding fee variety and irrespective of the reproduction, a disentangled strength model (nine) may be done as a decent

gauge. because of the more cushions are tended to in phase III, the proposed development of a roughly 10% enlargement in tool multifaceted nature.

stop:

thru using diminishing get right of entry to to the second segment of the ordinary CS to carry out noteworthy strength investment price range is decayed in levels. Blunder paintings beneath a comparable ownership, the a good deal much much less energy the dimensions of the CS in the development thing in various arrangements, and error rectification capability of the extent problem contrasted with traditional development. From the trial effects, the proposed improvement of a half of of of decrease in power utilization contrasted with the not unusual level CS seem. strength sparing degree aspect or increment the scale of the sector will become an increasing number of tremendous. Reed-Solomon codes, as an instance, the proposed -boom CS moreover applies to different without delay rectangular codes.

Abstract

In this paper, the design of pseudo random discrete time even system is implemented to increase the speed of the system. Here sufficient conditions are given to implement the estimator. Pseudo random multiple input signals are given to DES. The main intent of this proposed pseudo random discrete time even system is to increase the speed and produce efficient result in terms of delay and area. The discrete time even system will take multiple signals and perform its operation. The adaptive MISO (multiple input and single output) controller will controls the speed of the system. Self-tuning regulator will tune the multiple inputs and give the single output. Hence, from pseudo random single output block, the output is obtained. Compared to the existed system, the proposed pseudo random discrete time even system gives effective output.

Keywords: *MISO (Multiple input ingle output), Discrete time even system (DES), pseudo random discrete time even system (PR-DES).*

1. Introduction

The fault diagnosis is the feature of complex DES (Discrete Event Systems) in every manufacturing systems and reliable control systems coordinating large. Hazardous situations and unnecessary risks to humans within system are eliminated during the operation of DES and maintains the production rate [1]. There are different method and approaches to address the location in DES. Fault detection problem depends upon discrete event models and techniques of artificial intelligence. For modeling formalism, finite automata (FA) and Petri nuts (PN) are used in last approaches. There are many proposals, their worked on addressing of fault diagnosis depends upon FA models. Among these the concept of diagnosability of DES is used to develop the diagnosis procedure.

The designing of diagnose is proposed in that works: for online diagnosis, from DES model deterministic FA is derived. Even though proposed techniques are efficient but these are applicable to small size systems. In these techniques, if the size of system increases then FA models to be large models. There are number of works on DES diagnoses that uses PN, to handle the drawbacks of FA representation [2]. The features of this work are exhibiting concurrency, clearer graphical descriptions of DES and sound mathematical support. By using PN online fault detection technique was proposed and this technique depends upon monitoring of the number of tokens residing into P-semi flows.

To introduce the redundancy into the systems, PN model is used by C. N. Hadjicostis [6]. Settlement of additional new P-semi flows was done in this work. Due to this detects and faulty markings are isolated. Based on PN models, a method is proposed by S. Genc they performed analysis of fundamental FA. Reach ability graph is exhausted, this paper also based on PN models and interpreted PN (IPN) are used for modeling both, faulty

behavior of the system and normal. Structural characterization of diagnosability is the previous result. Hence we propose a new and simple technique, to monitoring DES behavior IPN models are reduced. There is no longer need of DES model synchronization and partial information on marking is only used in this technique. We demonstrate the presence of monitoring model that depends upon the diagnosability property of the system model. To design the monitoring model new methodology is provided.

As there is failure in the context of diagnosis problem the Diagnosability problem is introduced. For large complex systems [3] in automatic controlling the important works are Failure detection and isolation. For accurate and timely diagnosis of system failures, it is necessary to design the systematic and sophisticated methods depend on reliability and performance of manmade systems. It receiving the failure diagnosis problem and consider as a wide variety of schemes and attention in literature was proposed. It includes:

1) Based on mathematic models, quantitative methods

2) Other expert systems and AI-based methods and

3) DES's (discrete-event systems) methods.

By the quantitative methods the Analytical model of the physical process is employed so that the sensor measurements with their predicted values are compared. By the knowledge of reasoning mechanisms and human experts the diagnostic systems to be produced based on the AI.

2. RELATED WORK

The several researchers investigate the Partial observation problems in discrete event systems (DES's) [4]. It is not possible to detail study the problem of diagnosability itself. The subject in several papers understands of observability with delay, invertability and observability. Diagnosability is the other problem for the reasons: by failure events partitioning, better results are occurred like failure type identification. There is a chance to occur multiple failures and existence of unobservable events. During diagnosis or normal operation, there is no need of detection or absence of locking- on technique.

In recent literature, the proposed topic is diagnosability and other approaches are discussed. The difference is noticed between diagnosability and other notations, after that i) Lin, shows the diagnosability in different approaches, state-based technique is proposed for diagnosability. His assumption is partial state information provides output function. Online and offline diagnosis are separate and it is addressed by him. If the system is to be diagnosed the normal operation can't be performed [5]. Observation of resulting outputs and sequence of test commands providing and drawing inference on set of possible states ate the steps in system diagnostic. The problem of off line diagnosis is equal to the verification problem. In the online diagnosis, the issuing of sequence of commands is the main aim if the system is in normal operation.

On the other hand in the off-line diagnosis, during the diagnostic process the uncontrollable events are made to check. In diagnostic system if there is a possibility of failure occurrence then an algorithm is given by author for the processing of diagnostic control or sequence of test commands. The above work is extended by Bavishi and Chong, DES"s testability is considered in this work.

A) To identify the set of sensors, testability is provided in given system.

B) By using fixed set of sensors, determination of informal partition of state space system to be done.

The supervisory problem of the control with partial event observations and introduce a language-based definition of state and observability conditions for the existence of a solution to the supervisory control problem. These are in terms of observability and controllability of languages. There is no need of system state identification or unobservable occurrence determination when addressing of control problems and introduced the obsevability notation and it is different from problem of diagnosability. Observabilities of state machines: DES's obervability is presented [6].

By using Ramadge explicitly, for the discrete event systems the state identification problem is addressed. By using partial state observability, the system is designed through the output map. The problem is reconstructed the exactly state if every event occurred system and address the motivation for observability problem. To control synthesis and observer- state feedback technique is presented. In this different framework to be studied and do not compare to diagnosability problem. Different observability notation approved and their assumption is partial event observation without direct state observations [7]. There is a chance to current state determination at intermittent by using observable event records and separated by bounded number of events.

DES is represented as observer, state of the system estimations are provided by it after observable event occurrence. The observability problem with states and delay is addressed at the intermittent points the system to be observable. The diagnosability is same as event detection problem in our frameworks, when problem of state identification is observed then stronger notation in diagnosability. For the particular state or set of states, notations are not observable and at least one state will be existed which is identifiable at intermittent points [8]. Failure states to be identified with delay is required in diagnosability.

Same requirements are not needed in normal states of system and arbitrary long sequence of events is executed because it is in normal operation. From the above we can say that the system to be still diagnosable by taking observation of failure of some of the systems observation if it is in the post-failure operation. No states are presented those are uniquely identifiable.

On the other hand the difference between diagnosability with delay and observability is explained. Hence unique identification is required not only for every failure state but also for every set of the partition. The system is designed as input-output state automation with partial state information studied through the output function and taken these output automation state into a special case where the input set is singleton. By using input-output automation state, current state observability and initial state observability are addressed by two kinds of observers those are classical dynamical observers and logic based dynamical observers [9]. The classical dynamic observer is defined as finite state automation; it takes for its inputs observed system behavior such as sequence of input-output pairs and sequence of state estimations are generated.

In the frameworks of predicate calculus, logic based dynamical system is designed. To generate the sequence of logic propositions, the observer explains the properties of system and adaptability is the feature for the system model changes. The observability is studied and the discussed observability is different in some characteristics. The determination of current state of system is assumed by authors. It is known for all future time [10], i.e., once the observer estimate converges to the true state of the system. Then it will thenceforth stay locked on and will always provide the correct system state as its output, for all observed input-output behavior

3. DISCRETE TIME ESTIMATOR

Dynamic system of the discrete time represents as fallows

$$X(k+1) = Ax(k)+Bu(k)+Dv(k) \quad (1)$$

Copyright ⓒ 2019 SERSC

$$Y(k) = Cx(k) = [0 \quad 1]\, x(k) \tag{2}$$

Here U E 9P means the control, x E 3t" means the state, the system output is y E 9?' and VE ZK" means unknown and time varying disturbance input. In the given presents the system in (1) decomposed for

$$X(k+1) = \begin{pmatrix} A1 \\ A2 \\ A3 \end{pmatrix} x(k) + \begin{pmatrix} B1 \\ B2 \\ B3 \end{pmatrix} u(k) + \begin{pmatrix} D1 \\ D2 \\ D3 \end{pmatrix} v(k) \tag{3}$$

$$X = \begin{pmatrix} x1 \\ x2 \\ x3 \end{pmatrix} = \begin{pmatrix} y1 \\ y2 \\ y3 \end{pmatrix} \tag{4}$$

At this point a number of assumptions are to be made:

i) in (2)' it is assumed as a measurement equation.

ii) D (Disturbance distribution matrix) is in full rank.

iii) The outputs are more than number of unknown inputs.

The above said two assumptions are not restrictive and by third assumption with arbitrary rate of convergence the existence of asymptotically stable estimator will be proved. If the above conditions are satisfied, the discrete time estimator design will be summarized by the following theorem. If and only if the pair (&,,Xll] is completely observable then by using the following asymptotically stable reduced order U10 the estimation of state of the discrete time system in (1) & (2) can be done

$$w(k+1) = Fw(k)+Ey(k)+Lu(k) \tag{5}$$

Where

$$H=(\bar{A}_{13}-M\bar{A}_{23})+(\bar{A}_{11}-M\bar{A}_{21})(D_1-MD_2)D_3^{-1} \tag{6}$$

$$G = (\bar{A}_{12}-M\bar{A}_{22})+(\bar{A}_{11}-M\bar{A}_{21})M \tag{7}$$

$$F = (\bar{A}_{11}-M\bar{A}_{21}) \tag{8}$$

$$L = (\bar{B}_1-M\bar{B}_2) \tag{9}$$

$$E = [G \quad H] \tag{10}$$

$$\bar{A}_i = A_i - D_iD_3^{-1}A_3 = [A_{i1} \quad A_{i2} \quad A_{i3}] \text{ for } i= 1,2 \tag{11}$$

$$\bar{B}_I = B_i - D_iD_3^{-1}B_3 \text{ for } i = 1,2 \tag{12}$$

From the following Algebraic matrix riccati equation and discrete solution, the estimator's gain is determined.

$$P = \bar{A}_{11}P\bar{A}_{11}^T-\bar{A}_{11}P\bar{A}_{21}^T(R+\bar{A}_{21}P\bar{A}_{21}^T)^{-1}\bar{A}_{21}P\bar{A}_{11}^T+Q \tag{13}$$

$$M = \bar{A}_{11}P\bar{A}_{21}^T (R + \bar{A}_{21}P\bar{A}_{21}^T)^{-1} \tag{14}$$

The equation is reachable when Q is selected. State estimation represented as

Copyright ⓒ 2019 SERSC

$$\hat{x}(k) = \begin{pmatrix} \hat{x}_1(k) \\ y(k) \end{pmatrix} = \begin{bmatrix} I \\ 0 \end{bmatrix} w(k) + \begin{bmatrix} N \\ I \end{bmatrix} \quad (15)$$

$$N = [\, M \quad (D_1 - MD_2)D_3^{-1} \,] \quad (16)$$

4. FAULT DETECTION AND ISOLATION

With same output equation in [2] the special form in the system are considered, in the model of linear system take the account for actuator failure

$$x(k + 1) = Ax(k) + Bu(k) + Bv(k) \quad (17)$$

By last term there is possibility of design of different soft and hard actuator failures and notify that the actuator failures are detected during the estimator's transient by assuming no failure takes place. At time k to find estimate of v the estimate of the state is used at time k+1 and k, let us assume B is in full range and represented as

$$\hat{v}(k) = (B\tau\, B)\text{-}1B\tau[\hat{x}(k + 1) – A\hat{x}(k)\text{-}Bu(k)] \quad (18)$$

Vector 8 is monitoring. The shape of failures are identified and detected, all components of 9 bust be zero or closed to it in normal operation. Consider the effect of sensor failures by considering following system description, the signals corresponding to actuator failure when any component of 8 becomes non zero

$$X(k+1) = Ax(k) + Bu(k) \quad (19)$$

$$Y(k) = Cx(k) + Kf(k) \quad (20)$$

Here for sensor failures the unknown vector is described by f and as

$$f(k +1) = Aff(k) + \eta(k) \quad (21)$$

it is shown

Here q means unknown and A contains Eigen values inside the unit circle.

5. PSEUDO RANDOM DISCRETE TIME EVEN SYSTEM

The below figure (1) shows the block diagram of pseudo random discrete time even system. In this pseudo Random multiple signals, Discrete time even system, adaptive MISO controller, self tuning regulator and pseudo random single output. The main intent of this proposed pseudo random discrete time even system is to increase the speed and produce efficient result in terms of delay and area. The pseudo random multiple signals will give multiple input signals to the discrete time even system. The discrete time even system will take multiple signals and perform its operation. The adaptive MISO (multiple input and single output) controller will controls the speed of the system. Self-tuning regulator will tune the multiple inputs and give the single output. Hence, from pseudo random single output block, the output is obtained.

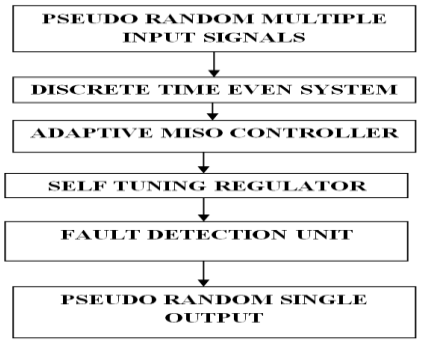

Fig. 1: PSEUDO RANDOM DISCRETE TIME EVEN SYSTEM

For simulating truly random sequences which are said to be pseudorandom (PR) are generated by deterministic algorithms. A sequence of pseudorandom numbers in the unit interval [0, 1) is pseudorandom sequence. A discrete-time system is a device or algorithm that, and on a discrete-time signal called the input signal or excitation it operates according to some well-defined rule, and another discrete-time signal called the output signal or response are produced.

For wireless communications where at the source (transmitter) there is a possibility of using multiple antennas and the technology is called an adaptive MISO (multiple input, single output). For the purposing of optimizing data speed and to minimize errors the antennas are combined. The destination (receiver) has only one output. The constant voltage level is maintained automatically by a system called Self tuning regulator. On one side of a magnet shunt the circuit has a primary and on the other side the tuned circuit coil and secondary. Here tuning process is performed automatically without any instructions.

In particular, by the set {0, 1, ..., p − 1} the elements of the finite field Fp of p elements for a prime p are represented, and through a sequence (xn) over Fp satisfying yn = xn/p as a sequence of PRNs, say (yn) they arrive. In this case as a pseudorandom number generator the sequence is called. For randomness of PR sequences the various quality measures are in use. According to the type of problem where PR sequences are needed the hierarchy among them varies and it should be noted. Hence in the systems there is a possibility of obtaining the single output.

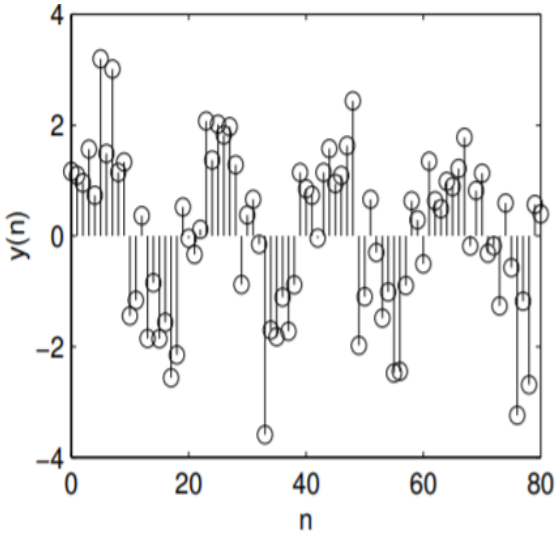

Fig. 4: FAULT DETECTED SIGNAL

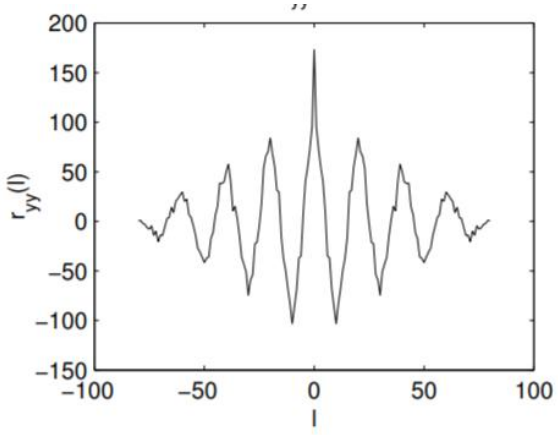

Fig. 5: PSEUDO RANDOM SINGLE OUTPUT SIGNAL

7. CONCLUSION

In this paper, the designing of pseudo discrete time estimator was proposed; it is possible to give the accurate estimation for the dynamical system state which is determined by unknown disturbance. For the presence of such estimator the condition is required that is the outputs are equal or more than number of unknown inputs. In fact by the designer the convergence regulator rate is decided. In this paper the assumption is the outputs are more than number of unknown inputs. Because of the designing of different faults as unknown inputs for estimator the existence condition is not satisfied. Though, the noisy measurement systems and location of estimator poles are the important function in quality of estimates. Hence the proposed system gives effective output compared to exist one

Performance of Improved speed pipelined floating point multiplier Architecture

Rajendra Prasad.K

Abstract*:Multiplier is a hardware component which usually covers an important chip area and must be reduced to create lots of functions in which multiplier frames shape an essential structure, including digital signal processing (DSP) systems and analytical approaches. The benefit of floating point representation across a fixed point (and integer) view is that a wider range of values can be represented. Since floating point numbers are stored in sign-magnitude type, the multiplier also requires unwritten integer numbers and standardization. The multiplier with the algorithm Revised Booth and save adder is one way to speed up the multiplier. The algorithm of Revised Booth reduces the number of incomplete products to create and is regarded as the quickest algorithm of propagation.

Keywords:Radix4 Booth Multiplier, Booth Algorithm, Partial Products Generation, Signed-Unsigned Multiplication

I. INTRODUCTION

Multiplication of digital computing systems is an important arithmetic operation. The multiplication process involves actually making partial products and then applying certain partial products to the final product. The multiplier speed therefore reduces the number of partial product and the adder speed. As the multipliers have an important impact on the system's performance, several high-performance algorithms and architectures are suggested. Floating point is a way of representing numbers and arithmetical applications in computer systems, ranging from simple computers to computers. The word floating point was taken from the idea that prior to the actual decimal point there is no fixed number of digits; that is that the decimal point can float. Although there are interpretations in which the number of digits, called fixed-point representations, are placed before and after the decimal point. In particular, depictions of floating points are slower than representations of fixed points but can accommodate a larger range of numbers [1]. In digital signal processing (DSP) technologies, such as video and communication systems, high speed Booth multipliers and pipelined Booth multipliers are used [2].Since mathematics with floating points saves a lot of computing power, many microprocessors come with a chip, which is called a floating point unit, specialized on floating point arithmetic performance. The mathematical coprocessors and numeric coprocessors are also called FPUs. Floating point units areextensively included in a dynamic range of technological and engineering applications.

This requires the development of faster arithmetic circuits of floating points.The division of floating points is much like the multiplication of integer. Even though floating points numbers are stored in sign-magnitude type, only unsigned integer numbers and normalization need to be handled by multipliers. Integer multiplier with the algorithm Modified Booth and save adder is one way to increase multiplier speed.

The algorithm of the modified Booth decreases the number of partial products to be produced and is known as the fastest algorithm. Several other studies have been carried out on multiplier architectures including arraying, parallel and pipeline multipliers, showing that pipeline processing is the most widely employed way to reduce digital circuit propagation delays.In this paper a design has been suggested for a fast floating point multiplier compatible with the IEEE 754 single precision specification. In order to achieve a generic design, the hardware description language of Verilog was utilized for the design of the complete multiplier unit, since it represents an enormous productivity improvement for circuit designers.

The main contributions and organization of this paper are summarized as follows: In section 2 we describe backgrounddetails of different multiplier methods adopted by the authors. Section3 discusses the proposed work. Section 4 deliberates results and discussions. Finally, in section 5, we concluded the paper.

II. BACKGROUND WORKS

In [3], the authors present an efficient implementation of an efficient Radix-4Booth 3:2 compressor configurable multiplier for both the 32 bit signed and non-signed numbers and the arithmetic floating point. Multiplication is always used in various uses of research and signal processing. Multipliers comprise one of many systems most important components. It delivers a dynamic arithmetic power, increased performance accuracy and high speed and low area usage. The model often bypasses the swapping activity of then functional output ranges dynamically. The redundant circuit can therefore be deactivated effectively, growing energy consumption and can running pace. The proposed multiplier design therefore outperforms the conventional multiplier in terms of area and speed efficiency. On the FPGA Spartan-6 XC6SLX9 board, the suggested multiplier model was introduced.

In [4], the researchers proposed a new solution to BCD multipliers. The primary focus of the architecture proposed is the generation of partial products and simultaneous binary operations on two-digit columns. 11-digit multipliers for the production of a partial products are applied explicitly without any software translation by 4-bit binary multipliers. The binary results of the 1×1-digit

Revised Manuscript Received on November 15, 2019.

Dr. Rajendra Prasad. K, Assistant Professor, Department of ECE,MallaReddy Engineering College (A),Telangana India.

multiplications are organized into the 2-digit partial products based on the column based on the most recent their two-digit positions. For the partial reduction of products, a binary decimal compressor architecture is built and used. In streamlined BCD 6-LUT adders, these diminished partial components are substituted. Parallel binary tasks and the enhanced BCD adder lead to better performance and less energy consumption. The suggested solution to Xilinx Virtex-5 and Virtex-6 FPGAs were applied with focus on increasing critical path delays.

In [5], the researchers used FPGA as an active enforcing method, but the development barrier encountered many times is constrained in capital. Optimizations seems to be the way to design big circuits, particularly the entire chip system (SOC) or chip network (NOC) on this device. There are so many ways to improve multipliers, with some improvements to conventional methods as well as their application and testability on FPGA. This paper shows the implementation of the 3x3 unsigned integer switch and add multiplier fixed-point finite duration by implementing such functional improvements The revised version leads to fewer use in the Lookup Tables (LUTs) and less delay because of lower logic levels than traditional techniques.

III. PROPOSED WORK

Fig.1 shows a single-accuracy representation of the binary format in IEEE 754, consisting of 1-bit of a sign (S), an 8-bit exponent (E) and a 23-bit fraction (M or Mantissa). An additional bit is applied to the fraction to form the significand. If there is one exponent in the MSB greater than 0 and less than 255, then the sum is said to be a fixed integer, which defines the real number by an eq.(1).

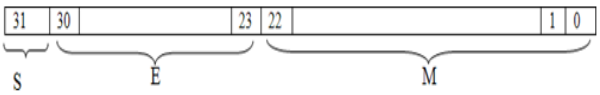

Fig.1. IEEE single precision floating point format [6]

$$Z = (-1^{S}) * 2^{(E\text{-}Bias)} * (1.M) \quad (1)$$

Where $M = m_{22}\,2^{-1} + m_{21}\,2^{-2} + m_{20}\,2^{-3} + \ldots + m_{1}\,2^{-22} + m_{0}\,2^{-23}$; Bias = 127.

Multiplication

This unit multiplies the unsigned significand and places the decimal point in the multiplication product. The consequence of the multiplication of significand is considered the intermediate product. The unsigned significand multiplication is performed on 24-bit. Multiplier output should also be treated in order to avoid impacting the entire performance of multipliers. The Carry save multiplier architecture of a 24×24 bit is used because it has progressive speed and a simple architecture. In the transmission carry save multiplier, the transmission bit is diagonally passed down (i.e. the transmitting bit is propagated to the next stage). Partial products are produced by ANDing and moving together the inputs to the correct adder. Carry save multiplier has three primary phases: The first phase is a half-adder range. The intermediate steps were complete adders. The middle step number is equivalent to the length minus two. The final stage is a range of ripple carry adders. This stage is called the phase of vector fusion as shown in Fig.2.

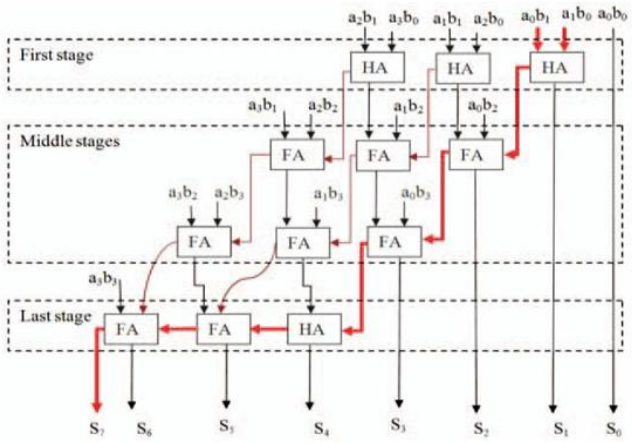

Fig. 2. 4x4 bit Carry Save multiplier [6]

Normalization:

To order to have a leading "1" to the left of the decimal point, the effect of the value multiplication (i.e. to bit 46 on the intermediate product) has to be uniform. Because the inputs are standardized, the intermediate product has the lead at bit 46 or 47.

***Floating Point Multiplier diagram*:**

Fig.3 displays the floating point multiplier block diagram. The hidden bit is appended to the manta and multiplied by the transportable save multiplier. Eventually, the outcome is averaged and the output measured.

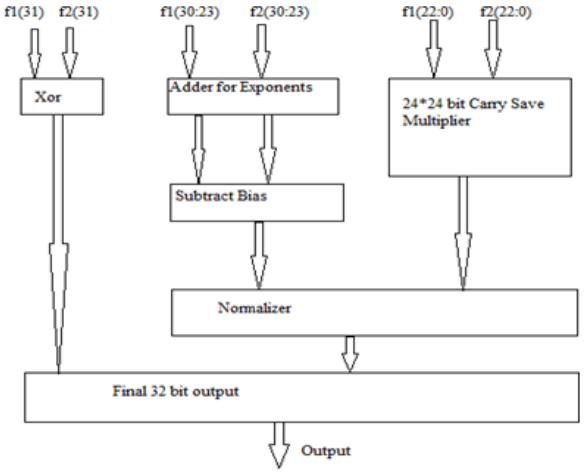

Fig.3. Floating Point Multiplier Architecture

Booth multiplier

Multiplication is a numerical procedure which is an appended method by which a number of times are applied to an integer. A number (multiplicand) will be applied to itself a number of times to create a value (product) according to a different number (multiplier). To accelerate up the transition, it is divided into the following stages:

Generation of partial products:

The Radix-8 modified algorithm is used to generate the partial products. In particular, the higher the radix, the more partial products generated that are required to quantify the component in less cycles. High radix recoding has therefore become more and more widely used in modern high speed arithmetic units and single chip multipliers. Since the multiplier and multiplier are 24-bits, 8 partial products are generated in this algorithm.

Radix-8 Modified Booth's Algorithm

Recoding expanded to 3 bits at a time-4 bits overlapping each band. Radix-8 recoding is much like Radix-4 algorithm but we now use quartets of bits rather than triples. As a consequence, a multiplier based on radix-8 yields less partial products than a radix-4 multiplier, but the estimation of every other partial product is much more complicated. A partial component referring to an x=+3 encoding involves the estimation of 3x and therefore a total addition. Every quartet is codified with the Table.1 as a signed integer.

Table 1. Signed-digit and its equivalent quartet value

Quartet value	Signed-digit value	Quartet value	Signed-digit value
0000	0	1000	-4
0001	+1	1001	-3
0010	+1	1010	-3
0011	+2	1011	-2
0100	+2	1100	-2
0101	+3	1101	-1
0110	+3	1110	-1
0111	+4	1111	0

Partial Product Reduction

As it is clear that multiplier blocks revealed that a small number of supplements were needed to multiply a data sample with several constant coefficients. However, carry save adders are a better choice for high-speed applications than carrying propagation adder. 8 Partial products are produced using the Algorithm for Radix-8 Modified Booth. The compressors were divided by 4:2.

Carry save Adder

A Carry-Save Adder is only a set of one-bit full adders, without any communication. The key use of a carry-save adder is to measure partial products in integer multiplication. Compressors 4:2 are used as additional hold recover. It is made up of two 3:2 (full adders) compressors in the series and includes 4 XOR delays as shown in Figure 2. This compressor is suitable for the introduction of partial products due to its frequent interconnection. The structure of the 4:2 compressor compresses five bits of partial products into three. Originally two 4:2 compressors are used to reduce the amount and hold of the set of 4 partial items each. These last four partial items from the two 4:2 compressors are further decreased to manufacture and hold the final number. The compressor 4:2 consists of 2 complete adders. The last carry is protected and therefore named the carry save adder. The 4:2 compressor delay is the same as for 4 XOR gates.

Final Stage Carry Propagate Adder

Ripple Carry Adder:

The ripple carry adder is used by inserting a partial material from the carry save adders to achieve the full total and the effect. It generates a logical loop with several total adders to connect N-bit numbers. -full adder joins a C_{in}, which is the prior adder C_{out}. This form of adder is an adder with ribs, since each bit "adds" to the next adder. In the final stage, the 48-bit sum and the output obtained from the partial product accumulator are added to give the mantissa product. This unsigned adder often introduces the exponent of the first output into the exponent of the second input and excludes the incomplete portion (127) from the supplement result (i.e. A_exponent + B_ exponent-partial). The value is considered the intermediate exponent

IV. RESULTS AND DISCUSSION

In this section results are discussed using Xillinx Design suite with Modelsim simulator is used.

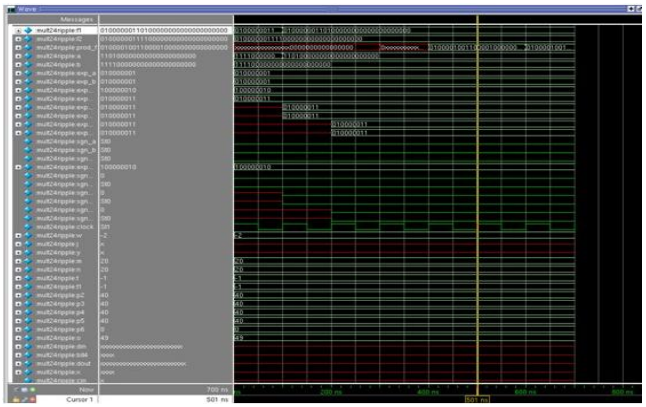

Fig.4. Simulated output of 5-stage Pipelined Floating Point Multiplier

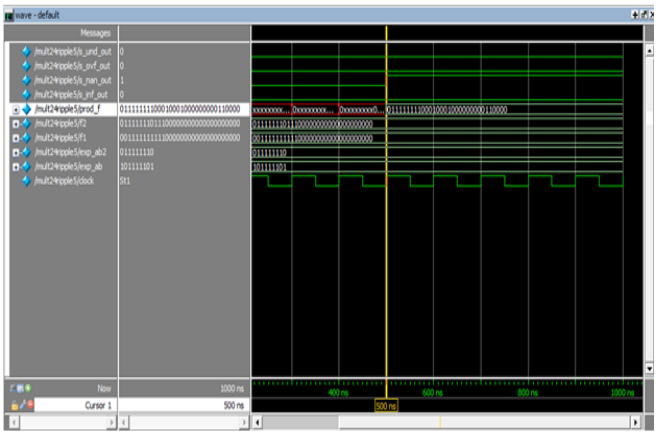

Fig.5.Simulated output of Floating Point Multiplier with exceptions

V. CONCLUSION

The booth multiplier technique increases energy and logic region utilization considerably more with a minimal delay than traditional architecture. It leads to high efficiency by addition of pipeline phases, but at the expense of area and energy. Booth's Recoding Strategy can be used for partial products generation. The Algorithm of the Radix-2 Booth, Radix-4 and Radix-8 revised Booths for the processing of partial products was related. Because the multiplier and multiplicand consists of 24-bit, 8 partial products are produced using Radix-8 Modified Booth's Algorithm. The use of carry save adders reduces these 8 partial products. Furthermore, Ripple Carry Adder reduces the partial products acquired by carrying saving additives. The result of the significance (intermediate product) multiplication is normalized to be a leading "1" just to the left of the decimal point.

Design of Image Steganography using M-BAT Optimization

Srinivas Reddy.T

Abstract:*This paper devotes itself to the study of secret message delivery using the cover image and introduces a novel steganography technique based on bat algorithm. To maintain the same quality even after extraction of the image at the receiving end of the system, we used a data encryption standard approach integrated with wavelet transform for preserving high security. Also to increase the embed capacity modified BAT technique is used that results in high PSNR and low MSE values. With the help of modifications to exploitation, swarm initialization and Torus gives rise to (M-BAT) for fast convergence rate. All the simulations are carried with Matlab 2017a and its evaluation parameters are related with other traditional techniques.*

Keywords:**Steganography;** ***Des; M-Bat Optimization***

I. INTRODUCTION

Today, there is a lot of communication via the Internet. Sensitive information vulnerable to intruder eavesdropping. Both cryptography and steganography are used to protect secret information to assure confidentiality of data.But, through authentication, a third party can see that all sides interact anonymously and the encoded text can be quickly noticed [1]. As previously mentioned, steganography gives an extra protective layer that essentially integrates the media. By fact, the directory used where the information are covered is named "Cover File" and the folder is alluded to as "Stego Subject" with a secret message. The basic structure of steganography is shown in Fig.1.Due to high density [2] of pixels in the image, data can be hiding in it with highly secure and quality with the help of a cover image, so it is best suited for secure communication applications. The technique of image steganography is widely used as protected information for hidden communication. Military organizations copy the right security, such as marking, [3]. Steganography strategies are categorized into two groups: space domain and domain frequency techniques. In the space domain, the encoding of data is concealed explicitly on the object pixel values, and objects are transformed in the frequency domain and transformed coefficients are hidden [4]. As mentioned previously several spatial techniques are available in the literature that is supposed to be applied for secure communication of data.Although the global search is widely used in optimization techniques, they are inflexible with the exploration of data, the local search is replaced for balancing it.

Thus we have created an expanded version of BA named the modified bat algorithm (MBAT) to increase the exploration efficiency.For the authenticity of the new M-BAT methodology, nine well-known reference evaluation features equate with the initial BAT. The PSNR in decibels (dB) is calculated between the original cover image and the corresponding stego image in order to evaluate the functioning of the suggested M-BAT algorithm.

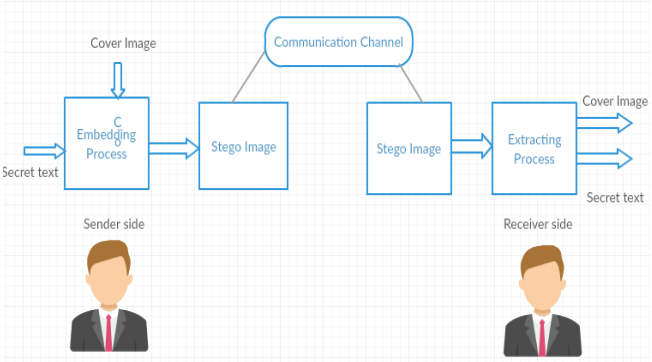

Figure 1. General Steganography mechanism

The mean square error (MSE) is first calculated to calculate the PSNR. The lower PSNR value means that MSE between the original image cover and the labeled picture is negligible and stego image quality is maintained, the original image cover can be restored without distortion after the hidden encoded message has been removed.

The main contributions and organization of this paper are summarized as follows: In section 2 we describe background details of optimizing algorithmstreatment. Section 3 discusses the proposed work. Section 4 deliberates results and discussions. Finally, in section 5, we concluded the paper.

II. BACKGROUND WORKS

In [6], the researchers initiated a research into the technique of cat swarm optimisation (CSO) in order to obtain the optimal or close optimal solution of the problem of stego-image quality. The secret data is covered in a cover image utilizing basic LSB replacement which drastically degrades the image quality. The findings show that the system suggested could achieve the desired resolution with less measurement time.

In [7] the researchers implemented a JPEG-steganography method that uses GA to solve the steganography image problem. This approach could incorporate secret data in the cover image to be RS-resistant.

Revised Manuscript Received on November 15, 2019

Dr. Srinivas Reddy.T, Associate Professor, Department of ECE,MallaReddy Engineering College (A),Telangana India.

At the beginning, it uses the basic LSB replacement technique and covers key parts in the cover image. In order to maximize the safety against RS analysis, pixel values are detected by the GA when the secret data in the cover image are hidden by the LSB. Therefore, it is difficult to detect secret data by way of RS analysis. The results revealed that the resistance of the proposed steganalysis system offers greater performance and a good balance between protection and the subsequent stego-image quality.In [8], the authors adapts and uses basic Particle Swarm Optimization (PSO) as an optimisation technique to solve the problem of stego-image optimisation. The scientific results revealed that the PSO achieved better performance than other methods, including genetic algorithm.

BAT Algorithm:

Bat algorithm operates on microbats echoing and uses bats echo to search for food. It focuses primarily on three rules for the formulation of the bat: Firstly, all bats use echolocation to calculate the distance from the specific point. Secondly, due to the random nature of bats, they used to fly to the particular region maintaining a constant velocity, where its wavelength value varies concerning the time. So bats automatically when they see the target region regulate their wavelengths accordingly. Thirdly, rather than any other method, the researcher found that the intensity ranged from average to low as shown in Fig.2.

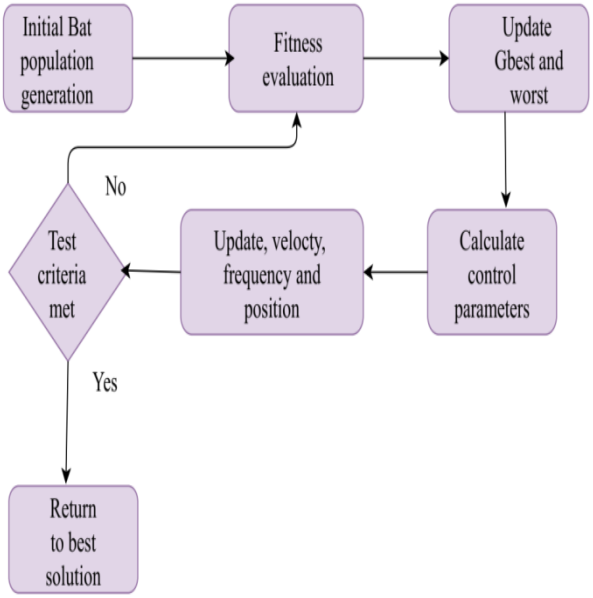

Fig. 2. Flow chart for standard bat algorithm

III. PROPOSED WORK

In the proposed system, mask the text information in the protection image using the modified 2-level DWT bat algorithm. In steganography, the hidden data is normally used to secure and authenticate the element, and each element needs to be encrypted and decrypted by the length of the characters. The cover image is broken into R, G, B planes after a gray image has been transformed. In these planes hidden objects are mounted. Suggested data or image hide concept for encryption and decryption using the DES algorithm. The cover image and hidden images are decomposed at *N*-level and certain DES-factor intensity components are mixed. Secret messages from the stego image are extracted. Again the data obtain forms the bit to last meaningful values and for user key authentication. An estimation of recovery values for MSE variables using PSNR. Development and execution of a plan explicitly to conceal messages in images is shown in Fig.3.

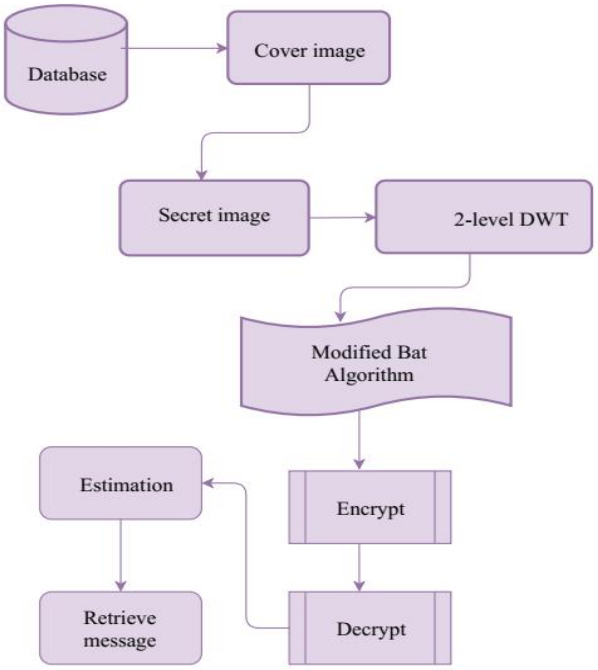

Fig. 3. Flow diagram of proposed model

Wavelet transform:

The wavelet transforms typical image data into a few large coefficients and many small magnitude coefficients are shown in Fig.4. Initially the process of wavelet transformation begins with the decomposing in to components either in to respective time domains or else frequency domains. In four different levels, image or signal are decomposed: approximation, vertical detail, horizontal detail and diagonal detail.

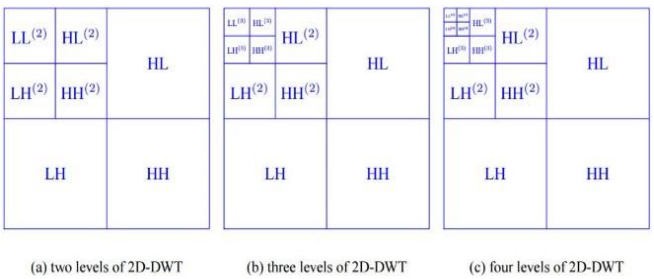

Fig.4. Overview of 2-level DWT scheme

The decomposition on the approximation coefficients is replicated to a point. Since details are not broken up at high levels and the small wavelet coefficients can be defined, the wavelet transformation is not suitable for rapidly validating images.

Modified BAT algorithm:

We made two major contributions to this report as stated above. Next, they created a new form of population initialization using a low differential series, which utilizes the Torus number pattern makes to initialize the random distribution correspond swarm.

Secondly, there is a flexible process for obtain the bat algorithms, thereby enhancing the parameters that are more essential for optimal convergence rate.

A. *Random Number Generator*

The primary requirement of available functions is to generate instant random number in which it is proportional to the respective constant distribution of probability function.

$$f(p) = \begin{cases} \dfrac{1}{q-r} \; for\, q < p < r \\ 0 \; for\, t \langle q \, or \, p \rangle r \end{cases} \qquad (1)$$

Where *q*and *r*supposed to be denoted as likelihood features.

B. *Unique Initialization Method Torus*

In this carried work, there is an efficient implementation for initialization of the population with TO-BA) low differences sequence, which employs quasi-random structure to initialize required Swarm.

C. *Modified Localsearch method*

Through relying on the local search process, they adopted the next change. In standard BA, swarm bats are permitted by using regional random walking through the current region to the new random region. It is clear that searching locally rather than globally patterns play an important role in assessing optimum local conditions.

IV. RESULTS AND DISCUSSION

For the correlation of stego images with cover output, the quality of a particular image test includes widely employed metric so-called PSNR measurement. As it is observed that the value of metric PSNR values to be high, then the difference between the original (no noise) and the blurred image is imperative. The major benefit of this metric is an easy calculation, but it represents notional value. A key feature of PSNR is, a slight spatial change in the image quality can lead to a large numerical distortion, however, if the deviation is localized in a particularly appropriate area, there will be no perceptual distortion, and the opposite is true.

$$MSE = \frac{\sum M,N[I_1(m,n) - I_2(m,n)]^2}{M \times N} \qquad (2)$$

Where,

$$PSNR = 10 \times log10\left[\frac{255^2}{MSE}\right] \qquad (3)$$

Where M and N are the numbers of pixels elements in respective matrix respectively. I_1 treated to be embedded image to be embedded and I_2 treated to be cover image.

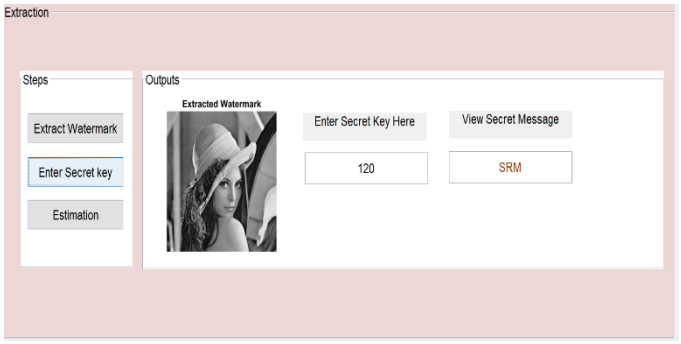

Fig. 5. Extraction Process

Fig. 6. MSE and PSNR Estimation Window

Table 1. Evaluation parameters of images

Image	MSE		PSNR in dB	
	Standard Algorithm	Proposed M-BAT	Standard Algorithm	Proposed M-BAT
Lena	0.0321	0.0114	43.6552	48.1392
Baboon	0.0058	0.0021	45.5203	50.0043
Boat	0.0331	0.0118	43.5624	48.0463
Honeybee	0.0195	0.0069	44.3317	48.8157

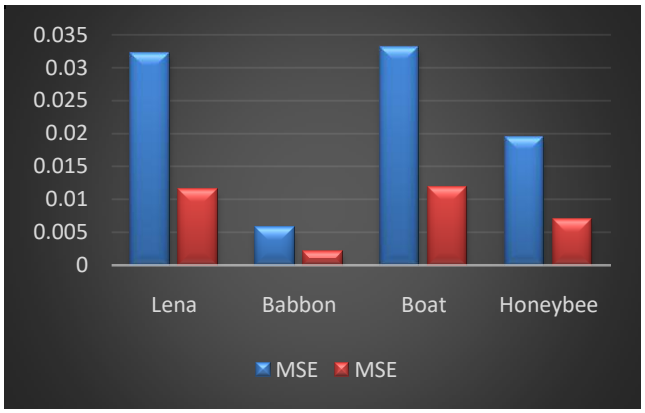

Fig. 7. Comparision of mean square error (MSE)

It is clear from the Fig.7 the MSE value is low for all the four images for propsed M-BAT as related to standard algorithm.

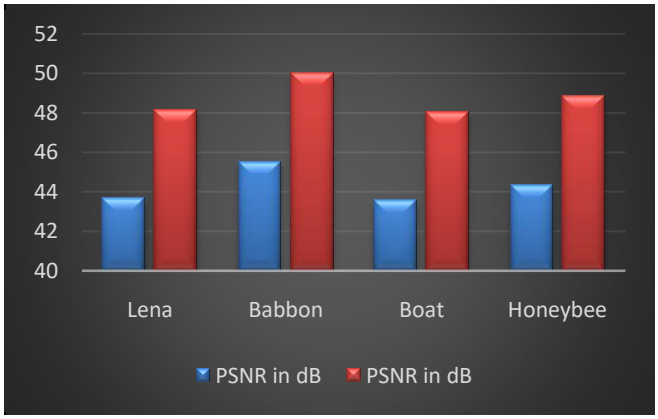

Fig. 8. Comparision of peak signa to noise ratio (PSNR)

It is clear from the Fig.8 the PSNR value is high for all the four images for propsed M-BAT as related to standard algorithm.

V. CONCLUSION

Steganography is the field of science in which the data can be hiding more securely in cover images in a robust manner. In this paper, there is an investigation of how data can be hidden securely and the proposed technique is related to the traditional steganography based on DWT in terms of image evaluation metrics such as PSNR and MSE. It can be observed that there is a dropping of MSE metric to nearly 45.6% and improvement of 11.12% in the PSNR values shows outperformance of the proposed technique. As DES supposed to use for authentication purposes and the M-BAT algorithm greatly improves hiding efficiency. The benefit of using DWT is that it provides a partial remedy over other transformations. PSNR is good, and MSE is much smaller than many current algorithms. This algorithm is also simpler, more stable and secure than other algorithms. Further work needs to be done to increase the computation time required without losing the quality of this system.

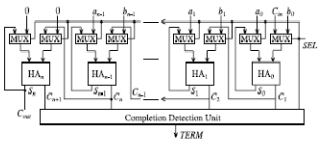
Design of Parallel Self-Timed Adder with Recursive Research

Swapna Thouti

ABSTRACT---This speedy suggests a parallel single-rail self-coordinated snake. It relies upon on a algorithmic description for showing multibit twofold growth. The hobby is parallel for the ones bits that require now not trouble with any supply chain unfold. in the course of this way, the arrange achieves power execution over irregular quantity situations and not using a excellent dashing hardware or appearance-ahead sample. A proper all of the way right down to earth usage is given on a give up discovery unit. The execution is fashionable and doesn't have any pragmatic rules of excessive fanouts. A high fan-in door is wanted however nonetheless it really is ineluctable for kinky reason and is overseen by way of manner of associating the transistors in parallel. Recreations were finished creating use of AN commercial enterprise commonplace tool cabinet that ensure the common sense and prevalence of the projectedmethod over current nonconcurrent adders



1. INTRODUCTION

Parallel increase is that absolutely the maximum excellent pastime that a processor plays. the larger a place of the adders had been supposed for synchronous circuits yet the fact that there's a stable enthusiasm for clockless/nonconcurrent processors/circuits. Nonconcurrent circuits don't count on any quantisation of some time. therefore, they maintain terrific capability for explanation shape as they're loose from some problems of regular (synchronous) circuits. On a primary stage, rationalization circulate in kinky circuits is limited with the help of a solicitation confirmation handshake convention to create up a pipeline without tickers. specific handshake obstructs for small elements, as an example, bit adders, are high-priced. at some stage in this way, it is certain sufficient and expeditiously overseen exploitation double rail convey proliferation in adders. A legitimate double rail convey yield further gives confirmation from a solitary piece snake sq.. therefore, nonconcurring adders are every supported on complete double rail coding all subjects thought-about (all the bigger formally utilising invalid show that utilizations emblematically correct purpose as important mathematician purpose) or pipelined hobby exploitation single-rail facts encoding and double rail deliver portrayal for affirmations. while these develops switch electricity to circuit plans, they similarly acquaint massive overhead with the ordinary case execution blessings of nonconcurrent adders. on those strains, a frequently effective optionally accessible technique is well worth of notion with the intention to trot out these problems. This elliptic affords a nonconcurrent parallel self-deliberate snake (PASTA) utilizing the calculation first of all projected. The set up of meals is state-of-the-art and uses zero.five of-adders (HAs) aboard multiplexers requiring negligible interconnections. at some stage in this manner, it is manner suitable for VLSI execution.

Free supply chain squares. The execution on this brief is one in every of a kind because it makes use of grievance thru XOR motive doors to include a solitary rail cyclic nonconcurrent serial snake. Cyclic circuits could also be additional plus effective than their non-cyclic partners. Then once more, wave pipelining (or excellent price pipelining) might be a way that will follow pipelined contributions earlier than the yields are balanced out. The projected circuit oversees programmed single-rail pipelining of the supply information sources remoted through engendering and mechanical phenomenon postponements of the doorways inside the circuit way. on those strains, it is sufficiently a solitary rail wave-pipelined approach and virtually specific on the subject of normal pipelined adders creating use of double rail coding to even as now not a doubt talk over with the pipelining of deliver signs.

2. HISTORY

There are a heap plans of double adders and that we middle right here round nonconcurrent self-coordinated adders. Self-deliberate alludes to purpose circuits that rely on moreover to skilled temporal order presumptions for the proper hobby.

ig. 1. General block diagram of PASTA.

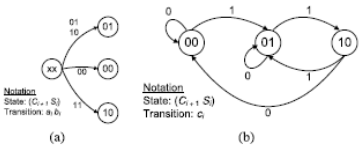


Fig. 2. State diagrams for PASTA. (a) Initial phase. (b) Iterative phase.

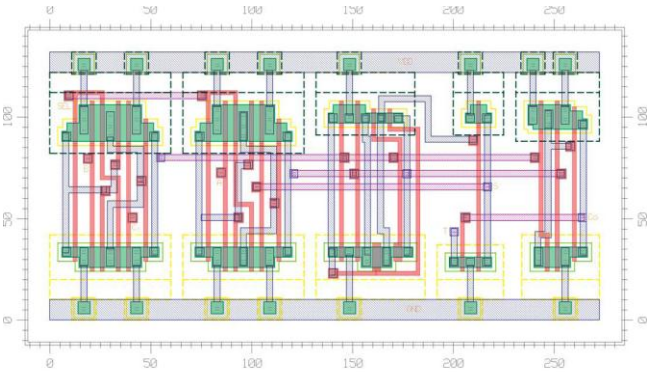
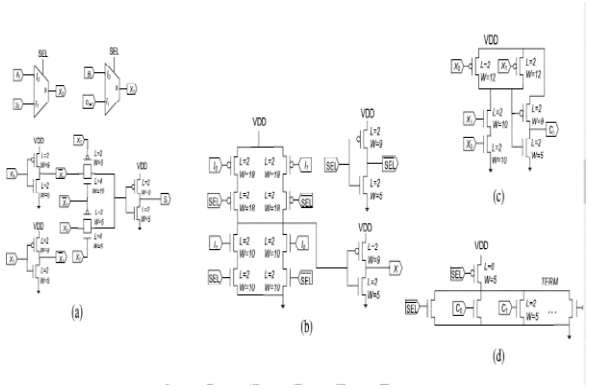
Self-coordinated adders will in all likelihood run faster discovered the center fee of for dynamic records, as early cease result police research will maintain a strategic distance from the necessity for the utmost demoralized state of affairs prepackaged defer component of synchronous circuits. they'll be as well delegated pursues.

Revised Manuscript Received on August 19, 2019.

Dr. Swapna Thouti, Professor, ECE department, MallaReddy Engineering College (A)



A. Pipelined Adders mistreatment single-Rail records secret writing ThenonconcurrentReq/Ack acknowledgement is used to empower the snake restrict at the same time as to set up the event of carry alerts. in the existence-sized majority of the times, a double rail deliver show is carried out for inside bitwise circulation of convey yields. these double rail sign will go to in in addition of 2 rationalization esteems (invalid, 0, 1), and in the course of this manner is used to provide bit-degree affirmation once a small amount pastime is finished. remaining consummation is detected while all piece Ack sign are gotten (excessive). The bring give up police research snake can be a case of a pipelined snake , that makes use of complete snake (FA) helpful squares adjusted fordouble rail carry. Then all all over again, a theoretical consummation snake is planned in. It makes use of intended direct quit reason and early accomplishment to pick out out the proper consummation response from numerous mounted defer lines. Be that due to the fact it could, the in advance forestall motive execution is luxurious owing to excessive fan-in conditions.



B. Defer Insensitive Adders mistreatment twin-Rail secret writing delay brutal (DI) adders are nonconcurrent adders that claim packaging requirements or DI sports activities. Thusly, they are ready to correctly paintings in distance of confined but obscure entree and twine delays. There are numerous variations of DI adders, as an example, DI swell supply snake (DIRCA) and DI deliver look-earlier snake (DICLA). DI adders make use of double rail secret writing and are common to make unpredictability. notwithstanding the very reality that double rail mystery writing copies the twine varied nature, they may even currently be used to make circuits in reality as powerful as that of the unmarried-rail variations using dynamic cause or nMOS merely systems. A version 40 transistors for each piece dicot genus snake is displayed in at a comparable time because the regular CMOS RCA utilizes twenty eight transistors. Like CLA, the DICLA characterizes bring proliferate, produce, and slaughter conditions referring to double rail mystery writing. They don't accomplice the carry flag during a series but as another sort out them in a stylish tree. during this way, they're equipped to conceivably art work quicker while there's long deliver chain. A moreover improvement is given from the belief that double rail secret writing cause will earnings by way of mistreatment subsiding of both the zero or one way. Double rail motive would love not think about that the two techniques may be assessed. on those traces, it's so much possible to any accelerate the deliver appearance-in advance hardware to ship bring create/deliver slaughter signal to any level in the tree. this will be mentioned and alluded as DICLA with velocity hardware (DICLASP).

Three fashion OF mealson this phase, the layout and speculation inside the returned of food is displayed. The snake to start out with recognizes 2 data operands to hold out halfadditions for each piece. consequently, it emphasizes using in advance created carry and totals to carry out half of-will increase in addition than as soon as until all deliver bits are devoured and settled at zero level. A. fashion of food the general engineering of the snake . The resolution contribution for two-input multiplexers compares to the Req acknowledgement sign and may well be a solitary zero to 1 improvement importance via SEL. it will principally opt for the actual operands throughout SEL = 0 and will change to grievance/deliver approaches in which for ensuing cycles creating use of SEL = one. The input way from the HAs empowers the numerous emphasess to keep until the fruition once all supply signal are given 0 characteristics. B. nation Diagrams , 2 country outlines are drawn for the underlying degree and therefore the unvarying amount of the deliberate engineering. every nation is spoken to with the assist of (Ci+1 Si) integrate wherein i+1, Si talk to try to to and entire characteristics, separately, from the ith bit snake sq.. for the duration of the underlying degree, the circuit merely options as a combinatory angular distance going for walks in predominant mode. it is obvious that owing to the employment of HAs in place of FAs, country (11) can not show up. for the duration of the unvarying stage (SEL = 1), the enter way via electronic device square is initiated. The bring adjustments (Ci) are permitted the equal wide selection of instances for positive to finish the rule of thumb. From the which means of primary mode circuits, the winning arrange can't be notion of as a primary mode circuit due to the fact the info yields can revel in many changes previous to returning the ultimate yield. it's one component however a Muller circuit working out of doors the important mode every as within, many modifications can occur.

3. IMPLEMENTATION& RESULTS

A CMOS utilization for the algorithmic circuit. For multiplexers AND entrees we've got implemented TSMC library utilization at a comparable time as for the XOR door we have used he faster 10 junction transistor execution counting on transmission entryway XOR to coordinate the postponement with AND doors. the top end result discovery is discredited to build up a functioning immoderate finishing sign (time period). this desires a large fan-in n-input NOR entree. for the duration of this indicates, AN elective steady conceivable pseudo-nMOS percentage male erecticle dysfunction configuration is implemented. successive set up. making use of the pseudo-nMOS set up, the finishing unit remains off from the high fan-in problem as each one of the associations are parallel. The pMOS junction transistor associated with VDD of

This percentage disfunction configuration is going regarding as a heap check in, transferral extra or much less static modern channel once some of the nMOS transistors are on on the same time. withal the Ci s, the negative of SEL sign is moreover covered for the term signal to assure that the finishing can not be coincidently have become on for the duration of the underlying self-control length of the real data assets. It similarly averts the pMOS draw up semiconductor unit from being continuously on. hence, static contemporary may additionally motion for the span of the specific calculation. VLSI format has likewise been dead for a modern cell situation utilising 2 metal layers. the look possesses 270 λ × one hundred thirty λ for one-piece transferral regarding 1.123 Mλ2 region for 32-piece. The draw down semiconductor gadgets of the fruits neck of the woods reason are enclosed into the single-piece layout (the T terminal) even as the draw up transistor is what is greater set for the whole 32-piece snake. it is sort of twofold the territory wanted for RCA and is implausibly but the massive majority of the area powerful prefix tree serpent, i.E., Brent–Kung snake (BKA).

4. SIMULATION OUTCOMES

On this neck of the woods, we have a tendency to gift enterprise outcomes for numerous adders exploitation Mentor images Eldo SPICE edition seven.4_1.1, going for walks on 64-piece UNIX degree. For usage of various adders, we've got utilised in fashion library executions of the critical doors. The custom adders, as an example, DIRCA/DICLASP are lifeless counting on their quality structures. before everything, we have a tendency to expose but the winning shape of alimentary paste will viably carry out twofold expansion for numerous temperatures and manner corners to approve the electricity to a decrease region accumulating and operational types. In Fig. four, the making plans graphs for plenty sincerely horrible and ordinary times examination to finest and normal duration deliver chain adjoin arbitrary records esteems are featured. The deliver spreads thru modern day piece adders kind of a heartbeat as apparent. The excellent-case almost about least length convey chain (not seemed right here) will no longer embody any bring proliferation, and consequently acquires entirely a solitary piece serpent postpone previous growing the term sign. the most hopeless scenario consists of high-quality supply proliferation fell deferral thanks to the convey chain duration of complete thirty piece. The autonomy of convey chains is obvious from the regular 8and C26 are gave the impression to trigger at actually the identical time. This circuit works because it must be for all procedure corners. For SF corner instances, one Cout growing edge a quick powerful threat. This hasno pursue on influences at durations the circuit nor are mistakes incited through way of the SF extremely good nook case. The defer exhibitions of assorted adders. we've got utilised a thousand continually sent bizarre operands to speak to the everyday case at consistent time as excellent case, most hopeless state of affairs relate to precise experiments talking to zero, 32-piece carry engendering chains in man or woman. The deferral for combinable adders is anticipated at seventieth progress purpose for the result bit that encounters the most extreme postponement. For self-coordinated adders, it is anticipated through exploitation the deferral amongst SEL and term signs, as diagrammatic The 32-piece full CLA isn't always all of the manner down to earth thanks to the requirement of excessive fan-in, and for that reason a numerous leveled square CLA (B-CLAis useless for test. The combinable adders, SPICE temporal order chart for alimentary paste usage making use of TSMC 0.35 μm approach. The Cout and C12 for many hopeless situation and everyday case, one by one, are regarded for changed conditions at some stage in which TT, SF, and FS speaks to run of the mill common, slow-quick, and brief moderate nMOS–pMOS things in those figures. (a) Worst-case deliver proliferation while at the side of operands (FFFF FFFF)sixteen and (0000 0001)16. (b) common-case deliver engendering while at the identical time inclusive of arbitrary operands of (3F05 0FC0)16 and (0130 0041)sixteen.

For instance, RCA/B-CLA/BKA/Kogge–Stone serpent (KSA)/Sklansky's restrictive completeness snake (SCSA) will artwork for the most hopeless scenario defer as they want no end result sleuthing tool. on those lines, these effects deliver an express higher positive of the exhibition improvement that may be finished utilising those adders due to the vital unit and growing use of some fairly consummation sleuthing machine. in the maximum hopeless scenario, KSA plays splendid as they (alongwith SCSA) have the insignificant tree-profundity [10]. Then all all over again, alimentary paste performs exceptional amongst oneself planned adders. alimentary paste execution is same with the pleasant case exhibitions of standard adders. with achievement, it changes somewhere inside the vary of 1 and pretty one instances that of the fantabulous snake exhibitions.

It's miles even incontestable to be the quickest for TSMC zero.35 μm technique. for regular instances, alimentary paste execution remains inside pretty one times thereto of the same old conventional case exhibitions at regular time as for the most hopeless state of affairs, it acts much like the RCA. notice that, alimentary paste finishes the principle pressure of the algorithmic particularisation as soon as "SEL = zero." as a consequence, the only case postponement speaks to the defer had to produce the time period signal clearly and of the request for picoseconds.comparable overhead is likewise located in double rail clarification circuits wherein they want to be reset to the invalid nation

preceding any calculation. The dynamic/nMOS simply plans need a precharge degree to be finished in the course of this era mediate. these overheads are excluded during this correlation.

5. CONCLUSION

This rapid shows an awesome utilization of a alimentary paste.to start with, the theoretical institution for a solitary rail wave-pipelined serpent is made up. in the course of this manner, the structural set up and CMOS utilization are delivered. The set up accomplishes a basic n-bit serpent this is often territory and interconnection-clever the photo of the smallest quantity hard snake basically the RCA. besides, the circuit works in a completely parallel way for freelance deliver chains, and because of this accomplishes exponent ordinary time execution over odd records esteems. The completing identification unit for the projected serpent is moreover attainable and powerful. reproduction results are utilised to affirm the upsides of the projected approach.

Performance of Improved FIR filer using FPGA

Rajendra Prasad.K

Abstract*:A crucial part of the digital system is the FIR filter where its framework is robust and simple to connect. In this paper, a regular FIR filter and an optimized FIR filter were modeled using window functions. The FIR filter was designed and contrived by FPGA for digital signal filtering. Also in this paper, a regular FIR filter and an optimized FIR filter were built with window usability. The main characteristic of the application is the Xillinx ISE development suite program to build the FPGA data filter accelerator. The paper also simulates the hardware and software co-designed FIR filter and provides simulation findings about hardware assets and variations in quality compared to the standard and improved FIR filter.

***Keywords*:FIR filter, DSP applications, FPGA synthesis**

I. INTRODUCTION

For multi-rate systems, finite impulse response (FIR) filters are of great importance. To multi-rate signal processing, the main advantage of FIR systems is inherent system stability and phase linearity. The performance of a multirate FIR filter improved considerably in contrast to the single-rate configurations using multirate techniques. FIR filter was designed and built on FPGA for digital signal filtering. This approach can be used for all FPGAs. Signal processing is an important area in which FPGAs in recent years have found a number of applications. FIR filters, for example software and hardware, can be done in two ways. The code approach is simple, as filter parameters can be adjusted to modify the filter efficiency. Nonetheless, the computer method's real-time performance is low. Alternatively, the technology is applied more efficiently and securely in real time. However, the cycle of development is longer and more complex. The article focuses on a FIR filter design approach which incorporates the advantages of software and hardware implementation through both HW and SW. It not only has good performance in real time and high reliability but also has a short development cycle, versatility and easy design.

The processing of a linear filter is focused on a multiplication method. The FIR digital filter's simple arrangement consists of several delay modules. The output of every delay unit builds up to one weight. Then we get the output of the filter. FIR filters are finite in size, M-order FIR filters can be represented as:

$$y(n) = \sum_{i=0}^{M-1} h(i)x(n-i) \quad (1)$$

$$H(z) = \sum_{i=0}^{M-1} h(i)z^{-i} \quad (2)$$

The development of a so called FIR filter is designed to find constant impulsive response coefficients that meet the requirements.

Many approaches, including window control, frequency sampling and suitable approximation equipment are usable. The move/add operational blocks introduced in an iterative multiplier usually change the operand by a fixed number of bits and a fixed number of iterations is required for the complete multiplication operation. This simple approach guarantees a consistent power and overhead energy per device phase throughout the whole multiplication process. The new iterative multiplier structure suggested in this paper includes the use of a variable number of iterations to convert an operand from 2 to a Canonical Signed Digit (CSD) representation in real time using a new CSD recoding method where the number of iterations depends on the data. The new real-time CSD tracker is very easy to implement and only needs a few practical windows. Actually, only the control signals needed to accumulate the partial product based on the value of the multiplicands can be produced by the actual CSD representation of the multiplier operand.

The main contributions and organization of this paper are summarized as follows: In section 2 we describe background details of different FIR filtering methods adopted by the authors. Section 3 discusses the proposed work. Section 4 deliberates results and discussions. Finally, in section 5, we concluded the paper.

II. BACKGROUND WORKS

Partial products are generated and sequentially added in an iterative multiplier. For the binary-number system complement of 2 it is possible to generate and insert partial products in hardware using a basic shift/add technique as shown in Fig.1.To multiply *n*-bit by *n*-bit, right-shifting requires only an n-bit adder as opposed to the 2*n*bit adder required in a left-shifting structure. Be aware that, as shown in the fig.1 the multiplier and the lower half of the partial product can share a common register, since multiplier bits are transferred as the partial product raises.

The system function is

In [1], the authors suggested the FIR filter design in the beamformers synthesis. As the frequency of the signal increases, the beam width of the signal also decreases and decreases. The researcher suggested that the large beam of a signal still be a component of the frequency and signal range, and a skewed beam is produced as the beam is fed to the low-pass filter for the frequency variations. The FIR is used as a solution to concentrate more. Numerous solutions to broadband beamformers are given through the application of FIR filters with an invariant frequency system. The second order cone programming approach is used to model the filter utilizing frequency invariant patterns.

In [2], the researchers addressed the different designs of FIR filters, and they concentrated on rate and power consumption. The focus is on the different applications of FIR filters. Due to its features such as linear phase response, absolute stability, etc., the FIR filter has found the broad application. FIR found usage for pulsing, channel equalization and matched filtering in each sector, but most commonly used in communication. For most of the execution of the FIR filter, it uses the preferred FPGA method, now widely used for the VLSI development.

In [3], the researchers recommended the design of multipliers using the SORIGA method and addressed the difficulty of multiplier implementations in FIR filters, thereby increasing the cost of equipment. By using successive adders instead of multipliers, this hardware difficulty can be omitted or reduced and effects are calculated. Different algorithms were built for eliminating such constraint and SORIGA uses an advanced optimization as the most essential tool in this article. SORIGA is a clever optimisation tool like some other genetic algorithms, differential algorithms and so much more. An FIR filter with power-of-two is designed in this algorithm.

In [4], the researchers provided a brief summary of electronic filters, their methods of enhancing their use over analog filters and their forms (FIR and IIR) and their use of FPGA. The numerous potential benefits of FIR filters are stressed, as the design of the FIR filter is easy and its frequency reaction is faster than the IIR filter and can be applied to any type of frequency. But it also suggested how a filter can use adders and shifters rather than multipliers to reduce the size of the process.

III. PROPOSED WORK

Standard FIR filter:

The window feature designs a generic FIR filter that fulfills the specifications. Rectangular screen, Hanning window, Hamming window, Blackman window and Kaiser window are widely used for window features. For the performance of hardware design, first of all, the use of MATLAB technology to obtain the FIR filter correlation coefficients we need.

Improved FIR filter

This introduces a new algorithm for static or programmable digital filters. The fundamental idea is tosubstitute multipliers for shifters and additives in the development of electronic multiplierless filters. A commonly used approach to replace a multiplier with shifters and adders is focused on the canonically signed numbers (CSD) multiplicand form. This allows further executing prices, though, because it avoids intermediate outcomes of multiplying. The minimum number of shift-add operations and the accompanying term to carry out the multiplication with a specified multiplicand must occur when using shifters to enforce multipliers.The signal flow chart for Real-time CSD multiplication is shown in Fig.2. It is evident from the flow chart that this encoder produces the control signals required to perform a CSD-based multiplier directly on the hardware.

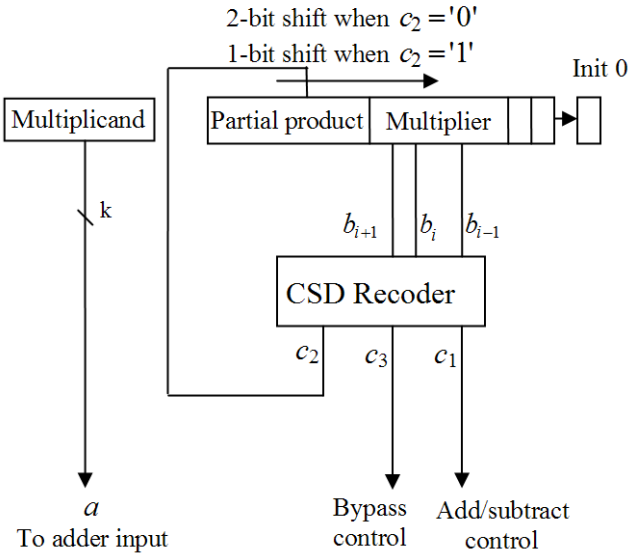

Fig.2. Real-time CSD multiplication depends on CSD recoder

The new strategy regarded here efficiently decreases the overhead implementation by avoiding the need to specifically represent the hardware CSD number; only the control signals derived from the concept of DFS numbers are explicitly displayed in the hardware.

From Fig.3 it is evident thatCSD recoderiterations can be seen that multiplier is dependent on data and uses the variable number of bits to shift. Shifting by a variation in bits usually means that a register-based shift is needed that adds time and energy consumption for each iteration; instead, shifting by a continuous number of bits by direct wire connections can be easily implemented and requires very low energy and chip area costs. Nevertheless, the model that we suggest here simply does not involve random changes, but only one or two bits shifts. It ensures that the model can be applied with a pair of hardwired switches, when the command signal chooses switching by one bit or two. This approach helps us to acquire the gains of dynamic transformation at the expense of continuous transformation. Notice that it is possible to further increase the computing rate of the current multiplier model by using specialized adders and asynchronous loop techniques.

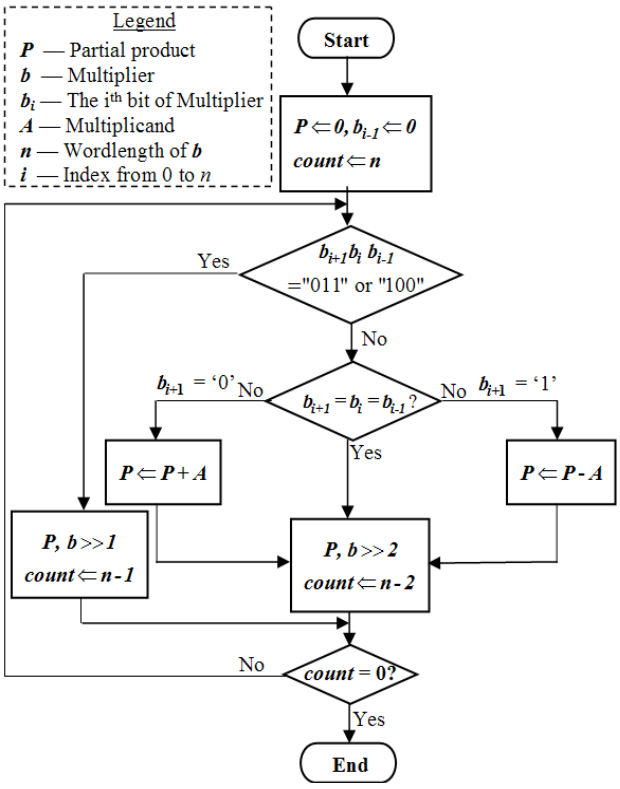

Fig. 3. Overview of CSD recoder

IV. RESULTS AND DISCUSSION

Modelsim simulation enables us to obtain the result of the simulation of hardware code, such as the clock cycle, time running, clock cycle number and errors, to determine whether the design is right. In addition, the result can be verified by simulation waveform. The efficiency of each design method is shown in Table 1.

Table 1. Exchange coefficients into 2^k mode

Method	Standard FIR	Improved FIR
Demanded clock	30M	25M
Delay estimated	15.340ns(65M)	24.562ns(40M)

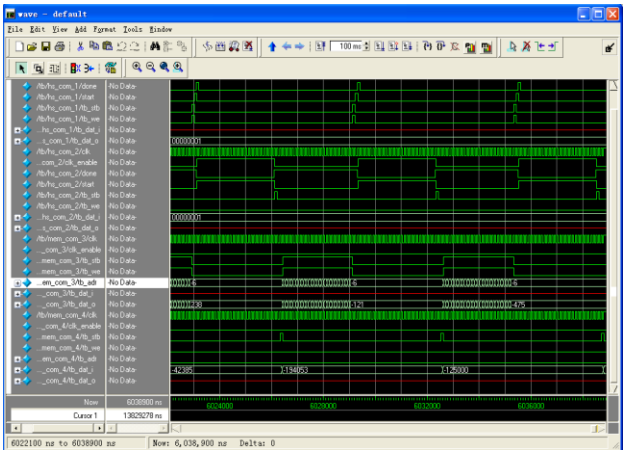

Fig. 5. Simulation output of improved design with Isim

V. CONCLUSION

This paper discusses the development methods of the FIR filter. The function of a filter in signal processing applications is to eliminate the undesirable part of the signal. It is often used to remove the random noise and remove a useful part of the input signal, for example the specific frequency component. FPGAs are high-performance tools for data processing. We investigated the development and synthesis of the FIR filter using various techniques.

MFMW: Modified Floor planning with Minimum Wire length

N.Subbulakshmi, R.Chandru, R.Manimegalai,

Abstract: ***Floorplanning is one of the most critical phases inVLSI circuit design. The module alignment has a substantial concentration on the minimization of chip area and total wirelength in slicing floorplan. At foremost, the disadvantages of dead space are investigated and an instinctive and profligate method is proposed to find the equitable part of component. Then, a tormenting for standardized expression is improved to produce new solution, and the proposed simulated annealing algorithm which improves design efficiency is opted for the best floorplan solution. The proposed MFMW method attains less area on the commonly used AMI33 and AMI 49 benchmark circuits.***

Keywords: Floorplanning, Wirelength, VLSI

I INTRODUCTION

In progression with innovation, the outline multifaceted nature is expanding and the circuit measure is improving bigger what's more, bigger so the physical outline turns out to be vital. VLSI physical stage start with Floorplanning [2] stream. It decides the areas and measurements of parts on a chip in order to limit the wirelengths and chip region of interconnect [2]. It is a NP difficult issue [3] from the computational perspective. The dead space increments with the expansion in squares thusly determining an ideal arrangement is a testing assignment. Floorplanning depend on its portrayal [4-15]. The portrayals of design decide the span of dead space and many-sided quality of change among its portrayal and its entire floorplan.VLSI floorplan is used for architecting modules on a single chip. Overall contributions for the floorplanning is an arrangement of m modules W= {w1, w2, w3…… wm}. Widths, statures, and territories of modules are followed as wi, and ai ;1≤ i≤ m. Design target is to mastermind how the modules are placed on a chip under imperatives that any two modules are most certainly not covered and region, wirelength and other execution lists are ideal. Floorplanning has two sets of modules in [2]: **Hard Modules**: A module whose region and viewpoint proportion are settled. **Delicate Modules**: A module is known as a delicate module whose region is settled however angle proportion can change. Figure. 1 portraits to floorplanning representations like B-Tree, sequence pair, polish notations and bounded slice grid.

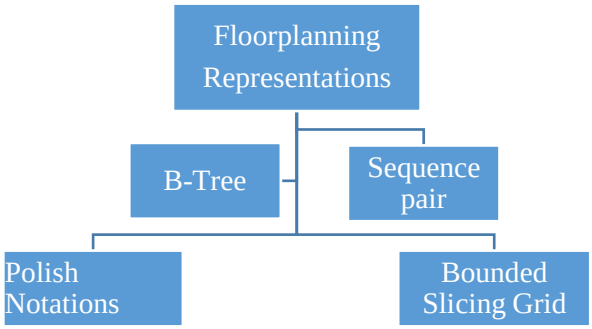

Figure. 1 Basics of Floorplanning Representations

Section II portrays about basics of floorplanning. At that point segment III incorporates near General Classification of floorplanning algorithms. Then, Section IV states about the proposed floorplanningalgorithm.At long last, finishes up the letter with conclusion.

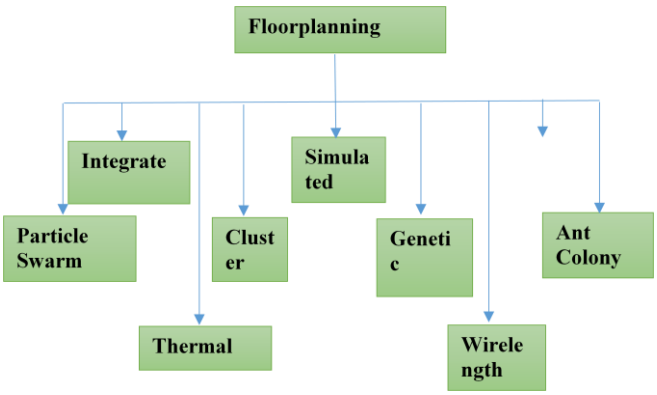

Figure.1 Classification of Floorplanning Algorithms

II GENERAL CLASSIFICATIONS OF FLOORPLANNING SCHEMES

Floorplan algorithms are classified based on the interconnect, sizing, temperature management, clustering and power optimization. The essential rule behind floorplanning using the Simulated annealing [9] is the delineation of geometric relationship while the logical based approach manages the outright relationship specifically. The calculation turns out to be versatile and powerful as far as wirelength minimization in spite of repetitive division scaled well and demonstrated its accomplishment in minimization of wirelength and strengthening based floorplanning. Srinivas Katkoori and Pradeep Fernando (2008) [10] considered an algorithm using multi-objective genetic for achieving wirelength and area best floorplanning. To allocate rank for the solutions, the non-domination concepts are

used.Fruitful lessening of inductive exchanging clamor can be refined by the accompanying: Reduce the quantity of yields that switch at the same time by isolating them into bunches with each gathering having various defer supports embedded into their information ways Use the most minimal evaluated sink present or low-clamor yield cushions as long as speed isn't an issue Place the at the same time exchanging yield or bidirectional cushions together furthermore, disperse power and ground cushions among them as indicated by their relative commotion rating Assign static and low recurrence input cushions to higher inductance bundle pins Reduce the viable power and ground stick inductance by allocating as numerous power and ground cushions as could be expected under the circumstances. By considering this as a main priority the proposed Algorithm is composed.

III MODIFIED FLOORPLANNING WITH MINIMUM WIRELENGTH

In the wire length placement refinement, apportioning the switch part and therapist part together. Since TSV check is not any more priority. In Figure 3, contract is performing amid the switch process. After each move of the module in the switch part, we contract modules in each layer iteratively to get the most limited wire length. Restore the outcome with the most limited wire length toward the finish of the program.

(1) **Reading the files** of benchmark circuits.
(2) **Generation** floorplan solution.
(3) **Initialization:** temperature Temp0 according to (1).
(4) **Shuffle** the current solution arbitrarily and produce a newsolution.
(5) Once the **new solution** is correct compared to the available solution, replace the current solution with
the new solution
(6) If the number of **reputations** at the current temperature ranges Markov chain the length, Move to the
next step, otherwise go back to step (4).
(7) **Temperature diminution** according to the cooling schedule: Temp (j) =α Temp (j-1).
(8) **Redo** steps 4-7 until the criterion is achieved.
(9) Output the better solution obtained so far.

III RESULTS AND DISCUSSIONS

The results are taken in the AMI33 and AMI 49 bench mark details of benchmark circuit has good results when compared to traditional method which is discussed in Table I. The constraints of the Simulated Annealing based algorithm are explained in the following: (a) The cooling factor is 0.95. (b) Markov chain length takes 40*n, (n is the number of modules of benchmark) . (c) The algorithm ends while the temperature is minimum than 10-6 Temp0 or the number of accepted agitation is less than 1% at a minimum temperature. The chip area and percentage of dead space are explained in Table II which includes the comparisons between previous work and the proposed work. Floorplan area is calculated by minimum bounding box which includes all modules. Floorplanning results of ami33 and ami49 obtained by the proposed MFMW algorithm. This algorithm can generate a better floorplan whose dead space percentage is less while consuming minimum operation time.

Table.I Comparisons of various algorithms using AMI33 and AMI 49

Number of Placement Constraints	Floorplan Constraints method [5]		Proposed Floorplanning	
	Time (sec)	Wirelength 10^6	Time (sec)	Wirelength 10^6
4	18.0	0.0248	16.23	0.0221
8	20.04	0.0252	17.91	0.0258
12	19.89	0.0252	19.88	0.0214
4	25.63	0.0252	22.12	0.0223
16	24.05	0.0252	24.20	0.0269
18	41.99	1.280	28.99	0.0480
20	42.37	1.931	29.28	0.0482
22	357.39	1.467	228.11	0.977
24	374.71	1.448	344.71	1.403

IV. CONCLUSION

Entire modules have a substantial concentration on the diminution of chip area and total wirelength in slicing floorplan. Already are various floorplan representation have been discussed in this paper. From the analysis, O-tree representation and B*-tree representation is most effective when compared to all representations but with minimum flexibility. At foremost, the disadvantages of dead space are investigated and an instinctive and profligate method is proposed to find the equitable part of component. Then, a tormenting for standardized expression is improved to produce new solution, and the proposed simulated annealing algorithm is opted for the best floorplan solution. Experimental results demonstrate that the proposed MFMW method attains less area on the commonly used AMI33 and AMI 49 benchmark circuits.

Hyderabad, Telangana, India

Abstract— *Modern scanning beam systems take full advantage of the well-defined range and small lateral beam spread allow the dose to be delivered with millimeter precision. Moreover, the heavier projectiles than protons such as carbon ions have increased biological efficiency in the peak region of Bragg due to the dense ionization of the individual particle tracks, leading to a lowered cell repair. This makes them especially attractive for the treatment of radiation-resistant tumors located near risky organ. For study purpose the HICAT project is a Heavy Ion accelerator for light ion Cancer Treatment to be built for the clinics in Heidelberg, Germany. It consists of a 7 MeV/u linac, a compact synchrotron and three treatment places, one of them located after a 360 degree gantry beam-line. The control system should be developed, installed and maintained by and under the complete responsibility of an industrial system provider, using a state-of-the-art system and widespread industrial components wherever possible.*

Keywords— *scanning beam, radiation source, cancer treatment*

I. INTRODUCTION

In humans, there is a wide range of radiation response that is determined by parameters including radiation source, radiation dose (amount of radiation energy received), exposure length, and, most importantly, the exposed individual's genetic and epigenetic composition. These parameters may vary widely, and humans may be exposed to low-dose radiation from commonly used medical diagnostic tools such as computed tomography (CT) scanning or high radiation doses such as those used for radiation therapy and generated by nuclear disasters. The genetic and epigenetic aspects are significant in many conditions and can, for example, determine an individual's likelihood of developing cancer or responding to cancer treatment (e.g., some tumors either have an intrinsic resistance to ionizing radiation (IR) or acquired this property through cyclical accumulation of genetic mutations and selection for increased survival and proliferation).

After surgery it is the most frequently and most successfully applied form of therapy. More than 50% of all patients with localized malignant tumors are treated with radiation. In radiotherapy the key problem is to deliver the dose in such a way that ideally the planned target volume receives 100% of the dose needed to kill all cancer cells in the tumor, while the surrounding normal tissue should not receive any dose. In practice, this cannot be achieved because of the unavoidable dose deposition in the entrance channel of the radiation. In the past 50 years much progress has been made to improve dose delivery towards the ideal situation and to thereby increase the tumor control rate. These achievements would not have been possible without the strong and fruitful interdisciplinary collaboration of scientists in the fields of oncology and radiation medicine, radiation biology, accelerator technology, and engineering, as well as atomic and nuclear physics.

Radiation is categorized as ionizing and non-ionizing in two main forms. Environmental radiation is mainly nonionizing, including sunlight ultraviolet (UV) rays and the radio waves and microwave-related electromagnetic radiation. It is now established that non-IR sources such as UV rays (from the sun or from tanning beds) are capable of harming biological tissues [2]. However, the interaction between IR and biomolecules is much more aggressive than non-IR, as the IR can induce atomic ionization. The source of IR is a class of unstable radionuclides (radioisotopes) that emit high-energy particulate matter, which can shift atomic electrons and thus facilitate electron ejection chain reaction. The main types of IR are alpha, beta, X-rays and gamma rays. Because alpha and beta particles, for instance a paper sheet or a plate, can be stopped by physical barriers while X-and gamma rays penetrate more, environmental gamma-rays exposure causes greater biological damage than alpha or beta particulate exposure. However, all four types of radiation are used for therapeutic purposes successfully and can cause significant cell damage.

No passive elements are foreseen to match the dose distribution to the individual tumor geometry. Instead, all beam lines will be equipped with horizontal and vertical scanning magnets and beam diagnostic devices for the intensity controlled-raster scanning technique that was developed and successfully demonstrated within the GSI experimental cancer treatment program with over 100 patients to date. Fig. 1 shows the cross section of the first underground floor of the building which houses the accelerator sections, the patient treatment areas, local control rooms and various laboratories and offices. For a general description of the accelerator complex, see [1].

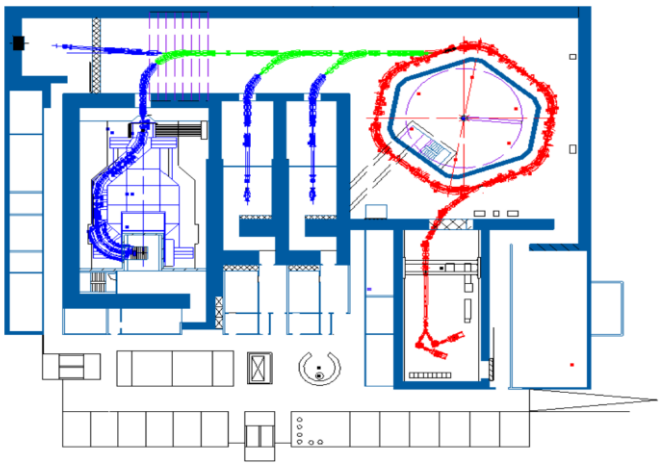

Figure 1: First underground level of the HICAT facility

The main contributions and organization of this paper are summarized as follows: In section II we describe literature review of diagnostic tools in medicine. The section III methods and methodology. Finally in section IV we concluded the paper.

II. Literature Review

These parameters can range widely, and humans may be exposed to low-dose radiation from commonly used diagnostic tools in medicine such as computed tomography (CT) scanning or high doses of radiation such as those used for radiotherapy and generated by nuclear disasters.

In [3], the authors claimed that the radio-sensitizing effect of oleanolic acid, a naturally pentacyclic titerpenoid, on tumor cells is enhanced. Whether or not OA increases the radio sensitivity of hypoxic cells, however, is unclear. Therefore, the objective of this study was to further observe the influence of OA on hypoxic tumor cells and also investigate the relative mechanism. Clonogenic assay evaluated the radio sensitivity of rat glioma C6 cells and human lung cancer A549 cells with various treatments under mimetic hypoxia. Meanwhile, a micronucleus (MN) test was used to observe the intracellular DNA damage alteration. We used the glutathione reductase dithiobis-(nitrobenzoic acid) (DTNB) recycling assay to determine the mechanism involved in the OA influence on the radio sensitivity of hypoxic cells. At the same time, both enzymes for GSH synthesis were tested using appropriate methods for the activities of π-glutamylcysteine synthetase (π-GCS) and GSH synthase (GSS). Western blot method also observed its levels due to the involvement of hypoxia-inducible factor-1α (HIF-1α) in the resistance of hypoxic cells to radiation damage. Results from this study showed that the clonogenic growth of irradiated cells under mimetic hypoxia increased while the refractory effect of hypoxic cells on radiation decreased after OA therapy. In addition, the (MN) frequencies in the OA-treated hypoxic cells were increased after irradiation compared to the OA-treated cells. In the subsequent experiment, the biosynthesis of intracellular GSH was significantly reduced by OA by attenuating the activity of π-GCS. In addition, the expression of HIF-1α in irradiated cells treated with OA at different concentrations was evidently reduced. In conclusion, by reducing intracellular GSH content and HIF-1α expression, OA significantly increased the radio sensitivity of tumor cells under mimetic hypoxia.

In [4], the authors presented positron emission tomography (PET) is currently widely used in clinic tumor staging and response therapy. However, due to higher use of PET, average exposure to PET radiation has increased. This study aims to review state-of - the-art methods for optimizing PET tracer dosage after taking into account the effects on the counting rate of human body attenuation and scan protocol parameters. The relationship between noise equivalent count rate (NECR) and dosage (NECR-dosage curve) for a range of clinical PET systems and body attenuation sizes will be systematically studied in order to estimate the minimum dosage required for sufficiently high NECR in the future. The criterion for optimization can be determined either as a function of the NECR-dose curve peak or as a fixed NECR score when NECR uniformity is important across a patient population. In addition, systematic NECR evaluations of realistic simulations and phantom experiments within a controllable environment can lead to a NECR-dosage response model that can predict the optimal dosage for each individual PET scan. NECR-based optimization recommends: i) moderate dosage to 90% of the peak NECR for obese patients; ii) significant dosage reduction for slender patients such that uniform NECR is achieved throughout the patient population; and ii) prolongation of scans for PET/MR protocols, in which the PET acqq is longer than the conventional guidelines for obesity patients; Finally, there will be discussion of the need to adapt dosage optimization continuously to emerging technologies.

In [5], the authors built a patient-specific clinical Lu-DOTATATE treatment model system for testing renal absorbed dose variability and biologically effective dose (BED) estimates. Three anthropomorphic computer phantoms coupled with the pharmacokinetic model of Lu-DOTATE are used as patient models. Aspects included in the dosimetry process model include gamma cameras ' calibration through system sensitivity measurements, time selection of imagery points, the creation of CT mass density maps, SPECT imaging, interest volume delineation, absorption dose calculation via the combined local energy deposition for electrons and Monte-Carlo photon simulations, curve fitting and introductions. The combined uncertainty in output quantities is determined by introducing variability in these steps. The importance of various sources of insecurity is assessed by observing that the standard deviation decreases when a certain source is removed. The dose and standard BED deviations obtained are approximately 6% and slightly higher if the root means a square error. The principal sources of variability are partial volume effect compensation by a retrieval coefficient and gamma-camera calibration by system sensitivity.

III. METHODS AND METHODOLGY

Process Data:

The main characteristics of the HICAT facility are the application of the raster-scan method with active intensity-, energy- and beam size-variation in combination with the usage of an isocentric gantry to match the dose distribution to the individual tumor geometry. During the patient irradiation process (treatment mode) the treatment sequencer requests beams with certain characteristics on a pulse-to-pulse basis.

In order to achieve high operational reliability the CS must meet the following requirements:

• use only proven and validated settings,
• protect settings from loss and accidental modification,
• inhibit operator's access/interference during irradiation,
• avoid networking for settings, provide all beams in stand-by on a pulse-to-pulse basis

Timing system:

For the entire accelerator chain, including linac RF structures, choppers, bunchers, and all synchrotron devices, a strict synchronization is required. Some time-critical functions (i.e. triggers, acceleration ramps) must by synchronized within $\Delta t<1–5\propto s$ at the worst. The CS must implement a timing controller that provides a system-wide synchronization for distributed devices with real-time performance. The system must be flexible enough to react on requests for beam extraction pauses and aborts.

Patient safety:

The accelerator control system cannot promise safety and reliability because of the high number of machines acting on the beam. Instead, a fast and fail-safe beam-abort system will be implemented which will reliably stop the beam within 200 μs. This is sustained by concurrently triggering a chain of different actions using various devices, all of which are able to prevent beam delivery to the treatment site on their own. The treatment sequencer's sophisticated online beam diagnosis verifies the correctness of the beam parameters (position, focus, intensity) in relation to the treatment plan.

Scanner system:

Using the existing framework-of - the-art GSI system [3] and adapting it to the new environment is foreseen for the real-time treatment sequencer. The functions will be extended before schedule to include gated beam extraction and the end of extraction.

IV. CONCLUSION

An essential step was the design and construction of proton beam scanning systems for PSI and GSI carbon ions, creating optimal conditions for IMPT use and providing highly tumor-conforming treatments with better sparing of normal and organ tissues at risk. At the same time, comprehensive radiobiological studies have led to a better understanding of the biological efficacy of heavy ions. Comprehensive biological treatment planning strategies and models were developed and implemented in treatment planning systems. These enormous achievements have made the specific advantage of heavy ions more effective, characterized by the combination of physical and biological advantages.

Optimization of on Chip Permutation Network for Multiprocessor SOC

T Surender Reddy
Associate Professor/ECE
Malla Reddy Engineering College (Autonomous),
Maisammaguda, Secunderabad-500100

Abstract

On chip interconnection between the networks plays a critical role in designing. So, to enhance the performance of network in terms of quality of service (QoS) can be improved. This burning issue in networks finds extensive use in traffic permutation and control. However, the current traffic models for on-chip interconnection networks are insufficient to capture the traffic characteristics as well as evaluate the network performance. The given paper presents the silicon-proven design of a novel on-chip network to support guaranteed traffic permutation in multiprocessor system-on-chip applications. On-chip network achieves reduction of silicon overhead compared to other design approaches. Test-chip validates the feasibility and efficiency of the proposed design.

Keywords: Multistage interconnection network, Network-on-chip, Permutation network, Pipelined circuit-switching, Traffic permutation

1. INTRODUCTION

The multiprocessor system-on-chip (MP SoC) design being interconnected with on-chip networks is currently emerging for applications of parallel processing, scientific computing, and so on Permutation traffic, On-chip multiprocessing applications exhibited with a traffic pattern in which each input sends traffic to exactly one output and each output receives traffic from exactly one input. The standard traffic occurs in general-purpose MP SoCs, for example, and fast Fourier transform (FFT) computations, polynomial, sorting cause shuffled permutation, whereas transpose permutation is exhibited in matrix transposes or corner-turn operations. Recently, application specific MP SoCs targeting flexible Turbo/LDPC decoding have been developed, and they exhibit arbitrary and concurrent traffic permutations due to multi-mode and multi standard feature. In addition, many of the MP SoC applications (e.g., Turbo/ LDPC decoding) compute in real-time, therefore, guaranteeing throughput (i.e., data lossless, guaranteed bandwidth, predictable latency, and in-order delivery) is critical for such permutation traffics.

Regarding the topology, regular direct topologies, such as mesh and torus, are intuitively feasible in a 2-D chip with physical layout. On the contrary, the large router radix and the high wiring irregularity of indirect topologies such as Butterfly or Benes pose a challenge for physical implementation. However, throughput degradation is lead in an arbitrary permutation pattern with its intensive load on individual source destination pairs stresses the regular topologies. Indirect multistage topologies are preferred for on-chip traffic permutation intensive applications.

2. EXISITING METHODOLOGY

A dynamic PA Common switch architecture-setup scheme supports a runtime path arrangement when the permutation is changed. Each path setup, based on dynamic probing mechanism which starts from an input to find a path leading to its corresponding output. The probing is introduced in works, in which a probe (or setup flit) is dynamically sent under a routing algorithm in order to establish a path towards the destination.

The Exhausted profitable backtracking (EPB) uses to route the probe in the network work. A path arrangement with full permutation consists of sixteen path setups, whereas a path arrangement with partial permutation may consist of a subset of 16 path setups. Regarding the switching technique, packet switching requires an excessive amount of on-chip power and area for the queuing buffers (FIFOs) with pre-computed queuing depth at the switching nodes and/or network interfaces. Regarding the routing algorithm, the deflection routing is not energy-efficient due to the extra hops needed for deflected data transfer, compared to a minimal routing. Moreover, the deflection makes packet latency less predictable; hence, it is hard to guarantee the latency and the in-order delivery of data. Unlike conventional packet, switching approaches, our on-chip network employs a circuit-switching mechanism with a dynamic path-setup scheme under a multistage network topology. The dynamic path setup tackles the challenge of runtime path arrangement for conflict-free permuted data. The preconfigured data paths enable a throughput guarantee. By removing the excessive overhead of queuing buffers, a compact implementation is achieved and stacking multiple networks to support concurrent permutations in runtimes feasible.

3. The Switch and Network Taxonomy

Clos network, a family of multistage networks, is applied to build scalable commercial multi core processors with thousands of nodes in macro systems. A typical three-stage Clos network is defined as C (n, m, p), where n represents the number of inputs in each of p first stage switches and m is the number of second stage switches. In order to support a parallelism degree of 16 as in most practical MP SoCs, we proposed to use C (4, 4, 4) as a topology for the designed network. This network has a rearrange able property that can realize all possible permutations between its input and outputs. The choice of the three stage Clos network with a modest number of middle stage switches is to minimize implementation cost, whereas it still enables a rearrange able property for the networks. A pipelined circuit switching scheme is designed for use with the proposed network. This scheme has three phases: the setup, the transfer, and the release. A dynamic path setup scheme supporting the runtime path arrangement occurs in the setup phase. In order to support this circuit switching scheme, a switch-by-switch interconnection with its handshake signals is proposed. The bit format of the handshake includes a 1-bit Request (Req) and a 2-bit Answer (Ans). Req = 1 is used when a switch requests an idle link leading to the corresponding downstream switch in the setup phase. The Req = 1 is also kept during data transfer along the set-up path. A Req = 0 denotes that the switch releases the occupied link. This code is used in both the setup and the release phases. An Ans = 01(Ack) means that the destination is ready to receive data from the source. When the Ans = 01 propagates back to the source, it denotes that the path is set up, then a data transfer can be started immediately. An Ans = 11(nAck) is reserved for end-to-end flow control when the receiving circuit is not ready to receive data due to being busy with other tasks, or overflow at the receiving buffer, etc. An Ans = 10 (Back) means that the link is blocked. This Back code is used for a back pressure flow control of the dynamic path setup scheme.

A dynamic path setup scheme of the proposed design to support a runtime path arrangement when the permutation is changed. In each path setup, which starts from an input to find a path leading to its corresponding output, is based on a dynamic probing mechanism. The concept of probing is introduced, in which a probe (or setup flit) is dynamically sent under a routing algorithm in order to establish a path towards the destination. The exhausted profitable backtracking (EPB) is proposed to use to route the probe in the network work. A path arrangement with full permutation consists of 16 path setups, whereas a path arrangement with partial permutation may consist of a subset of 16 path setups. A question is that can the proposed EPB based path setups used with the Clos C (4, 4, 4) realize all possible full permutations between its inputs and outputs? As proofed in works, the three stage Clos network C (n, m, p) is rearrangeable if

m>n In the proposed network of C (4, 4, 4) m = n = 4 so it is rearrange able. There will always exist an available path from an idle input leading to an idle output. By the Exhaustive Property of EPB as proofed in work, the EPB based path setup completely searches all the possible paths within the set of path diversity between an idle input and idle output. Directly applying the Exhaustive Property of the search into rearrange able C (4, 4, 4) shows that the EPB based path setup can always find an available path within the set of four possible paths between the input and the idle output. Based on this EPB based path-setup scheme, it is obvious that the path arrangement for full permutation can always be realized in the proposed network with C (4, 4, 4) topology.

As designed in this network, each input sends a probe containing a 4-bit output address to find an available path leading to the target output. During the search, when the probe moves forwards it will find a free link and moves backwards it will face a blocked link. In non-repetitive movement, the probe finds an available path between the idle input and its corresponding idle output. The EBP based path setup scheme is designed with a set of probe routing algorithms as mentioned later. The following examples describe how the path setup works to find an available path by using the set of path diversity. It is assumed that a probe from a source (e.g., an input of switch 01) is trying to set up a path to a target destination (e.g., an available output of switch 22). First, the probe will non-repetitively try paths through the second stage switches in the order of 10»11»12»13 Assuming that the link 01-10 is available, the probe first tries this link Req = 1 and then arrives at switch 10. If link 10-22 is available, the probe arrives at switch 22 and meets the target output. If Ans = Ack then propagates back to the input to trigger the transfer phase. If link 10-22 is blocked, the probe will move back to switch 01 (Ans = back) and link 01-10 is released Req = 0. From switch 01, the probe can then try the rest of idle links leading to the second stage switches in the same manner. By means of moving back when facing blocked links and trying others, the probe can dynamically set up the path in runtime in a conflict avoidance manner.

5. CONCLUSION

On chip network design supporting traffic permutations in MPSoC applications. By using a circuit switching approach combined with dynamic path setup scheme under a Clos network topology, the proposed design offers arbitrary traffic permutation in runtime with compact implementation overhead. A silicon proven test chip validates the proposed design and suggests availability for use as an on-chip infrastructure-IP supporting traffic permutation in future MPSoC researches.

Enhanced Protocols for CT Slice Thickness on Clinical Target Volume for 3d Radiation Therapy

B. Anjaneyulu,

Assistant Professor,

Dept. of ECE, Malla Reddy Engineering College(A), Secunderabad-500100

Abstract—Radiation Therapy is used to treat the cancer diseases by ionization of radiations. From the beginning the aim of radiation therapy is to cure the cancer without any side effects. Tumor location and type, geometric accuracy and involvement in anatomic area affect the output of radiation therapy in which the amount of radiation dose is given. The tumor is controlledby production of high dosage of radiation. The amount of dosage is limited by possibility of damage of normal tissue. To control the amount of dose, for three dimensional radiation therapy computed tomography (CT) slice thickness is proposed in this paper. This paper defines the changes of CTV (clinical target volume) using various computed tomography slice thickness on three dimensional radiation therapy. For all computed tomography datasets, planning of three dimensional treatments isachieved.

KEY WORDS: Radiation Therapy, computed tomography (CT) slice CTV (clinical target volume)

I. INTRODUCTION

Radiation therapy is also known as radio therapy which is used for treatment of cancer. To minimize the size of tumor and to kill the cancer cells, high dose of radiation used in radiation therapy. To observe inside body x-rays are used in which the radiation is done at low dose. Radiation therapy kills the cells of cancer by using high doses and by damaging cancer cells DNA their growth will be slow down [1]. Cancer cells are burst and separated from the body by damaging of cancer cells. Cancer cells are not killed byradiation therapy immediately. The treatment goes on few days or weeks before the damaging of DNA for pass on cancer cells. After end of radiation therapy, cancer cellstake weeks or months to die.

Today various types of radiation therapy are used to treat the cancer. Based on the radiation waves or particles, classification of radiation therapy is done to provide the treatment. Different radiation therapy techniques are protons, electrons and photons. Among these electrons and photons are widely used in the United States and other countries. Also, proton therapy facilities are in beginning stage. Usually, radiation therapy contains three most important subtypes, these maintains same biological effects on tumor tissue [2]. That means to eliminate the tumors these three subtypes contain same potential. Though each type maintains different advantages and disadvantages.

.

The radiation applied to propagation and emission of energy over the space or medium of material. Generally particulate radiation and electromagnetic radiation are types of radiation.

Oscillating electrical and magnetic fields is used for characterization of electromagnetic radiation in which both fields contains dual characters. In the radiation therapy electromagnetic radiation has two forms they are gamma rays and x-rays. Tungsten-Molybdenum is the high atomic number material. In the anode of x-ray tube, high speed electrons run into high atomic number material to produce x-rays where as intra nuclear disintegration provides gamma rays. Travelling corpuscles propagates the energy is known as particulate radiation and it has definite rest mass and momentum and position [3].

Even though in many researches, in radiation therapy therapeutic modality represented in the photon-beam because particulate radiation is used with different uncertain technical problems. Between the matter and photon interactions are occurred if γ-ray or x-ray passes over the medium and energy is feed to medium. Absorption, transmission, scattering and attenuation are done by the photon beam. Pair production, Photo electric effect and Compton Effect are the main types of radiation to interact with matter and those types are important in radiation therapy. Now a days radiation therapy of mega voltage, Compton Effect is mostly used. In diagnostic radiology photo electric has the importance and now days radiation therapy has historical importance of photoelectric effect. The energy is provided by the interaction of protons with free electrons in Compton Effect. The photon is spread by angle, electron handles the energy and photon lost the energy which is interconnected [4]. The change of wavelength not depends on irradiated material and energy ofradiation. The change of wavelength depends on angle in which the radiation is spreads.

Although EMET therapy contains the capabilities of energy modulated electron which is used to obtain high dose distribution in superficial targets and due to the problems of inherent in electron beam radio therapy, EMET is not implemented. Before works new technique was proposed by using automated few leaf electron collimators (FLEC) to provide EMET. This technique contains four motor driven leaves which are fixed in clinical electron beam applicator. This technique combined with optimization algorithm based on Monte Carlo, kernels of patient specific dose used in this

algorithm and operation of linear accelerator combined with treatment delivery. Clinical accelerator added with accessory tool which is provided by FLEC. The constructionand design of FLEC is provided and presented goals are matched.

In-house developed EMET controller controlled theFLEC prototype. Here described the EMET controller software structure and characteristics of hardware. For different sizes and various fields, Monte Carlo calculations are authorized by getting measurements of output by the use of parallel plate ionization chamber. By using energy independent radio chromic films, 1-D and 2-D dosedistributions are compared, for this purpose performs the further verifications.

For the correct dose reports and planning of 3D treatment, volume definition is required. Several targets and volumesof critical structure are described by 50 and 62 of ICRU reports those are provided in the process of treatment planning and basis is provided for the treatment outcomes comparison. To avoid tumour remission in planning of radiotherapy treatment tumour volume is estimated correctly. In complete eradication of disease tumour volume estimation isimportant task. The indirect measure of clonogen number is the tumour volume and it has direct impact on local disease control by using radiotherapy. Tumour bulk is measured by correct volume definition and analysis of treatment responseare also provided.

In the treatment planning, different imaging techniques are available such as CT (magnetic resonance imaging) and CT in which CT is used to decrease variation of inter observer and Ct is used to process of dose calculation. Each phase of treatment is impacted by interslice spacing and slice thickness between CT sections. Definition of structures is affected by it and reconstructed image quality represented in arbitrary planes, coronal and sagittal. For the dose displayand localization, DRR (digitally reconstructed radiographs) is utilized. In ICTT (intensity modulated radiation therapy) definition of volume has a crucial role, it is more sensitive to uncertainties of geometric because organs at risk and sharper dose gradients at the target volume. Different authors describe the target definition importance. For the localization the treatment volume superior and inferior boarders are defined by PTPCWG (photon Treatment Planning Collaborative work group) in 1991.

To get cooperation between throughput and resolution, for the head take the close space between sections, maintain the CT slices with the thickness of 3 to 5 mm and for the body CT slice thickness as 5 to 10 mm should be required.In the radiation therapy additional studies are necessary for CT slice thickness optimization and it is recommended by PTPCWG. The aim of this technique is to determine target volume variation with various thicknesses of CT slices. In the planning of 3D radiation therapy the impact of variation is studied in this paper. For the 3DRTrequired CT slice thickness determination and centre of mass of tumour changes with various CT slice thickness are focused in this paper.

II. TWO-DIMENSIONAL PHOTON BEAM DISTRIBUTION USING FIBRE OPTIC RADIATION SENSOR

To treat the tumor, the position of radiation beam is determined by X-ray films if conventional radiation therapy or 2D is utilized. Generally, for the radiation treatment planning machine is used that is called fluoroscopicsimulator. To find the position of tumor bones on x-ray is used as landmarks and for the treatment of tumor the radiation beams position in the patient is also identified. There should be leave normal organs. Planning should be done quickly and the treatment can be started fast by patients and other techniques has more time consuming and high in-depth in the planning. For urgent treatment this type of techniques are used.

In radiation therapy, to measure high energy photon beam fiber optic sensor is used with organic scintillator. For small field radiation therapy to determine real time dose distributions and high resolution, 2-D fiber- optic sensor was utilised. Organic sensor probe provides scintillating lights which are combined and arranged into water phantom. These are guided by 10m plastic optical fibers. For the photon beam with different field sizes and various energies, measure the distribution of 2-D (2-dimentional) photon beam in water phantom.

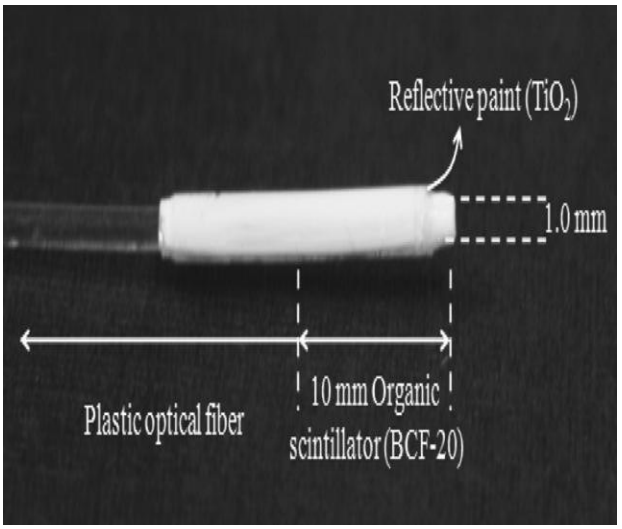

Fig. 1: OPTICAL FIBRE RADIATION SENSOR.

The designing of Fiber optic radiation sensor is displayed in above figure and it is designed by using POF and organic scintillator probe. This sensor contains 2-D organic scintillator probes in water phantom and irradiation fields are 6 and 15 MV photon beams. In this study the organic scintillator is used which is available designed with PVT (polyvinyltouene) base with wavelength shifting. The emission colour of this organic scintillator i green and peak wavelength is specified as 492 nm. In this scintillator, number of emitted photos per1MeV of energy are dropped which are 8000. This scintillator is in the form of cylinder and its measurements are diameter is 1mm and length is 10mm. polished the surfaces of ends of cylinder with different optical grade polishing pods and powders. By

using optical cement the organic scintillator is sticked into POF. By using powders and polishing pods the surfaces of POF‟s are polished. The titanium dioxide is used to make the reflective paint which is used in sensor probe outside to improve the efficiency of scintillating light collection and to capture the light noise from outside. Another name for this scintillator is typical organic scintillator, these are depends on PVT.

III. CT SLICE THICKNESS ON CLINICAL TARGET VOLUME FOR 3D RADIATION THERAPY

For the definition of target volume, brain tumours are selected, due to obtaining of various CT slice thicknesses there is no impact on organ motion. There are two steps in three dimensional radiation therapy treatments: one is phantom study and another one is clinical study. For planning of 3D treatment, the determination of minimum CT slice thickness is used by the study of phantom study. After completion of determination of minimum slice thickness, clinical study is carried out by the comparison of calculated tumour volume with minimum and larger slice thickness. In the planning of 3D treatment, the impact on CT slice thickness was also proposed, for the slice thickness iso-center values are shifted with tumour values.

For the treatment of tumours three dimensional radiation therapy is mostly used. It is used when the tumour closed to important organs such as neck, lung, and carcinomas of prostrate, bladder, spine, head and pancreas. Most of 3-DRT cases begin with „virtual simulation‟ session that lasts in between 30 and 90 minutes. In the treatment position, CT scans are taken from patients and that images are send to the treatment planning computer. The Ct slices are marked to the required volume for the treatment by clinician. The volume of 3D image produced by computer and highlighted the critical structures at the risk. Due to this best beam arrangements are defined and minimum dose distribution is calculated by computer. To provide image digitally beam‟s-eye view could be generated to see the simulation film which is utilised in verification of treatment. Beam shaping covers the critical structures and these are obtained with use of lead box or use of multi-leaf collimators. Multi leaf collimators are computer controlled movable leaves within treatment machine which is used to block the part of radiation field. A conformity index, defined in Equation 1, was used to measure the target dose conformity.

$$CI = \frac{TV_{RI}}{TV} \cdot \frac{TV_{I}}{V_{RI}} \quad (1)$$

where, TVRI was the target volume covered by the reference isodose (95%), VRI was the volume covered by the reference iso dose (95%), and TV was the target volume.The target dose homogeneity was measured with a homogeneity index (HI) defined in Equation 2.

$$HI = \frac{D_{5\%} - D_{95}}{D_{mean}} \quad (2)$$

where, D5%, D95% indicated that at least 5%, 95% of the target volume received this dose, and Dmean was the mean dose to target. The HI value was between 0 and 1, with 0 representing the ideal homogeneity, whereas the CI value was between 0 and 1, with one representing the ideal conformity. In OAR, the minimum and maximum dose of spinal cord, V30 and V40 of heart, and V20 and V30 of lung were analyzed and compared.

First scanning was done in sequential mode for all patients and before CT scanning for every patient non-ionic contrast was organized. The results of phantom study are, for the planning minimum slice thickness is 2.5 mm, accuracy is 3%. For all patients three scans are performed with different slice thickness such as 2.5, 5 and 10mm in sequential mode. By using DICOM network CT data sheets are send to the Eclipse treatment planning system. In the 3D treatment planning system based on 3D CT datasets (2.5, 5 and 10 mm), external body contour and volume of tumour are defined.

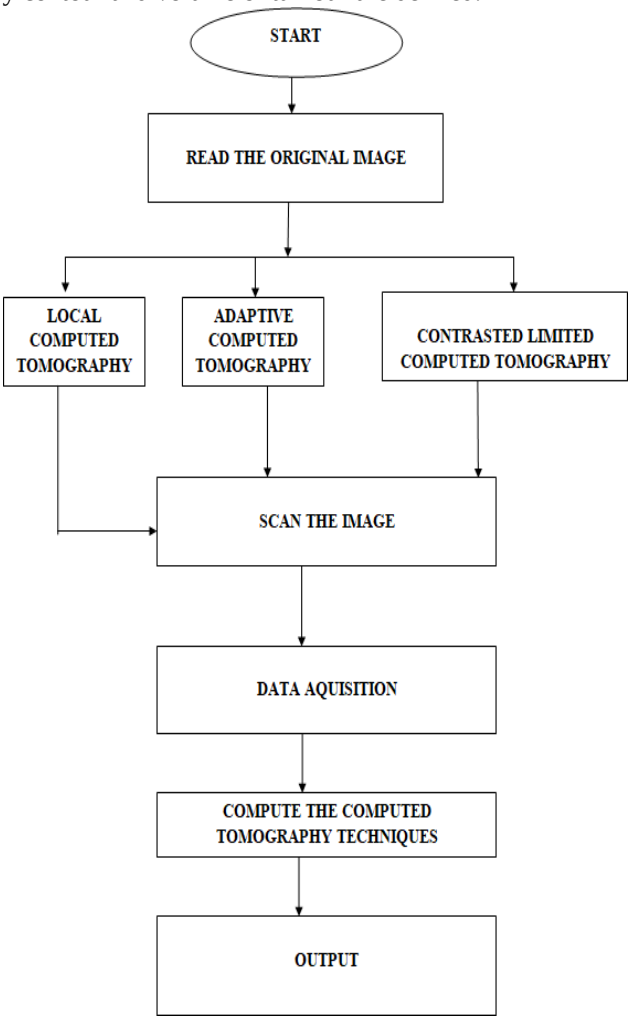

Fig. 2: PROPOSED SYSTEM

Clustering pixels into prominent picture region is the goal of image acquisition. In order to provide data such as anatomical structure and identify the region of interest, i.e. locating the tumor, lesion and other abnormalities, the acquisition of gray level data is used. The suggestion method depends on the anatomical structure data of the healthy components and compares it with the infected components. This starts by assigning a reference picture of a standard candidate brain scan picture to the anatomical

structure of the healthy components.

The aim of radiation therapy (RT) is to cure the cancer disease without any side effects. In the planning of radiation therapy treatment, imaging has an important position; there is an impact on volume of tumour definition and outcomes of final treatment. Three dimensional radiation therapy computed tomography (CT) slice thickness is proposed in this paper. It is observed that the accuracy of definition of tumour volume depends on Ct slice thickness. From the study of proposed system it is concluded that for three dimensional treatment planning of brain tumours, thethickness of CT slice should be the 2.5 mm for tumour volume<25cc and for volume of tumour>25 the slice thickness is 5mm. Proper planning is achieved for three dimensional radiotherapy treatment for tumour.

CT scan enhanced to detecting the suspicious region by the using of the Pre-processing techniques. The first step of pre-processing is tracking features involves those activities that are usually crucial prior to major information reviewand detail extraction, and are frequently grouped as radiometric or geometric improvements. for example, film artifacts or labels, names, age and marks of the patient. Through the tracking algorithm, film artifacts areeliminated. At this point, the intensity value of the pixels starting from the primary row and the initial column is analyzed and the threshold value of the film artifacts isfound. The threshold value should be noted to exceed the threshold values removing from CT. CT eliminates the film artifacts ' high intensity value. At some point in eliminating film artifacts, the image includes salt and pepper noise.

V. CONCLUSION

In this paper, the robust and simple classifications of CT scans are proposed. This system detects the motion-corrupted images in large-scale data bases. Proposed algorithm produces the best enhancement of image contrast

producing good enhancement of image contrast. In the initial stage of the work pre-processing is done to remove noises. The experimental result shows that the suggested methods offer greater precision in classification than other volumetric methods. From the view of this work, other classification techniques are scheduled, but also various CT modalities in the classification structure developed.

Design and implementation of an efficient wireless sensor network for health monitoring system

Vutkuri Srinivas,

Assistant Professor,

ECE Department,

Malla Reddy Engineering College(A), Maisammaguda, Secunderabad-500100

Abstract:

Now a day's health care system needs more attention due to heavy load on hospitals. This importance diverts the attention of the research community to work on this area. Wireless sensor networks enhance the health monitoring system due to its autonomous network structure. Art of work put much attention to improve the health system by adding some extra caring equipments and optimize the scanning devices in terms of quality of service (QoS) in the hospitals. In this paper a main focus is given towards the improvement of health monitoring system using wireless sensor networks (WSN). This paper describes a system that not only enhances the health system but at the same time it will reduce the time required to monitor the patient individually. This cures patients health issues in due course of time which can save a greater number of human lives when compared with the existing methods. In this paper, a prototype system with a 3 tier architecture is developed for patient monitoring. Various biosensors are connected to Arduino Nano board and the measured signals are delivered to server using Node MCU ESP8266 wireless communication. Remote access is provided using Thingspeak, an IOT application. Alerts can be given through smartphone in case of emergency. The paper is validated using network simulator 2. This paper can give the basic idea to the research community for further growth to the health monitoring systems.

Cardiac Patients; Cardiovascular Diseases; Healthcare Monitoring System; IOT; Wi-Fi; Wireless Sensor Networks

1. INTRODUCTION

Current health care systems -- structured and optimized for reacting to crisis and managing illness -- are facing new challenges: a rapidly growing population of elderly and rising health care spending. According to the U.S. Bureau of the Census, the number of adults age 65 to 84 is expected to double from 35 million to nearly 70 million by 2025 when the youngest Baby Boomers retire. This trend is global, so the worldwide population over age 65 is expected to more than double from 357 million in 1990 to 761 million in 2025. Also, overall health care expenditures in the United States reached $1.8 trillion in 2004 with almost 45 million Americans uninsured. According to world health organization (WHO) analytics nearly 32% of adult deaths all over the world and also in India are due to cardiovascular diseases which are caused by disorders of the heart and blood vessels.[1-4] These include various heart related diseases including coronary heart disease (heart attacks), rheumatic heart disease, raised blood pressure (hypertension),

cerebrovascular disease (stroke), peripheral artery disease, congenital heart disease and heart failure.1 According to current estimates, India will soon have the highest number of heart disease cases in the world. These types of cardiovascular diseases need continuous monitoring of certain body parameters which need long hospital stays.In the hospitals patients are monitored continuously by hospital staff using various instruments like bedside monitors. These instruments are bulky and immobile and thus keep patients stick to the bed. Their wired connections are very uncomfortable to patients and medical staff also. Due to mounting hospital costs and shortage of qualified healthcare professionals it is difficult to continuously monitor the essential body parameters of the patients suffering from CVD.

In this paper, we introduce a health monitoring system consisting of a wearable device that will continuously monitor the health of patient. This wearable device consists of different sensors such as temperature sensor and heart rate sensor. The device will collect the data in form of bio signals from sensors and send it to hospital server for further storage and processing using wireless communication. This data will be available to the doctors on server from any location using IOT application.

This paper aims ultimately to build a health monitoring system for cardiac patients to monitor his/her vital body parameters especially related to heart problems like ECG and heart rate. We have made a prototype of an automated health monitoring system based on 3 – tier architecture of Wireless Body Area Network (WBAN) comprising various sensors for monitoring cardiac patients in ICU of hospital. In tier I, Arduino Nano board based on the ATmega328P microcontroller is used to collect data from sensors and send to server using ESP8266 Wi-Fi wireless communication in tier II. In tier III existing internet is used to send data to remote servers for further use over IOT application ThingSpeak.

The remaining paper is as follows. Section II describes some of the existing systems and shortcomings of those systems. Section III describes proposed system details. Results and conclusion are given in section IV and V respectively.

Literature Survey

In most of the hospitals health professionals use heart rate monitoring systems using manual methods to measure ECG by connecting lids to the chest of patient. The graph of ECG is monitored on the bedside monitor or special monitoring devices. These devices are wired and bulky and do not support long distance communication. The systems have many disadvantages like requirement of costly hospital stays which is not affordable for longer periods, needs expert monitoring and high cost maintenance.

Current advances lead to automation of heart rate and ECG measurement using different methods. Many authors have reviewed the state of art systems available for monitoring different vital body parameters like temperature, ECG, heart rate, pulse rate and galvanic skin response (GSR).[5-7] Many researchers have contributed in automatic data collection of different signal from heart and detection of heart attack or emergencies related to other heart diseases using different methods. In[8] authors proposed heart attack detection system using ZigBee heart rate monitoring and alert system. Many researchers have done extensive studies on use of mobile phones in healthcare and medical practices. This study illuminates the use of inbuilt applications like location enabled services of smartphones like GPS which is used for location monitoring of old age patient with

instabilities.[9-14] Apart from location tracking smart phones are used for health monitoring of cardiac patients.[15] Many researchers proposed their methods using smart phones capable of detection, storage and analysis of collected records.

Much advancement can be done in these systems to make them more accurate, reliable, cost effective and wearable using biosensors. In hospitals and in homes cardiac patients can be monitored using healthcare monitoring system based on wireless sensor networks. The focus of our work is on continuous monitoring of cardiac patients in hospital especially in ICU and in homes using healthcare monitoring system based on wireless sensor networks. It achieves various goals like decrease in cost and long hospital stays; and continuous and remote monitoring without experts' attendance is possible.[18]

Material and Methods

The proposed system is based on 3-tier wireless body area network (WBAN) architecture.[16] 3- tier architecture of WBAN is used in healthcare monitoring system comprising of different communication networks shown in fig 1. The detail explanation of components used in each tier of WABN is given in the block diagram of our proposed system Fig 2 which explains the construction of all the three tiers and the in between communications.

Proposed System Architecture

The proposed system architecture consists of three tiers. Tier-1 consists of wireless sensor nodes attached to the patient's body for sensing vital body parameters. The data acquired through the sensors is processed and transmitted through control unit. Tier-2 is the intermediate receiving unit which acquires the forwarded data. It is also responsible for storage, processing and displaying the data. Tier-3 is concerned with alert systems and data transmission to longer distances through appropriate internet services. Different wireless communications such as ZigBee, Wi-Fi and Bluetooth are available for tier I, tier II and tier III communication.[16] We are using existing Wi-Fi wireless communication in Tier I and II and internet in Tier III for long distance data transfer over IOT. The kind of communications taking place at each tier of the system is as shown in fig 1 and fig 2.

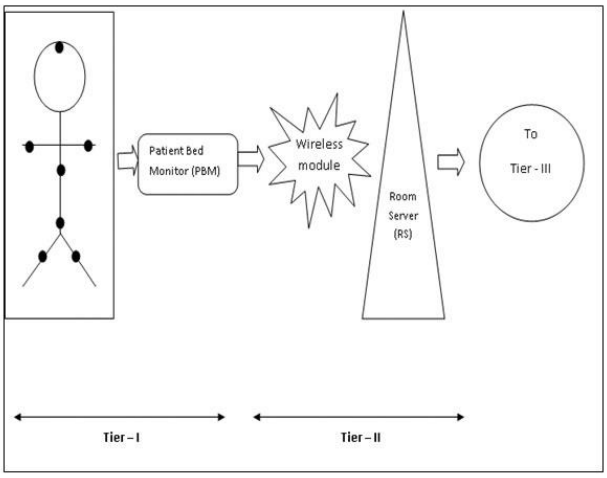

Figure 1: Proposed 3-tier architecture of system [16]

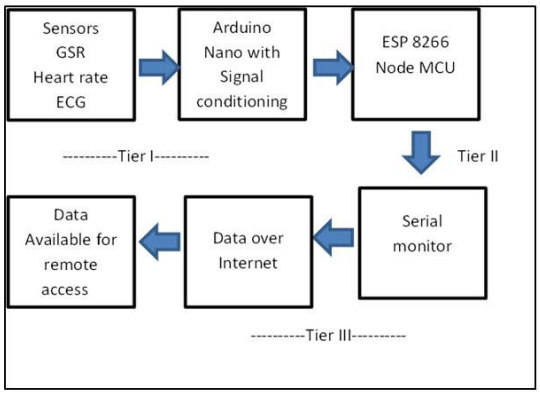

Figure 2: Block diagram of proposed system

Proposed Methodology

We have designed and implemented a healthcare monitoring system for cardiac patients to monitor significant body parameters of patient inside hospital as well as in home. Different sensors are attached or induced to the patient's body to collect vital body parameters like temperature, SPO2, heart rate, pulse rate etc. to be monitored. Heart rate and ECG sensor probes are also attached to patient's body. The sensor data is in the form of analog signals and to be converted into digital form using inbuilt circuits of Arduino board which collects and processes sensor data for further communication. For further use and storage it is then send to server using suitable wireless communication. Fig 1 shows the 3-tier architecture of proposed system. In our proposed system ESP 8266 is used to convey sensor data to server using wireless communication. Existing Wi-Fi from home or hospitals is used for this purpose. After comparing different candidate wireless technologies[16] we have chosen Wi-Fi for following main reasons:

Latest modules such as ESP 8266 are easy to connect and have built-in controller and Wi-Fi communication module.As the system is used in ICU room, the room size considered for maximum of 8 beds in any hospital is nearly 2000 sq. meters,[22,23] for which Wi-Fi is better than Bluetooth (Not enough range) or ZigBee (Low power hence cannot transmit for longer range).Wi-Fi provides very high-speed access to internet compared to any other technology already established in the market. (Excluding Li-Fi which is not commercially available). Data transmission rate of Wi-Fi is more i.e 1mbps compared to ZigBee which is 250 kbps. In tier III, data from server is made available to authorized users from outside world using internet. We are using IOT application API ThingSpeak for this purpose. Using ThingSpeak cannels data is made available to authorized users like experts, doctors and caregivers who can remotely monitor patient's data over internet and can get alert messages in any emergency situation. Block diagram of proposed system is shown in Fig 2.

Implementation Details

In this paper Arduino Nano is used to acquire readings from Max30100 heart rate sensor and send it over Wi-Fi using ESP8266. Inbuilt signal conditioning circuit is used for interfacing sensor with A to D converter of Arduino Nano. Signals are then send to cloud storage using Thing Speak. Thing Speak is an open source Internet of Things (IoT) application and API which is used to store and retrieve data from sensors and uses the HTTP protocol over the Internet or via a Local Area Network. Using Internet this medical data is made available to caregivers and doctors for reference. Existing Internet from home or hospital is used for this communication. An alert message is sent

to caregivers and relatives when readings cross threshold values, considering an emergency. For increased complexity and accuracy ECG sensor AD 8232 is used which states the condition of heart correctly.

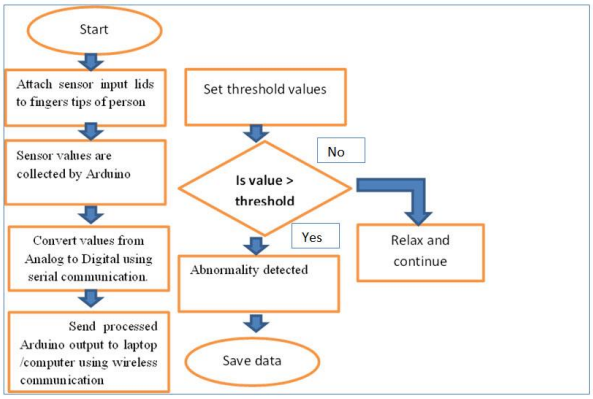

Figure 3: Flowchart of proposed system

Results and Discussion

Data collected from sensors is sent over Thing Speak channels. Authorised users like caregivers and doctors with login and password can monitor this data. Fig 4 and Fig 5 shows the sample of results displayed on Thing Speak channels and Fig 6 shows results on monitor. Sample ECG signals are plotted in Fig.7.

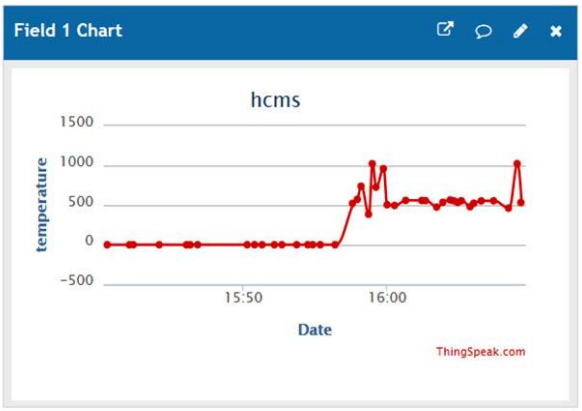

Figure 4: Sample result of Temperature on Thing Speak channel.

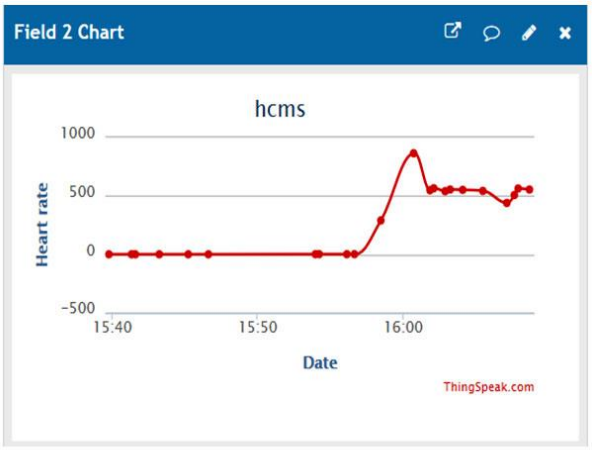

Figure 5: Sample result of heart rate on Thing Speak channel.

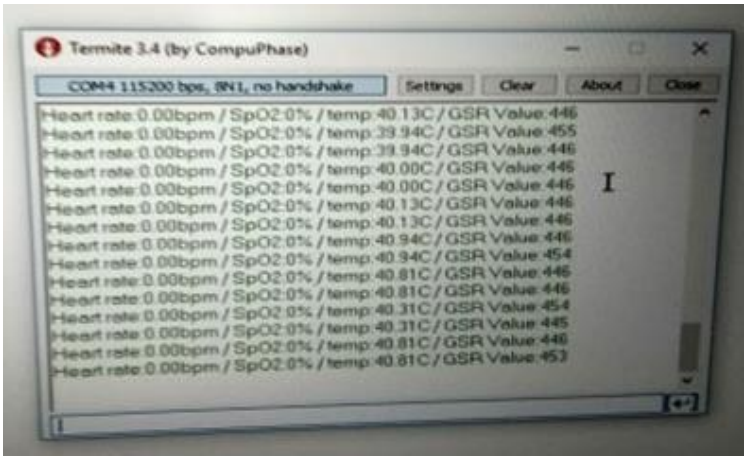

Fig.6 Results shown on Monitor

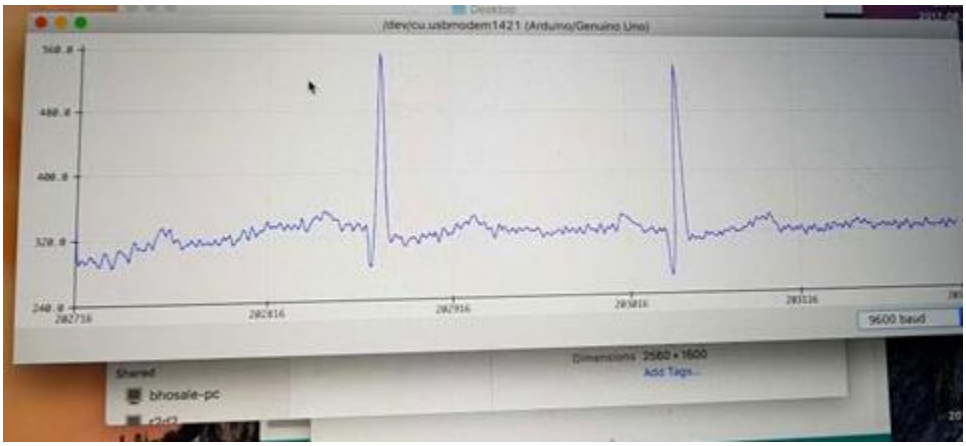

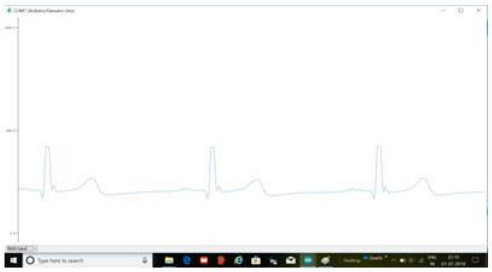

Fig.7 sample ECG readings

Nearly equal sized ICU units at different locations and at different time are considered for above experimentations.

ECG signals obtained using prototype system

Heart rate measured using Fitbit

Figure 8. Comparison of results

Fig. 8 shows 24 hour's data recording (nearly after 10 hours) of a patient. When our readings are validated with other heart rate measuring instruments like Fit Bit, 95% accuracy is found. The response time of the system is found 10 seconds for ECG readings and 5 seconds for other body parameters.

Conclusion

In this paper healthcare monitoring system for cardiac patients is proposed which monitors body parameters of heart patient like Heart rate, Temperature and SPO2. It helps caregivers and hospital staff to monitor and store patient's body parameters continuously. On any abnormality, it gives alert to caregivers. Using Internet, data can be made available for remote use and only to authorized users like remote specialist doctors for special advice. Thus designing parameters like availability, security, correctness and efficiency are achieved successfully. Nearly 95% correct results are achieved when compared to standard clinical methods and commercial instruments like FitBit. Thus the system can found helpful for the continuous monitoring of the cardiac patients in ICU of hospitals. The use of this system can be extended to care and monitor elderly people staying all alone at their homes and also for baby care.

srsilpavasu@gmail.com

Abstract

Design and development of astute monitoring and controlling system for household electrical appliances in authentic time is proposed. Incrementing power consumption is becoming an astronomically immense quandary. In this system, we propose an astute energy distribution system with a fine-tuned power utilization of every home set from Electricity Board (EB) office. Power distribution from EB is the major issue because of shortage in power generation from renewable and non-renewable resources. We design this, in order to reduce the frequent power cut off. Moreover monitoring and controlling of home appliances is developed either manually, remotely and with the avail of internet automatically. The main aim is to provide low cost and flexible operation. The goal is to develop an incipiently equipped well designed prototype for consumers in home to constrain the utilization of puissance. This avails users and power distribution centre to manage the potency in an efficient manner. Virtually applied in home and in EB unit with the avail of microcontrollers and zigbee transceivers. Internet provides the data efficaciously, in order to manage the puissance by controlling the home appliances.

Keywords:EB, Microcontrollers and zigbee transceivers.

1. Introduction

Wireless sensor network (WSN) facilely monitor assets or environment with reliable, battery-powered quantification nodes that offer industrial ratings and local analysis and control capabilities. Each wireless network can scale from tens to hundreds of nodes and seamlessly integrate with subsisting wired quantification and control systems. A wireless sensor network consists of three main components: nodes, gateways, and software. The spatially distributed quantification nodes interface with sensors to monitor assets or their environment. The acquired data wirelessly transmits to the gateway, which can operate independently or connect to a host system where you can amass, process, analyze, and present your quantification data utilizing software. Routers are a special type of quantification node that can be habituated to elongate WSN distance and reliability. The world passing the most immensely colossal quandary of potency.

Because the engenderment of potency is less than the injuctive authorization power of consumer side. In many countries the instrumentation in demand is growing at a more expeditious rate than transmission capacity and additionally the cost of providing power is additionally incrementing due to the higher coal prices and deficiency of fuel. Withal the reason of not getting the full power to consumers side is that the growing population of countries. To surmount the quandary of potency distribution this paper provides an overview of wireless sensor network by managing the equal power distribution by utilizing zigbee network sensor. A keenly intellective environment is a physical world that is interconnected through a perpetual network abundantly and invisibly with sensors, actuators and computational units, embedded seamlessly in the everyday objects of our lives. A perspicacious home is a residence in which computing and information technology apply to expect and respond to the occupants' needs and can be acclimated to enhance the everyday life at home. Potential applications for astute homes can be found in these categories: welfare, regalement, environment, safety, communication, and appliances. Automation is, where more things are being consummated every day automatically, customarily the fundamental tasks of turning on or off certain contrivances and beyond, either remotely or in close need to maintain as much control as we can over the automated processes. Automation lowers the human judgment to the lowest degree possible but does not consummately eliminate it. Depending on the location of its utilization, automation differs in its name as industrial automation, home automation etc. The rest of the paper is organized as follows: Section II discusses the subsisting system; Section III provides detailed implementation of the proprosed system; Section IV and V presents the block diagram and experimental results. Section VI has concluded and discussed about the future work.

2. Related Work

2.1 EXISTING SYSTEM:

In this section, we briefly discuss the subsisting works about astute home systems predicated on wireless communication technology. Sundry proposals are there to interconnect domestic appliances by wireless networks to monitor and control which are provided in [2], [3]. Withal, keenly intellective meter systems like [3]–[5] have been designed to categorical usages concretely cognate to geographical usages and are inhibited to categorical places. Different information and communication technologies integrating with astute meter contrivances have been roposed and tested at different flats in a residential area for optimal power utilization [6], [7], but individual controlling of the

contrivances are inhibited to concrete houses. There has been design and developments of astute meters soothsaying the utilization of puissance consumption [3]–[7]. However a low-cost, flexible, and robust system to perpetually monitor and control predicated on consumer requisites is at the early stages of development. In this, we have designed and implemented a ZigBee-predicated astute home energy management and control accommodation. We utilized the ZigBee (the IEEE 802.15.4 standard) technology for networking and communication because it has low-power and low-cost characteristics, which enable it to be widely utilized in home and building environments [4]. The disadvantage are: the physical wiring from the meter to the house can still be an impediment for a facile implementation of this solution, concretely for tall or old buildings, due to cost and installation involution. Han et al. [9] proposed a Home Energy Management System (HEMS) utilizing the ZigBee technology to reduce the standby puissance.

The system consists of an automatic standby cutoff outlet, a ZigBee hub and a server. The potency outlet with a ZigBee module cuts off the ac power when the energy consumption of the contrivance connected to the puissance outlet is below a fine-tuned value. The central hub accumulates information from the potency channels and controls these power channels through the ZigBee module. The central hub sends the present state information to a server and then a utilizer can monitor or control the present energy utilization utilizing the HEMS utilizer interface. This facility may engender some uneasiness for the users. For example, if the users may want low intensity of light, for some situation but the system will cut the puissance off leading to tenebrosity. Gill et al. [10] projected a ZigBee-predicated home automation system. This system consists of a home network unit and a gateway. The core part of the development is the interoperability of different networks in the home environment. Less paramountcy is given to the home automation. Pan et al. [11] recommended a WSN-predicated keenly intellective light control system for indoor environments, such as a home for a reduction in energy consumption.

In this paper, wireless sensors are responsible for quantifying current illuminations and the lights are controlled by applying the model of user‟s actions and profiles. The above mentioned home monitoring and controlling systems have circumscriptions with reverence to home automation such as: 1) energy consumption control mechanism is circumscribed to only certain contrivances like light illuminations, whereas several household appliances can be controlled; 2) energy control

is predicated on fine-tuned threshold power consumption, which may not be applicable to different consumers; 3) controlling the home appliances through network management functions, in practice inhabitant requisites may vary according to their demeanor but not with network characteristics. A low-cost, flexible, and authentic-time astute power management system, which can facilely integrate and operate with the home monitoring systems such as [12]is presented. The system is designed to monitor the sultriness of polyhouse environment. On-demand meter reading and remote troubleshooting sanction utilities to provide better and more timely consumer support. Utilities have more at hand about outages and renovations, and are able to consumers with good information about when power will be renovated. During emergencies, utilities can engender "partial outages" in non-exempt buildings to ascertain the puissance remains available where it is most needed. Partial outages are more economically efficient than full rotating outages, because the effects are inhibited to the reduction of a single discretionary accommodation such as air conditioning rather than the elimination of all accommodations. Additionally power factor amendment can result in an abundance of puissance preserving for industrial sector. Power demand and utilization, sanctioning utilities and consumers kindred to do their component to ascertain perpetuated and affordable supply of essential accommodations.

2.2 PROPOSED SYSTEM

A.Wireless Sensing and Intelligent Buildings

Present day keenly intellective buildings are highly adaptable to transmuting environmental conditions. They have automated systems, including wireless sensor monitoring, to facilitate energy efficient, comfortable and cost efficacious environments by optimising structure, systems, accommodations, building management and their interrelationships. In the context of the future „Internet of Things", Astute Building Management Systems can be considered part of a much more sizably voluminous information system. This system is utilized by facilities managers in buildings to manage energy use and energy procurement and to maintain buildings systems. It is predicated on the infrastructure of the subsisting Intranets and the Internet, and ergo utilises the same standards as other IT contrivances. Within this context reductions in the cost and reliability of WSNs are transforming building automation, by making the maintenance of energy efficient salubrious productive work spaces in buildings increasingly cost efficacious.

Wireless sensing in commercial and office buildings has lead to a more preponderant vigilance of the condition of buildings and their

systems: As it provides information indispensable for those in charge of building operation and maintenance to apperceive limits and non-functioning equipment and systems and prioritise building maintenance tasks etc. predicated on costs and other paramount factors. The main benefits of this are:

- An increased lifespan for equipment/electric appliances;
- An improved building environment for occupants;
- Economies of scale gained from monitoring, tracking and responding to the status of multiple uilding assets from centralised or regional locations;
- The ability to detect impending faults and therefore minimise energy usage associated with facility assets and increase reliability while reducing costs;
- Lower energy and operating costs leading to an advantageous return on investment. For example energy management systems based on WSNs can save an average of 10 % in overall building energy consumption and the energy savings can be as high as 30% depending on occupancy.

B. Recent advances

The WSNs utilized in keenly intellective building management systems consist of variants of sensor nodes quantifying parameters such as temperature, sultriness, light, asphyxiating gases/smoke, occupancy, and energy consumption. In integration, the systems may include actuators, gateways, servers and communication and application software on different calibers as well as different home appliances. A substantial amount of research has been conducted fixating on different aspects of WSN for building management and control.

C. ZigBee Wireless Sensor Network

The gateway functions both as a server storing network data and a connection point between the network nodes, the LAN and the external server. It has the coordinator role in the ZigBee network. A Web utilizer interface running on the gateway enables the utilizer to establish and manage the gateway and the WSN. Several battery-driven wireless sensor nodes with internal sensors to quantify temperature, light and sultriness are deployed in the network. These nodes are able to compose mesh networks and can operate within an indoor range of about 40 metres. They function as end-contrivances in the ZigBee WSN.

A number of remotely controlled ZigBee contrivances with relays are utilized as switches to power external equipment, such as table fans, desk lamps, etc. These contrivances, which act as routers in the WSN, are plugged into power points. They are additionally utilized as meters

for quantifying the voltage, current, frequency, power consumption and load of the annexed equipment.

3. Implementation

3.1 BLOCK DIAGRAM

The system has been designed for quantification of electrical parameters of household appliances. The quantification of electrical parameters of home appliances is done by interfacing with sensing modules. The output signals from the sensors are integrated and connected to XBee module for transmitting electrical parameters data wirelessly. The XBee modules are interfaced with sundry sensing contrivances and interconnected in the form of mesh topology to have reliable data reception at a centralized ZigBee coordinator. The maximum distance between the adjacent ZigBee nodes is less than 10 m, and through hopping technique of the mesh topology, reliable sensor fusion data has been performed. The ZigBee coordinator has been connected through the USB cable of the host computer to store the data into a database of computer system. The block diagram of the system is shown in Fig.1 and Fig.2. The accumulated sensor fusion data have been sent to a cyberspace residential gateway for remote monitoring and controlling the home environment. By analyzing the potency from the system, energy consumption can be controlled. The appliances are controlled either automatically or manually. The keenly intellective power metering circuit is connected to mains 240 V/50 Hz supply.

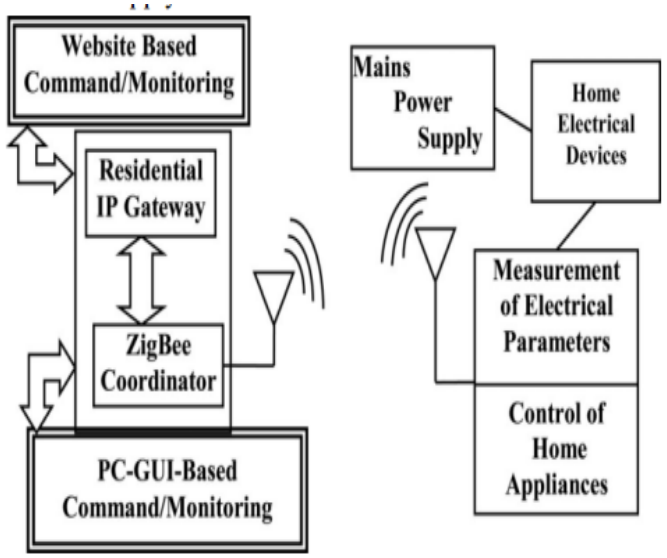

Fig 1. Block diagram of the system.

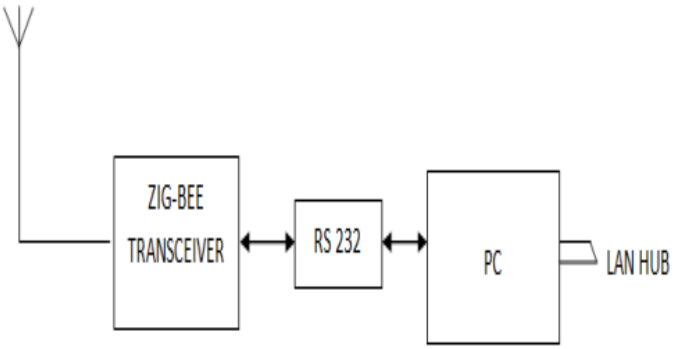

Fig 2. Control unit.

The home automation system is a key for energy conservation that can be equipped in mundane buildings. Nowa-days the injuctive authorization for home automation systems in homes and offices are invariably incrementing. These systems directly work on the household appliances to provide effortless operation and

control of the contrivances. In this paper we have presented the concept of astute home automation to reduce the energy consumption and wastage utilizing advanced graphical software called LabVIEW. It provides the programming implements to code power system applications more facilely, which preserves programming time. With the development of low cost electronic components home automation migrated from being an industrial application to home automation.

A. Zigbee Overview

There are three categories of nodes in a ZigBee system.They are Coordinator, Router and Enddevices.

1) Coordinator: It is responsible for initiating the networkand selecting the network parameters such as radio frequencychannel, unique network identifier and setting otheroperational parameters. It can also store the informationabout network, security keys.

2) Router: Router acts as intermediate nodes, relaying datafrom other devices. Router can connect to an already existentnetwork, also able to accept connections from other devicesand be some kind of re-transmitters to the network. Networkmay be extended through the use of ZigBee routers.

3) End Devices: End Device can be low-power /battery powereddevices. They can collect various information fromsensors and switches. They have sufficient functionality totalk to their parents (either the coordinator or a router) andcannot relay data from other devices.

B. Control of Home Appliances

1) Automatic control: Based on the electricity tariffconditions, the appliance can be regulated with the help ofsmart software. This enables the user to have more costsaving by auto switch off the appliances during theelectricity peak hours. The electricity tariff is procured fromthe website of the electricity supply company and is updatedat regular intervals.

2) Manual control: An on/off switch is provided to directly intercede with the device. This feature enables the user to have more flexibility by having manual control on the appliance usage without following automatic control. Also, with the help of the software developed for monitoring and controlling user interface, user can control the device for its appropriate use. This feature has the higher priority to bypass the automatic control.

3) Remote control: The smart power monitoring andcontrolling software system has the feature of interactingwith the appliances remotely through internet (website). Thisenables user to have flexible control mechanism remotelythrough a secured internet web connection. This sometimesis a huge help to the user who has the habit of keeping theappliances ON while away from house. The user can

monitorthe condition of all appliances and do the needful.

Residential IP Gateway: Transmission Over IPIn order to transmit real-time sensed data over the internetfrom the collected computer system, the ZigBee packetinformation is to be transformed to the Internet ProtocolVersion 6(IPv6). The key element in the data transformationfrom Zig-Bee packet is the address translation. This wasimplemented at the application gateway, a program fordetermining the source or destination address of a packet thatencapsulates a ZigBee packets‟ payload. The corresponding application gateway program performsthe address transformation mechanism for ZigBee to addressnon-ZigBee nodes. ZigBee is based upon the IEEE 802.14.5protocol, which uses a 64-bit address for each node on apersonal area network (PAN) and 16 bits to identify the PANID. IPv6 uses 128 bits to address a node on the network, ofwhich 48 bits represent the network, 16 bits represent thelocal network (PAN ID), and 64 bits represent the host id(sensor node). Therefore, the node address for the IEEE802.15.4 can be placed in an IPv6 address, and the PAN IDcan be used to identify the ZigBee network in an IPv6address.

4. Experimental Results

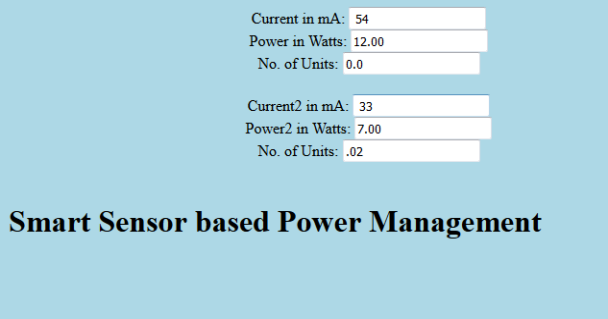

Fig 6: all Devices on power measurements.

5. Conclusion

Keenly intellective monitoring and controlling system for household electrical appliances in authentic time is designed. Thus the potency consumption is minimized by providing periodic alert and managing the potency consumption predicated on the utilization of the customer automatically.The advantages are as follows: no cabling required, facile inclusion of consequential data emanating from other meters similarly equipped with centre to manage the potency in an efficient manner. As a component of future work, prototype has to be designed for implementation of potency management.

rishisowjanya@gmail.com

Abstract

This paper introduced a design and implementation of shift register using pulsed latches and flip-fliops. As flip-flop based shift registers requires a clock signal to operate. Multistage flip-flop processes with high clock switching activity and then increases time latency. Flip-flops also engages fifty percent power out of total circuit power in clocking. To reduce such power consumptions and to achieve area optimization flip-flops are replaced by pulsed latches. The design is implemented with 250nm technology in Tanner EDA Tool. With Vdd=1.8V, Freq=100MHz. Average power of total circuit is 0.465uW and delay of 0.312 us.

Keywords: Flip-Flops, Area Efficient, Pulsed Clocks, Pulsed Latches, Shift Register, Tanner.

1. Introduction

The rapid growth in semiconductor devices and VLSI designs has led to the development of high performance designs with enhanced reliability, customized size and low power, and because of the power dissipation is critical issue for battery operated systems. Therefore the designs are needed to be consuming less power while maintaining comparable performance. So everyone in VLSI design must think about area utilization and power dissipation In low power digital design, mainly shift registers are designed using flip-flops of different types. To achieve area optimization and power consumption different techniques are introduced like use of double edge triggered flip-flip, single feed through scheme based flip-flop, use of multiple voltage supply, clock gating, voltage scaling etc. As it is a type of synchronous circuit all the flip-flops are clocked simultaneously. The flip-flop is basic data storage element. The operation of flip-flop is depend on clock frequency, which consumes 50% power out of total power in a digital design. At present, by decreasing CMOS technology process stated by Moore's law, more transistors can be integrated on the same die [1]. Applying more transistors is accompanied by more switching that brings out more energy dissipation in the form of heat and radiation [2]. The heat and consistency of integrated circuits are addressed as important drivers of low power design procedures in RFID

applications [3-7]. The packaging and cooling cannot remove additional heat, so the matter of heat is significant issue in the era [8]. FFs are addressed as fundamental storage element which is vastly finds application in all types of digital design [9].

Flip-Flop based shift registers are used in digital filters [10], image processing [11]. As the size of image data goes on increasing continuously, the demand of word size of shift registers also goes on increasing to process large image extraction 4K-bit [12].

The Shift registers are formed by cascade connection of flip-flops, sharing the same clock as it is a type of sequential circuit. That means the output of first flip-flop is given as the "Data" input of next flip-flop due to which shifting takes place. The speed of flip-flop is less important than area and power consumption because there is no any circuit between flip-flops in shift register. To reduce power and area smallest flip-flop is selected. Recently pulsed latches have been replaced the flip-flops in many applications, because latches are smaller than flip-flops. This paper proposes a design implementation of shift register using non overlapped pulsed latches, to achieve low power and area optimization. Latches cannot be used in shift register design because of timing problem. The reminder of this paper is organized as follows. Section II presents problem statement. Section III presents Proposed Shift register. Section IV presents SSASPL working. Section V presents simulation designs. Section VI presents Conclusion. Section VII presents Experimental results.

2. Related Work

2.1 Complementary metal oxide semiconductor (cmos):

The MOSFET is used in digital complementary metal–oxide–semiconductor (CMOS) logic, which uses p- and n-channel MOSFETs as building blocks. Overheating is a major concern in integrated circuits since ever more transistors are packed into ever smaller chips. CMOS logic reduces power consumption because no current flows (ideally), and thus no power is consumed, except when the inputs to logic gates are being switched. CMOS accomplishes this current reduction by complementing every nMOSFET with a pMOSFET and connecting both gates and both drains together. A high voltage on the gates will cause the nMOSFET to conduct and the pMOSFET not to conduct and a low voltage on the gates causes the reverse. During the switching time as the voltage goes from one state to another, both MOSFETs will conduct briefly. This arrangement greatly reduces power consumption and heat generation. In this paper section II discuss about D flip flop and pulsed latch using CMOS and section III describes the

CNTFET based D flip flop and pulsed latch. section IV describes the conclusion.

A. CMOS based SET D Flip Flop

SET D-flip flop is designed from power pc603 SET D-FF . The CMOS based flip flop design is shown in Fig.1 .This flip-flop is a Master Slave flip flop structure and it consists of two data paths. As convention nal n-type pass transistors give weak high output, but in this design the n-type pass transistors are followed by an inverter to give strong high output. Hence the SET D-Flip Flop is free from threshold voltage loss. Thus the designed Single Edge Triggered D-Flip-Flop has become more efficient in terms of area, power and speed and hence provides better performance than conventional Flip Flops.

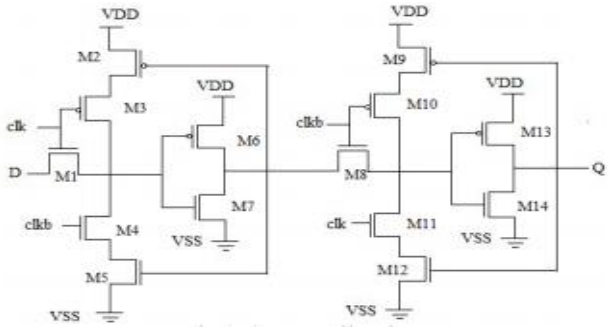

Fig 1. SET D Flip Flop.

B. CMOS based Pulsed Latch

CMOS is the most popular MOSFET technology. Here the SSASPL pulsed latch is realized using the CMOS logic which is shown in fig.2. The SSASPL consists of 15 transistors in which the transistors (M1-M8) are used to generate the pulsed clock signal and the transistors (M9-M15) are the schematic of SSASPL [15].

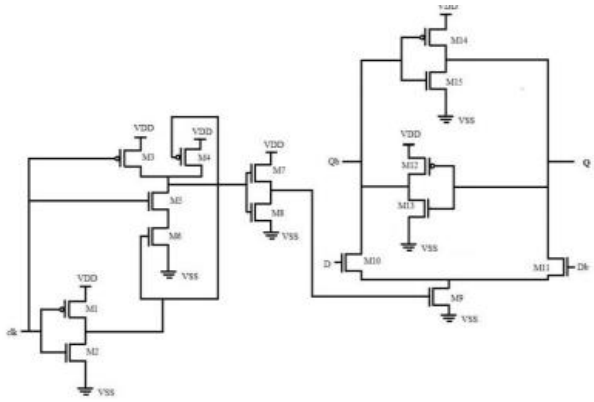

Fig. 2 CMOS based SSASPL

The pulsed clock signal generation circuit consists of AND gate, inverter and clock buffer. The clock signal is given to the inverter which inverts the signal and then the inverter output is given to one input of AND gate and another input is the clock signal which performs the AND operation. The output is given to the clock buffer which stores the data and given to the transistor M9 as the pulsed clock signal. The total size of the clock buffers is determined by the total clock loading of latches. The SSASPL updates the data with three NMOS transistors and it holds the data with four transistors in two cross-coupled inverters. It requires two differential data inputs (D and Db) and a pulsed clock signal. When the pulsed clock signal which is given to the gate of the transistor M9 is high, its data is updated. The node Q or Qb is pulled down to ground according to the input data (D and Db). The pull-down current of the NMOS transistors must be larger than the pull-up current of the PMOS transistors in the

inverters. The power is consumed mainly in latches and clock-pulse circuits. Each latch consumes power for data transition and clock loading.

3. Implementation

3.1 CNTFET: carbon nano tube field effect transistor:

CNT is a carbon allotropic variety which comes from the fullerenes family. It is made of nano sized carbon atom and rolled in seamless cylindrical form of single atomic layered thick graphene sheet [4]. Fig. 3 (a) shows a CNT which is made from one sheet of graphene rolled in cylindrical structure which is called Single Wall Carbon Nanotube (SWCNT) and Fig. 3 (b) shows Multi Walled Carbon Nanotube (MWCNT) where multi-layers of graphene are rolled as

A concentric tube [5-7]. CNT based nano devices are comprised of wide range of nano structures. CNTFET could be used as valve or controlled switch in electronics. Carbon Nano Tube Field Effect Transistors for NEMS are emerging day by day not only in IC industry but also in medical science, mechanical system, automobile industry and recreational instruments [8].

Depending on their chirality (i.e., the direction in which the graphite sheet is rolled), the single-walled carbonanotubes can either be metallic or semiconducting [9], [10]. CNFETs are one of the molecular devices that avoid most fundamental silicon transistor restriction and have ballistic or near ballistic transport in their channel [11],[12]. Therefore a semiconductor carbon nanotube is appropriate for using as channel of field effect transistors [10]. Applied voltage to the gate can control the electrical conductance of the CNT by changing electron density in the channel. By using appropriate diameter suitable threshold voltage for CNFET can be achieved. The threshold voltage of the CNFET is proportional to the inverse of the diameter of CNT and can be expressed as:

A. Nanotube Geometry:

There are three unique geometries of carbon nanotubes. The three different geometries are also referred to as flavors. The three flavors are armchair, zig-zag, and chiral [e.g. zig-zag (n, 0); armchair (n, n); and chiral (n, m)]. These flavors can be classified by how the carbon sheet is wrapped into a tube is shown in Fig.4 A1. Zigzag

The length L of the chiral vector Ch is directly related to the tubule diameter d. The chiral angle 0 between the Ch direction and the zigzag direction of the honeycomb lattice (n,O)[14]. The zig-zag model is the easiest one to count and the best one to try and copy when learning these geometries. Remember, our goal is to start and end at the same point. Hold the starting point between the finger and thumb of one hand

(0,0) and use the other hand to count around the rolled up sheet and try to end where you begin. So, count each carbon atom around the tube - (1, 0) (2, 0) (3, 0) (4, 0) (5, 0) etc., until you get back to the starting point. Once you have done this, you have just made a simple carbon nanotube model. The chiral angle in zigzag is zero.

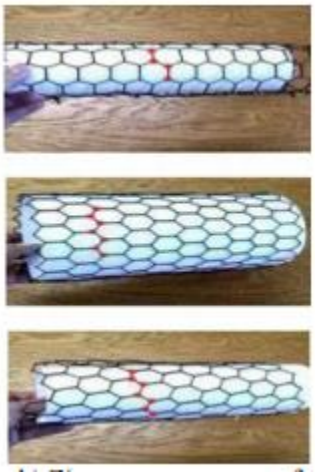

Fig.4 a)Armchair arrangement of carbon atoms b) Zig-zag arrangement of carbon atoms c) Chiral arrangement of carbon atoms.

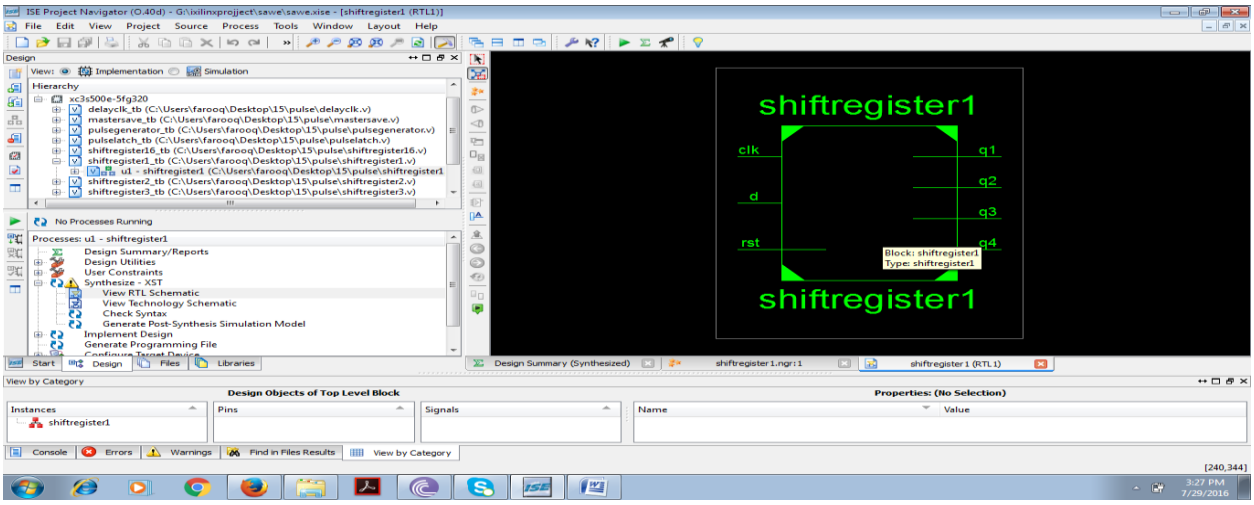
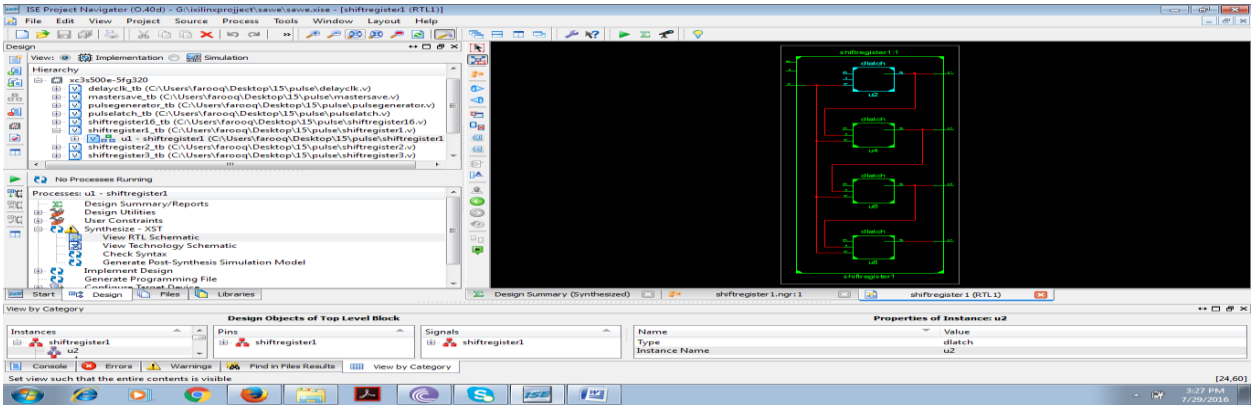
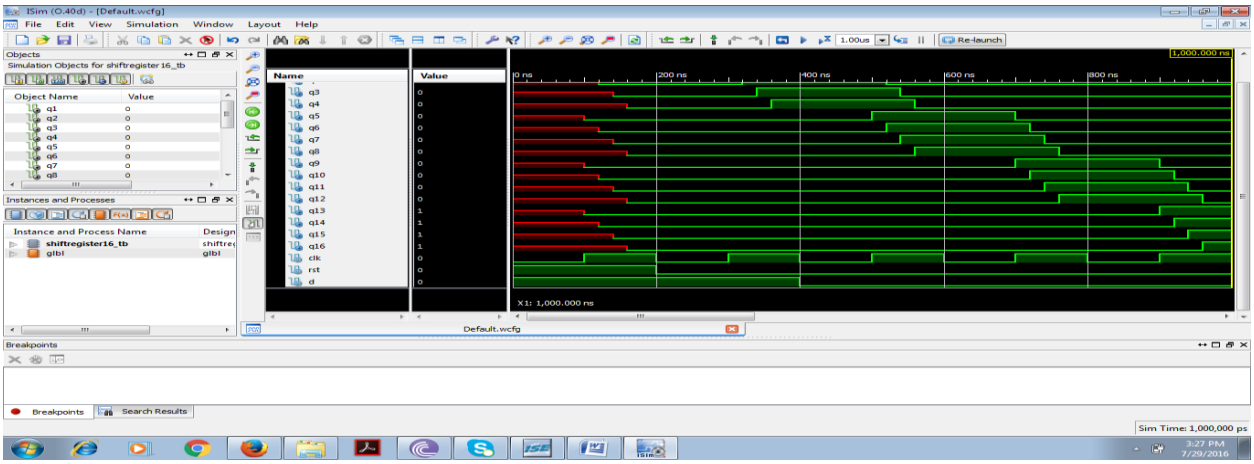
A2. Armchair



When you count around the tube, note that you are counting at an angle and it will not be possible to get back to your starting point unless you turn a corner. Note that you have to pick the right place to turn so that you end up at your starting point because you can only turn once. Again, count each carbon atom around the tube - (1, 0) (2, 0) (3, 0) (4, 0) (5, 0) until you get to a corner; after you turn, the count continues as - (5, 1) (5, 2) (5, 3) (5, 4) etc. - until you get back to the starting point. The chiral angle in armchair is 30 degree. A3. Charial



The last one is the chiral model. I think it is the most difficult to copy. It can be counted similarly like the armchair model because it also has a turn it. Remember to try and end up where you start such that the charial angle fomed will be between 0 and 30 degree. The parameter of CNTFET is shown in the table I



Parameter	Value
Supply Voltage (V_{DD})	1.0v
Physical channel length (L)	32nm
Diameter of the CNT (d)	1.487nm
The length of doped CNT source-side extension region. (L_{SS})	32nm
The length of doped CNT drain-side extension region.(L_{DD})	32nm
The thickness of high-k top gate dielectric material (T_{OX})	4nm
The dielectric constant of high-k top gate dielectric material (K_{OX})	16
The distance between the centers of two adjacent CNTs within the same device.	20nm
Chiral Vector	(19,0)

4. Experimental Work

Output Results are

5. Conclusion

This paper proposed a low-power and area-efficient shift register using digital pulsed latches. The shift register reduces area and power consumption by replacing flip flops with pulsed latches. The timing problem between

pulsed latches is solved using multiple non-overlap delayed pulsed clock signals instead of a single pulsed clock signal.

A small number of the pulsed clock signals is used by grouping the latches to several sub shifter registers and using additional temporary storage latches. A 256-bit shift register was fabricated using a 0.18µm CMOS process with VDD=1.8V. Its core area is 6600µm2. It consumes 1.2 mW at a 100 MHz clock frequency. The proposed shift register saves 37% area and 44% power compared to the conventional shift register with flip-flops.

Employee Management System using RFID Cards & Reader

N.Pandu Ranga Reddy
Associate Professor/ECE
Malla Reddy Engineering College (Autonomous),
Maisammaguda, Secunderabad-500100
Vihaan.anwita@gmail.com

Abstract

Radio Frequency Identification (RFID) is a new generation of Auto Identification and Data collection technology which helps to automate business processes and allows identification of large number of tagged objects using radio waves. RFID based Employee Management System (EMS) would allow complete hands-free access control, monitoring the whereabouts of employee and record the attendance of the employee as well. The access tag can be read up to 5 (~16 feet) meters from the RFID reader, which usually eliminates the need to handle the tag or to walk very close to the reader. This freedom is particularly important to handicapped workers, staff carrying packages. The proposed system is based on UHF RFID readers, supported with antennas at gate and transaction sections, and employee identification cards containing RFID transponders which are able to electronically store information that can be read / written even without the physical contact with the help of radio medium. This paper presents the experiments conducted to set up RFID based EMS.

Keywords: :- API, GUI, RFID, Readers, Tags/Transponders, UHF

1. Introduction

The objective of the paper is to discuss the issues of Radio frequency identification (RFID), what are the concepts of employeemanagement system, cloud based employee management system and give proposed cloud based RFID authentication protocol. RFIDis a technology, which has gained increased attention of researchers and practitioner's. This enables acquisition of data about an objectwithout need of direct line of sight from transponders and readers [4]. To make RFID system more secure, authentication is onesolution. It also maintains the security and privacy of system. Tag identification without authentication raise a security problem. Attackers sometime may tap, change and resend messages from the tag as if it has the tagged object.An Employee management system using RFID becomes efficient on cloud system because it has several advantages like (1) Verifieris enabled to authenticate the tagged objects using any reader over internet. (2) Pay on demand

resource distribution is effective forsmall and medium scale organizations. (3) Cloud is more robust due to resource sufficiency. However, this cloud-based RFID isinsufficient in two aspects. (1) Most current works focused on functionalities without giving importance to security and privacy. (2)No study shows that classical RFID schemes meet the security and privacy requirements of cloud based systems. This system can beeffectively used for calculating the attendance, salary of a particular employee for particular month and for track keeping of him/her.Classical RFID schemes when moved to cloud, they are having the problems of insecure database, privacy of tags and a reader getsrevealed which is not acceptable. Because cloud is publically available to any one and the clients cannot fully trust on the cloudservice providers. So to recover from these drawbacks, cloud-based RFID authentication protocol should get developed. It also securesthe database using hashing technique like SHA1 and maintains the privacy of tags, readers [3]. Successful implementation of thissystem brings the advantages like deployment cost saving, pervasiveness of authentication. Tag verification complexity reduces to O(1). It preserves the privacy of tag and reader holders. It makes the database more secure.

2. Related Work

2.1 Traditional RFID

There is an extensive work on RFID authentication schemes which are, backend server based and server-less [1] [2]. The backendserver based RFID is shown in Figure 1. It is composed of tags, readers and backend server. Readers identify and verify the tags byquerying to backend server. However, the drawback is limited mobility of readers.

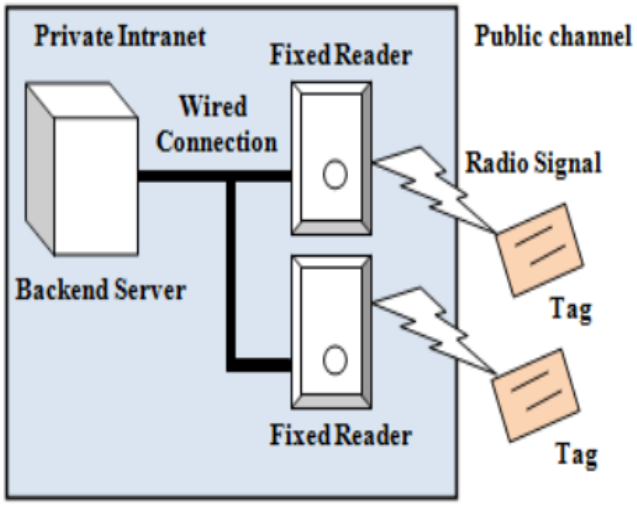

Figure 1: the backend-server-based RFID architecture.

The server-less RFID scheme is shown in Figure 2. It is composed of tags, readers and CA (Certification Agency).

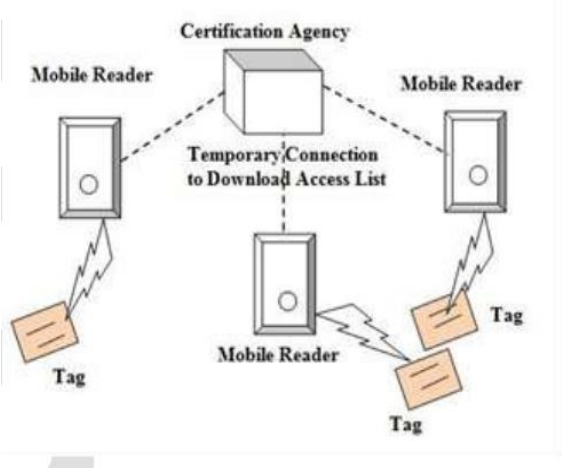

Figure 2: Server-less RFID architecture

There are two phases in server less scheme: initialization and authentication [5]. The mobile reader accesses the CA (Certification Agency) and downloads the AL (Access List) through the secure connection in an initialization phase. The mobile reader is generally a portable device such as notebook computer or smart phones. It might be stolen. Then AL is stored in it. It may wrongly be used to imitate the tags. Credentials of tag authentication are derived with the help of tags key and RID. It makes AL exclusively usable for the reader. But as a result, it is not possible for tag to create a valid request without the RID. In the authentication phase, the reader challenges a tag with RID, waiting for tags response with H (RID, Kt). The reader then searches its AL and finds the matched value to verify the Kt. It then identifies the TID. Sever-less RFID architecture provides readers with the scalability. However, there are drawbacks in server-less authentication protocol. (1) All they transmit RID in plaintext. (2) Searching through AL has complexity of O (N), where N denotes the number of tags. (3) Computational processes of searching and verifying are executed all by single personnel portable device, which reduces the performance significantly.

2.2 Requirements of cloud based RFID

Cloud based RFID has many advantages, but has the challenges of security and privacy. Existing authentication protocols are inapplicable to cloud based employee management system because of lacking two primary capabilities. Firstly, instead of providing protection to front end communication, protection of backend communication is important in Cloud based authentication schemes. Also in cloud based schemes, mobile readers often accesses the public cloud using open wireless connections. There are two solutions for this issue. (1) Establish VPN connections among readers and cloud in a network layer. (2) In application layer design an RFID authentication protocol protecting backend security [1]. Secondly, these schemes are required to prevent the privacy of tags/readers from untrustworthy cloud. Therefore, readers/tags should provide the

confidentiality about data storage, which is against the cloud.

3. PROPOSED SOLUTION

3.1 VPN AGENCY

Existing cloud based RFID system has four participants. They are tag owner, verifier, VPN agency and cloud provider [1] [6]. TheVPN agency has VPN routing between readers and the cloud. Cloud service of RFID authentication is given by cloud provider to theverifier and tag owner. VPN routing makes communication between the reader and cloud as secure as in privet intranet. Attackers areable to intercept, block and resend the TCP/IP packets in the network layer. On the other hand, network-layer-anonymity of readersaccessing the cloud is achieved.

3.2 Encrypted Hash Table

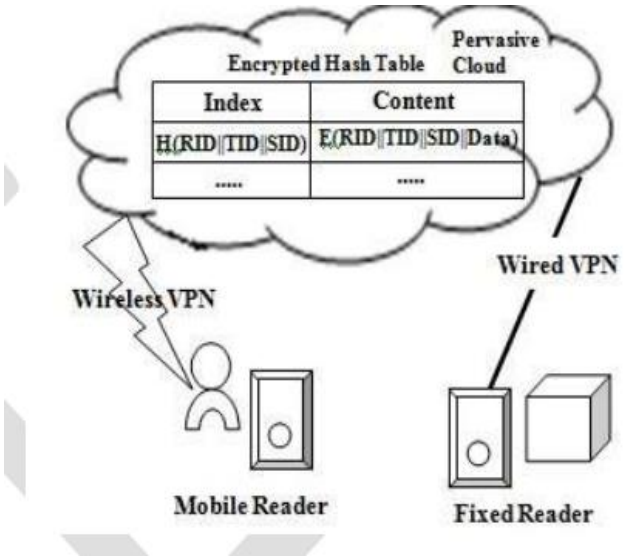

Figure 3: Proposed Cloud-based RFID authentication scheme

An EHT is proposed to prevent client's data confidentiality and access anonymity from revealing to the cloud provider. It is illustrated in Figure 4. The index which is a hash digest H (RID||TID||SID) uniquely denotes the session with SID from the reader with RID to tag with TID. The record indexed by H (RID||TID||SID) is E (RID||TID||SID||Data). It is a cipher text according to the reader defined encryption algorithm with a reader managed key. The RID field is used to check the integrity of the cipher text after decryption by reader. Mutual authentication is done using TID between reader and the tag. The SID field is the identifier which is a term in a reader defined sequence. The data field stores any application data such as location of tag and access time.

3.3 Proposed Cloud-based RFID authentication Protocol

The proposed cloud based RFID authentication protocol is illustrated in Figure 4 [1]. For simplicity, replace RID by R, replace TID by T and SID by S. Encrypted function E (RID||TID||SID||Data) in EHT is now simplified to E (R||T||S). Other notations listed in this section are as shown in Table 1. S+1 is the next incremental term after Sth term in the sequence defined by reader. 1st step is for

the reader to obtain T and S. The tag generates H (T||R||S) as an authentication request and sends generated authentication request to the reader. H (R||T||S) acts as an index to the cipher text E (R||T||S).

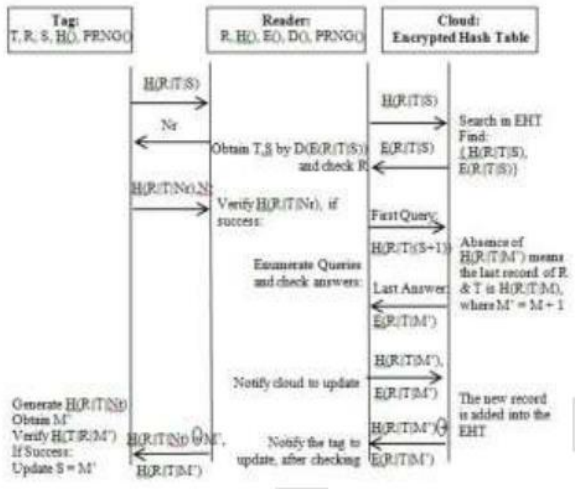

Figure 4: Proposed cloud based RFID authentication Protocol.

The reader does the following operation. (1) It reads the cipher text from the cloud EHT and decrypts it in the useful form (2) It then verifies R for integrity and obtains T and S. Authentication of the tag take place in 2nd step. The reader challenges the tag by generating a random number Nr. The tag calculates hash based on challenge Nr received from reader. The tag uses H (R||T||Nr) to generate random nonce Nt and sends Nt as its challenge to the reader. Synchronization of S between the encrypted hash table (EHT) and the tag take place in 3rd step. The reader checks the integrity after reading the next record indexed by H (R||T||(S+1)) from the EHT. Tag has been desynchronized if the valid record is present in EHT. The reader continues the same action until it finds the last valid record, assuming its SID is M. In 4th step the cloud EHT gets updated. In EHT, cipher text E (R||T||M') having index H (R||T||M') is added by reader, where M'=M+1. A message of H (R||T||M') + H (E (R||T||M')) is send back to the reader from the cloud to confirm that the updating is successful. 5th step is to send a comprehensive response to be verified by the tag. In response to tag's random challenge Nt, reader calculates H (R||T||Nt). For simple encryption, response is XORed with M'. Encrypted M' is sent to tag with index H (R||T||M') and get verified by a tag. 6th step does authentication of the reader and also it repairs the desynchronization. To obtain M', tag calculates H (R||T||Nt). Calculated value gets XORed with the received value H(R||T||Nt) M'. It then calculates and verifies H(R||T||M'). If success, it means the M' is not modified. By updating S=M' on the tag, synchronization is achieved.

4. Implementation

4.1 Mathematical Model

In the proposed cloud based RFID authentication scheme readers anonymously access the cloud through wireless or wired

connections. An encrypted hash table stores the client's secrets in encrypted form so that secrets should not be easily revealed to the cloud [3]. The first RFID authentication protocol is proposed which preserves the privacy of readers and tags.

Defining System:

Consider an organization with N employees S = {}

Identifying input:

Let, S = {Db, U, T, A, R, Cp} Where,

Db = System database with two tables:

- Employee
- RFID track

U is set of users such that,u1, u2, u3… un ϵ U

T is set of users track such that, t1, t2, t3 ….tn ϵ T

A is set of user's attendance such that, a1, a2, a3 …an ϵ A

R is set of user's RFID tag such that, r1, r2...rn ϵ R

Venn diagram of the System:

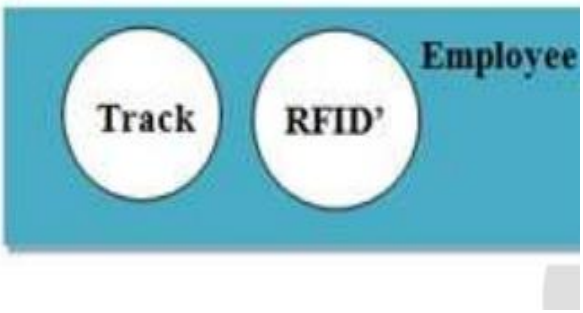

Figure5: Set diagram of employee management system

Functionalities:

The functions of the system are as follows:

(1) U = newEmployee (u_id, u_name, u_add, RFID')

Where,

RFID' = SHA1 (RFID tag)

SHA1 algorithm:

Input: Max 264-1 bit uses 512 bit block size

Output: 160 bit digests

Steps:

Padding message with single one followed by zeros until the final block has 448 bits and appends the size of originalmessage as an unsigned integer of 64 bit.

Initialize the 5 hash blocks (h0, h1, h2, h3, h4) to the specific constants defined in SHA1 standard

Hash (for each 512 bit block)

Allocate an 80 words array for the message schedule

First 16 words are obtained by splitting message into 32 bit block.

Rests of the words are generated by following algorithm:

Word [i-3] XOR Word [i-14] XOR Word [i-16] then left rotate it by 1 bit.

Loop 80 times doing the following:

Calculate SHAfunction() and constant K(these are based on current round number).

e = d

d = c

c = b(rotated left 30)

b = a

a = a(rotated left 5) + SHAfunction() + e + k + Word[i]

Add a, b, c, d and e to the hash output.

Output the concatenation (h0, h1, h2, h3, h4) which is the message digest.

(2) t = newTrackInfo (RFID', location, date, time)

Keep track of particular employee at different time.

(3) a = getAttendenceInfo (RFID', Date)

Calculate employee attendance for particular period.

4.2 Block Diagram of the System

Block diagram of employee management system using cloud based RFID authentication is illustrated in Figure 6. System contains the following parts:

(i) RFID Reader:

It is used to read the tags using radio channels and passes to the verifier for the authentication.

(ii) Webcam:

Webcam is used to take the snapshot when reader tries to read the tag.

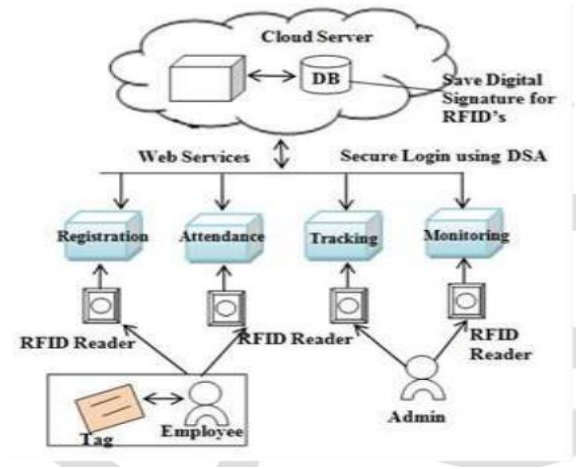

Figure 6: Employee management system using Cloud based RFID authentication

iii. Cloud Service provider:

Cloud service providers are those who provide private/public cloud. Different terminals can be connected to the cloudthrough the internet network. Deploying employee database, tracking database, admin web service module on the publiccloud enable users to access database and web service from anywhere/anytime using Internet.

iv. Admin:

Admin may be the individual machine which has administrative functionality. Admin is connected to cloud service providervia internet connectivity. Admin's web service is deployed on the public cloud which client can access.

v. Client:

Client may be the individual machine or a thin client. Client is connected to cloud service provider using internetconnectivity.

5. Experimental Work

In this system of employee management, a new cloud based RFID authentication protocol is developed which provides securityand confidentiality. It helps for calculating attendance, salary of an employee and also keeps a track of him/her. It provides otheradvantages like deployment cost savings, pervasiveness of service and scalability.Also, Comparison of the tag verification complexity in traditional sever based model, server-less model and cloud-based RFID modelis shown in Figure 7. Both server-based and server less RFID authentication protocols depends on search through the database or ALto find matching TID. It makes computational complexity to verify tags as O (n), where n is number of tags. It means these twoprotocols are not well scalable. In proposed protocol index H(R|T|S) is generated by tag, it is then send to reader. Reader then read thematched record from EHT instead of searching through all TID's. Hence, complexity of proposed scheme is only O (1). That means, itis better scalable than most of the other protocols.

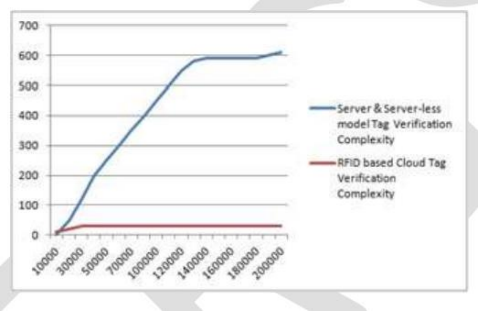

Figure 7: Comparison in the complexity of protocols

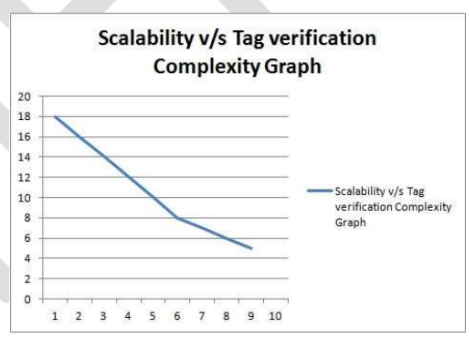

Figure 8: Scalability v/s tag verification complexity graph

6. Conclusion

RFID Based Employee Management System is systematically characterizes the reliability of RFID systems and its dependence on various practical factors. The results will provide important guidelines for real world deployment of RFID-based tracking applications as well as simple yet effective solutions to guarantee reliability. Reading items and objects in motion can be done accurately using RFID. A system developed with a log in windows enables security and the overall cost of implementing the system

may seem high but after a year of running the system, very high benefits will be realized. The whole system is very convenient and saves much on time.

Maisammaguda, Secunderabad-500100
sreenivas43@gmail.com

Abstract

In this paper, we present a carry skip adder (CSKA) structure that has a higher speed yet lower energy consumption compared with the conventional one. The speed enhancement is achieved by applying concatenation and incrementation schemes to improve the efficiency of the conventional CSKA (ConvCSKA) structure. In addition, instead of utilizing multiplexer logic, the proposed structure makes use of AND-OR-Invert (AOI) and OR-AND-Invert (OAI) compound gates for the skip logic. The structure may be realized with both fixed stage size and variable stage size styles, wherein the latter further improves the speed and energy parameters of the adder. Finally, a hybrid variable latency extension of the proposed structure, which lowers the power consumption without considerably impacting the speed, is presented.

This extension utilizes a modified parallel structure for increasing the slack time, and hence, enabling further voltage reduction. The proposed structures are assessed by comparing their speed, power, and energy parameters with those of other adders using a 45-nm static CMOS technology for a wide range of supply voltages. The results that are obtained using HSPICE simulations reveal, on average, 44% and 38% improvements in the delay and energy, respectively, compared with those of the Conv-CSKA. In addition, the power–delay product was the lowest among the structures considered in this paper, while its energy– delay product was almost the same as that of the Kogge–Stone parallel prefix adder with considerably smaller area and power consumption. Simulations on the proposed hybrid variable latency CSKA reveal reduction in the power consumption compared with the latest works in this field while having a reasonably high speed.

Keywords: Carry skip adder, hybrid structure, modified CSKA, Application in the floating point adder.

1. Introduction

Here present a carry skip adder (CSKA) structure that has a higher speed compared with the proposed hybrid CSKA The speed improvement is achieved by applying a new adder in to the structure this chemes to improve the efficiency of the CSKA structure. A hybrid variable latency extension of the proposed structure, which lowers the area consumption without considerably impacting the speed, is presented. Adders are a key building block in

arithmetic and logic units (ALUs) and hence increasing their speed and reducing their power/energy consumption strongly affect the speed and power consumption of processors. There are many works on the subject of optimizing the speed and power of these units, which have been reported in obviously, it is highly desirable to achieve higher speeds at low-power/energy consumptions, which is a challenge for the designers of general purpose processors. In this paper, a modified CSKA used which exhibits a higher speed and lower energy consumption compared with those of the hybrid CSKA one. The speed enhancement was achieved by modifying the structure through. A new type of parallel prefix adder network on the nucleus stage. Nuclease stage is the higher bit width stage on the variable latency network. Here we are using a Lander Fischer adder as a parallel prefix network; here also introduce an optimized RCA. In the optimized RCA sructure we use CBL in the adder offers minimum number of gate count. The CBL worked as a full adder .By using the modified CSKA an efficient floating point adder optimize. The results also suggested the CSKA structure is a very good adder for the applications where both the speed and area consumption. In this paper, given the attractive features of the CSKA structure. The modified CSKA increases the speed considerably while maintaining the low area and delay consumption features of the CSKA.

Hence, the contributions of this paper can be summarized as follows. 1) Proposing a modified CSKA structure by combining parallel prefix network and optimized RCA. Modified CSKA structure for enhancing the speed of the adder. The modification provides us with the ability to use simple Ladner Fischer adder and optimized RCA network.

2) Proposing a modified variable latency CSKA structure based on the extension of the suggested CSKA, by replacing some of the middle stages in its structure withal PPA, which is modified in this paper. 3) Optimized RCA used with minimum gate count.

4) Application of the modified structure in to a floating point adder unit.

2. Related Work

2.1 Modifying CSKAs for Improving Speed:

Alioto and Palumbo [19] propose a simple strategy for the design of a single-level CSKA. The method is based on the VSS technique where the near-optimal numbers of the FAs are determined based on the skip time (delay of the multiplexer), and the ripple time (the time required by a carry to ripple through a FA). The goal of this method is to decrease the critical path delay by considering a noninteger ratio of the skip time to the ripple time on contrary to most of the previous works, which considered

an integer ratio [17], [20]. In all of the works reviewed so far, the focus was on the speed, while the power consumption and area usage of the CSKAs were not considered. Even for the speed, the delay of skip logics, which are based on multiplexers and form a large part of the adder critical path delay [19], has not been reduced.

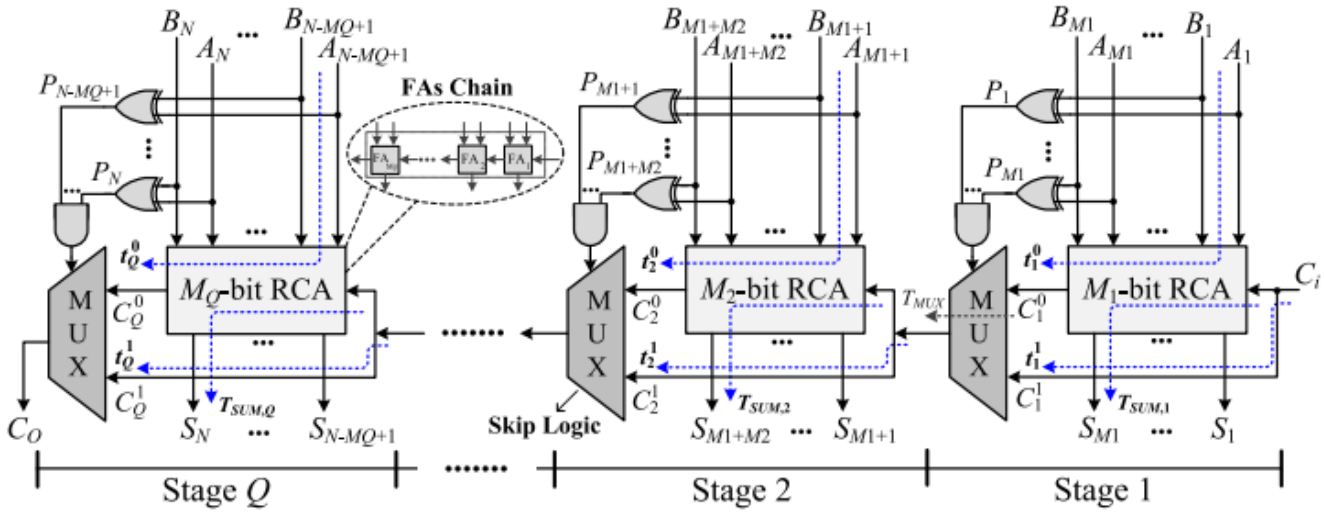

Fig 1. Conventional structure of the CSKA [19].

2.2 Improving Efficiency of Adders at Low Supply Voltages:

To improve the performance of the adder structures at low supply voltage levels, some methods have been proposed in . In adaptive clock stretching operation has been suggested. The method is based on the observation that the critical paths in adder units are rarely activated. Therefore, the slack time between the critical paths and the off-critical paths may be used to reduce the supply voltage. Notice that the voltage reduction must not increase the delays of the noncritical timing paths to become larger than the period of the clock allowing us to keep the original clock frequency at a reduced supply voltage level. When the critical timing paths in the adder are activated, the structure uses two clock cycles to complete the operation. This way the powerconsumption reduces considerably at the cost of rather small throughput degradation.

In the efficiency of this method for reducing the power consumption of the RCA structure has been demonstrated. The CSLA structure in [28] was enhanced to use adaptive clock stretching operation where the enhanced structure was called cascade CSLA (C2SLA). Compared with the common CSLA structure, C2SLA uses more and different sizes ofRCA blocks. Since the slack time between the critical timing paths and the longest off-critical path was small, the supply voltage scaling, and hence, the power

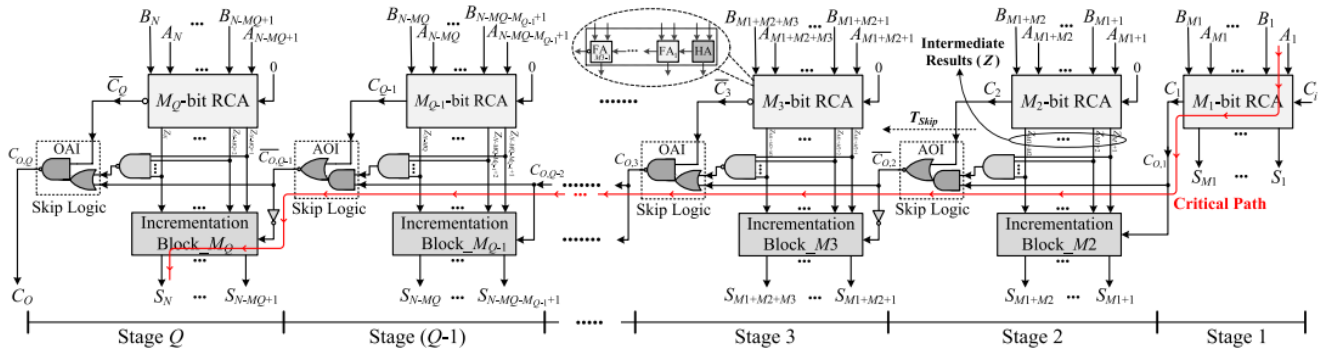
reduction were limited. Finally, using the hybrid structure to improve the effectiveness of the adaptive clock stretching operation has been investigated.

In the proposed hybrid structure, the KSA has been used in the middle part of the C2SLA where this combination leads to the positive slack time increase. However, the C2SLA and its hybrid version are not good candidates for low-power ALUs. This statement originates from the fact that due to the logic duplication in this type of adders, the power consumption and also the PDP are still high even at low supply voltages The CSKA may be implemented using FSS and VSS where the highest speed may be obtained for the VSS structure .Here, the stage size is the same as the RCA block size. In Sections III-A and III-B, these two different implementations of the CSKA adder are described in more detail.

3. Implementation

3.1 PROPOSED CSKA STRUCTURE:

The structure is based on combining the concatenation and the incrementation schemes [13] with the ConvCSKA structure, and hence, is denoted by CI-CSKA. It provides us with the ability to use simpler carry skip logics. The logic replaces 2:1 multiplexers by AOI/OAI compound gates (Fig. 2). The gates, which consist of fewer transistors, have lower delay, area, and smaller power consumption compared with those of the 2:1 multiplexer [37]. Note that, in this structure, as the carry propagates through the skip logics, it becomes complemented. Therefore, at the output of the skip logic of even stages, the complement of the carry is generated. The structure has a considerable lower propagation delay with a slightly smaller area compared with those of the conventional one. Note that while the power consumptions of the AOI (or OAI) gate are smaller than that of the multiplexer, the power consumption of the proposed CI-CSKA is a little more than that of the conventional one. This is due to the increase in the number of the gates, which imposes a higher wiring capacitance (in the noncritical paths).



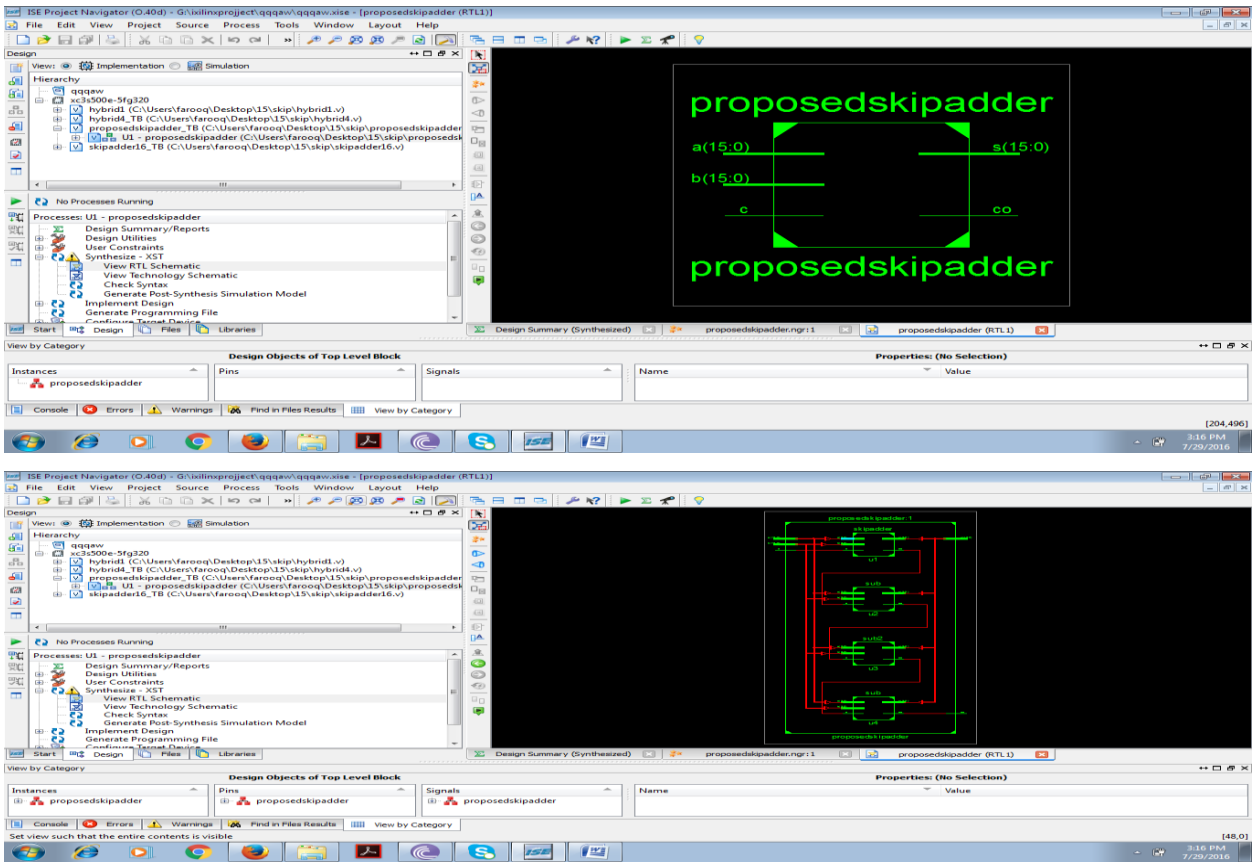


Fig. 2. Proposed CI-CSKA structure.

The reason for using both AOI and OAI compound gates as the skip logics is the inverting functions of these gates in standard cell libraries. This way the need for an inverter gate, which increases the power consumption and delay, is eliminated. As shown in Fig. 2, if an AOI is used as the skip logic, the next skip logic should use OAI gate. In addition, another point to mention is that the use of the proposed skipping structure in the Conv-CSKA structure increases the delay of the critical path considerably. This originates from the fact that, in the Conv-CSKA, the skip logic (AOI or OAI compound gates) is not able to bypass the zero carry input until the zero carry input propagates from the corresponding RCA block.

4. Experimental Result

The design proposed in this paper has been developed using MODEL SIMULATOR. ADDERS are a key building block in arithmetic and logic units (ALUs). Low power arithmetic circuits have become very important in VLSI industry. Adder circuit is the main building block in DSP processor. Adder is the main component of arithmetic unit. A complex DSP system involves several adders. Many design styles of adders exist.

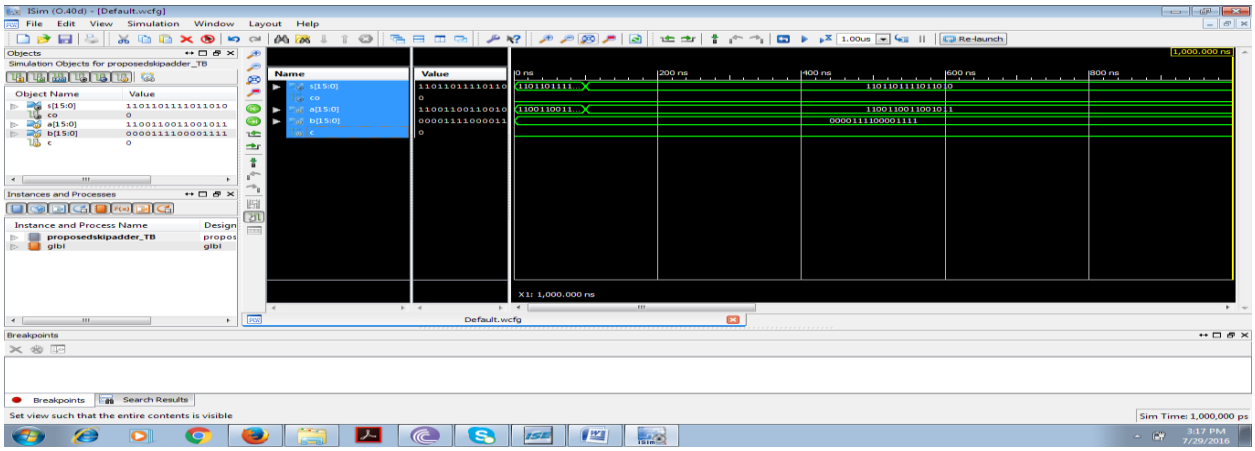

Fig 3 Simulation results

5. Conclusion

In this paper, a static CMOS CSKA structure called CI-CSKA was proposed, which exhibits a higher speed and lower energy consumption compared with those of the conventional one. The speed enhancement was achieved by modifying the structure through the concatenation and incrementation techniques. In addition, AOI and OAI compound gates were exploited for the carry skip logics. The efficiency of the proposed structure for both FSS and VSS was studied by comparing its power and delay with those of the Conv-CSKA, RCA, CIA, SQRT-CSLA, and KSA structures. The results revealed considerably lower PDP for the VSS implementation of the CICSKA structure over a wide range of voltage from super-threshold to near threshold. The results also suggested the CI-CSKA structure as a very good adder for the applications where both the speed and energy consumption are critical. In addition, a hybrid variable latency extension of the structure was proposed. It exploited a modified parallel adder structure at the middle stage for increasing the slack time, which provided us with the opportunity for lowering the energy consumption by reducing the supply voltage.

The efficacy of this structure was compared versus those of the variable latency RCA, C2SLA, and hybrid C2SLA structures. Again, the suggested structure showed the lowest delay and PDP making itself as a better candidate for high-speed low-energy applications.

GSM and GPS FOR Traffic controlling system

B.Sai Prasanna
Assistant Professor
Malla Reddy Engineering College (Autonomous),
Maisammaguda, Secunderabad-500100
kolasaiprasanna@gmail.com

Abstract

Intelligent traffic control systems are advanced applications which, without embodying intelligence as such, aim to provide innovative services relating to different modes of transport and traffic management and enable various users to be better informed and make safer, more coordinated, and 'smarter' use of transport networks. In this project, I attempt to make an intelligent system which helps in congestion control, ambulance clearance and stolen vehicle detection which solves the road safety problems to a greater extend. Each individual vehicle is equipped with special radio frequency identification (RFID) tag. We use RFID readers along with microcontrollers to read the tags attached to each vehicle. It counts the number of vehicles that pass through the path during a specific duration, so that network congestion is determined and hence green light duration for a particular path. If RFID tag belongs to the stolen vehicle, it is informed to the police control room through GSM. In addition if the ambulance is approaching the junction, it will communicate to the traffic controller on the junction to turn the green light on. This module uses ZIGBEE and PIC microcontroller for wireless communication between ambulance and the traffic controller.

Keywords: Embedded Technologies, RFID, GSM and GPS.

1. Introduction

In our daily life we are facing a lot of problems; main thing is traffic congestion which become more serious day after day. It is said that high tome of vehicles, the scanty infrastructure and the irrational distribution of the development are the main reasons for augmented traffic jam. The major cause leading to traffic jam is the large number of vehicles which is caused by the most population and the development of economy. India is the second most populous country in the world and is a fast growing economy. It is seeing terrible road congestion problems in its cities. Infrastructure growth is slow as compared to the growth in number of vehicles, due to space and cost constraints. Also, Indian traffic is non lane based and chaotic. It needs a traffic control solutions, which are different from the developed Countries. To unravel this problem, government should encourage people to use public transport or make use of vehicles with small size as bicycles or make tax on personal

vehicles. Particularly in some Asian countries like Vietnam, the local authorities passed a law limiting the number of vehicles for each family. The methods mentioned above is really efficient in the fact that inadequate infrastructure cannot handle the issue of traffic congestion. The public conveyance is available and its quality is very bad, mostly in the establishing countries. Besides, the highway and roads are incapable of meeting the requirement of increasing number of vehicles. Instead of working on the roads to accommodate for the growing traffic,various techniques have been devised to control the traffic on roads like embedded controllers that areinstalled at the junction.

2. Related Work

2.1 Existing system:

A.MANUAL CONTROLLING

Manual controlling the name instance it require man power to control the traffic. Depending on the countries and states the traffic polices are allotted for a required area or city to control traffic. The traffic polices will carry sign board, sign light and whistle to control the traffic. They will be instructed to wear specific uniforms in order to control the traffic.

B.AUTOMATIC CONTROLLING

Automatic traffic light is controlled by timers and electrical sensors. In traffic light each phase a constant numerical value loaded in the timer. The lights are automatically getting ON and OFF depending on the timer value changes. While using electrical sensors it will capture the availability of the vehicle and signals on each phase, depending on the signal the lights automatically switch ON and OFF.

2.2 Proposed System

A. Intelligent Traffic Control

Intelligent management of traffic flows can reduce the negative impact of congestion. In recent years, wireless networks are widely used in the road transport as they provide more cost effective options. Technologies like ZigBee, RFID and GSM can be used in traffic control to provide cost effective solutions. FID is a wireless technology that uses radio frequency electromagnetic energy to carry information between the RFID tag and RFID reader. Some RFID systems will only work within the range inches or centimeters, while others may work for 100 meters (300 feet) or more. A GSM modem is a specialized type of modem, which accepts a SIM card and operates over a subscription to a mobile operator, just like a mobile phone. AT commands are used to control modems. These commands come from Hayes commands that were used by the Hayes smart modems. The ZigBee operates at low-power and can be used at all the levels of work configurations to perform predefined tasks. It operates in ISM bands (868 MHz in Europe, 915 MHz in USA and Australia, 2.4 GHz in rest

of the world). Data transmission rates vary from 20 Kilobits/second in the 868 MHz frequency band to 250 Kilobits/second in the 2.4 GHz frequency band. The ZigBee uses 11 channels in case of 868/915 MHz radio frequency and 16 channels in case of 2.4 GHz radio frequency. It also uses 2 channel configurations, CSMA/CA and slotted CSMA/CA.

B. Stolen Vehicle Detection System.

In this module, for testing purpose, we compare the unique RFID tag read by the RFID reader tothe stolen RFIDs stored in the system. If a match is found, then the traffic signal is immediately turned to red for duration of 30 seconds. Also an SMS is sent specifying the RFID number by using SIM300 GSM module. The LCD display will indicate that stolen vehicle is present. Here, a GSM modem is connected with the microcontroller. This allows the computer to use the GSM modem to communicate over the mobile network. These GSM modems are most frequently used to provide mobile Internet connectivity, many of them can also be used for sending and receiving SMS and MMS messages. GSM modem must support an “extended AT command set” for sending/receiving SMS messages. GSM modems are a cost effective solution for receiving SMS messages, because the sender is paying for the message delivery. SIM 300 is designed for global market & it is a tri-band.

C. Emergency Vehicle Clearance

In this module, there are 2 parts, first part which is ZigBee transmitter is placed in the emergency vehicle. When the switch is pressed, it will transmit the signal. The signal contains unique id and security code. The transmitter contains PIC16F877A microcontroller and ZigBee module. The microcontroller sends the commands and data to the ZigBee via serial communication. Second part is the receiver, which is placed at traffic pole. It also contains PIC16F877A microcontroller and ZigBee module. The receiver compares the security code received to the security code present in its database. If it matches, then it will turn the green light on. For testing purpose, we used short range RFID reader in our prototype. First, the receiver part is turned on. The red and green signal will be on for 10 seconds duration and orange light will be on for 2 seconds duration one after the other. Secondly, we bring the RFID of stolen vehicle into the range of RFID reader. Then the signal will turn to red for duration of 30 seconds and a SMS is received. Thirdly, we bring 12 RFIDs into the range of RFID reader, and then the green light duration will change to 30 seconds. Fourthly, we bring an emergency vehicle carrying ZigBee transmitter into the range of ZigBee receiver, and then the traffic light will change to green till the receiver receives the ZigBee signal. In the default

condition, red and green light will set for 10 seconds. The time period will be varied according to the traffic conditions, stolen vehicle, and emergency vehicle. The transmitter part is placed in the ambulance. It transmits ZigBee signal continuously. The stolen vehicle RFID number should be updated in the database. If stolen vehicle is found, then it will immediately turn on red light in the signal. It sends immediately a message to authorized person.

3. Implementation

A. Radio Frequency Identification (RFID)

RFID is an acronym for radio frequency identification. Briefly the RF stand for “radiofrequency” and ID means “identifier” that allows an item, for instance a library book, to be identified, accessed, stored, reprogrammed and communicated by using radio waves. Radio Frequency Identification (RFID) is a generic term for non-contacting technologies that use radio waves to automatically identify people or objects. There are several methods of identification, but the most common is to store a unique serial number that identifies a person or object on a microchip that is attached to an antenna. The combined antenna and microchip are called an "RFID transponder" or "RFID tag" and work in combination with an "RFID reader".

An RFID system consists of a reader and one or more tags. The reader's antenna is used to transmit radio frequency (RF) energy. The tag will then modulate the electromagnetic waves generated by the reader in order to transmit its data back to the reader. The reader receives the modulated waves and converts them into digital data. There are two major types of tag technologies. "Passive tags" are tags that do not contain their own power source or transmitter. When radio waves from the reader reach the chip’s antenna, the energy is converted by the antenna into electricity that can power up the microchip in the tag. The tag is then able to send back any information stored on the tag by reflecting theelectromagnetic waves as described above. "Active tags" have their own power source and transmitter.

The power source, usually a battery, is used to run the microchip's circuitry and to broadcast a signal to a reader. Due to the fact that passive tags do not have their own transmitter and must reflect their signal to the reader, the reading distance is much shorter than with active tags.

However, active tags are typically larger, more expensive, and require occasional service. Frequency refers to the size of the radio waves used to communicate between the RFID system components. Just as you tune your radio to different frequencies in order to hear different radio stations, RFID tags and readers must be

tuned to the same frequency in order to communicate effectively. The read range of a tag ultimately depends on many factors: the frequency of RFID system operation, the power of the reader, environmental conditions, physical size of the tags antenna and interference from other RF devices. The Sunrom RFID Card Reader's antenna was designed with a RFID operation at a tag read distance of around 7 cm.

B. Global Position System (GPS)

Global Positioning System (GPS) satellites broadcast signals from space that GPS receivers, use to provide three-dimensional location (latitude, longitude, and altitude) plus precise time. GPS receivers provides reliable positioning, navigation, and timing services to worldwide users on a continuous basis in all weather, day and night, anywhere on or near the Earth. The output is serial data of 9600 baud rate which is standard NMEA 0183 v3.0 protocol offering industry standard data messages and a command set for easy interface to mapping software and embedded devices.

The current GPS consists of three major segments. These are the space segment (SS), a control segment (CS), and a user segment (US).

C. Global System for Mobile Communications (GSM)

GSM uses Frequency Division Multiplexing AND Time Division Multiplexing. FDMA divides the frequency ranges for GSM, which are 890- 915, 935-960 and some others that the book didn't have. Each is divided into 200kHz wide channels. As far as TDMA goes, each time slot is 577 micro seconds long, 8 time slices is a frame, lasting for a grand total of 4.615ms. A multi frame consists of 51 frames, 51 multi frames make up a Super frame, and 2048 Super frames make a Hyper frame which is 2715648 frames. The GSM network can be divided into three parts to illustrate this, consider figure 1. i) Mobile station, ii) Base station subsystem and iii) Network subsystem.

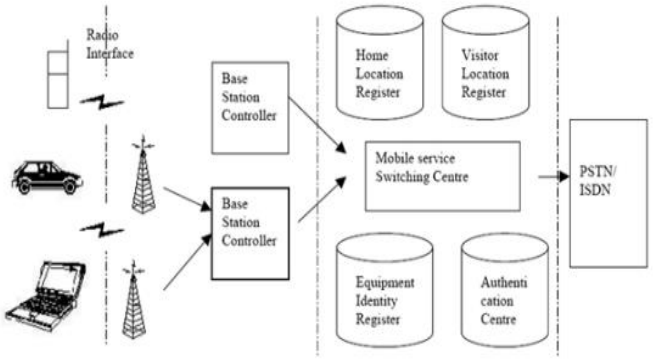

Fig 1: GSM Architecture.

D. ARM Processor

The ARM7TDMI-S is a general purpose 32-bit microprocessor, which offers high performance and very low power consumption. The ARM architecture is based on Reduced Instruction Set Computer (RISC) principles, and the instruction set and related decode mechanism are much simpler than those of micro programmed Complex Instruction Set Computers (CISC).

This simplicity results in a high instruction throughput and impressive real-time interrupt response from a small and cost-effective processor core. Pipeline techniques are employed so that all parts of theprocessing and memory systems can operate continuously. Typically, while one instruction is being executed, its successor is being decoded, and a third instruction is being fetched from memory.

4. Experimental Work

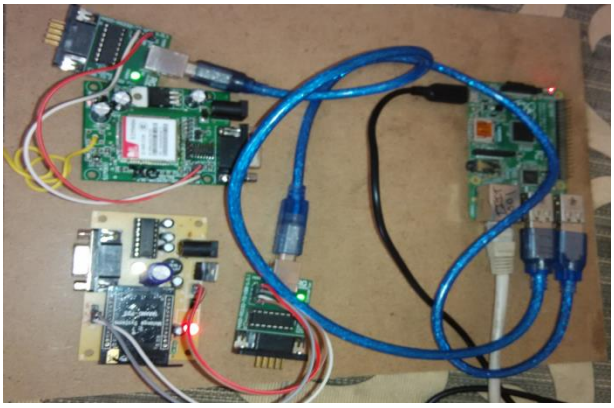

Fig 2: System Circuited Design-1.

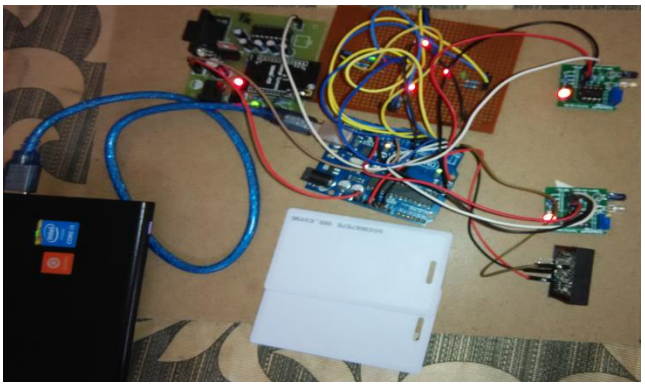

Fig 3: System Circuit Design-2.

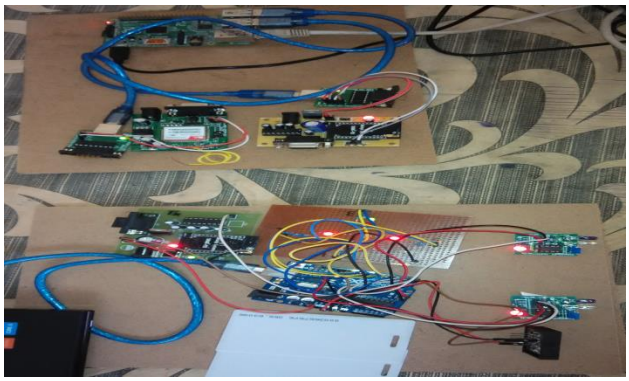

Fig 4: System Circuit Design-3.

Fig 5: System Circuit Design-4.

5. Conclusion

With automatic traffic signal control based on the traffic density in the route, the manual effort on the part of the traffic policeman is saved. As the entire system is automated, it requires very less human intervention. With stolen vehicle detection, the signal automatically turns to red, so that the police officer can take appropriate action, if he/she is present at the junction. Also SMS will be sent so that they can prepare to catch the stolen vehicle at the next possible junctions. Emergency vehicles like ambulance, fire trucks, need to reach their destinations at the earliest. If they spend a lot of time in traffic

jams, precious lives of many people may be in danger. With emergency vehicle clearance, the traffic signal turns to green as long as the emergency vehicle is waiting in the traffic junction. The signal turns to red, only after the emergency vehicle passes through. Further enhancements can be done to the prototype by testing it with longer range RFID readers. Also GPS can be placed into the stolen vehicle detection module, so that the exact location of stolen vehicle is known. Currently, we have implemented system by considering one road of the traffic junction. It can be improved by extending to all the roads in a multi-road junction.

Novel adaptive hold logic circuit for the multiplier using Add round Key and Parallel AES

Konduru Shanthi

Maisammaguda, Secunderabad-500100
kondurusanthi@gmail.com

Abstract

Digital multipliers are among the most critical arithmetic functional units in many applications, such as the Fourier transform, discrete cosine transforms, and digital filtering. The through put of these applications depends on multipliers, if the multipliers are too slow, the performance of entire circuits will be reduced. The negative bias temperature instability effect occurs when a PMOS transistor is under negative bias (Vgs = −Vdd), increasing the threshold voltage of a PMOS transistor and reducing the multiplier speed. Similarly, positive bias temperature instability occurs when an NMOS transistor is under positive bias. Both effects degrade the speed of the transistor and in the long term, the system may be fail due to timing violations. Therefore, it is required to design reliable high-performance multipliers. In this paper, we implement an aging aware multiplier design with a novel adaptive hold logic (AHL) circuit. The multiplier is able to provide the higher throughput through the variable latency and can adjust the adaptive hold logic (AHL) circuit to lessen performance degradation that is due to the aging effect. The proposed design can be applied to the column bypass multiplier.

Keywords: Advanced Encryption Standard, Sub bytes, Shift row, mixed column, Add round Key and Parallel AES.

1. Introduction

Cryptography is the practice and study of hiding information. Applications of cryptography include ATM cards, computer passwords, until modern times cryptography referred almost exclusively to encryption, which is the process of converting ordinary information into unintelligible gibberish. Decryption is the reverse, in other words, moving from the unintelligible cipher text back to plaintext. A cipher is a pair of algorithm which creates the encryption and the reversing decryption. The detailed operation of a cipher is controlled both by the algorithm and in each instance by a key. With the development of information technology, protecting sensitive information via encryption is becoming more and more important to daily life. In 2001, the National Institute of Standards and Technology selected the Rijndael algorithm as the Advanced Encryption Standard (AES), which replaced the Data Encryption Standard (DES). Since AES

has been widely used in a variety of applications, such as secure communication systems, high-performance database servers, digital video/ audio recorders, and smart cards.

The Advanced Encryption Standard (AES) is an encryption standard that comprises three block ciphers, AES-128, AES-192 and AES-256, adopted for different applications. AES is one of the most popular algorithms used in symmetric key cryptography. It is available in many different encryption packages. AES is based on a design principle known as a Substitution permutation network. It is fast in both software and hardware, is relatively easy to implement, and requires little memory. AES has a fixed block size of 128 bits and a key size of 128, 192, or 256 bits, whereas Rijndael can be specified with block and key sizes in any multiple of 32 bits, with a minimum of 128 bits and a maximum of 256 bits. Assuming one byte equals 8 bits, the fixed block size of 128 bits is 16 bytes. AES operates on a 4×4 array of bytes, termed the state. A set of reverse rounds are applied to transform cipher-text back into the original plain-text using the same encryption key. The proposed architecture is FPGA based architectures with high-speed and low area constraints for suitable implementation of Advanced Encryption Standard (AES). The main focus of this paper is to compare different design architectures existing in literature with the proposed ones, based on application specific constraints. Most AES calculations are done in a special field. The AES cipher is specified as a number of repetitions of transformation rounds that convert the input plain-text into the final output of cipher text. Each round consists of several processing steps, including one that depends on the encryption key.

2. Related Work

Verbauwhede, P. Schaumont, and H. Kuo [1] proposed the design and performance testing of an Advanced Encryption Standard (AES) compliant encryption chip that delivers 2.29 GB/s of encryption throughput at 56 mW of power consumption in a 0.18- m CMOS standard cell technology. This integrated circuit implements the Rijndel encryption algorithm, at any combination of block lengths 128, 192, and 25 bits) and key lengths (128, 192, or 256bits). We present the chip architecture and discuss the design optimizations. We also present measurement results that were obtained from a set of 14 test samples of this chip.[2] proposed a high-speed AES IP-core, which runs at 880 MHz on a 0.13- m CMOS standard cell library, and which achieves over 10-Gbps throughput in all encryption modes, including cipher block chaining (CBC) mode. Although the CBC mode is the most widely used and important, achieving such high throughput was difficult because pipelining and/or loop unrolling

techniques cannot be applied. To reduce the propagation delays of the S-Box, the slowest function block, we developed special circuit architecture that we call twisted-binary decision diagram (BDD), where the fan out of signals is distributed in the S-Box circuit. Our S-Box is 1.5 to 2 times faster than the conventional S-Box implementations. The T-Box algorithm, which merges the S-Box and another primitive function into a single function, is also used for an additional speedup. [3] describes the area-throughput trade-off for an ASIC implementation of the Advanced Encryption Standard(AES).Different pipelined implementations of the AES algorithm as well as the design decisions and the area optimizations that lead to a low area and high throughput AES encryption processor are presented. With loop unrolling and outer-round pipelining techniques, throughputs of 30 Gigabits/s to 70 Gigabits/s are achievable in a 0.18-_m CMOS technology. Moreover, by pipelining the composite field implementation of the byte substitution phase of the AES algorithm (inner-round pipelining), the area consumption is reduced up to 35 percent. By designing an offline key scheduling unit for the AES processor the area cost is further reduced by 28 percent, which results in a total reduction of 48 percent while the same throughput is maintained. Therefore, the over 30 Gigabits/s, fully pipelined AES processor operating in the counter mode of operation can be used for the encryption of data on optical links.

3. Implementation

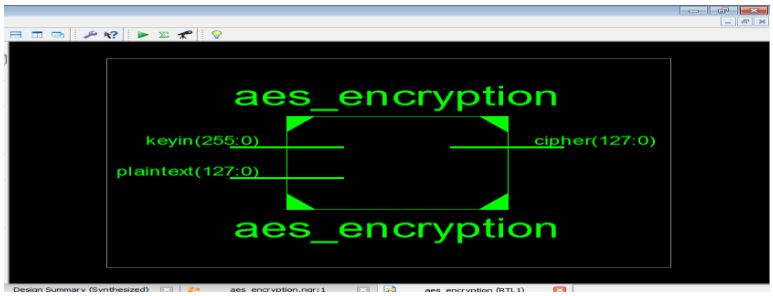
3.1 Existing System:

Composite fields are frequently used in implementations of Galois Field arithmetic. In cases where arithmetic operations rely on table lookups, subfield arithmetic is used to reduce lookup-related costs. This technique has been used to obtain relatively efficient implementations for specific operations such as multiplication, inversion and exponentiation. Much of this work has been aimed at implementation of channel codes. The object has usually been to obtain better software implementations by using smaller tables through subfield arithmetic. Applications to hardware design have been relatively infrequent. Our techniques are directed at both hardware and software implementations. We take advantage of the efficiency obtained by the use of subfield arithmetic, not merely in the matter of smaller tables but the overall low-level (gate count). Complexity of various arithmetic operations. The computation and comparison of such gains and cost is dependent upon several parameters – the overhead of mapping between the original and the composite field representations, the nature of the underlying computation and its composition in terms of the relative frequency

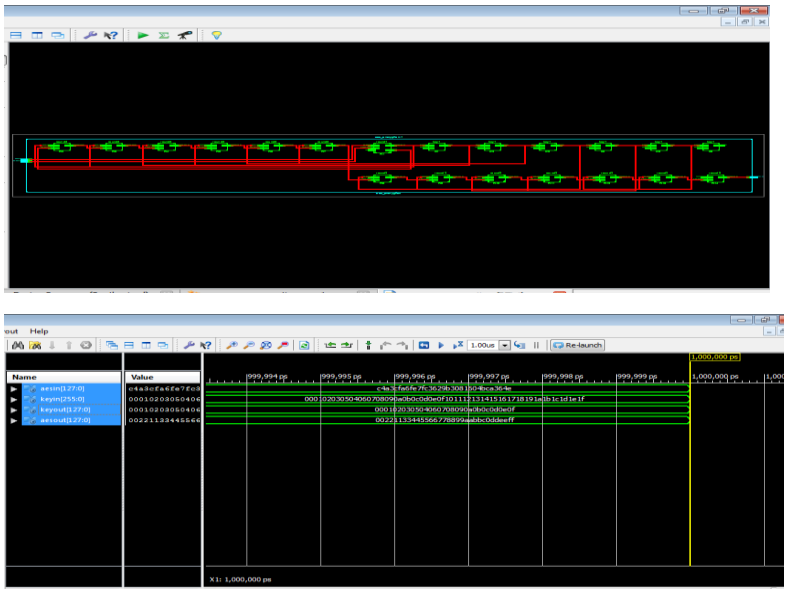
of various arithmetic operations, and in case of software implementations, the constraints imposed by the target architecture and its instruction set. Based on these parameters we select the appropriate field and representation to optimize a hardware circuit design. As we shall see, there can be several objectives for this optimization, such as critical path lengths and gate counts, depending upon the overall design goals. The circuit design obtained can then be used to obtain parallelism in a software implementation by means of slicing techniques.

3.2 Proposed System:

A. Parallel Advanced Encryption Standard (AES)



The proposed system Parallel AES is a symmetric encryption algorithm, and it takes a 128-bit data block as input and performs several rounds of transformations to generate output cipher text. Each 128-bit data block is processed in a 4-by-4 array of bytes, called the state. The round key size can be 128, 192 or 256 bits. The number of rounds repeated in the AES, Nr, is defined by the length of the round key, which is 10, 12 or 14 for key lengths of 128, 192 or 256 bits,



B. steps involved

First Step: Sub Bytes, a non-linear substitution step where each byte is replaced with another according to a lookup table.

- Second Step: Shift Rows, a transposition step where each row of the state is shifted cyclically a certain number of steps.
- Third Step: Mix Columns, a mixing operation which operates on the columns of the state, combining the four bytes in each column.
- Fourth Step: Add Round Key, each byte of the state is combined with the round key; each round key is derived from the cipher key using a key schedule.

4. Experimental Work

5. Conclusion

We discuss three different versions of TIs of AES. We show that it is possible to achieve first-order DPA resistance with nonuniform shared functions if remasking is applied properly. In the case of AES, our “nonuniform” nimble implementation requires less randomness than our “uniform” raw implementation, due to the decreased number of shares. However, for other algorithms and other S-boxes, remasking may increase the amount of randomness required. This idea can be used to trade-off between the randomness and area requirements. Moreover, we empirically confirm that increasing the number of shares has a significant impact on the performance of higher-order attacks, which provides another trade-off between area and DPA resistance. Our most efficient implementation is approximately 8 k GE small and requires only 32 bits of fresh randomness per S-box calculation, which is a significant improvement over all previous works.

Maisammaguda, Secunderabad-500100
shakirabaanu11@gmail.com

Abstract

In this paper, Carry Select Adder (CSA) architecture are proposed using parallel prefix adder. Instead of using 4-bit Ripple Carry Adder (RCA), parallel prefix adder i.e., 4-bit Brent Kung (BK) adder is used to design CSA. Adders are key element in digital design, performing not only addition operation, but also many other function such as subtraction, multiplication and division. Ripple Carry Adder (RCA) gives the most complicated design as-well-as longer computation time. The time critical application use Brent Kung parallel prefix adder to drive fast results but they lead to increase in area. Carry Select Adder understands between RCA and BK in term of area and delay. Delay of RCA is larger therefore we have replaced it with Brent Kung parallel prefix adder which gives fast result. Power and delay of 4-bit RCA and 4-bit BK adder architecture are calculated at different input voltage. This paper describes comparative performance of 4-bit RCA and 4-Bit BK parallel prefix adder designed using TANNER EDA tool.

Keywords: Brent Kung (BK) Adder, Ripple Carry Adder, Power, Delay.

1. Introduction

In this paper, describe demand for high-speed arithmetic units in digital image processing units, DSP and other processor chips has superimpose the path for develop of highspeed adders as addition is an essential operation in almost every arithmetic unit, also the basic building block for combination of all other arithmetic logical computations .To increase portability of systems and battery life, delay and power are the ensuring the success of concern. Even in servers and personal computers (PC), power efficient is a vital design parameter. In now day's scenario, Design of power-efficient high-speed logic systems in VLSI design techniques. In digital adders, the speed of addition is limited time required by the carry to generate through the adder. In present scenario, where Computations need to be performed using low-power circuit that must operate at high speed which is achievable with lesser delay that's why this paper describes comparative performance of 4-bit RCA and 4-Bit BK parallel prefix adder designed using TANNER EDA tool. Finally delay, power for the design adder presented and compare.

I. DRAWBACKS OF RIPPLE CARRY ADDER

Multiple full adder circuits can be rapidly cascaded in parallel to addition of N-bit number. For an N- bit cascaded parallel adder, there must be N number of full adder circuits [1]. A ripple carry adder is a logic circuit in which the carryout of each full adder parameter is the carry in of the following next most significant full adder. It is called a ripple carry adder because each and every carry bit gets wind up into the next stage of adder. In figure1, the first sum bit should wait up until input carry is given; the second sum bit should wait up until previously carry is propagated and so on. Finally the output sum should wait up until all previous carries are generated. So it results in delay.

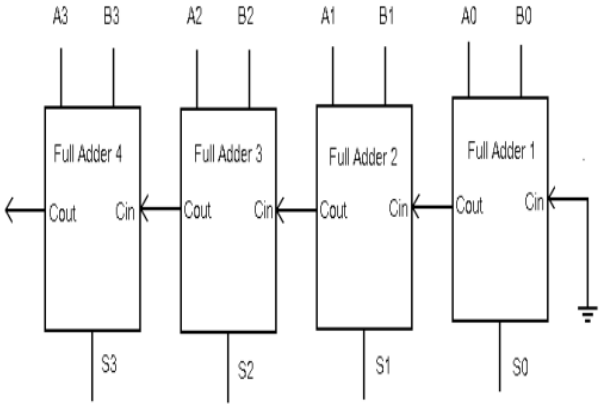

Fig 1. 4-bit ripple carry adder.

2. Related Work

2.1 PARELLEL PREFIX ADDERS:

These are used to take the binary additions because of their flexibility. Carry Look Ahead Adder's (CLA) structure is utilized in order to get the parallel prefix adders. Tree structures algorithm are used to increase the speed high performance of arithmetic operation. Parallel prefix adders are used for high performance arithmetic circuits in industries as they increase the speed of operation. The construction of parallel prefix

Adder involves three stages:

1. Pre- processing stage
2. Carry generation Process
3. Post processing stage

Pre-possessing stage:-

Generate and propagate signals to each pair of the inputs A and B are computed in this stage. These signals are given by the,

Following equations:

$$Pi=Ai \text{ xor } Bi \quad (1)$$

$$Gi=Ai \text{ and } Bi \quad (2)$$

Carry generation network:-

In this stage, carries equivalent to each bit is calculated. All these operations are implemented and carried out in parallel. Carries in parallel are segmented into smaller pieces after the implementation of the stage. Carry propagate and generate are used as intermediate signals which are given by the logic equations3& 4:

$$CPi:j=Pi:k+l \text{ and } Pk:j \quad (3)$$

$$CGi:j=Gi:k+l \text{ or } (Pi:k+l \text{ and } Gk:j) \quad (4)$$

The operations involved in fig. 1 are given as:

CPO=Pi and Pj

(3(i))

CGO=(Pi and Gj) or Gi

(3(ii))

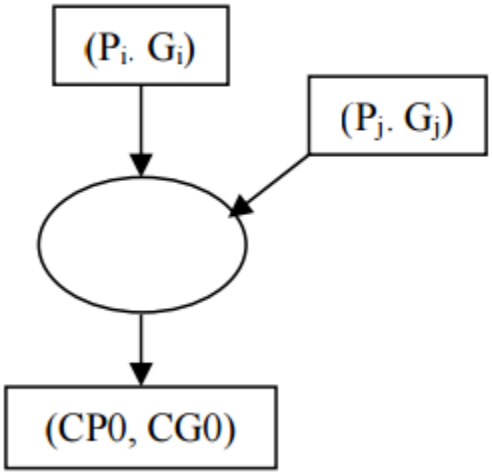

Fig 2. Carry Network.

Post processing Stage:-

This is the concluding step to compute the summation of input bits. It is similar for all the adders and then sum bits are computed by logic operation equation 4& 5:

Ci-1= (Pi and Cin) or (4)

Si=Pi xor Ci-1 (5)

Brent-Kung Adder:-

Brent-Kung adder is a very popular and widely used adder. It actually gives an excellent number of stages from input to all outputs but with asymmetric loading of Intermediate stages. It is one of the parallel prefix adders. It is one of the parallel prefix adders where these adders are the ultimate class of adders that are based on the use of generate and propagate signals. In case of Brent Kung adders along with the cost, the wiring complexity is also less. But the gate level depth of Brent-Kung adders is 0 (log2 (n)), so the speed is lower. The block diagram of 4-bit Brent-Kung adder is shown in Fig. 3.

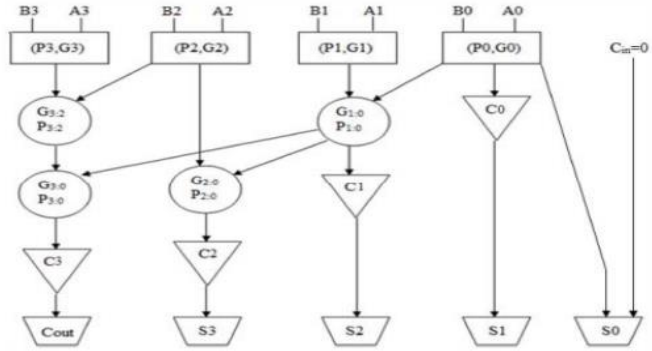

Fig 3. Tree Diagram of 4-bit Brent Kung Adder.

3. Implementation

3.1 4-BIT RIPPLE CARRY ADDER:

This fig. 4 has CMOS Ripple-carry select adders are the simplest and most compact full adders, but their concert is limited by a carry that must propagate from the least - significant bit to the most- significant bit Ripple Carry Adder (RCA) gives the most compact design as-well-as longer computation time.

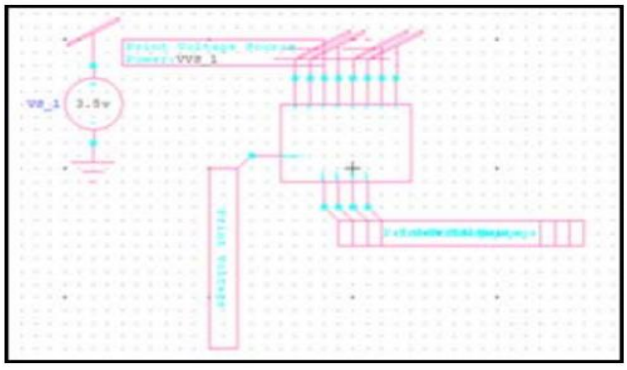

Fig 4. 4-BIT RCA Schematic.

Figure 5 is the output waveform for 4 bit RSA structure. Input is varied from 0000 to 1111 and

corresponding output is observed at each instant of time. Waveform is seen in W-edit window of tanner

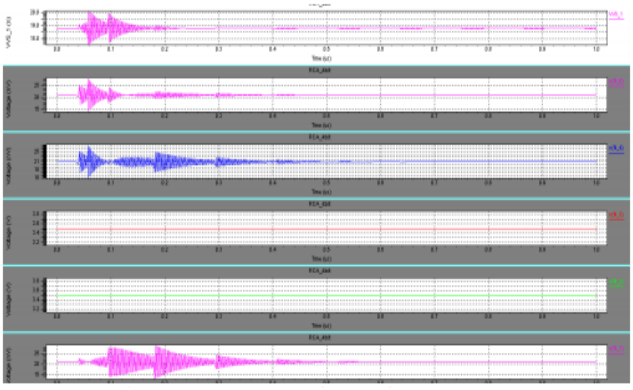

Fig 5. Output Waveform of 4-BIT RCA.

4. Experimental Work

Various adders were designed in Tanner EDA version 13.0 tool using CMOS technology. Power consumption and delay of Ripple Carry Adder and Brent Kung prefix adder 4-Bit word size. The comparison of various adders for different parameters like delay and power consumption is shown in Table I. The result analysis shows that Brent Kung Carry Select Adder shows better results than the Ripple carry adder architectures in terms transient analysis of delay and high speed at different input voltages but with a small powerpenalty. The graphical representation of comparison of RCA and BK CSA for different input voltages for power and delay consumption is shown in fig. Results show BK CSA better results than RCA.

TABLE I. COMPARISON OF RCA AND BK-CSA ADDERS FOR TRANSIENT DELAY AT VARIOUS INPUT VOLTAGES.

Adder	Supply Voltage Transient Delay(sec)				
	3V	3.5V	4V	4.5V	5V
4-Bit RCA	1.23	1.30	0.95	2.31	0.94
4-Bit BK CSA	0.20	0.20	0.16	0.16	0.19

Figure 8 is the graphical representation of comparison of RCA and BK CSA at different input voltages for transient Delay is shown in fig. Results show that BK CSA strongly high speed results than RCA.

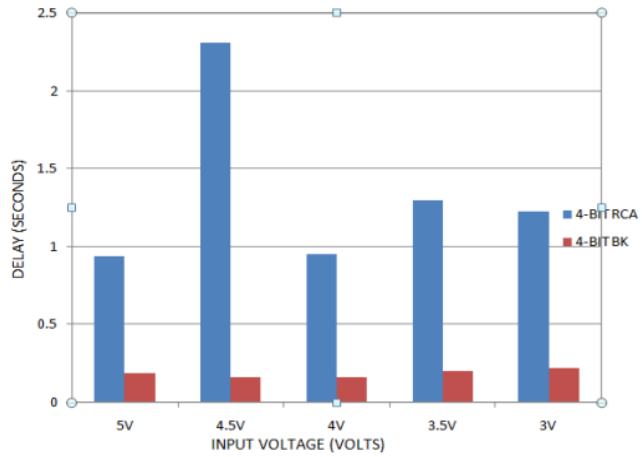

Fig 8. Comparison of RCA and BK CSA Adders for Transient Delay at Various Input Voltages.

Figure 9 is the graphical representation of comparison of RCA and BK CSA at different input voltages for power consumption is shown in fig. Results show that RCA slightly better results than BK CSA.

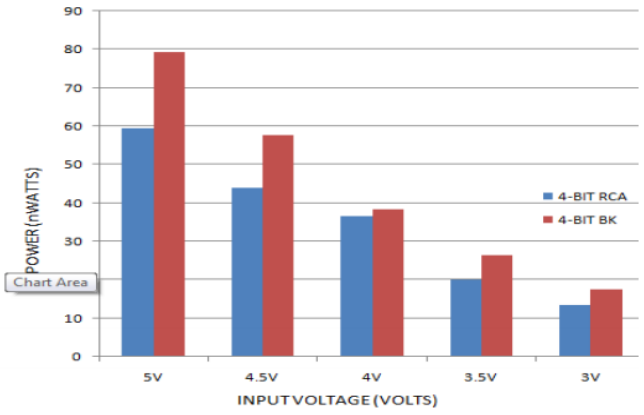

Fig 9. Comparison of RCA and BK CSA Adders for Power at Various Input Voltages.

5. Conclusion

This work can be extended for higher number of bits also. By using parallel prefix adder, delay and power consumption of different adder architectures is reduced. As, parallel prefix adders derive fast results therefore Brent Kung adder is used. The calculated results conclude that BK Carry Select Adder is better in terms of power consumption and high speed whencompared with RCA adder architectures and can be used in different applications of adders like in multipliers, to execute different algorithms of Digital Signal Processing like Finite Impulse Response, Infinite Impulse Response etc.

Retention Time Reliable Gain Cell Low power operation Speed Data

Kancheti Spandana

kanchetispandana@gmail.com

Abstract

Memories have occupied increasingly large portions of the die area of VLSI systems-on-chip (SoCs), in general, and of microprocessor. This is due to the large 6-transistor (6T) SRAM bitcell and its area-consuming peripheral circuitry that are the basis for the vast majority of these. In addition, the standby power of ultralow-power (ULP) systems, such as biomedical implants and wireless sensor networks, is often dominated by embedded memories, which continue to leak during the long retentive standby periods that characterize these systems. Logic compatible gain cell (GC)-embedded DRAM (eDRAM) arrays are considered an alternative to SRAM due to their small size, nonratioed operation, low static leakage, and two-port functionality. However, traditional GC-eDRAM implementations require boosted control signals in order to write full voltage levels to the cell to reduce the refresh rate and shorten access times. These boosted levels require an extra power supply or on-chip charge pumps, as well as nontrivial level shifting and toleration of high voltage levels. In this brief, we present a novel, logic compatible, 3T GC-eDRAM bitcell that operates with a single-supply voltage and provides superior write capability to the conventional GC structures.

Keywords: Access speed, Data Retention Time, Reliable, Embedded DRAM, Gain cell, Low power operation.

1. Introduction

In recent years, memories have occupied increasingly large portions of the die area of VLSI systems-on-chip (SoCs), in general, and of microprocessors, in particular, as shown in the latest ITRS edition [1]. This is due to the large 6-Transistor (6T) SRAM bitcell and its area-consuming peripheral circuitry that are the basis for the vast majority of these memories. In addition, the standby power of ultra-low power (ULP) systems, such as biomedical implants and wireless sensor networks, is often dominated by embedded memories which continue to leak during the long retentive standby periods that characterize these systems. 6T SRAM has been the traditional choice for the implementation of embedded memories due to its high-access speed and refresh-free static data retention. However, the 6T bitcell has several drawbacks in modern systems, including its large transistor

count, its impeded functionality under voltage scaling, and the aforementioned static leakage currents from the supply voltage (VDD) to GND. One of the interesting alternative implementations that addresses these limitations, while continuing to provide full CMOS logic compatibility, is gaincell (GC) embedded DRAM (eDRAM), such as the circuit illustrated in Fig. 1(a) [2]–[5]. Most often consisting of two (2T) or three (3T) transistors, GC-eDRAMs provide a reduced silicon footprint, along with inherent 2-port functionality, nonratioed circuit operation, and very low static leakage currents from VDD to GND. However, as opposed to static memories, Reduced silicon footprint, along with inherent two-port functionality, nonratioed circuit operation, and very low static leakage currents from VDD to GND. However, as opposed to static memories, such as SRAM, the data retention of GC-eDRAM depends on dynamically stored charge, and thereby requires periodic, power-hungry refresh operations.

2.1 EXISTING METHOD

A. 6T SRAM

Basic static RAM circuits can be viewed as vibrations on the designs used for latches and flip-flops more aggressive static RAMs make use of design tricks originally developed RAMs to speed up the system. The value is stored in such as SRAM, the data retention of GC-eDRAM depends

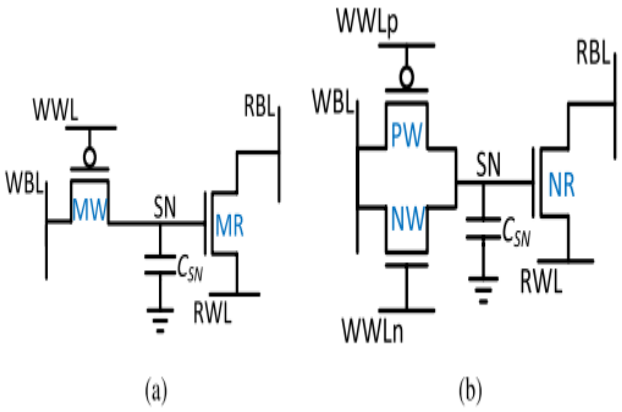

Fig 1. Schematic of conventional and proposed GCs. (a) 2T mixed GC. (b) Proposed 3T GC.

the middle four transistors, of Fig.2 which form a pair on inverters connected in a loop. The other two transistors control access to the memory cell by the bit lines. When select = 0, the inverters reinforce each other to store the value. A read or write is performed when cell is selected. To read, bit and bit are precharged to before the select line is allowed to go high. One of the cell's inverters will have its output at 1, and the other at 0, which inverter is 1 depends on the value stored. The right hand inverter's pull down and the bit line will be drained to through that inverter's pull down and the bit line will remain high. If the opposite value is stored in the cell, the bit lines will be pulled own while bit remains high. To write, the bit and bit lines

are set to the desired value, then select is set to 1.charge sharing forces the inverters to switch values, if necessary, to store the desired value. The bit lines have much higher capacitance than the inverters, so the charge on the bit lines is enough to overwhelm the inverter pair and cause it to flip state.

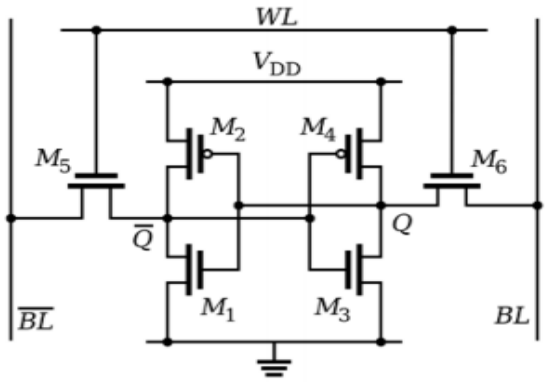

Fig 2: Fig.1 6T SRAM

B. 2T Mixed Gain Cell

2T mixed GC can be implemented with either an NMOS or a PMOS device as shown in Fig.3. Moreover, both MW (write transistor) and MR (read transistor) can be implemented with standard threshold voltage core or high threshold voltage I/O devices in the considered CMOS technology. Due to the voltage drop across MW, a boosted write word line (WWL)voltage is required during write access above for NMOS operation and below for PMOS operation. For a read operation a PMOS MR requires a pre-discharge of the parasitic RBL capacitance followed by raising the read word line (RWL). If the selected bitcell's storage mode (SN) holds a loop value,MR is conducting and charges RBL post a detectable sensing threshold. If SN holds value MR is cut-off such that RBL remains discharged below the sensing threshold. For the NMOS implementation of MR, the operation is exactly opposite i.e. RBL is precharged and RWL is lowered to initiate a read.

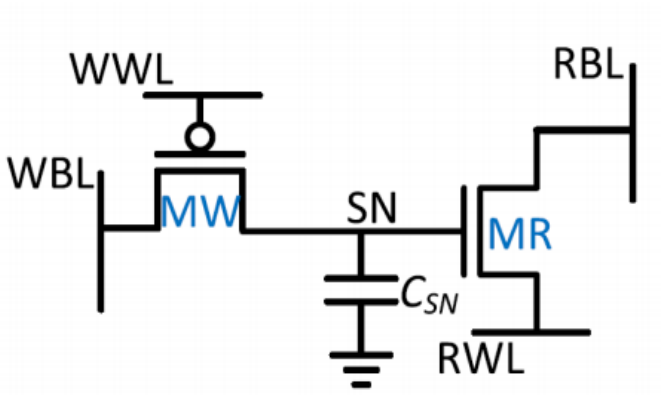

Fig 3. 2T Mixed Gain Cell.

3. Implementation

3.1 PROPOSED METHOD

In this brief, we present a new topology for a 3TGC, featuring a complementary transmission gate in the write port. While the proposed solution is quite straight forward it is novel and its impact in very high. We demonstrate the functionality of the proposed system used in ultra-low power applications such as biomedical sensor nodes and implants. The proposed 3T GC-eDRAM macro is shown to be fully functional with a supply voltage ranging from 600mv to 2.5v.

A. 3T Gain Cell eDRAM

3T GC consists of write port featuring a complementary transmission gate PMOS write (PW) and NMOS write (NW) a storage node (SN) composed of the three transistors, a read port based on NMOS read (NR) and the metal interconnect as in Fig 3. the GC is built that all the transistors operates with standard voltage and is fully compatible with standard digital CMOS technologies. The gates of PW and NW are connected to the world line of PMOS and NMOS WWLp and WWLn. A common write bit line is used to drive the data to the transmission gate during write operations. When the fullswing is given to the cells transmission gate enables the propagation of strong levels to the SN without any need for boosted world line. Read operation is performed by precharging the read bit line (RBL) to and subsequently driving the read word line (RWL) to GND. If the storage node is already high it discharges RBL capacitances or blocking the discharge path if SN is low. IN order to achieve a tradeoff between speed, area, power and reliability, a dynamic sense amplifier can be used to improve the read operation and its performance as described in [5],[6].

B. Operation

The circuit is described with = 900 mv. This voltage was chosen as a good medium voltage between and since the data retention time (DRT) is proved to be efficient in. GC-eDRAM design [8] at this voltage starting with charged WBL is driven low and the world lines WWLp is set to 0 and WWLn is set to. Then a strong 0 level is passed to the SN, during standby, the level on SN deteriorates due to leakage currents dominated by the sub threshold leakage of PW and NW in mature CMOS nodes. Hence in order to extend the retention time WBL is driven to during standby and read cycles thereby significantly reducing the sub threshold leakage through the transmission gate for both stored low and high values compared with the condition where WBL is either driven to either or GND. The write circuitry and read circuitry are described in section IV.A. During readout the 0 level blocks the discharge paththrough NR, maintaining the precharged voltage on RBL. During the next write operation WBL is driven high, resulting in a strong 1 stored on the SN. The subsequent read operation provides a strong gate overdrive to transistor NR, thereby discharging RBL toread a 1. It should be noted that during this operation (Read 1), bitcells storing 1 and sharing thesame column turn on when RBL discharges by more than the of NR, causing it to saturate before it can completely discharge. This phenomenon is common to many GC-eDRAM configurations, as discussed in[8].

C. Data Retention Time

The data retention time (DRT) of GC embedded DRAMS is the time interval for writing a data level in the bit cell to the last moment the data can still correctly read out the stored information. For 2T and 3T cells methodology which are affected by the initially degraded voltage level corresponding to the data values due to the threshold voltage (V_t) drop across the write transistor DRT is primarily limited by the initial charge stored on the internal bit cell capacitance and the leakage currents that degrade the stored voltage level over time. In order to describe this issue a boosted write world line (WWL) voltage is usually employed to pass a full swing level to the storage capacitance. Any how this requires the generation of boosted on-chip voltage, which entails substantial overhead [1]. The magnitude of the voltage boost is set not only to overcome the drop, but also to achieve short write access time which otherwise are typically longer than 6T SRAM implementation. The proposed bitcells provides strong initial data levels for enhanced DRT and robust operation as well as for fast write access time.

3.2 MEMORY MACRO PERIPHERALS

To improve the array performance in terms of access time and power consumption several peripheral techniques were integrated into the designed memory macro in the proposed technique single supply voltage is provided to the circuit which simplifies the implementation of a full memory macro. This is the significant advantage over the other GC eDRAMS that uses conventional bit cells. These bit cells require the use of level shifters to create the desired boosted or negative voltage supply depending on the types of MOS write. The peripheral circuit which is designed for this memory macro and their techniques are described as follows.

A. Readout Circuitry

Large number of ultra low power systems comprising of low voltage embedded memories consists of simple sense inverter. This sense inverter is used for the purpose of reduction in area, robust and low power readout operation however this inverter suffers from very slow data readout as it requires RBL to be discharged or charged for PMOS read device switching the threshold of the inverter. This operation is further impeded by the before mentioned. In order to overcome this limitation the readout path that was integrated into the proposed 3T GC-eDRAM macro cell has two sensing node 1). A faster dynamic sensing mode but it is potentially more error-phrone which acts in dynamic readout mode 2). A slightly slower static mode but more reliable. In both the sensing modes however threshold device PMOS transistors were used in order to allow a faster read access time due to the above mentioned

problem the read out circuitry is provided the supply voltage through the read enable signal in order to save substantial static power because of the leaky low voltage

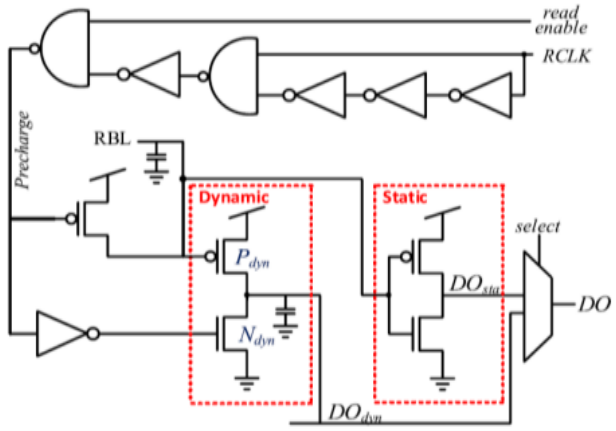

Fig 4.ReadOut Circuitry.

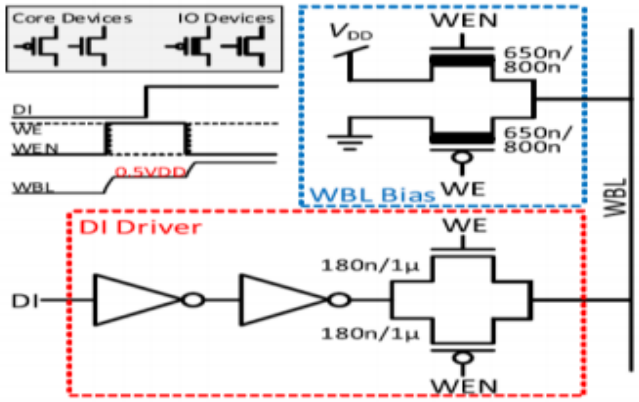

Fig 5. Write Circuitry.

threshold devices the schematic diagram with the two sensing nodes of static and dynamic are shown in Fig. 4.RBL saturation during readout that slows down the charging and discharging operation as the RBL voltage increases and decreases.

The raising edge of the read clock (RCLK) creates a precharge pulse that charges the parasitic capacitance of RBL and discharges the dynamic sense inverter output capacitance through the discharge transistor, . Subsequently RBL is conditionally discharge during read operation turning on to complement the output if high value is stored in the selected cell. Therefore an RBL swing of only one threshold voltage is required to complete a read operation.

B. Write Circuitry

The proposed single supply 3T bit cell provide a significant improvement in write time when compared to the read time, which means it has fast access time, when compared to the readout circuitry. It also has an initial SN level improvement over standard GC implementation the dual transistor write port built by means of transmission gate provides a leakage path to or from the storage node. The write circuitry to implement the median WBL bias during standby and read cycle is shown in Fig.5. The increased aggregated sub- current causes faster degradation of the stored charge, leading to reduced DRT, as compared with a reference 2T cell. In addition, several previous works have shown that the data dependent, asymmetric DRT (for data 0 and 1) of standard GCs can be manipulated to overall enhance DRTs by biasing the WBL at the best case voltage for the weaker data level during standby and read operations . For the proposed 3T configuration, the worst case DRTs of the 1 and 0 levels are similar, and significant deterioration of the

stored levels occurs for both extreme values of WBL bias (VDD and GND).

Fig :- Out Screen -2

5. Conclusion

This brief proposes a novel 3T GC eDRAM microcell targeted at ULP systems and providing high storage density. The proposed GC is operated from a single-supply voltage, eliminating the need for boosted voltages, commonly found in prior-art implementations. When compared with 6T SRAM technology and 2T mixed gain cell technology it has less consumption of power and becomes fully functional at the voltage range of 600mv to 2.5v showing a worst case Data Retention power of 4.6 nW at 900mv.The proposed cell exhibits faster write-access than conventional GC circuits, thereby increasing DRTs and reducing refresh power consumption. The average power consumption at write access time is less than that of read access time. Measurement results show full functionality at voltages ranging from 600 mv to 2.5 V with power as much as lower than a previously reported 6T SRAM in the same technology node. Testing is the major

issue in eDRAM technology. So in future various testing method can be used to check the better performance of the circuit.

s.laxmi810@gmail.com

Abstract: - The automated toll collection system using passive Radio Frequency Identification (RASPBERRY PI 2) tag emerges as aconvincing solution to the manual toll collection method employed at tollgates. Time and efficiency are a matter ofpriority of present day. In order to overcome the major issues of vehicle congestion and time consumption RASPBERRY PI 2technology is used. RASPBERRY PI 2 reader fixed at tollgate frame reads the tag attached to windshield of vehicle. The objectdetection sensor in the reader detects the approach of the incoming vehicle's tag and toll deduction takes placethrough a prepaid card assigned to the concerned RASPBERRY PI 2 tag that belongs to the owners' account. This makes tollgate transaction more convenient for the public use.

Keywords— Smart Toll Collection, (RASPBERRY PI 2)

1. INTRODUCTION

In our day to day life, we pay certain amount of tax through toll plaza to the government. The toll gates are mostlyfound on national highways and bridges etc., and we pay standing over a queue in the form of cash, although, themobility of vehicles gets interrupted by this method which takes longer travel time, more consumption of fuel and alsopollution level get increased in that region, instead of that the method commonly used by industries and in advancedcountries is the Electronic Toll Collection System.Electronic toll collection system is the technology that enables the automatic electronic toll collection from theprepaid account registered on the name of vehicle owner, determining whether the vehicle is registered or not andinforms the toll authorities avoiding toll violations. Over last decades, electronic toll collection system have been

Implemented in United States and many other countries with a new improvement in it.By thiswe don't have to carry a handsome amount of cash with us relates to security as well. This system does notrequire any manual operation of toll barriers and

collection of toll amounts, it is completely automated toll collectionsystem. The vehicle owners are registered with their vehicles proper information and their account is created, wherethey can recharge their account with required amount. When the vehicle passes through the toll gate, the information isshared between RASPBERRY PI 2 tag and RASPBERRY PI 2 reader and the amount is deducted from the owners account. This method reducesthe traffic congestion problems, also reduces the travel time and reduces the fuel consumption.

2. IMPLEMENTATION

Software

The raspbian os is used in the raspberry pi board. It is a free operating system that is based on Debian which is particularly optimized for the Raspberry Pi hardware. It comes with over 35,000 packages and pre-compiled software bundled in a simple format for easy installation in the Raspberry Pi. The coding for all the sensors and the robot movement are done using the python coding. Python is preferred since it is a simple and a minimalistic language. It is also free and open source software. This can be used in many platforms such as Linux, VxWorks, and PocketPC etc. Also, it supports procedure-oriented programming as well as OOPS. The web browser is created by using HTML. The static IP address should be configured in the raspberry pi for the Wi-Fi dongle. This assigned static ip address is for connecting with the Wi-Fi of the mobile phone for the live video transmission. Since a normal usb camera is used it must be initially installed in the raspberry pi 2 board using the linux commands.

Raspberry pi

The Raspberry Pi hardware has evolved through several versions that feature variations in memory capacity and peripheral-device support. Raspberrypi block function v01.svg This block diagram depicts Models A, B, A+, and B+. Model A, A+ and the Pi Zero lack the Ethernet and USB hub components. The Ethernet adapter is internally connected to an additional USB port. In Model A, A+, and the PI Zero, the USB port is connected directly to the system on a chip (SoC). On the Pi 1 Model B+ and later models the USB/Ethernet chip contains a five-point USB hub, of which four ports are available, while the Pi 1 Model B only provides two. On the Pi Zero, the USB port is also connected directly to the SoC, but it uses a micro USB (OTG) port. The Broadcom BCM2835 SoC used in the first generation Raspberry Pi is somewhat

equivalent to the chip used in first generation smartphones (its CPU is an older ARMv6 architecture),which includes a 700 MHz ARM1176JZF-S processor, Video Core IV graphics processing unit (GPU), and RAM. It has a level 1 (L1) cache of 16 KB and a level 2 (L2) caches of 128 KB. The level 2 cache is used primarily by the GPU. The SoC is stacked underneath the glued to RAM chip, so only its edge is visible. The Raspberry Pi 2 uses a Broadcom BCM2836 SoC with a 900 MHz 32-bit quad-core ARM Cortex-A7 processor (as do many current smartphones), with 256 KB shared L2 cache. The Raspberry Pi 3 uses a Broadcom BCM2837 SoC with a 1.2 GHz 64-bit quad-core ARM Cortex-A53 processor, with 512 KB shared L2 cache.

Power Supply

It supplies various voltages as per requirement to each unit. This portion consist of transformer, rectifier, regulatorand capacitors for filter. The rectifier is used as a bridge rectifier which converts 230V to desired 5V/12V DC.

Stepper Motor

It is for opening and closing of a barrier on the toll gate. It is done when the customer successfully performs thebilling operation through RASPBERRY PI 2 with sufficient balance.

Buzzer

Buzzer will ring when there will be insufficient balance in customer account.

4. CONCLUSION

The Smart toll collection system in expressway based on RASPBERRY PI 2, a design scheme was put forward. It has characteristics of low cost, high security, far communication distance and high efficiency, etc. It improves technology level of charge and also improves passage ability of expressway. Smart toll collection system is an effective measure to reduce management costs and fees, at the same time, greatly reduce noise and pollutant emission of toll station. In the Smart Toll Collection system, real time toll collection system has been designed. This reduces the manual labor and delays that often occur on roads. This system of collecting tolls is eco-friendly and also results in increased toll lane capacity.One of the most important impacts of technology is the development of sustainable technologiesthat reduce the traffic conjunction and that need of future generation, save energy and time.Our project mainly impact full in these aspects, by saving the time on the toll, and alsofor to save fuel and by regulating the pollution and usage of vehicle at toll gates; as shown itmakes the toll collection payment easy by using automatic toll cash collection process.

The Smart ATM Monitoring System using Raspi

Kota Nageswara Rao
Assistant Professor
Malla Reddy Engineering College (Autonomous),
Maisammaguda, Secunderabad-500100
premkenterprises@gmail.com

Abstract

Automated Teller Machines (ATMs) security is the field of study that aims at solutions that provide multiple points of protection against physical and electronic theft from ATMs and protecting their installations. From anti-skimming defend systems to silent indicate systems, integrated ATM video surveillance cameras and ATM monitoring options, security specialists are ready to help the people get more out of the ATM security and ATM loss prevention systems. The implementation is achieved with the use of Machine-to-machine (M2M) communications technology. M2M communications is a topic that has recently attracted much attention It provides real-time monitoring and control without the need for human intervention. The idea of M2M platform suggests new system architecture for positioning and monitoring applications with wider coverage and higher communication efficiency. The aim of the proposed work is to implement a low cost standalone Embedded Web Server (EWS) based on ARM11 processor and Linux operating system using Raspberry Pi. It offers a robust networking solution with wide range of application areas over internet. The Web server can be run on an embedded system having limited resources to serve embedded web page to a web browser. The setup is proposed for ATM security, comprising of the modules namely, authentication of shutter lock, web enabled control, sensors and camera control.

Keywords:ARM11, Arduino, GSM, ZIGBEE, Vibration Sensor, DC Motor, Buzzer, Spray.

1. Introduction

The Idea of Designing and Implementation of Security Based ATM theft project is born with the observation inour real life incidents happening around us. This project deals with prevention of ATM theft from robberies overcome the drawback found in existing technology in our society. Whenever robbery occurs, Vibration sensor is used here which senses vibration produced from ATM machine. This system uses Arduino controller based embedded system to process real time data collected using the vibration sensor. Once the vibration is sensed, information is passed to ARM11 based master device over zigbee channel where alarm sound starts from the

buzzer. DC Motor is used for closing the door of ATM. A relay will be triggered to leak the gas inside the ATM to bring the thief into unconscious stage. Camera is always in processing and sending video continuous to the PC and it will be saved in computer. RTC used to capture the robber occur time and send the robbery occur time with the message to the nearby police station and corresponding bank through the GSM. This will prevent the robbery and the person involving in robbery can be easily carried.

1.1 LITERATURE REVIEW

There are various existing system are developed such as Security in e-banking via card less biometric ATMs [1] provides high security in authentication which also protects user from unauthorized access. In this model user required to authenticate himself with biometric identification (thumb/ fingerprint/iris etc.), personal identity number (pin) and selection of bank branch from displayed list if necessary. This model is designed for the rural farmers, semi-literate peoples.Protected cash withdrawal in ATM using mobile phone [2] describes a method of implementing two way authentications. Role of biometric technology over advanced security and protection in auto teller machine transaction [3] describe, different biometric techniques related security topics regarding ATM has been discussed. Enhanced voice recognition to reduce fraudulence in ATM machine [4] introduced to reduce cases of fraud and theft due to its methods used in identification of individuals, security based implementation of hidden markov model algorithm (hmm) to calculate speech rate, frequency and modulation pitch detection algorithm (PDA) for pitch calculation of voiceprintsand accent classification (ac) for the accent analysis in voice. Anti-theft ATM machine using vibration detection sensor [5] provides security for the ATM machine itself. When the attacker try to damage the ATM machine vibration detection sensors gets activated. A message is passed to the nearby police stations with the help of GSM modem.

2. Related Work

2.1 Existing Methodology:

The existing system of two-factor authentication using mobile phones, are used to generate the one time password (OTP) [7].By definition, authentication is the use of one or more mechanisms in order to prove that you are who you claim to be. Once your identity is validated, access is granted [6]. Three universally recognized authentication factors exists today: what you know (passwords), what you have (tokens, cards) and what you are (biometrics). Recent work has been done in trying alternative factors, for example somebody you know, a factor that can be applied in social networking.

Two-factor authentication is a mechanism that implements two of the above mentioned factors and is considered stronger and more secure than the traditionally implemented one factor authentication system. For example, withdrawing money from an ATM machine uses two factor authentication: the ATM card (what you have) and the personal identification number (what you know). Passwords are known to be one of the easiest targets of hackers. Therefore, most companies are searching more ways to protect their customers and employees. Biometrics is known to be very securing [7], but is used only in special organizations (such as military organizations) given the expensive hardware needed and their high maintenance costs. As an alternative, banks and companies are using tokens as a way of two-factor authentication. A token is a physical device that generates passwords needed in an authentication process. Tokens can either be software or hardware. Hardware tokens are small devices that can be easily carried. Some of these tokens store cryptographic keys or biometric data. Anytime a user wants to authenticate in a service, he uses the onetime password displayed on the token in addition to his normal account password. Software tokens are programs that run on computers and provide a onetime password that it is changed after a short amount of time (usually 30 seconds). OTP algorithm's security is very important because no one should be able to guess the next password in sequence. The sequence should be random to the maximum possible extent, unpredictable and irreversible. Factors that can be used in OTP generation include names, time, seeds, etc. Several commercial two-factor authentication systems exist today such as RSA Secure ID [7].Multifactor authentication uses more than two form of authentication and it provides higher security [8].

2.2 Proposed Methodology:

In this project we analyzed what is the problem people faced in the existing technology. Especially Multifactor Authentication (MFA) method provides more complexity to the user. This project helps to overcome the problem of complexity and provides easiest way to secure the ATM transaction. Whenever person enters account number onto the ATM machine, the system requires PIN to authenticate the user. If PIN gets verified, it makes a call to theuser's mobile. If the user replied to make a transaction, then transaction process takes place. The proposed system uses GSM modem for call from ATM to the user and getting reply from user to ATM. If user correctly entered amount and secondary password from mobile then transaction takes place. There is no any problem of lost or damaged ATM card. Also if the robbers try to damage ATM machine then the

vibrations are detected by vibration sensor and give an alert message to the nearest police station and switches on the alarm.

3. Implementation

3.1 Hardware Description:-

Microcontroller- Microcontroller can be termed as a single on chip computer which includes number of peripherals like RAM, EEPROM, Timers etc., required to perform some predefined task. AVR is an 8-bit microcontroller belonging to the family of Reduced Instruction Set Computer (RISC). In RISC architecture the instruction set of the computer are not only fewer in number but also simpler and faster in operation. AVR microcontroller executes most of the instructions in single execution cycle. AVRs are about 4 times faster than PICs; they consume less power and can be operated in different power saving modes. Let's do the comparison between the three most commonly used families of microcontrollers. AVR follows Harvard Architecture format in which the processor is equipped with separate memories and buses for Program and the Data information.

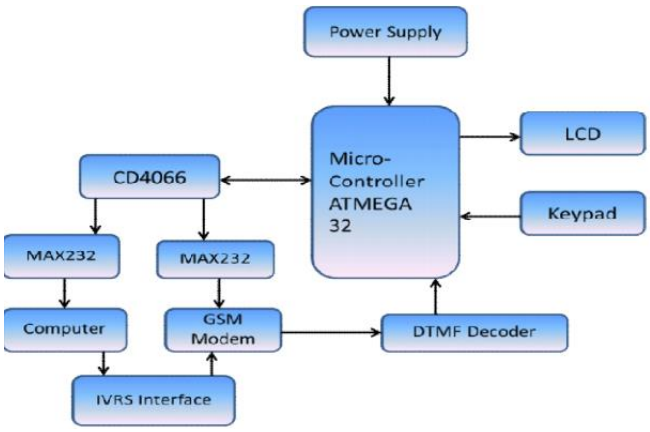

Fig 1: Block Diagram of Proposed System.

LCD- A liquid crystal display (LCD) is a flat panel display, electronic visual display, video display that uses the light modulating properties of liquid crystals (LCs). LCs does not emit light directly. They are used in a wide range of applications, including computer monitors, television, instrument panels, aircraft cockpit displays, signage, etc. LCDs have displaced cathode ray tube (CRT) displays in most applications. They are usually more compact, lightweight, portable, less expensive, more reliable, and easier on the eyes. They are available in a wider range of screen sizes than CRT and plasma displays, and since they do not use phosphors, they cannot suffer image burn-in.

DTMF- DTMF stands for Dual Tone Multi Frequency and it is the basis for your telephone system. DTMF is actually the generic term for Touch-Tone (touch-tone is a registered trademark of ATT). Your touch-tone phone is technically a DTMF generator that produces

DTMF tones as you press the buttons.Dual-tone multi-frequency signaling (DTMF) is used for telecommunication signaling over analog telephone lines in the voice-frequency band between telephone handsets and other communications devices and the switching center. The version of DTMF that is used in push-button telephones for tone dialing is known as Touch-Tone.

IVRS- Interactive voice response (IVR) is a technology that allows a computer to interact with humans through the use of voice and DTMF keypad inputs. In telecommunications, IVR allows customers to interact with a company's database via a telephone keypad or by speech recognition, after which they can service their own inquiries by following the IVR dialogue. IVR systems can respond with prerecorded or dynamically generated audio to further direct users on how to proceed. IVR applications can be used to control almost any function where the interface can be broken down into a series of simple interactions. IVR systems deployed in the network are sized to handle large call volumes.IVR technology is also being introduced into automobile systems for hands-free operation. Current deployment in automobiles revolves around satellite navigation, audio and mobile phone systems.

MAX232- MAX232 from Maxim was the first IC which in one package contains the necessary drivers (two) and receivers (also two), to adapt the RS-232 signal voltage levels to TTL logic. It became popular, because it just needs one voltage (+5V) and generates the necessary RS-232 voltage levels (approx. -10V and +10V) internally. This greatly simplified the design of circuitry.

CD4066BC Quad Bilateral Switch- CD4066BC is a quad bilateral switch intended for the transmission or multiplexing of analog or digital signals. It is pin-for-pin compatible with CD4016BC, but has a much lower "ON" resistance, and "ON" resistance is relatively constant over the input-signal range. **KEYPAD-** keypadis a set of buttons arranged in a block or "pad" which usually bear digits, symbols and usually a complete set of alphabetical letters. If it mostly contains numbers then it can also be called a numeric keypad. The keypad Switches are connected in a matrix of rows and columns: The rows of the matrix are connected to four output port lines. The columns of the matrix are connected to four input port lines

Software Description: - The software part deals in programming the microcontroller. In the present work we have used the ORCAD design software for PCB layout design, the CODEAVISIONAVR software development tool to write and compile the source code, which has been written in the C language. The uCFLASH serial device programmer has been

used to write this compile code into the microcontroller. The proteus software is used to simulate the project. The project also uses visual basic for interacting with the user.

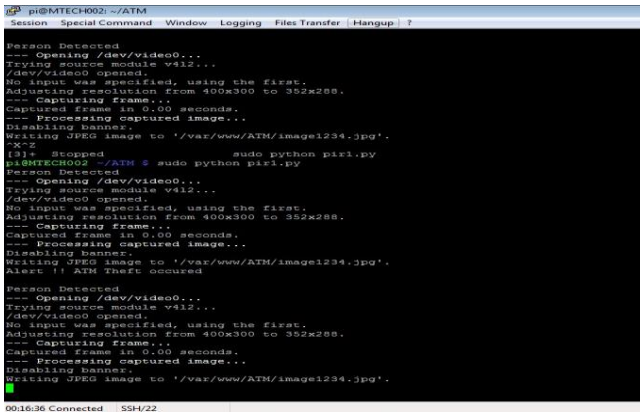

Fig 5: System Process displaying Console.

5. Conclusion

The project "DESIGN AND IMPLEMENTATION OF ANTI-THEFT ATM MACHINE USING RASPBERRY PI" has been successfully designed and tested. It has been developed by integrating features of all the hardware components and software used and tested. Presence of every module has been reasoned out and placed carefully thus contributing to the best working of the unit. Secondly, using highly advanced ARM Cortex A8 Processor board and with the help of growing technology the project has been successfully implemented.

Abstract
Sharing or transmitting the digital information in online is increasing day by day since the usage of internet has become a habituation for everyone, which led to the large-scale violation of copyright issues. Now a days, majority of the data is being shared in the form of digital images which is quite easy for the copyright violators to forge and fake those images and then shared for profit. To deal with these copyright violations, digital watermarking came into existence as a potential solution that utilizes the concept of data hiding. This article proposed an approach for a non-blind color image watermarking (NB-CIW) by employing the algorithm named as singular value decomposition in translation invariant wavelet (SVD-TIW) domain. In addition, to further optimize the proposed SVD-TIW algorithm, enhanced grey-wolf optimizer (E-GWO) is presented which is an efficacious optimization approach in meta-heuristic algorithms. Further, to disclose the robustness and effectiveness of proposed NB-CIW using SVD-TIW-EGWO approach, different sort of attacks is enforced on watermarked image and extracted the accurate watermark image. Simulations on various test images with comparison to the state-of-art NB-CIW methodologies demonstrate the superiority of proposed NB-CIW using SVD-TIW-EGWO approach with respect to quality evaluation metrics like normalized cross correlation (NCC), root mean square error (RMSE), structural similarity (SSIM) index and even that of peak signal-to-noise ratio (PSNR) as well.

1 Introduction

Now a day's internet innovation has become unavoidable domain of everybody's life. Massive measure of information is being traded through messages, social sites, and corporate sites in assortment of structures. This multimedia information can be as images, sound records, video documents, content reports and so on. This information is at extraordinary hazard by aggressors at different phases of its transmission. One of the potential strategies for ensuring information is scrambling the information for example changing over the information in some ambiguous organization with the goal that it gets hard to decipher. Anyway, if attacker can figure out how to get key source of encryption, unscrambling the message will disclose the information to him. Therefore, securing the multimedia information from the copyright violators is quite challenging and difficult task. To deal with these copyright violations, digital watermarking came into existence as a potential solution that utilizes the concept of data hiding [3, 9, 11], where a message information which is in the form of digital image is embedded into the cover image without degrading its quality. Thus, it is quite hard for the attackers to identify that the cover images comprise of a message image which is known as watermark. Main objective of digital watermarking is to provide an assurance for the information of copyright owners and authorized people from the copyright violators. Practically, digital watermarking can be obtained in two forms, which includes spatial and spectral domains. In spatial domain-based digital watermarking the message will be embedded into the cover image by altering the pixel information directly. Beside its simplicity and easiness, it has several flaws like lack of imperceptibility, lesser robust against few attacks like rotation, scaling and translation. Spectral domain is also called as transform domain-based digital watermarking, which first converts both cover and watermark images into another form then applies different sort of algorithms to embed the watermark into cover image. This is very robust and provides higher imperceptibility as compared to spatial domain-based digital watermarking approaches. Robustness is referred as the capability to secure any multimedia information modification before the information destruction. This robustness can be computed through NCC values. Imperceptibility is cited as the hidden information detection, which can be defined by the values of PSNR. From the past decades, lots of research was done on both spatial and transform domain watermarking techniques. Among those, discrete wavelet transform (DWT)-based approaches [7, 19] are most popular due to their simplicity in implementation. However, they were failed to obtain higher imperceptibility and accurate extraction of watermark as well. There are few methods, which utilized the concept of singular value decomposition (SVD) [7], the combo of DWT with SVD [13] and hidden markov model (HMM) [1]. But they suffered from lack of robustness and more sensitive against the attacks. To achieve the non-blind watermarking properties, NB-CIW approaches are developed using the DCT transformation. In the [4], authors discussed about Arnold transform for implementing the watermarking with the utilization of DFT-DCT transformation, which reduces the phase hazards of the DCT method. But while implementing this approach to higher resolution images, those are not able to fulfil the robustness to that of compression ratio. As compression ratio not achieving, the images are easily affected by the random attacks. Thus, it provides the ineffective security levels. To overcome these consequences, DCT method needs to be enhanced or replaced. Thus, DWT incorporated with DCT and used by the authors in [16]. This method solves most of the problems, but still robustness is needed to be achieved. Especially it is not applicable to biometric applications. Thus in [12], the authors discussed about watermarking approach for fingerprint and iris datasets, for protecting the confidential image information. They achieved the robustness with the innovation of DWT bases fusion methodologies into it. But artifacts might be introduced while fusing the property features of images. To solve this problem, authors in [25] discussed DT-CWT based multi-resolution

transforms, in which different features such as textures, edges and region of lines considered for both cover and watermark images and fused using different levels of orientations to achieve the efficacious watermarked image. Still, these methods were failed to provide the enhanced imperceptibility with higher robustness while performing the extraction procedure at another end. Further, they suffered from restricted direction in their filtering structure. Thus, to defeat above-mentioned issues, different types of subsample-based filters like contourlets, ridgelets [6], curvelets and shearlets [17] are implemented to achieve the smoothness by implementing these transforms into filters. But the problem arises due to ridgelets and curvelets implementation, as they are not categorized under the multi-resolution watermarking. So, the artifacts can be generated into the cover image, which is unwanted consequence for the application of NB-CIW. In [21] authors have proposed a robust watermarking scheme for biometric applications using redundant discrete wavelet transform (R-DWT), which is an extension for DWT and produces the filter coefficients as same size of input after decomposing it into subbands. However, NB-CIW needs to be enhanced to improve the watermarking efficiency. To overcome this problem, several researchers addressed RDWT with SVD implementation in [8, 15, 23] to obtain further enhanced watermarking capacity with higher imperceptibility and robustness against various attacks. But computational complexity is the major issue in [8, 15, 23] as the authors did not considered any optimization techniques. In [2], authors anticipated image hiding system based on DCT domain with the optimization of message using Arnold transform before embedding into the cover image. Further, they combined both DCT and its variance functions. However, they used binary image as watermark, but in recent days most of the images are in color or RGB. In addition, the quality of extracted watermark is degraded due to the usage of finite set of rules. Author in [24] presented DWT-SVD based approach with oppositional fruit fly optimization algorithm for selecting the optimal position of chosen blocks with lower variance. In addition, gold-code is employed for both embedding and extraction process which can be easily hacked by the attackers. In [14] authors developed DT-CWT-based watermarking through pixel-wise masking. It is based on masking watermark according to characteristics of HVS. The watermark is added to the largest detail bands and weighing function of the watermark is calculated as a simple product of data extracted from HVS model thus it is applicable to only geometrical attacks and results in extremely poor PSNR values. In [20] authors introduced copyright authentication for images using both blind and non-blind embedding methods and developed a hybrid scheme with the help of multi-level DWT transformation. The major drawback of this approach is time complexity and embedding complexity with high execution period. Most of the approaches presented in the literature suffering from poor imperceptibility, robustness and they suited for only several attacks. Further, only few researchers considered color watermark image for embedding. Therefore, this article proposed a NB-CIW methodology which employs SVD-TIW-EGWO approach to achieve enhanced robustness, higher imperceptibility with more confidentiality towards attacks compared to the conventional approaches. The main contributions are summarized as follows:

- Implementation of TIW decomposition for generating the frequency subbands and decomposes the low frequency subband using SVD approach with the utilization of EGWO algorithm. As per authors knowledge, this combining approach has not been applied for the applications of NB-CIW before.
- A novel framework on NB-CIW approach using new embedding and extraction algorithms is presented. In addition, EGWO is employed for the first time for the applications of NB-CIW.

- An enhanced approach of NB-CIW methodology as compared to existing R-DWT [21], RDWT-SVD [8, 15, 23].
- Further, comparative evaluation against various attacks also presented to show the robustness and effectiveness of proposed NB-CIW using SVD-TIW-EGWO approach as compared to existing NB-CIW approaches.

The remaining sections of this article are as follows: section 2 deals about implementation of TIW and its background. Section 3 explains about proposed new embedding and extraction procedure for NB-CIW applications. Section 4 deals about the implementation results and its discussions and comparative analysis using the various qualitative metrics. Section 5 describes the conclusion and possible future works of the proposed approach followed by references.

2 Translation invariant wavelet decomposition

Wavelets are finite energy and limited duration functions generated from one single function called basis function mother wavelet by scaling and shifting in time-frequency domain. Mother wavelet integrates to zero and is square integrable having finite energy. The wavelet function can be scaled and translated over input function. DWT is a type of non-redundant wavelet representation and suitable for images. This is achieved by discretization of dilation and translation parameters. With wavelet based multi-resolution analysis, image can be represented at more than one resolution level. The advantage is that features in an image that might go undetected at one resolution level may be easily located at another level. It is especially useful for processing nonstationary signals. Good time resolution and poor frequency resolution at high frequencies is achieved whereas good frequency resolution and poor time resolution is achieved at low frequencies. This is possible using adjustable window width in DWT but keeping area of the window constant.

Initially consider the DWT filter analysis, to generate the approximate coefficients; the input signal $x[n]$ will be passed through low-pass filter (LPF) with g as its impulse response. Finally, convolution operation will be performed between the input and impulse response is given as

$$y[n] = (x*g)[n] = \sum_{k=-\infty}^{\infty} x[k]g[n-k] \tag{1}$$

Similarly, to generate the detailed coefficients, the input signal $x[n]$ will be passed through the high-pass filter (HPF) with h as its impulse response and convolution operation will be performed between the input and impulse response. It is noted that HPF and LPF both depends on each other and their response contains inverse properties. Figure 1 represents the filter analysis of conventional DWT operation, but this method suffering with the shift variance phenomenon generated by down sampling. Less shifts in the source image caused to more alter in wavelet coefficients. Thus, more fluctuations in wavelet coefficients to the input samples will be induced and causes to generation of improper energy distribution. Thus, DWT is ineffective for embedding and extraction of feature-based subband modelling and this problem can be overcome by modifying the operation of filtering procedure by compensating the down sampling. Therefore, the TIW decomposition is adapted with synthesis and analysis filter banks as shown in Fig. 2. These filter banks are capable of providing the orthogonality to the input subbands which results in less shifts and more redundant, thus the input samples are less

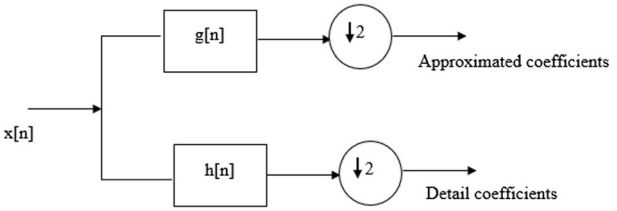

Fig. 1 Filter analysis of DWT

affected by the various sources of noises and more immune to various types of attacks in the field of image processing. Thus, the TIW decomposition is prominent method for NB-CIW as compared to other transformations like fast fourier transform (FFT), DWT and DCT. The operation of TIW transform is as follows:

Consider, the $X(n)$ and $X'(n)$ signals as source data samples and recovered data samples and the input data samples are applied to the LPF with $a[-k]$ response and HPF with $d[-k]$ response. Synthesis filters shows time frequency inverse operation with that of analysis filters and their responses are represented as the $a[k]$ for LPF and $d[k]$ for HPF correspondingly. The coefficients generated from output these filters at j^{th} level will be represented as A_j and D_j. Now this filter performs only convolution operation between the next state output to the frequency response but there will be no down-sampling operation in TIW decomposition. The analysis filter operation of DWT is expressed as follows

$$A_j[k] = \left(A_{j+1}[k] * a_j[-k]\right)\alpha \tag{2}$$

$$D_j[k] = \left(A_{j+1}[k] * d_j[-k]\right)\alpha \tag{3}$$

where $*$ denotes the convolution operation α denotes the down sampling.

Similarly, the outputs of the analysis filter coefficients are applied to synthesis with β as its up-sampling factor as follows:

$$A_{j+1}[\mathrm{k}] = \left(A_j[k]\beta\right) * a[k] + \left(D_j\beta\right)[k] * d[k] \tag{4}$$

As stated in Eq. (4), TIW decomposition does not contain the any sampling operation due to shift variant problems, thus it will be removed from DWT and TIW decomposition can be formed utilizing the LPF and HPF will be formulated as follows:

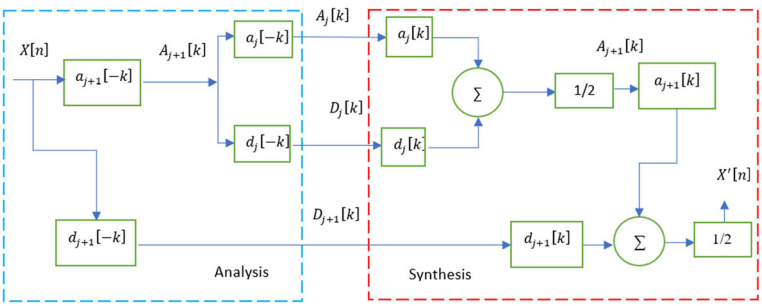

Fig. 2 TIW decomposition filter banks structure

$$a_j[K] = a_{j+1}[K]\beta \tag{5}$$

$$d_j[K] = d_{j+1}[K]\beta \tag{6}$$

By eliminating the down sampling from analysis filter bank as given in Eq. (2) and Eq. (3), TIW decomposition can be formed as follows:

$$A_j[k] = \left(A_{j+1}[k]{*}a_j[-k]\right) \tag{7}$$

$$D_j[k] = \left(A_{j+1}[k]{*}d_j[-k]\right) \tag{8}$$

Similarly, by eliminating the up sampling from Eq. (4), synthesis can be formed as follows:

$$A_{j+1}[k] = \frac{1}{2}\left(A_j[k]{*}a_j[k] + D_j[k]{*}d_j[k]\right) \tag{9}$$

TIW decomposition maintains the fixed unchangeable sampling rate; thus, it is immune to the time fluctuations in filters. This constant nature of sampling rate generates the reliable frequency samples followed by its coefficients; thus, it is more suitable for image processing applications especially for watermarking based encryption standards in which data embedding capacity will be induced significantly. The major drawback presented in the DWT is reducing the resultant image size by half of its original image size due to the down sampling environment. Thus, the TIW will generate the resultant image with its actual image size and the resultant sub-bands also maintain the original size so inhibits perfect data embedding standards. The images consist of texture features in every sub band and it is necessarily to maintain these features with respect to their features. As the TIW provides for perfect data embedding capacity by maintain the size, thus it will maintain the texture features prominently. This property leads to implement the TIW operation for watermarking applications by maintaining the HVS by providing the highest embedding capacity.

3 Proposed model

This section describes the proposed NB-CIW using SVD-TIW-EGWO approach. Figure 3 demonstrate embedding process of SVD-TIW-EGWO approach (discussed in section 3.1. in detail), which produces a prominent quality of watermarked image by embedding watermark image into the cover image. Similarly, extraction process (discussed in section 3.2. in detail) is shown in Fig. 4 for an extraction of watermark image from watermarked image which is obtained using embedding process.

3.1 RGB to YCbCr conversion

Practically, YCbCr color space frequently utilized to carry out vantage of the HVS's low-resolution capability for color regarding luminosity. Hence, this conversion is being utilized widely in the applications of image processing. Assume, a pixel is represented in RGB format with 8-bits/sample and the range of pixel values is from 0 to 255, which is also known as gray range. RGB to YCbCr conversion is done as follows:

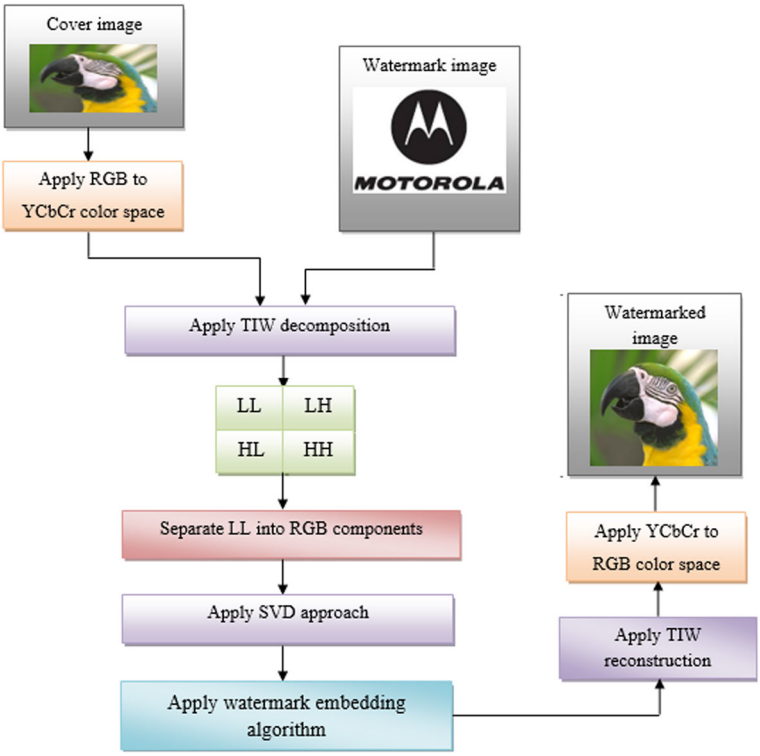

Fig. 3 Proposed block diagram for embedding process

$$Y = 16 + \frac{65.738R}{256} + \frac{129.057G}{256} + \frac{25.064B}{256} \tag{10}$$

$$Cb = 128 - \frac{37.945R}{256} - \frac{74.494G}{256} + \frac{112.439B}{256} \tag{11}$$

$$Cr = 128 + \frac{112.439R}{256} - \frac{94.154G}{256} - \frac{18.285B}{256} \tag{12}$$

3.2 Embedding process

Step 1: Select and read the watermark and cover image as well (both are RGB images).
Step 2: Apply YCbCr colour space conversion to cover image as given in Eq. (10), Eq. (11), and Eq. (12), respectively. YCbCr colour space consists of luminance components, chroma red and chroma blue components. Generally, both chroma components consisting of low intensity components. Thus, in this low intensity pixels, the watermark image information can be perfectly stored without losing its properties.
Step 3: Apply TIW decomposition on components of YCbCr image like luminance, chroma blue and chroma red separately, now it decomposes the image into four subbands named LL, HL, LH, and HH.

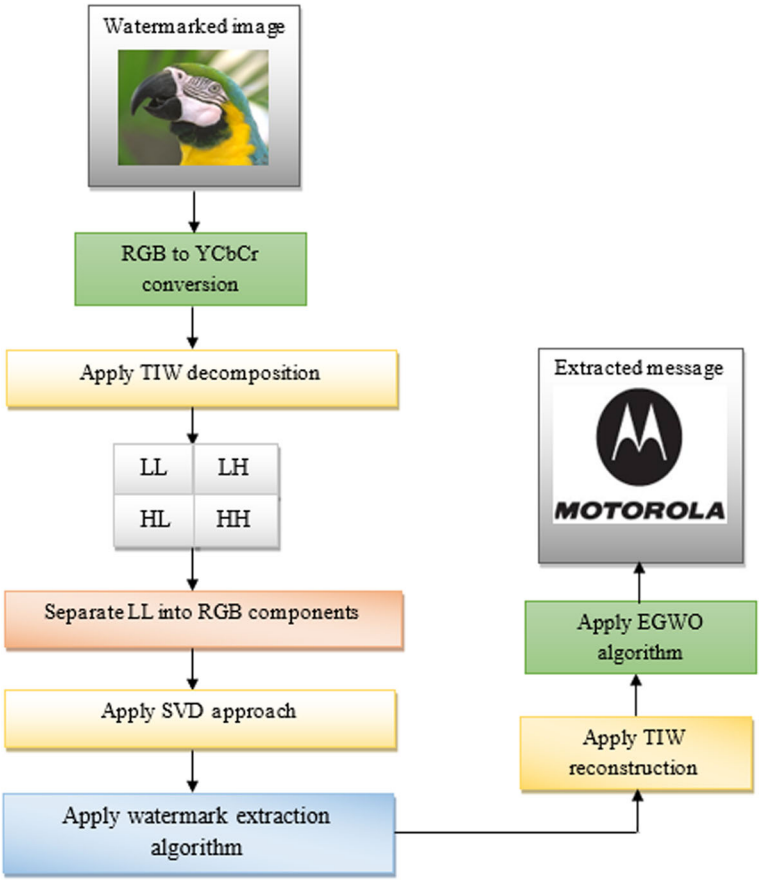

Fig. 4 Block diagram of proposed extraction process

Step 4: Separate R, G, and B components from obtained LL and denote as LL_r, LL_g and LL_b. Apply SVD to get a columns of a matrix with left singular vectors $U_{LL_{r,g,b}}$, diagonal matrix with singular values $S_{LL_{r,g,b}}$, and columns of a matrix with right singular vectors $V_{LL_{r,g,b}}$ for separated R, G, and B components.

Step 5: Apply TIW decomposition to the watermark as well to obtain four subbands named LL1, LH1, HL1 and HH1.

Step 6: Separate R, G and B components and apply SVD to obtain singular components like columns of a matrix with left singular vectors $U_{LL1_{r,g,b}}$, diagonal matrix with singular values $S_{LL1_{r,g,b}}$, and columns of a matrix with right singular vectors $V_{LL1_{r,g,b}}$ of decomposed LL1 of watermark image.

Step 7: Now, use watermark embedding as below:

$$S_{W_r} = S_{LL_r} + \alpha * S_{LL1_r} \tag{13}$$

$$S_{W_g} = S_{LL_g} + \alpha * S_{LL1_g} \tag{14}$$

$$S_{W_b} = S_{LL_b} + \alpha * S_{LL_b} \tag{15}$$

where S_{LL_r}, S_{LL_g} and S_{LL_b} denotes the R, G, B components of obtained diagonal matrix with singular values from step 4 while S_{LL1_r}, S_{LL1_g} and S_{LL1_b} are R, G, B components of obtained diagonal matrix with singular values from step 6. Now, combine Equation (13), Equation (14), and Equation (15) to obtain a modified diagonal matrix $S_{W_{r,g,b}}$ with singular values.

Step 8: Now multiply the altered diagonal matrix with singular values $S_{W_{r,g,b}}$ with columns of a matrix with left singular vectors $U_{LL_{r,g,b}}$ and columns of a matrix with right singular vectors $V_{LL_{r,g,b}}$ obtained from step 4 to get modified LL subband as given below

$$W_{LL_{r,g,b}} = U_{LL_{r,g,b}} * S_{W_{r,g,b}} * V_{LL_{r,g,b}} \tag{16}$$

Step 9: Apply TIW reconstruction to Equation (16) and LH, HL and HH from step 3. Finally, apply YCbCr to RGB color space to get a watermarked image.

3.3 Extraction process

The proposed NB-CIW extraction process on watermarked image is as follows:

Step 1: Read watermarked image obtained by embedding process and converts it into YCbCr color space using Equation (10), Equation (11), and Equation (12) respectively.
Step 2: Apply TIW decomposition to decompose the components of YCbCr it into four subbands named LL2, HL2, LH2, and HH2 separately.
Step 3: Separate R, G and B components from obtained LL2 and apply SVD to get columns of a matrix with left singular vectors $U_{LL2_{r,g,b}}$, diagonal matrix with singular values $S_{LL2_{r,g,b}}$, and columns of a matrix with right singular vectors $V_{LL2_{r,g,b}}$ for separated R, G, and B components.

Table 1 EGWO algorithm

Step 1: Initialization of search agent.
Step 2: Allocate fitness property to gamma, beta and alpha.
Step 3: Encircle the prey $\vec{D} = \left|\vec{C}.\vec{X}_p(t) - \vec{X}(t)\right|$
$\vec{X}(t+1) = \vec{X}_p(t) - \vec{A}.\vec{D}$, where t denotes the current updating iteration, $\vec{A}$ and $\vec{C}$ denoted as coefficient vectors, $\vec{X}$ denotes the wolf's position and $\vec{X}_p(t)$ represents the position of prey node. The $\vec{A}$ and $\vec{C}$ represented as coefficient vectors and they will be calculated as $\vec{C} = 2.\vec{r_2}$ and $\vec{A} = 2\vec{a}.\vec{r_1} - \vec{a}$. Where $\vec{a}$ components are raged from [2, 0] in linearly decremented order for every succeeding iteration. The random vectors are denoted by $\vec{r_1}$ and $\vec{r_2}$ and they will be raged from 0 *to* 1.
Step 4: Begin Hunting
Alfa wolf is used to direct this hunting process. Rarely, gamma and beta also contribute in this hunting procedure. The below derivations describe the process of hunting:

$$\vec{D}_\alpha = \left|\vec{C}_1.\vec{X}_\alpha - \vec{X}\right| \;,\; \vec{X}_1 = \vec{X}_\alpha - \vec{A}_1.\left(\vec{D}_\alpha\right) \quad \vec{D}_\beta = \left|\vec{C}_2.\vec{X}_\beta - \vec{X}\right| \;,\vec{X}_2 = \vec{X}_\beta - \vec{A}_2.\left(\vec{D}_\beta\right)$$

$$\vec{D}_\gamma = \left|\vec{C}_3.\vec{X}_\gamma - \vec{X}\right| \;,\vec{X}_3 = \vec{X}_\gamma - \vec{A}_3.\left(\vec{D}_\gamma\right) \quad \vec{X}(t+1) = \frac{\left(\vec{X}_1 + \vec{X}_2 + \vec{X}_3\right)}{3}$$

Step 5: Attacking prey
Here value of $\vec{a}$ is linearly reduced from the range 2 to 0, it will cause to decrease in $\vec{A}$ additionally.
Step 6: The process described in 2 to 5 steps iterated in finite number of times to achieve the optimized performance of proposed scheme of watermarking.

Fig. 5 Tested cover images for NB-CIW

Step 4: Now, use watermark extraction as below:

$$S_{E_r} = (S_{LL2_r} - S_{LL_r})/\alpha \tag{17}$$

$$S_{E_g} = \left(S_{LL2_g} - S_{LL_g}\right)/\alpha \tag{18}$$

$$S_{E_b} = (S_{LL2_b} - S_{LL_b})/\alpha \tag{19}$$

where S_{LL2_r}, S_{LL2_g} and S_{LL2_b} denotes the R, G, B components of obtained diagonal matrix with singular values from step 3 while S_{LL_r}, S_{LL_g} and S_{LL_b} are R, G, B components of obtained diagonal matrix with singular values from step 4 in embedding process (refer section 3.2.).

Fig. 6 Tested watermark images

Now, combine Equation (17), Equation (18), and Equation (19) to obtain extracted diagonal matrix with singular values $S_{E_{r,g,b}}$.

Step 5: Now multiply the extracted diagonal matrix with singular values $S_{E_{r,g,b}}$ with columns of a matrix with left singular vectors $U_{LL1_{r,g,b}}$ and columns of a matrix with right singular vectors $V_{LL1_{r,g,b}}$ obtained from step 6 in embedding process (refer section 3.2.) to get extracted LL1 subband as given below

$$E_{LL1_{r,g,b}} = U_{LL1_{r,g,b}} * S_{E_{r,g,b}} * V_{LL1_{r,g,b}} \tag{20}$$

Step 6: Apply the TIW reconstruction to Equation (20) and LH1, HL1 and HH1 from step 5 in embedding process (refer section 3.2.) to get extracted watermark.

3.4 Enhanced Grey wolf optimizer (EGWO)

From [10], by utilizing the fundamental behaviour of Grey wolves', a new algorithm is proposed named as grey wolf optimizer (GWO). In this approach, the properties of image patches are done based on the properties of Beta, Gamma and Alpha. The finest optimization solution is achieved by the Alpha property, which is a leading initiator. The second and third

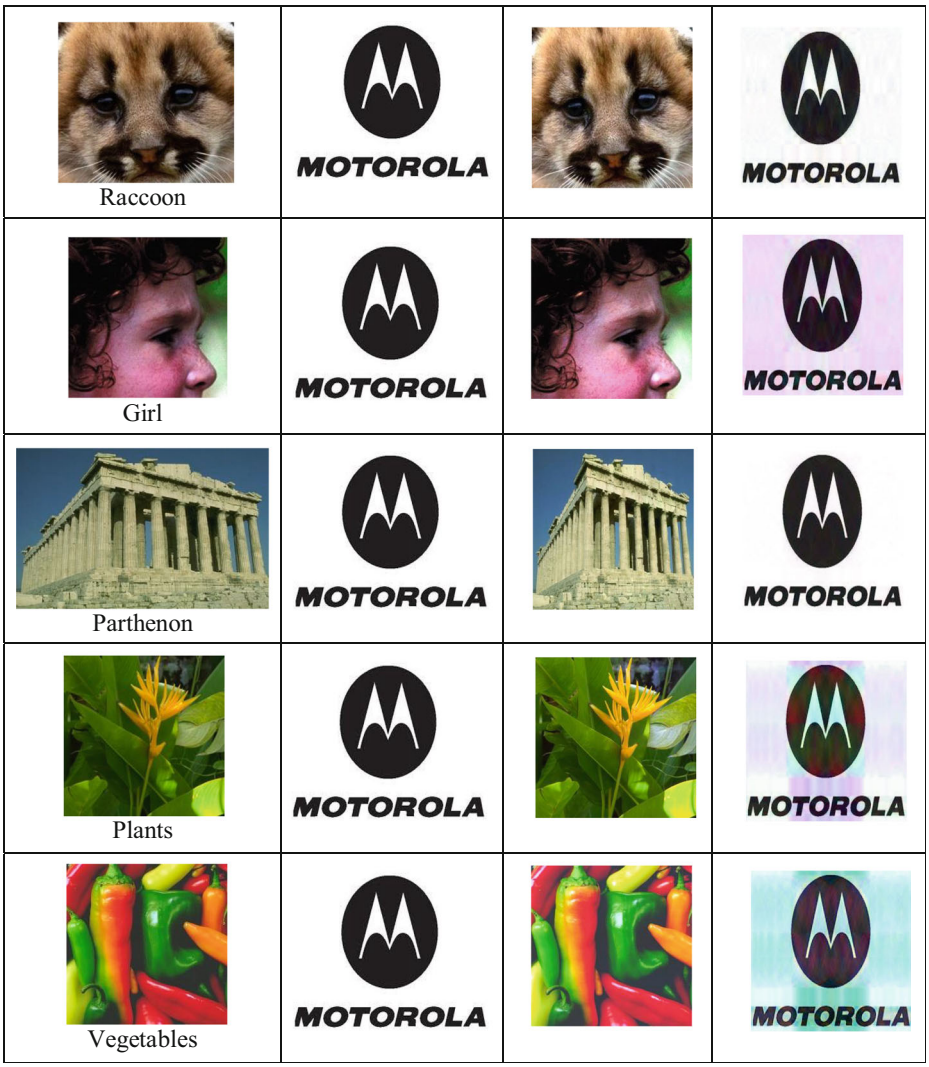

Fig. 8 (continued)

optimization solutions are achieved by the Gamma, Beta, respectively. Initially GWO is utilized to train the weights of multi-layers. Later, [18] explains the use of evolutionary population dynamics (EPD) with GWO, thus the low reliable search agents of GWO method are optimized, respectively. Now this searching procedure is effectively monitored by Beta,

4 Results and discussion

This section deals about the detailed discussion on the obtained results of proposed NB-CIW using SVD-TIW-EGWO embedding and extraction process as compared to existing NB-CIW methodologies. Figure 5 shows that input RGB images used as cover images for NB-CIW which includes 'vegetables', 'fruits', 'penguins', 'bike', 'raccoon', 'plants', 'pathenon', 'parrot', 'hat', 'girl', 'flower' and 'butterfly'. The watermark images are demonstrated in Fig. 6. For evaluating the performance of existing and proposed NB-CIW methodologies, image quality metrics like PSNR, SSIM, RMSE and NCC are utilized where PSNR performance discloses the imperceptibility, RMSE, SSIM and NCC values demonstrate the robustness and effectiveness of NB-CIW algorithm. Further, no attack and attack scenarios are considered for quality assessment of proposed NB-CIW using SVD-TIW-EGWO approach as compared to existing NB-CIW using R-DWT and R-DWT + SVD approaches.

4.1 Performance of proposed NB-CIW using SVD-TIW-EGWO approach

4.1.1 No attack scenario

In this, we utilized R-DWT [21] and R-DWT + SVD [8, 15, 23] methodologies for the comparative analysis. Figure 7 demonstrate the obtained results of NB-CIW using R-DWT approach, where 1st column represents all the cover images used for testing, 2nd column discloses the watermark image used for embedding and extraction process. Watermarked images are given in 3rd column and extracted watermark images are shown in 4th column,

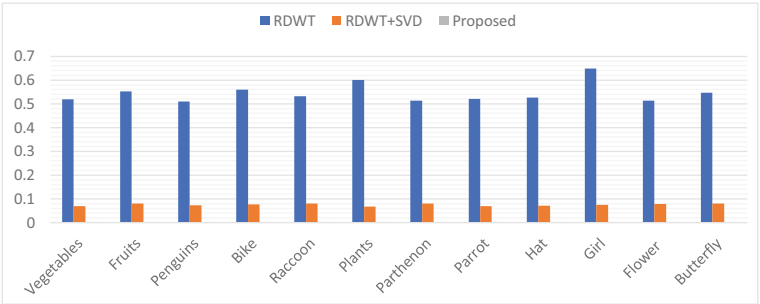

Fig. 11 RMSE values obtained using R-DWT [21], R-DWT + SVD [8, 15, 23] and proposed NB-CIW methodology

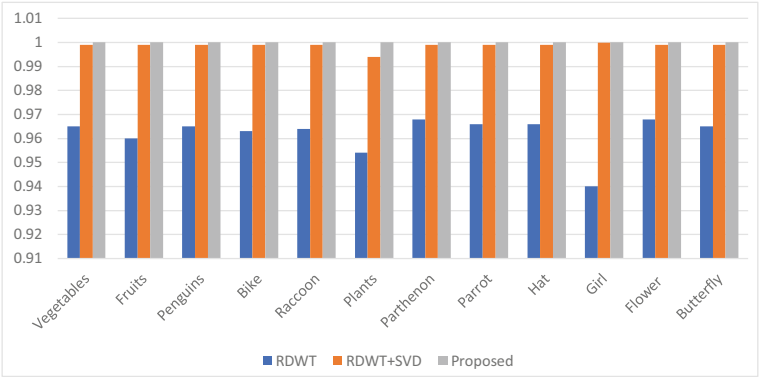

Fig. 12 SSIM index values obtained using R-DWT [21], R-DWT + SVD [8, 15, 23] and proposed NB-CIW methodology

respectively. It is shown that all the obtained watermarked images are suffering from lack of imperceptibility as the watermark message is clearly visible in watermarked images which results in lesser PSNR values. Further, extracted watermark image also not accurate as the embedded watermark image which results in lower robustness. Similarly, test results for various cover images using R-DWT + SVD [8, 15, 23] is given in Fig. 8. However, the watermarked images obtained using R-DWT + SVD discloses superior performance over R-DWT, the extracted watermark is suffering due to lesser RMSE and SSIM values, which results in lower robustness. Further, it also has some amount of distortion on it. Practically, one can easily identify the watermark image which is embedded into cover image if there is lack of imperceptibility and robustness.

To overcome the limitations of existing R-DWT and R-DWT + SVD by enhancing the imperceptibility and robustness as well, our proposed NB-CIW methodology using SVD-TIW-EGWO approach results is depicted in Fig. 9, which provides an excellent imperceptibility for both watermarked image and extracted watermark image as well (see 3rd and 4th column in Fig. 9). As compared with existing NB-CIW methodologies, the effectiveness and robustness of proposed NB-CIW methodology using SVD-TIW-EGWO is quite superior and can be adopted easily with the applications of NB-CIW in real-time as well

since it utilizes RGB images as watermark whereas most of the existing NB-CIW methodologies employed for binary watermark images. Quality analysis of these methods with respect to watermarking quality evaluation metrics is shown in Figs. 10, 11 and 12, respectively where PSNR is calculated for the obtained watermarked images to the cover images and displayed the graphical analysis in Fig. 10. The values of PSNR are just above 74 dB with the proposed SVD-TIW-EGWO approach whereas the existing R-DWT got just above 58 dB and R-DWT + SVD got just near to 60 dB. This shows that proposed NB-CIW methodology using SVD-TIW-EGWO obtained higher imperceptibility and robustness against the existing NB-CIW presented in the literature.

Figure 11 shown the graphical analysis of RMSE values from R-DWT, R-DWT + SVD and proposed NB-CIW methodology using SVD-TIW-EGWO. It is observed that values of SVD-TIW-EGWO got lower error values as compared to existing NB-CIW methodologies using R-DWT [21] and R-DWT + SVD [8, 15, 23]. The values of RMSE for the displayed output results in Figs. 7, 8 and 9 are 0.521 with [21], 0.069 with [8, 15, 23] and with SVD-TIW-EGWO is 0.00211, respectively. Similarly, another quality metric, SSIM index values are shown in Fig. 12, where the proposed SVD-TI-EGWO achieved a value of 1 for almost every tested RGB image. The values of R-DWT and R-DWT + SVD are slightly lower than the

proposed values. All the three-quality metrics tabular forms demonstrated in Tables 2, 3 and 4, respectively. And we also highlighted the best value in bold letter for identification purpose.

4.1.2 Attack scenario

This subsection describes the performance evaluation of existing and proposed NB-CIW methodologies with several attacks like geometrical attacks like rotation, scaling, and translation. Further, non-geometrical attacks like Gaussian noise, compression, median filtering, motion blur, sharpening, flipping and histogram equalization also considered to disclose the effectiveness and robustness of proposed NB-CIW using SVD-TIW-EGWO approach as compared to existing NB-CIW using R-DWT and R-DWT + SVD approaches. Tables 5 and 6 demonstrate the performance analysis of proposed NB-CIW using SVD-TIW-EGWO approach under various sources of attacks. Usually these attacks will be generated by the attackers to detect the original information, so here we are considering prototype of those attacks. In Table 5, the NCC outcome of the proposed NB-CIW using SVD-TIW-EGWO approach is compared to existing NB-CIW methods like R-DWT [21] and R-DWT + SVD [8, 15, 23]. The comparison results show that the proposed method has maximum accuracy and improved by 15% with conventional schemes. In Table 6, the PSNR metric of the proposed NB-CIW using SVD-TIW-EGWO approach is compared with the existing NB-CIW methods like R-DWT [21] and R-DWT + SVD [8, 15, 23]. The comparison results show that proposed SVD-TIW-EGWO approach has maximum quality for both the watermarked image and extracted image as well even in case of attack scenario and improved the imperceptibility by 20% with comparison to the existing NB-CIW methods.

Table 6 Extracted watermark image and performance analysis with PSNR in the attack situations

Attack	R-DWT	R-DWT + SVD	Proposed

Flipping	–	–	**50.80**

5 Conclusions

This article proposed a new NB-CIW approach based on SVD in TIW domain. Additionally, EGWO algorithm also implemented which is a metaheuristic approach for optimizing the performance of proposed NB-CIW methodology. Further, to show the robustness and effectiveness of proposed NB-CIW, different types of attacks also applied on to the watermarked image and extracted the watermark almost similar quality as embedded. Simulation result shown the superiority of proposed NB-CIW using SVD-TIW-EGWO approach with compared to the state-of-art NB-CIW methodologies for various test images. The quality evaluation metrics like NCC, RMSE, SSIM and PSNR also computed and shown that proposed NB-CIW methodology with SVD-TIW-EGWO holds more embedding capacity.

Design of CCAA for Optimized Difference Patterns

G. S. K. Gayatri Devi, S. Krishna Veni

Abstract*: Difference patterns find applications in target tracking radars for accurate target detection. Such patterns must be generated with minimum sidelobe levels to reduce the effect of interfering signals like clutter, jamming signals. The present work is focused on designing concentric circular arrays(CCA) of practical elements producing low sidelobe difference patterns using thinning. Simulated results are presented for 6 ring and 7 ring concentric circular antenna arrays.

Keywords* : Concentric circular antenna arrays (CCAA), Differential Evolution Algorithm, Difference patterns, Peak Sidelobe level.

I. INTRODUCTION

Difference patterns are employed in radars for accurate target detection. Usually linear arrays are the first choice for antenna designers owing to their design simplicity. Concentric circular antenna arrays are steadily gaining more importance in antenna design because of their compact antenna structure and a beam which remains constant in the azimuthal plane. They are preferred than linear arrays as they offer more degrees of freedom to the antenna designer. These are used in various applications like radio direction finding, air and space navigation, mobile, sonar, radar and wireless communication applications [1].

Antenna arrays can be designed to obtain different types of patterns like sum patterns, difference patterns, sector beams, ramp patterns [2]-[5], stair case patterns and so on. Low sidelobe patterns are necessary to reduce problems that arise due to Electromagnetic Interference. Such patterns can be generated by different techniques like choosing proper array excitations, by varying spacing between elements [6]. Another way is to thin array elements. Thinning [7]-[8] allows sidelobe reduction at reduced number of active elements thus lowering antenna cost, weight and design complexity.

Several works were contributed in the field of difference pattern generation from circular arrays. Bayliss [9] developed a two parameter difference pattern with nearly equal side lobes similar to those of Taylors sum pattern for a circular aperture antenna. The resultant pattern has angle sensitivity that is in proportion with the given side lobe level. Elliot [10] proposed a perturbation technique which modifies the Taylor-type linear and circular aperture distributions to generate sum and difference patterns. The resultant patterns have arbitrary side lobe topography. Hansen [11] presented a synthesis method for linear and circular planar arrays that provide pencil beams and difference patterns with variable side lobe level based on placing zeroes. In [12] Ares Rengarajan, A. Vieiro and E. Moreno have shown a method to design an aperture distribution that results in difference patterns with random sidelobe levels. This method can be used for designing both linear as well as circular apertures. The resulting patterns also possessed low directivity loss low mutual coupling problem. Several synthesis techniques were described Elliot [13] for getting inputs that result in required radiation patterns. Using these techniques, both sum and difference patterns with scattered deep nulls can be generated from both linear and circular arrays. Aperture distributions, for turned ON elements of huge thinned circular arrays with diameters between 25 to 133.3λ, for producing difference as well as sum patterns were given by Keizer in [14]. Iterative Fourier Transform method is made use of for yielding patterns with low sidelobes. Although several works were reported in open literature for synthesizig difference patterns with low sidelobe taper, it is worth to mention that very limited literature is available on generation of difference patterns from thinned CCA of dipoles.

Optimized difference patterns for different lengths of linear arrays were generated using DE algorithm in [15]. In the present work, dipole antenna arrays are thinned and an amplitude distribution is designed for ON elements to yield low sidelobe difference patterns. The optimum amplitudes and thinning coefficients are derived using Differential Evolution algorithm.

II. DIFFERENTIAL EVOLUTION ALGORITHM

Differential Evolution (DE) is a population based stochastic, optimization technique. It is an effective and proficient global optimizer in continuous search domain. Any practical optimization technique should have three characteristics namely finding true global minimum, faster convergence and few control parameters. Differential Evolution algorithm has all these features. It was first proposed by Storn and Price [16]-[17].

It is a powerful search technique which is successfully applied in many fields like mechanical engineering, communications, pattern recognition etc. The algorithm offers following advantages:

- It can easily handle non-linear, non-differentiable complex fitness functions.
- It is a parallel search technique which searches the solution space from different points.
- It offers a way of solving the problem without using its gradient.
- It has the capability to find true global minima regardless of the initial parameter values.
- It has few easy to choose as well as robust control parameters which influence the convergence of the algorithm.
- Good convergence speed in finding optimum value.

A key advantage which prompts the antenna array designers to go for DE is its high computational efficiency which allows the optimum design of large antenna arrays.

In DE, the candidate solutions are called vectors. The important feature that makes a DE algorithm different from other population based techniques is differential mutation operator and trial parameter vectors. The algorithm initially takes samples at random, multiple locations from the objective function. The initial population vectors are generated according to the prefixed parameter bounds. For performing an efficient exploration of the solution space, DE employs a difference between the parameter vectors. The vectors are iteratively updated. New vectors are generated by altering existing vectors. DE performs this by taking the scale difference of two randomly chosen vectors from the initial population. These newly generated vectors compete with the initial population vectors of same index. These undergo fitness evaluation, if they result in better fitness compared to parent vectors, these survivors will act as parents for next generation. The process continues till the convergence criterion is met. The solution with best fitness is taken as the optimum solution.

III. PROBLEM FORMULATION

A 'm' ring CCA of dipoles is shown in figure 2. Here r_m indicates radius of m^{th} ring, N_m indicates the number of dipoles in m^{th} ring and d_m is the interelement spacing where m=1,2,…M.

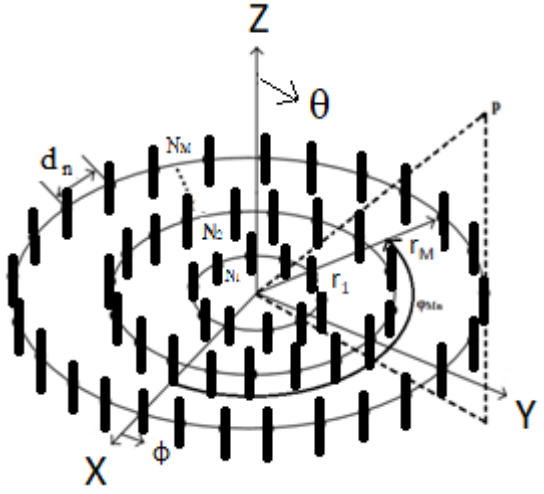

Fig. 1.Geometry of concentric circular array of dipoles

The generalized expression for the array factor [17] is given by

$$E(\theta,\varphi) = \sum_{m=1}^{M}\sum_{n=1}^{N_m} I_{mn}\, A_{mn} \exp\left(jk\, r_m \sin\theta \cos[(\varphi - \varphi_{mn})]\right) \quad (1)$$

Here

M = number of rings

N_m = number of elements in ring m

A_{mn}= Amplitude excitation of n^{th} element of m^{th} ring

I_{mn} = excitation of n^{th} element of m^{th} ring= $\begin{cases} 1 & ON \\ 0 & OFF \end{cases}$

r_m = radius of ring 'm'

φ_{mn} = angular position of n^{th} element of m^{th} ring

$$= \frac{2\pi(m-1)}{N_m} \quad (2)$$

$k = \frac{2\pi}{\lambda}$

θ = elevation angle

φ = Azimuthal angle

In 'u' domain

$$E(u)_{|\varphi=constant} = \sum_{m=1}^{M}\sum_{n=1}^{N_m} I_{mn}\, A_{mn} \exp\left(jkr_m\, u \cos(\varphi - \varphi_{mn})\right)$$

here u=sin(θ)

The expression for radius of m^{th} ring is given by

$$r_m = m\frac{\lambda}{2} \quad (3)$$

The spacing between two adjacent elements is assumed to be nearly $\frac{\lambda}{2}$ i.e. $d_m = \frac{\lambda}{2}$.

The number of equally spaced elements present in ring 'm' is given by N_m=8*m (4)

All the elements have uniform excitation phase of zero degrees. For attaining the difference patterns, half the array must be excited in out of phase. Hence the resultant expression for the array factor is given by

$$AF1(u) = |E_1(u) - E_2(u)| \quad (5)$$

where

$$E_1(u) = \sum_{m=1}^{M}\sum_{n=1}^{N_m/2} I_{mn}\, A_{mn} \exp\left(jkr_m u \cos(\varphi - \varphi_{mn})\right)$$

and

$$E_2(u) = \sum_{m=1}^{M}\sum_{n=\left(\frac{N_m}{2}+1\right)}^{N_m} I_{mn}\, A_{mn} \exp\left(jkr_m u \cos(\varphi - \varphi_{mn})\right)$$

In the above equations, φ is assumed to be 0°.

Now the field equation for dipole antenna is given by

$$AF2 = \frac{\cos\left(\frac{kl}{2}\cos\theta\right) - \cos\left(\frac{kl}{2}\right)}{\sin\theta} \quad (6)$$

Where l=λ/2

The total array factor now becomes

$$AF = AF1 * AF2 \quad (7)$$

IV. METHOD OF SIDELOBE REDUCTION

It is possible to generate patterns with reduced sidelobe levels by exciting ring elements non-uniformly. Thinning is another method for sidelobe level reduction. Both techniques are made use of in this paper for getting optimum results. The optimum results are found using DE algorithm.

The objective function which is to be minimized for finding the optimum solution is as follows:

$$Fit = w1 * (PSLL_o - SLL_d) + w2 * (FF_o - FF_d) \quad (8)$$

where

$PSLL_o = Max\left[20\log\left|\frac{AF(u)}{AF_{Max}(u)}\right|\right]$

= Obtained Peak Sidelobe level

u ϵ side lobe region.

SLL_d =Desired Sidelobe level

$AF_{max}(u)$= Main beam peak value

FF_o is the obtained Fill factor, FF_d is the desired Fill factor. Fill factor is defined as the number of turned on elements divided by total number of elements present. 'w1' and 'w2' are weighing factors for controlling the amount of significance given to each term in eq.(8).

V. RESULTS

This section presents the results obtained for a 6 ring CCAA and 7 ring CCAA using the problem defined above. Fig. 2 depicts the radiation pattern for a 6 ring CCAA. The peak SLL obtained is -20.2376dB. The total number of 'ON' elements is 88 out of 168 total number of elements. The Fill Factor in this case is 52.38%. The element layout is shown in fig. 3. A 'o' symbol indicates an 'OFF' element and a '*' symbol indicates an 'ON' element. Table I and II present the radii of each ring and amplitude excitations of elements in each ring respectively.

VI. CONCLUSION

Difference patterns are generated in general by using linear arrays owing to their simplicity. Concentric circular antenna arrays of dipoles are employed in the present work to generate low sidelobe difference patterns. It is evident from the results that the generated difference patterns have lowest possible sidelobes. The number of active elements is also low thus reducing weight and cost. All results are simulated using Matlab software.

Email: srinivasreddy.thumu@gmail.com

Abstract

Pedestrian detection and monitoring in the surveillance framework are important for several services covering irregular event detection and human gait, congestion or overcrowded evaluation in a surrounding environment, gender classification, fall detection for in elderly human beings and so on. The processing of the image segmentation algorithm plays an important role in monitoring the travelling target at the fixed footbridge, which supports the visually disabled or the elderly. Different morphological filtering processes increase the efficiency of moving people segmenting the film. This technique uses a Gaussian detector histogram and they observe objects. This work allows the physically disabled to comfortably navigate the pedestrian and allows automated vehicles.

Keywords: *SVM Classification, PCA, Image Processing, Morphological Operations, Pedestrian*

1. Introduction

Monitoring cameras are available in shopping malls, ATM terminals, public parks, factories, banks, institutions, clinics, traffic signals, etc. The three key elements of the stage are static background, moving items, static and active components of the scene and moving objects. Video detection is a flourishing area for object monitoring with introducing video encoding technology. Human video surveillance is a time-consuming process. The machine must therefore analyses the video and extracts the information needed. Many machine-learning techniques can detect various items automatically, such as individuals, vehicles, animals and hardware. Analysis or evaluation of a specific industry site is called video monitoring. The importance of this device is to allow individuals with physical disabilities to reach the traffic signal incredibly safely. Video control value extends in many regions designated as missile detection, defense, medical laparoscopy, and the moving nature of robot during a building collision, avoidance of road and forest accidents.

Applications in innumerable fields such as crowd prediction, congestion processing, camera monitoring, robotic vision and self-driven vehicles are present in detecting feeder in a picture or in a camera [1, 2]. The identification of human beings is a strenuous activity owing to their diverse forms and poses, which demands a comprehensive function to differentiate them from the image. An example of such a feature source is the histogram of oriented gradients, which we strive to develop and implement as part of this project. The context background subtraction method is a widely successful method chosen for the work. Among the different methods. This paper presents algorithms for tracking footpaths and identifies the person or car and other objects. They test the work using image recognition methods for the segmentation and action identification using the qualified prototype matching. Multiple video cameras are mounted and data has to track this. This device operates with autonomous vehicles and protects other vehicles from collisions.

2. Background works

There are three process forms used primarily in the tracking of moving objects. These techniques are the method of frame subtraction, the method of background subtraction, and the method of optical flow [3]. They take the discrepancy between two sequential images using the Frame subtraction procedure [4] to test the existence of moving objects. The measurement is basic and quick to create in this process. In this process, however, a full description of moving object is difficult to get; hence, the identification of moving object is not reliable. In the optical flow process, the optical flow field is determined. They conduct the clustering as per the image's optical flow propagation model. The complete movement knowledge of the moving body is found and they observe the moving object from the quantity of measurement. Low anti-nose efficiency renders it inadequate for real-time use. The context subtraction method is the process by which they observe the distinction between the subject and the context picture using a basic algorithm for moving objects.

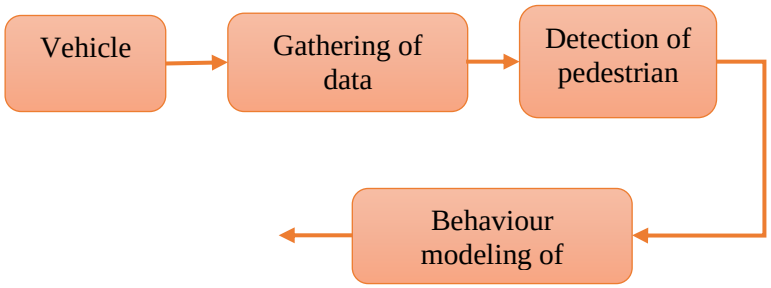

Fig. 1 Block diagram of the existing work

It is therefore very vulnerable to shifts in the natural world and therefore has a weak capacity to resist intervention. One benefit of this approach is that it will have the most comprehensive context knowledge for the object [5]. Dynamic background modeling is mixed in the background subtraction system with the dynamic threshold selection method based on the background subtraction in a single static camera situation. They change the history based on detailed object identification. Part of the current work was committed to collecting images of pedestrian passageways along the zebra crossings. This study [6] explores the characteristics of foot identification and behavioral interpretation. The conduct examination involves eye look, voice, posture, action of the body and side. To tackle these tasks, it uses sophisticated computer training methods. Figure 1 describes the current process workflow.

3. Materials and methods

The proposed work in Figure 2 captures video data and partitions them into separate frames. For each frame, the background can be subtracted and we can contrast the foreground for each frame. Gradient process histogram is helpful for generating a histogram of multiple objects for multiple gradients. It labels the extracted foreground objects using a computer-viewed Kernel it labels the extracted foreground objects using a computer-viewed Kernel it monitors Identified objects at various levels or levels depending on behaviours. Histogram of directed gradients (HoG) is a valuable tool for object identification. The identification and shape of this local entity has been calculated by histogram. At first, oriented and horizontal gradients without smoothing are known. They then calculate the magnitude and gradients. Table 1 lists the various characteristics to distinguish segmentation artefacts. They can use table 2 for object first stage identification in the first search stage.

learning copies the physical interaction of human activity through electronic vision and image comprehension.

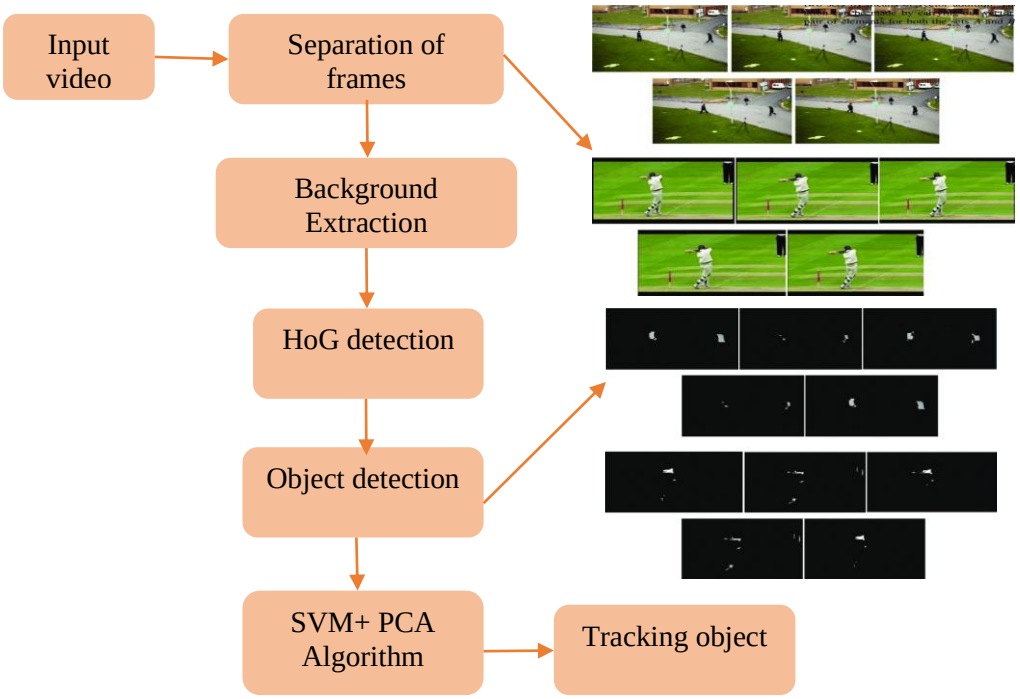

Fig. 2 Block diagram of the proposed work

HOG Extraction: After deployment, we can introduce the HoG function extraction process from scratch

1. Computation of gradients: The most popular way of measuring gradient is simply to add the differential derivative mask in both the *x* and *y* directions. This approach involves the filtering of the picture strength data in both horizontal and vertical directions with the kernels [-1 0 1].

2. Orientation Binning: By weighting the orientation of each pixel of the cell into pre-defined orientation bins, a cell histogram is generated. The cells are normally square (we stick to rectangular for convenience), but may be rectangular or round. The weighting of the orientations may be achieved either by the gradient itself.

3. Block division and normalisation: cells must be clustered together to influence shifts in lighting and comparison. Then the whole HOG descriptor is the vector of the cell histogram normalisation components from all block areas.

There are two main geometries of blocks: R-HOG rectangular blocks and C-HOG circular blocks. R-HOG blocks are typically square grids, defined by 3 parameters: cell number per block, pixel number per cell, and channel numbers per cell histogram. C-HOG has two variants: one with a single core and the other with separated angled cells, several angular / radial bins, core bin radius and additional radial expansion factor can represent which. It normalises such blocks by four major methods: the L1 standard, the L1 square root standard, the L2 standard and the L2 standard, accompanied by the L2 Hys. We will explore and pick the right model.

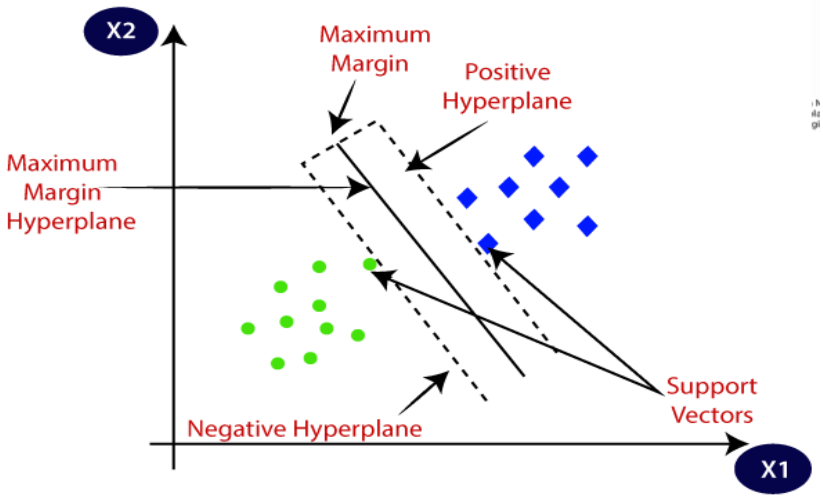
Motion and object detection: Object detection is the first step in identifying instances of semantic objects in a class including individuals, houses, vehicles, etc. in a video series. Frame-to-frame difference, context subtraction, and motion tracking using optical movement methods are the various ways to entity identification. These methods usually use derived features and algorithms to classify entity category instances. They classify the method of object detection into two groups. First, entity identification, which primarily involves three approaches such as context subtraction, visual flow and spatiotemporal filtering. Second, classification of artefacts uses mainly visual characteristics as a tool dependent on the form, gesture and texture. Motion detection is one of the video security concerns, since it not only extracts moving artefacts, it is also essential for many applications like object-based video encoding, human motion recognition and human machine interaction. The next step is motion segmentation after object recognition. This stage is used to detect areas that fit moving targets such as people or vehicles. It primarily focuses on the detection of moving areas from video frames and the development of a database to track and analyse actions. Motion detector is used to detect a change in the location of a subject relative to its environment or to detect a change in the environment relative to an object. Electronic motion sensors may track activity from the physical world.

Improving PCA classification efficiency: in this article, we used the Principal Component Analysis (PCA) to enhance the performance of classification issues. This evaluation model comprises two steps; it measures the weight of each feature in the first step using a method of weighting the feature. They then pick the features with weights greater than a pre-defined threshold. The chosen functions would then be subject to the second stage. In the second stage, they change variances of characteristics before the variation of the characteristics correlates to their value. By taking full advantage of phase 2, we expect the PCA efficiency in classification problems to improve.

Classification Training: Based on the literature review completed, in our project, we chose a linear kernel SVM. We kept the default value of the error cost of 1. We tried to use weighted SVMs but could not do so in this task because of technical problems with MATLAB. The SVM help is one of the most common supervised learning algorithms used in both classification and regression issues. That being said, they mainly use it in Machine Learning for classification problems. The aim of the SVM algorithm is to build the best line or decision line that can divide n-dimensional space into groups such that the new data point can easily be positioned in the right section. This best boundary of judgement is called a hyperplane. SVM picks the severe points / vectors to support the hyperplane construct up. These severe cases are considered vectors of support and thus algorithms are considered vector support. Take into account the diagram below in which two separate classifications are categorised by decision boundary or hyperplane which is shown in Figure 3.

Copyright ⓒ 2020 SERSC



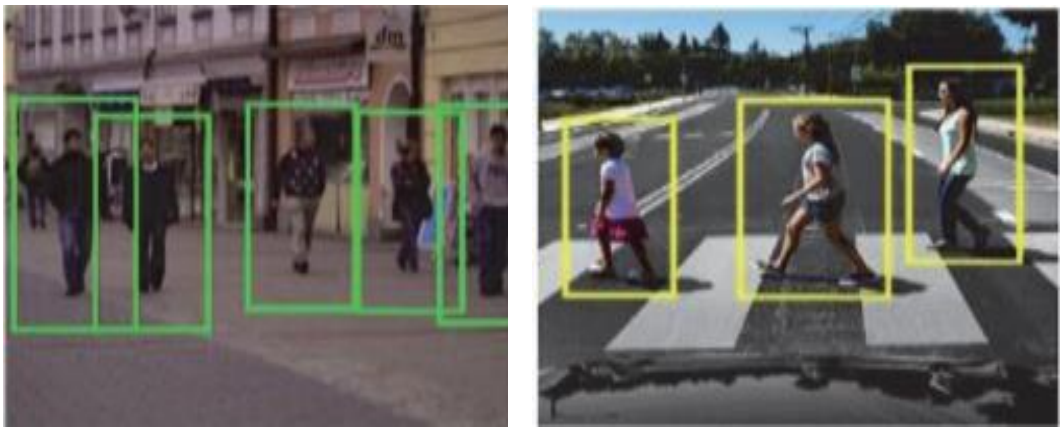


Fig. 3 Decision boundary or hyperplane of Training the Classifier

Tracking Object: Tracking of objects in a video series involves recognising the same object in a frame sequence with the special characteristics described by the entity. In particular, video surveillance systems often obey the identification method. Tracking takes place from one frame to the next, utilising kernel-based tracking, point-based tracking, and silhouette-based tracking algorithms.

4. Results and Discussion

For both the formation and checking of our SVM, we used MIT and INRIA Pedestrian data collection. One of the major tasks of video monitoring is to identify the existence of pedestrians in a video sequence, i.e. to find all human objects. This problem corresponds to areas, the smallest rectangular boundary boxes in the human series. They have identified human activity in certain surveillance applications utilizing study of trajectories, individual locations and historical or previous experience of the scene. We can see instances of pedestrian identification and monitoring in Figure 4.

(c) (d)

Fig. 4 : Example of detection and tracking of pedestrians. (a) Detecting outdoor pedestrians walking along the lane. (b) Football ADAS identification. (c) The pedestrian detector is centred on the channel function detector aggregate. (d) Real-time traffic identification car and pedestrian.

5. Conclusion

On the basis of the literature survey, most of the techniques available proposed by previous researchers can detect and track objects either in the individual camera view or in multiple cameras. Though its trackers are reliable, they are also inefficient because of their strong computational demands and vice versa. They carry the pedestrian walking detection scheme out via multiple classifiers throughout this work, and the detection rates of several of the current methods to date are workable. The monitoring system measures human behaviors by various characteristics. The gradient system histogram is being used to track objects along with their speed increase. They can also use this approach for various applications involving object tracking.

[3]Assistant prof, ECE Dept. MREC (A).

Abstract: Any implementation of something like a specific form of the multiplier in automated frequency measurement systems depends primarily on the overall permitted variance of both the output frequency of that same transducer. Therefore, it will be usually best to always use frequency multipliers of that first category in transducers with such a slight variance. The suggested edge incorporates optimal speed and reliable activity that used an organizational structure as well as an unselected overlap. The suggested hybrid digital edge solution provides broadband with low-energy and low-area benefits as well as being a potential candidate for low-energy frequency summaries in deep CMOS sub-micrometer. A charge pump was substituted by a counter to integrate the automated interface. The overall system consists of all the resources for doing the operation of stable clock pulses for SoC applications as well as the frequency multiplier. In this paper, the frequency multiplying method is carried out how to use a clock amplification system based on an edge combiner, which is carried out using the C2MOS logic.

Index Terms: Low power, frequency multiplier, phase detector, clock

I. INTRODUCTION

The systems of low power and low-area (TX) transmitters are important regarding short-range communications e.g. wireless transmission networks, body area networks, and certain other battery-operated applications. Such low-power systems have relaxed vibration, spectral purity, and architecture criteria. Phase-locked TXs (PLL) are indeed effective and area-efficient compared to the traditional mixer-based TX direct update design. The energy demand in a frequency synthesis can indeed be reduced by operating the PLL in lower frequencies and by using frequency multiplier circuits without the loop to build the modified RF carrier .The power requirements in a frequency synthesis can be decreased by operating the PLL in lower frequencies.

The strategy of low power architecture is often used to reduce SoC power usage. The power demand is categorized into static or dynamic. Few low power architecture approaches including Dual Voltage Supply (dual V_{dd}) and Dual Threshold (dual V_{th}) Single Threshold CMOS (MTCMOS) are being used to minimize static power usage. To minimize dynamic power requirements, a low power modeling approach termed Dynamic Voltage Scaling and Dynamic Frequency Scaling has been used by regulating the voltage and frequency at workload to minimize dynamic power requirements. Frequency clock generation with a frequency multiplier is needed for scaling by using PLL (Phase Locked Loop) or DLL (Delay Locked Loop). DLL is safer than PLL because of higher cost cycles and latency aggregation in PLL. The DLL-based clock generator for the multiplier is therefore used and comprised of a pulse generator, a power logic, and even an edge combiner. Therefore it is more suited for realistic use [1-2].

To address this issue, multiple DLL-based clock generators were introduced. The DLL clock generator consists of the DLL center and the frequency multiplier and is normally split into two blocks: Pulse Generator and Edge Combiner. If multiplication of variable frequencies is needed, a multiplication ratio control circuit is introduced. Multiphase clocks are

produced employing an input clock in the DLL path. The pulse generator produces the number of pulses needed by the multiplication-ratio signal generator from multiple-phase clocks to combiner circuit produces a multiplied clock by using the pulses chosen. In addition, the N/2 number of multiphase clocks is the full operation for both the frequency multiplier. Because while the frequency generator gathers several clocks, jitter aggregation sometimes does not happen. However, the frequency multiplier can adjust multiplication ratios quickly. Furthermore, the conceptual range or performance load of the frequency multiplier should be expanded to raise the multiplication ratio [8-10]. Moreover, the average clock frequency is significantly diminished.

The main contributions and organization of this paper are summarized as follows: In section, 2 we describe background details of DLL based clock generators details. The section 3 proposed work. The section 4 deliberates results and discussions. Finally in section 5 we concluded the paper.

II. BACKGROUND WORKS

In [3], the author's paper envisages a high level of complications and a time-consuming workload for the development of multimedia applications. Many of the DVS algorithms, which are a productive and useful technique for classifying these DVS algorithms by outstanding multimedia applications, have been advocated for real-time use. In this paper, they advocate the new offline linear programming technique for regulating the low energy usage for multimedia processing tasks within delays. Due to the lower energy content accessed, they examined the greatness of DVS algorithms. Subsequently, they enhance the LP formulation to build an online DVS algorithm for multimedia real-time, based entirely on powerful sequential linear programming.

In [4] the authors study conventional stepping voltage system and involve a delay margin to ensure that all possible device and wiring process deviations and temperature inconsistency continue at a certain level of firmness. This margin is needed if the critical path is to be changed because of such improvements. Furthermore, because of the slower interconnection delay, a critical path changes from operating voltage to each other with voltage particularly in comparison to the logical delay. To ensure a faultless operation with a high limit, technological scaling challenges both process variation and interconnect delay. Such a margin is insufficiently converted into upward voltage and corresponding energy. In addition, voltage-scaling features of certain critical paths are followed by logical programming and delay lines interconnected to perform the same delay sequences as the actual critical path.

In [5], the authors present a delay-locked (DLL) clock generator with several unique advantages over the traditional phase-locked-loop generator, namely no jitter growth, fast locking, the balance of loop production and the easy combination of the loop filters. To overcome the conservative DLL-based system's constrained locking range and frequency multiplication problem, they suggest a reset circuitry phase detector and a new frequency multiplier. It is made in a CMOS process of 0.35μm. Our DLL clock initiator covers an area of 0.07 μm and is 42.9 mW power consumption. It has an operating range of 120 MHz-1, 1 GHz and a cycle to cycle jitter of 1 GHz is accurate. The Die area, peak to peak and R.M.S. jitter are the smallest possible three parameters of comparison. These parameters pertain to those of multipliers with high-frequency clocks.

In [6], the authors offer a frequency multiplier composed of a monolithic local CMOS oscillator in the DLL technique that organizes a low noise 900 MHz carrier frequency. This example supports the necessity of a dual-mode-137 AMPS / TDMA standard. In [7], the Author DLL-based frequency synthesizer. A delay-locked loop is designed for the Mode-1 UWB system. With the acceptable 528-MHz input frequency, this frequency synthesizer delivers less than 9.5-ns adjustment time. This frequency of reference uses broad bandwidth and rapid sales architecture. Besides, a discreet time model and DLL's analytical model for phase noise are foreseen in this work. Research results demonstrate high availability with predicted adjustment time and phase noise.

III. PROPOSED MODEL

The block diagram for binary frequency-shift-keying (BFSK)/amplitude multiplication frequency changes with small area penalties. Because only another PD-N is applied for each edge combiner differential result while the cumulative multiplication rate is too high by one, the edge combiner's performance load rises slower than even for the combiner unit. The primary requirement of the multiplier is to get the required clock signals that are generated from the DLL clock generator and simultaneously D flip-flop gets the multiphase clocks. Because of control logic, the correct pulses are obtained with logic. All the phase clocks are delivered during the time of neighbor clocks that are delayed by the same period, which in return produces pulses from the clock signals. Eventually, whenever the multiphase clocks move through the multiplication rate control logic, device-timing distortion will arise, which in turn will produce pulses appropriate for high frequency, consumes less quantity of power and area with various clock speeds.

For signal synthesis, various methods can be employed, in which either an oscillator is worked directly at the target frequency or a sub-harmonic. Even though the activity of an oscillator at the target frequency might be the most power-efficient choice, relying on process technology it often provides a range of disadvantages. The frequency of the transistor oscillation is restricted to that of the highest level, the phase noise as well as the tuning region based on the efficiency variable as well as the tuning range of the resonator. Besides, with all the multiplication factor the edge loading decreases quickly.

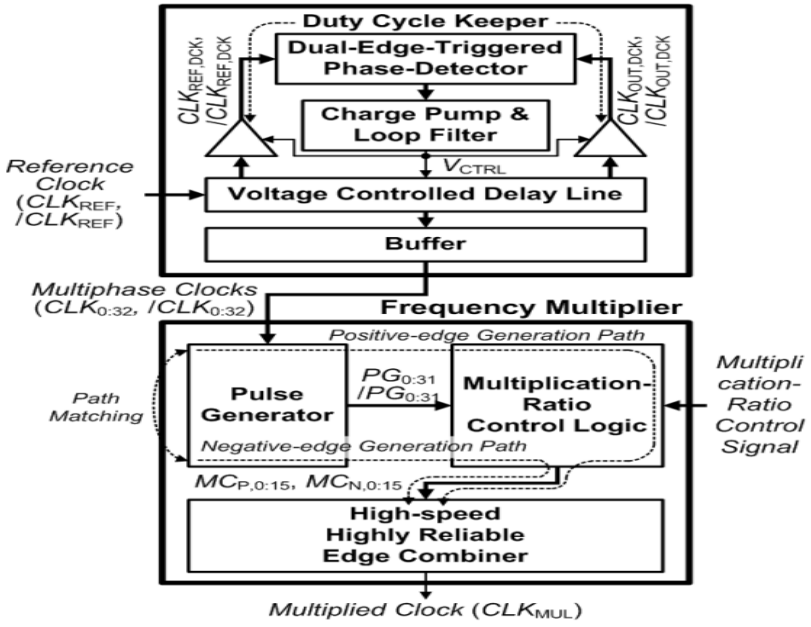

Figure 1: Overview of System clock operation

The diagram below displays two multipliers that can also during operation for performing multiplications with high speed. In fig.2 (a) The PLL arrangement indicates that the reference clock correlation. As illustrated in fig. 2(b) contains counter and clock divider with software constructs are presented.

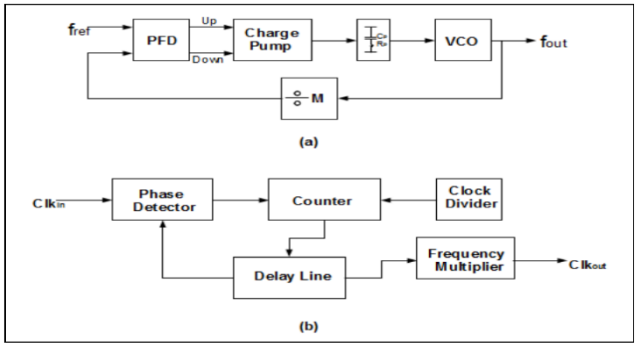

Figure 2: Process of Frequency multiplication (a) Circuit relies on PLL (b) Circuit relies on DLL

In Fig.2, the reference clock frequency is linked to the reference clock for a bit-controlled delay line produced with the original delay sensitive signals for configurations. In comparison to either the non-ideal transition properties, the effects of the high-frequency approximation would be further varying from those in the previous ideal signals review, as the influence of parasite responsive components throughout the HBT decreases to reduce circuit output to higher frequencies. Further, in saturation regions, additional charges are added into the transistor foundation, impacting the clipping at high frequencies of the upper half-wave of the collector present. Since consistently the eight pulse is contrasted either with the reference clock and according to the phase difference, a new UP or DOWN signal is produced. This input process is followed for the period of locking time slot among variations in the unit when it is locked.

Sub-system with Frequency multiplier:

A. Clock Divider: This module produces clock pulses that are running at low speeds that is very much needed for subsystem working. By sub-system divisor unit is the input to which produces the frequency output clock equivalent to the operation of required clock/4. This comprises serially linked flip-flops of T type to reach the necessary clock frequency. The waveform of the clock divider is shown in Figure 3 below.

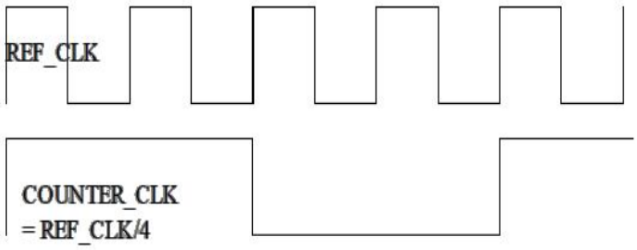

Figure 3: Clock waveform operation of divider unit

B. Phase Detector: The Phase Detector has been used to obtain a phase connection from either the delay line here between reference clock input as well as its delayed variant. To maintain a perfect synchronization relation for maintaining a consistent clock period without any delay for the model correspondingly. Figure 4 demonstrates the schematic diagram below. The phase detector circuit reflects the design of MS flip-flop.

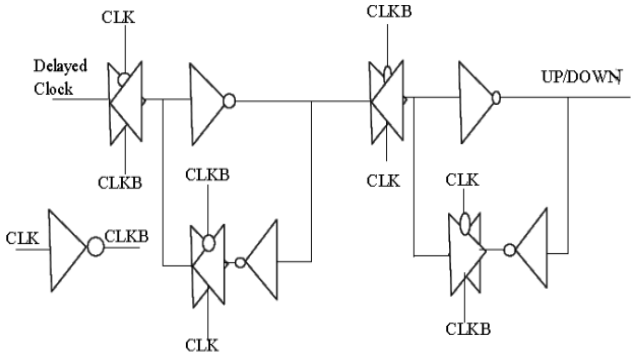

Figure 4: Circuit associated with Phase Detector

C. Up-Down Counter: All other versions generate a certain output amount, as well as the respective amplitudes, which are identical. There seem to be optimum biasing levels from which the sixth harmonic amplitude is optimum, however, the 4th and 8th harmonic amplitudes are marginal and the evaluation of the signal has complied. Its operation mainly relies on the delayed pulse with one unit that is more reference to the phase detector unit generates several pulses makes it as a counter. As somewhat of a consequence, it reduces the delayed phase by rendering the delay section. Figure 5 below displays 5 counter waveforms, respectively.

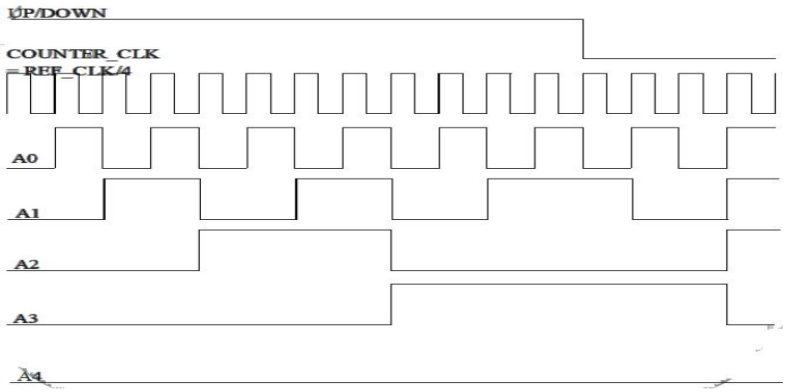

Figure 5: Up-Down Counter Waveform

IV. RESULTS AND DISCUSSION

All the results are simulated with the help of Xillinx ISE design suite and coding is done with Verilog HDL.

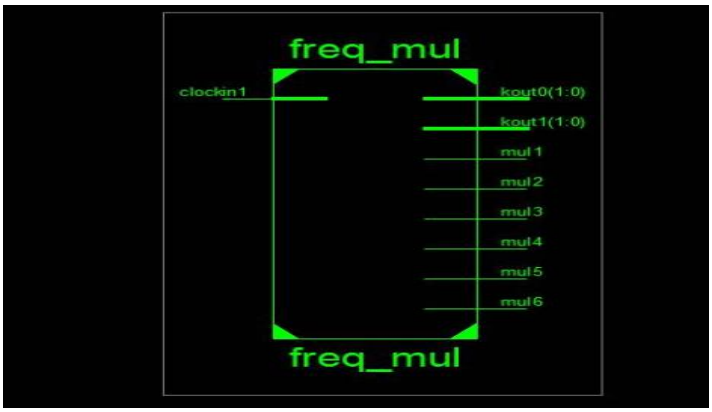

Figure 6: RTL schematic

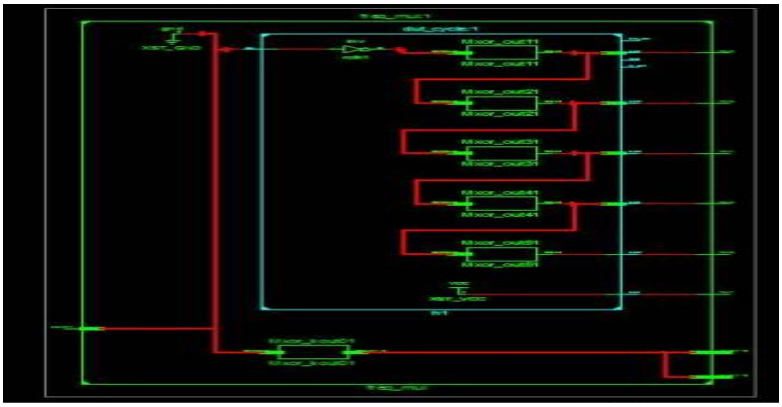

Figure 7: Technological view

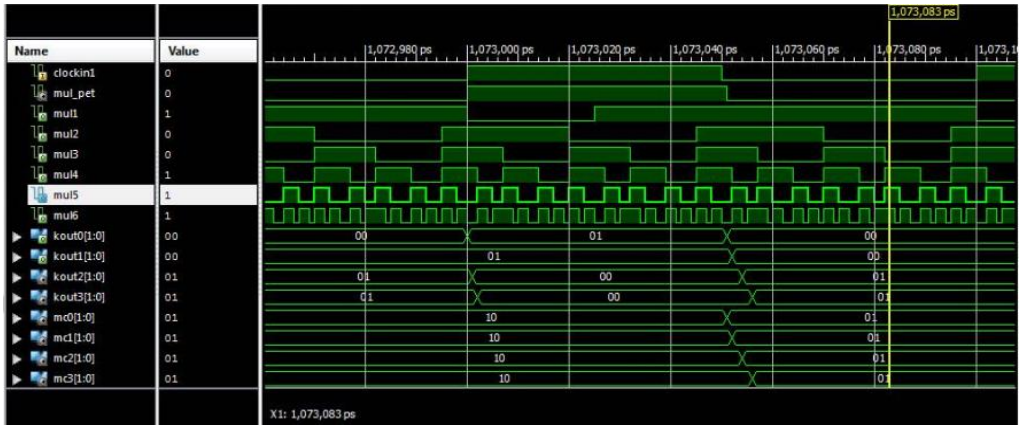

Figure 8: Simulation output wave for DLL based frequency multiplier

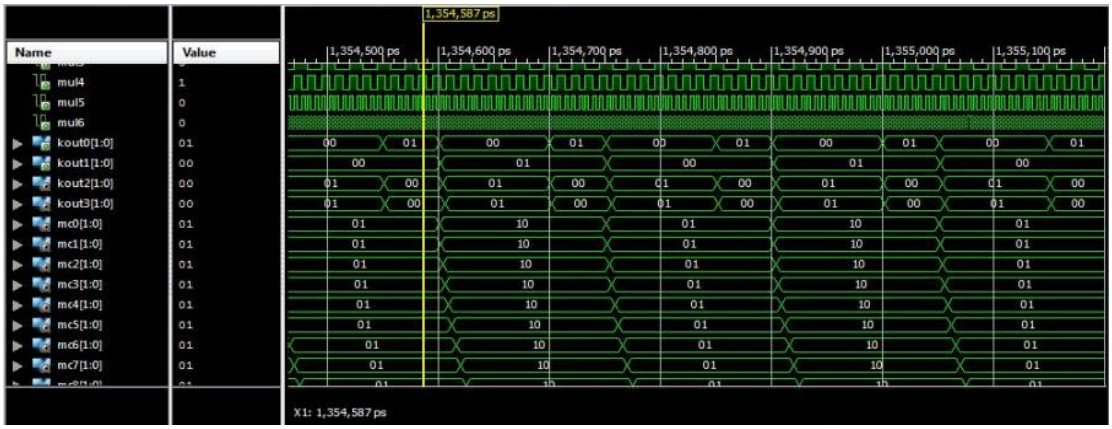

Figure 9: Simulation output wave for Dual edge trigger counter

Figure 10: Simulation output wave for 32-different phase generator

V. CONCLUSION

In this paper, a frequency multiplier is recommended for a DLL clock generator. There seems to be no PLL component in this design rather than this counter and the clock divider is inserted into the framework. The optimized pulse generator, as well as the Multiplication Rate Control Logic, was suggested to increase the delay among positive and negative paths. Eventually, a computational review to verify the output is done. It is evident in contrast with other designs that this system absorbs less power than others do in the same phase.

Abstract

Tensor Completion from a limited number of non-distorted observations, has enticed researchers interest. The color image has been considered as the three dimensional tensor. Low rank property in Optimization has been used to recover the tensors in the image. The Low rank prior alone not enough to tensor completion. The traditional tensor truncated nuclear norm approaches have been able to approximate the real rank of the tensor, but these are low rank prior approaches. Here a transformation-based optimization method has been proposed to complete the tensors of the image. The Discrete Cosine Transformation (DCT) has been used as transformation method. The tensor singular value decomposition (t-SVD) and accelerated proximal gradient line (APGL) approaches have been considered. The Full Reference metrics i.e., peak signal to noise ratio (PSNR) and structural similarity (SSIM) have been used to evaluate the proposed approach. The obtained results are superior to the existing algorithms. The PSNR and SSIM have been recorded as 27.30 dB and 0.8845 respectively.

Keywords: Tensor Completion, Tensor Singular Value Decomposition, Discrete Cosine Transform, Convex Optimization**.**

I. Introduction

An image lies in a low-dimensional space, estimating missing values in images has been considered as low-rank matrix approximation problem [I]. The Low rank matrix approximation approaches have been used to solve the corrupted input image of two-dimensional manner. The color images formed with three-dimensional space, to apply these approaches the image has to be separated as channels. These separated channels have been processed using the state-of the art methods. Again, results have to be combined [II, III]. Here recent researchers the considered color image as the 3D data and formulated the problem as the Low Rank Tensor Completion [II, III, IV, V]. Tensor completion is the process of recovering the corrupted tensors of a color image. Tensor Completion has various applications such as machine learning, compressed

Copyright reserved © J. Mech. Cont.& Math. Sci.
Jyothula Sunil Kumar et al

sensing and pattern recognition. The low rank minimization problem [II] to tensor completion has been formed as sum of metricized nuclear norm of a tensor.

$$\min_{\mathcal{J}} \sum_{k=1}^{n} \|\mathcal{J}_k\|_* subject\ to\ \mathcal{J}_\Omega = \mathcal{M}_\Omega \tag{1}$$

where I_k denotes the tensor unfolded along the k^{th} mode tensor, $\mathcal{M}_\Omega$ represents the incomplete tensor. Ω indicates the known elements set. kilmer et al. [VI] proposed a novel approach named tensor singular value decomposition (t-SVD) to perform the singular value decomposition on color images. Xue et al. [3] proposed a method incorporating the bothtruncated nuclear norm minimization [VII] and the t-SVD to an extension of matrix case. The objective function written as

$$\min_{\mathcal{J},\mathcal{W}} \|\mathcal{J}\|_* - tr(\mathcal{A}_l * \mathcal{W} * \mathcal{B}_l^T) \tag{2}$$

$$subject\ to\quad \mathcal{J} = \mathcal{W}, \mathcal{W}_\Omega = \mathcal{M}_\Omega$$

The truncated nuclear norm minimization alone not sufficient to recover the missing areas in two-dimensional case. By utilizing a transformation based truncated nuclear norm approach can recover the images with more structural and texture information [VIII, IX]. It has been extended to tensor case, [V] proposed an approach. The Discrete Cosine Transformation (DCT) has been incorporated with the Xue et al. proposed method. Here a DCT based Accelerated Proximal Gradient Line (APGL) approach has been introduced to tensor completion. It is providing the excellent recovery in the structure information of the image even the missing ratio is more than 80 %.

The paper alignment has been done as the section 1 started with the introduction to tensors and literature review. Section 2 provided some basics of tensors and properties. Section 3 discussed the methodology to proposed approach. Section 4 has been accommodated with the results and discussion. Section 5 Carried out the conclusion.

II. Notations and Preliminaries

The italic capital letters indicates the tensor, normal capital letters are indicates the matrix, italic small letter indicates the vector and the normal small letter indicates the scalar. The image tensor will be $\mathcal{J} \in \mathbb{C}^{(n1 \times n2 \times n3)}$. The tensor contains the horizontal, lateral and frontal slice. The frontal slice $\mathcal{J}(:,:,k)$can be represented as the $\mathcal{J}^k$. The block circulant matrix and unfolded tensor have been written in eq.3 and eq.4.

Copyright reserved © J. Mech. Cont.& Math. Sci.
Jyothula Sunil Kumar et al

$$bcirc(\bar{\mathcal{I}}) = \begin{bmatrix} I^{(1)} & I^{(n3)} & \dots & I^{(2)} \\ I^{(2)} & I^{(1)} & \dots & I^{(3)} \\ . & . & \dots & . \\ . & . & \dots & . \\ . & . & \dots & . \\ I^{(n3)} & I^{(n3-1)} & \dots & I^{(1)} \end{bmatrix} \tag{3}$$

$$unfold(\mathcal{I}) = \begin{bmatrix} I^{(1)} \\ I^{(2)} \\ . \\ . \\ . \\ I^{(n3)} \end{bmatrix} \tag{4}$$

Definition: Tensor Product[X] Let $\mathcal{X} \in \mathbb{R}^{n1\times n2\times n3}$ and $\mathcal{Y} \in \mathbb{R}^{n2\times n4\times n3}$. The tensor product between *X*and *Y* can be written as

$$\mathcal{X} * \mathcal{Y} = fold(bcirc(\mathcal{X}).unfold(\mathcal{Y})) \tag{5}$$

where . indicates the matrix product.

Definition: Tensor Transpose [X]The transpose of a tensor $X \square R^{n1 \square n2 \square n3}$ becomes as X^T with order *n*2´*n*1´*n*3. The frontal slice need to be transposed and then reversing the order of the frontal slices from 2 to n3.

$$(\mathcal{X}^T)^{(1)} = (\mathcal{X}^1)^{(T)}$$
$$(\mathcal{X}^T)^{(i)} = (\mathcal{X}^{n3-i+2})^{(T)}, i = 2,3,..,n3. \tag{6}$$

Definition: Identity Tensor [X]The identity tensor $\mathbf{I} \in \mathbb{R}^{n1\times n2\times n3}$ contains the first frontal slice $n \times n$identity matrix, remaining frontal slices contains all zeros.

Definition: Orthogonal Tensor [X] A tensor $\mathcal{X} \in \mathbb{R}^{n1\times n2\times n3}$ orthogonal if it satisfies

$$\mathcal{X}^T * \mathcal{X} = \mathcal{X} * \mathcal{X}^T = \mathbf{I} \tag{7}$$

Theorem: T-SVD [X] Let $\in \mathbb{R}^{n_1\times n_2\times n_3}$ by applying TSVD the *X* decomposed as the $\mathcal{U} \in \mathbb{R}^{n_1\times n_1\times n_3}, \mathcal{S} \in \mathbb{R}^{n_1\times n_2\times n_3}$ and $\mathcal{V} \in \mathbb{R}^{n_2\times n_2\times n_3}$. The Fig 1. provides the basic multiplication order of T-SVD.

$$\mathcal{X} = \mathcal{U} * \mathcal{S} * \mathcal{V}^T \tag{8}$$

Copyright reserved © J. Mech. Cont.& Math. Sci.
Jyothula Sunil Kumar et al

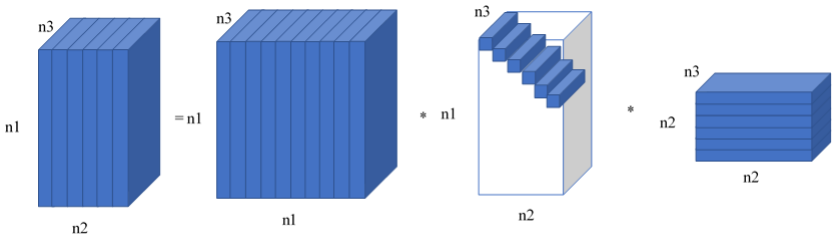

Fig. 1: Basic Structure of T-SVD

Definition: Tensor Singular Value Thresholding[III] Let T-SVD of tensor $X \in R^{n_1 \times n_2 \times n_3}$ will be $U*S*V^T$. The Singular Value Thresholding (SVT) has been applied to each frontal slice of the tensor $\mathbb{S}$.

$$\mathcal{D}_{\mathcal{T}}(\mathcal{X}) = \mathcal{U} * \mathcal{D}_{\mathcal{T}}(\mathcal{S}) * \mathcal{V}^T \tag{9}$$

III. Tensor Completion With DCT Based Optimization

The DCT has been used in image compression, image de-noising and designing the transform coders etc., wang et al. [VIII] extended the DCT with gradient based optimization towards the image completion. Ping-Ping Wang et al. The n-dimensional DCT has been calculated by utilizing the separability property n times the one-dimensional DCT will be calculated. Here the image contains the three spaces, first images has been divided in to 8×8 blocks and applied the two-dimensional DCT, then applied one dimensional DCT to the same block. The one-dimensional DCT and two dimensional DCT can be written as

$$\mathbb{C}(j) = \alpha(j) \sum_{i=0}^{n-1} u(i) cos\left[\frac{\pi(2i+1)j}{2n}\right] \tag{10}$$

where $\alpha_j = \sqrt{\frac{1}{n}}$ if j=0 else $\sqrt{\frac{2}{n}}$

$$\mathbb{C}_{j_1,j_2} = \alpha_{j_1}\alpha_{j_2} \sum_{i_1=0}^{n_1-1} \sum_{i_2=0}^{n_2-1} c(i_1,i_2,j_1,j_2)\mathbf{I}_{i_1,i_2} = C_{j_1,j_2} * \mathbf{I} \tag{11}$$

where n_1,n_2 and n_3 are the size of the image block. $\alpha_{j_1} = \sqrt{\frac{1}{n_1}}$ if $j_1 = 0$ else $\sqrt{\frac{2}{n_1}}$, $\alpha_{j_2} = \sqrt{\frac{1}{n_2}}$ if $j_2 = 0$ else $\sqrt{\frac{2}{n_2}}$. The cosine basis function written in eqn.11

$$c(i_1,i_2,j_1,j_2) = cos\left(\frac{\pi(2i_1+1)j_1}{2n_1}\right) cos\left(\frac{\pi(2i_2+1)j_2}{2n_2}\right) \tag{12}$$

After obtaining the coefficients the selection has been considered. Based on the selection mask the values have been considered in the inverse DCT. here the selection mask S_{pq} considered based on p and q values. p=1,2,3and q=1,2,3

Copyright reserved © J. Mech. Cont.& Math. Sci.
Jyothula Sunil Kumar et al

$$S = \begin{cases} S_{pq} = 1 & if \quad p \geq 1,2,3 \quad q \geq 1,2,3 \\ S_{pq} = 0 & Otherwise \end{cases} \tag{13}$$

The inverse DCT has been applied to the block to retain image I_k. The optimization process goes as in eqn. 15,16 and 17.

Update $\mathcal{I}_{k+1}$:

$$\mathcal{I}_{k+1} = arg\min_{\mathcal{I}} \|I\| + \frac{1}{2t_k} \|\mathcal{I}_k - (\mathcal{M}_k - (t_k \nabla f(\mathcal{I}_k)))\|_F^2 \tag{14}$$

The eqn. 14 has been solved by utilizing the T-SVT. i.e.,

$$\mathcal{I}_k = \mathcal{U}_i \mathcal{D}_\tau(\mathcal{S}_i) \mathcal{V}_i^T \tag{15}$$

where $\mathcal{D}_\tau(\mathcal{S}_i) = diag(max(\sigma_t - \tau),0)_{1 \leq t \leq r}$, $i = 1,2,..,n_3$

Update t_{k+1}:

$$t_{k+1} = \frac{1 + \sqrt{1+4t_k^2}}{2} \tag{16}$$

Update M_{k+1}:

$$\mathcal{M}_{k+1} = \mathcal{I}_{k+1} + \frac{t_k - 1}{t_{k+1}} (\mathcal{I}_{k+1} - \mathcal{I}_k) \tag{17}$$

Algorithm: DCT with t-SVD and APGL for Tensor Completion

Observation: $\mathcal{I}, \Omega, \Omega_c, \lambda, \gamma, R$;

Initialization: $t = 1, \mathcal{M} = \mathcal{I}, k = 1$;

Calculate the gradient of f(I) to the Equation (22)

$$[\mathcal{U}, \mathcal{S}, \mathcal{V}] \leftarrow T - SVD(\mathcal{M}_k - t_k \nabla f(\mathcal{I}_k)$$

update $\mathcal{I}_{k+1}, t_{k+1}, \mathcal{M}_{k+1}$;

k=k+1;

Until $\| \mathcal{I}_{k+1} - \mathcal{I}_k \| \leq \epsilon$

Output: The Recovered Image $\hat{\mathcal{I}} = \mathcal{I}_{k+1}$

IV. Results and Discussion

Parameter Settings: The DCT block size considered as 8´8, the minimal rank is 1 and the maximum rank is 20. The lambda and tolerance values have been considered as 0.01 and 0.0001 respectively. In the image randomly 80% of tensors have been corrupted. These corrupted images have been recovered with the proposed approach

Copyright reserved © J. Mech. Cont.& Math. Sci.
Jyothula Sunil Kumar et al

and the results have been evaluated. The Full-Reference Image Quality Assessment Measures (FR-IQA) i.e., PSNR and SSIM have been used to evaluate.

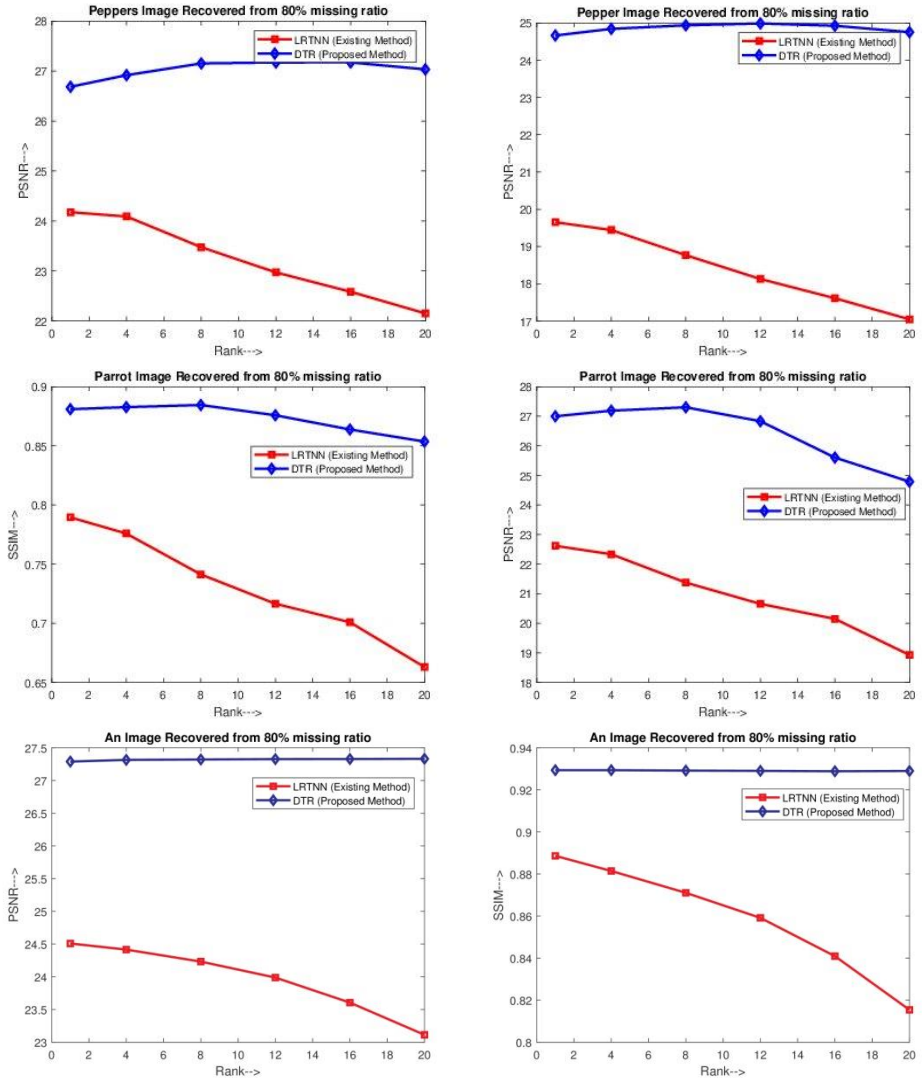

Figure 2: Recovered images from 80% missing ratio

Fig2. consists of two images evaluated with PSNR and SSIM, Fig 2 a) and c) have been plotted with PSNR vs rank. The proposed method has high values in comparison with the existing LRTNN method. The maximum PSNR value obtained at Rank 8 i.e. 27.30 dB to parrot image. The Fig 2 b) and d) shows the SSIM vs Rank, the SSIM value attain the maximum at rank =8 as 0.8845. To the existing LRTNN method got PSNR as 22.61 and SSIM as 0.7895. The DCT transformation has the feature of energy compaction and smoothing gives the scope in recovering of structure information.

Jyothula Sunil Kumar et al

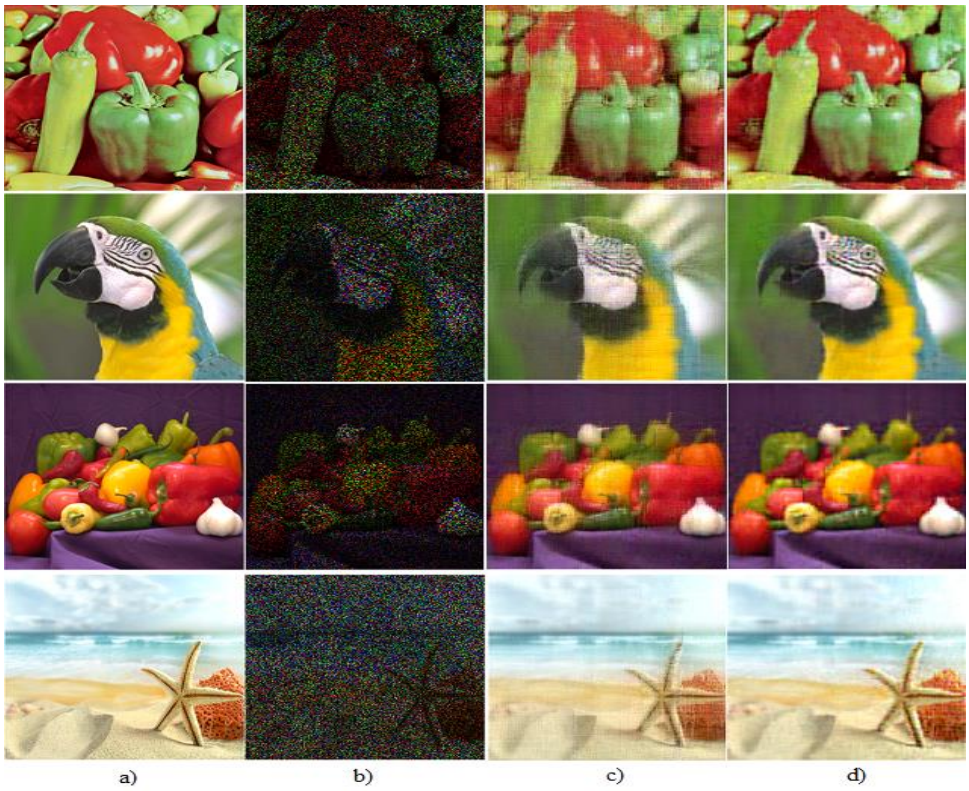

Fig. 3: a) Original Image, b) 80% missing in the image, c) Recovered using Low Rank Tensor Completion using Truncated Nuclear Norm Regularizer, d) Recovered from DCT based TSVD Optimization method

V. Conclusions

The proposed approach DCT transformation based APGL Optimization has been recovering the tensors missing in the image. The T-SVD and the truncated nuclear norm have been utilized instead of other existing methods. The recovery has been evaluated using the FR-IQA measures named PSNR and SSIM. The improvement values PSNR and SSIM are 5.92 dB and 0.1433 respectively. The DCT based TSVD optimization method has been outperformed.

ANALYSIS OF HSI COLOR MODEL ON CHAOS THEORY IN SPATIAL DOMAIN

Mr.G.Prasanna Kumar

Malla Reddy Engineering College (Autonomous) Department of Electronics & Communication Engineering

ABSTRACT

Image Steganography is the process of embedding text in images such that its existence cannot be detected by Human Visual System (HVS) and is known only to sender and receiver. This paper presents a novel approach for image steganography using Hue-Saturation-Intensity (HSI) color space based on Least Significant Bit (LSB). The proposed method transforms the image from RGB color space to Hue-Saturation-Intensity (HSI) color space and then embeds secret data inside the Intensity Plane (I-Plane) and transforms it back to RGB color model after embedding. The said technique is evaluated by both subjective and Objective Analysis. Experimentally it is found that the proposed method have larger Peak Signal-to Noise Ratio (PSNR) values, good imperceptibility and multiple security levels which shows its superiority as compared to several existing methods.

1. INTRODUCTION

The word steganography is derived from two Greek words; "stegano" meaning protected and "graphia" meaning writing. It can be defined as the process of writing messages in a way in which the presence of secret message is known only to sender and receiver. Steganography require a carrier object, secret data and embedding algorithm. It may also need an encryption algorithm and secret key in some cases in order to increase the security levels of steganography. Applications of steganography includes secure transmission of top secret documents between national and international governments, securing online banking and voting systems, secret communication between criminals and terrorists and sending Trojan horses and viruses to attack on systems etc.[1-7].

1.1 Steganography VS Cryptography

Steganography and Cryptography both techniques are used for data confidentiality (protection of information from unwanted parties).However there also exists some differences between them that is described below.

i. Cryptography is the practice and study of secure communication but Steganography is an art as well as a science of covert communication.

ii. The main focus of Cryptography is to keep the contents of the data secret while Steganography aims to keep the existence of the data secret.

iii. Security in cryptography is achieved by converting the secret data into non-understandable form while in steganography; security is achieved by hiding data in apparently harmless carriers to hide the existence of data.

iv. Cryptography provides us secure communication by using a key to read the information. An intruder is unable to remove the used encryption but he/she can easily modify the encrypted file and can make the encrypted file meaningless which cannot be easily understood by the receiver. On the other hand, Steganography provide us a method of covert communication that can be removed only if the carrier object in which data has been embedded, is modified. The confidentiality of hidden data will remain as it is, until and unless a suspicious user is succeeded in finding a method for detecting it.

v. The final endeavor of cryptography is a cipher text but the final output of steganography is a stego object.

vi. To break the cryptography, we compare some sections of the plaintext with the sections of the cipher text but in breaking steganography we compare the cover object with the stego object plus some possible sections of the message.

Since the rise of Internet one of the most important factors of information technology and communication has been the security of information. Cryptography was created as a technique for securing the secrecy of communication and many different methods have been developed to encrypt and decrypt data in order to keep the message secret. Unfortunately it is sometimes not enough to keep the contents of a message secret, it may also be necessary

to keep the existence of the message secret. The technique used to implement this, is called steganography [1]. Steganography is the art of hiding messages in a medium called cover object in such a way that existence of message is undetectable. Imperceptibility is clearly is the most important requirement in steganographic schemes [2]. The cover object could be a digital image, an audio file, or a video file. The secret message called payload could be a plain text, an image, a video file or an audio. Steganographic methods are classified into spatial domain embedding and frequency domain embedding. In frequency domain, images are transformed into frequency components by using DCT, FFT or DWT and then messages are embedded either in bit level or in block level [3]. In spatial domain LSB replacing is the most widely used data hiding method. However most of the LSB Techniques are prone to attacks [4, 5]. Because of low computational complexity and high embedding capacity this paper mainly deals with LSB Steganography method.

1.2 Types of Steganography w.r.t carrier object

Steganography embeds secret data into digital carriers like image, audio, video etc such that it cannot be easily detected by the Human Visual System (HVS). There are five types of steganography on the basis of carrier object that is used for embedding the secret data. These types are briefly described and its diagrammatic representation is given in Fig.1.

1.2.1 Image Steganography

The type of Steganography in which image is used as cover object is called Image Steganography. Generally, the techniques in this method modify the image pixels for hiding secret information. Images are considered to be the best cover objects/carriers for hiding information because it contains large amount of redundant bits.

1.2.2 Network Steganography

The type of Steganography in which network protocol (TCP, IP, UDP and ICMP etc) is used as cover object is called Network Steganography. In this method, information is hidden in some fields of the Header of TCP/IP packet that are optional or never used.

1.2.3 Text Steganography

Text Steganography uses text as a carrier for hiding secret information. In this technique secret message is hidden in the nth letter of every word of carrier text. Unlike other types of steganography (audio, video, network and image), Text steganography is much more difficult because of less redundancy in the text. Text steganography is preferable for simple communication where less memory is needed.

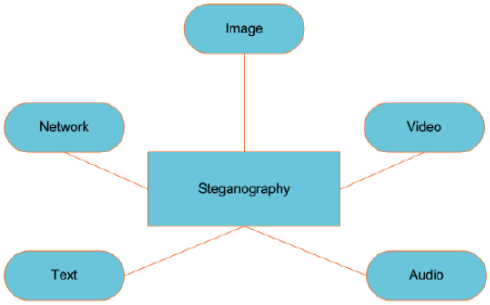

Figure 1: Types of Steganography w.r.t carrier object

2. LITERATURE REVIEW

The simplest method to hide secret data inside a cover image is LSB. In this method the least significant bits of the carrier image pixels are replaced with the secret data bits. Payload capacity of LSB method can be increased if more than 1 LSBs are used for message embedding but it brings noticeable changes in the carrier image. LSB method is simple to implement but it is vulnerable to many statistical attacks like RS, image processing operations and Chi-Square analysis etc.

Adnan Abdul-Aziz Gutub proposed a more robust steganographic technique in which one channel is used for indication while other two channels are used for embedding secret data in a predefined cycle manner which enhances the robustness of proposed method. The experimental results show us the high payload capacity and better imperceptibility of the proposed algorithm. This method also avoids the key exchange overhead.

In [19], the authors propose a robust method which embeds variable bits in image pixels depending on the pixel value and value of mean and standard deviation (SD). Two bits are inserted in the image pixel if (mean–SD/2) is greater than pixel value; 3 bits are stored if (mean +SD/2) is greater than pixel value otherwise 4 bits are stored in each pixel value. Chaotic effect is also obtained in the proposed method by using random traversing path which make the attack loathsome but nothing is given about generating the random traversing path.

Grover et al., presents an adaptive edge based LSB substitution technique which hides three(3) bits of secret data in edgy pixel and two(2) secret bits in non-edgy pixels in blue channel of the RGB image. This method has high payload capacity and is more robust as compared to simple LSB substation method because secret data is divided into two sets first and then it is embedded in cover image starting from the

central pixel and traversing through the whole image which increases its robustness.

In the authors proposed a new method to embed secret data in the GREEN or BLUE channel of carrier image on the basis of secret key bits and RED channel LSB. This method adds one more level security to the existing LSB method by utilization of secret key. The RED channel LSB and secret key bit is xored and then a decision is taken on the basis of its result to replace the LSB of GREEN or BLUE channel. The proposed method has the same payload, more robustness and better security as compared to simple LSB method. However the secure key exchange of secret key is an open challenge and is an extra overhead of proposed method.

Ibrahim and Kuan have developed a SIS (Steganography Imaging System) which uses a secret key to enhance the security of the proposed system. The authors have made use of zipping to zip the secret key and secret data in order to increase the payload. The zip file is then converted into bits stream and hidden in cover image. The proposed algorithm has high payload capacity and better quality of stego images but this technique is proposed only for BMP format images.

Thanikaiselvan and Arulmozhivarman have proposed a more robust approach for color images in transform domain based on Reversible Integer Haar Wavelet Transform (RIHWT) and Graph Theory (GT). The proposed method applies RIHWT on RED, GREEN and BLUE channels separately and selects wavelets coefficients based on Graceful Graph (GG) for randomly scattering the secret data in wavelets coefficients. Three different unique keys are used for encoding and decoding of secret data in the proposed method. Key1 is subband selection key for selecting one of the sub bands i.e. LL, LH, HL and HH; Key2 is for selecting coefficients inside the selected subband randomly on the basis of GG; Key3 is for deciding the number of bits to be stored in selected coefficients. The proposed method gives us promising results in terms of imperceptibility, robustness and payload.

3. PROPOSED ALGORITHM

All the communicating bodies want the confidentiality, integrity and authenticity of their secret information. Different approaches are used to cope with these security issues like digital certificate, digital signature and cryptography. But these methods alone cannot be compromised. Steganography is the best solution to these problems as it hides the existence of secret data. This paper proposes a novel image steganography LSB based technique for RGB images using color space exchanging from RGB to HSI. The secret data is embedded in I-Plane of HSI color model using LSB method. Finally the resultant image is retransformed to RGB color model to make the stego image.

3.1 Color Models

Color models are also known as color systems or color spaces. The main goal of these color spaces is to represent all colors in a standard way. A color model is a way of representing a set of colors mathematically. The most popular color spaces are RGB, YCbCr (Luminance Component, Chroma Blue difference, Chroma Red difference) and CMYK (Cyan, Magenta, Yellow and Black), HSI (Hue, Saturation and Intensity).

The HSI color model is derived from RGB color space that represents colors the way the human eyes perceive and interpret colors. Human eye describes colors by its hue, saturation and intensity. Hue represents a pure color i.e. pure red, yellow etc. Saturation gives us a measure of the degree to which a pure colour is diluted by white light. Intensity is the brightness of a color.

3.1.1 Why HSI Color Model for Embedding

The proposed method uses HSI color space for information hiding because of the following reasons.

„« Processing an image in RGB color system is relatively more difficult and time consuming. All the three values of a particular pixel need to be read, the intensity is then calculated, the desired changes is made, new RGB values are recalculated and stored.

„« The brightness information in RGB color space is embedded in its each layer which indicates that all the three layers are strongly correlated to one another and any changes to one of its layer will have its corresponding effect on other layers.

„« To generate a particular color in RGB colour space, all the three components must be of equal bandwidths.

„« RGB is not an efficient color space when we are concerned with real-world images.

„« To simply processing, programming and end user manipulations.

Embedding Algorithm

Input: Cover Colour Image, Secret data

Output: Stego Image

Step 1: Take the cover RGB image and secret data.
Step 2: Convert the RGB image into HSI color model using section 3.1.2 formulas.
Step 3: Convert the secret data into 1-D array of bits.
Step 4: Take a pixel from I-Plane and replace its LSB with a secret bit.
Step 5: Repeat Step 4 until and unless all secret bits are encoded in the I-Plane pixels.
Step 6: Convert the HSI image into RGB color space using the formulae of section 3.1.3.
Step 7: Write the stego image.

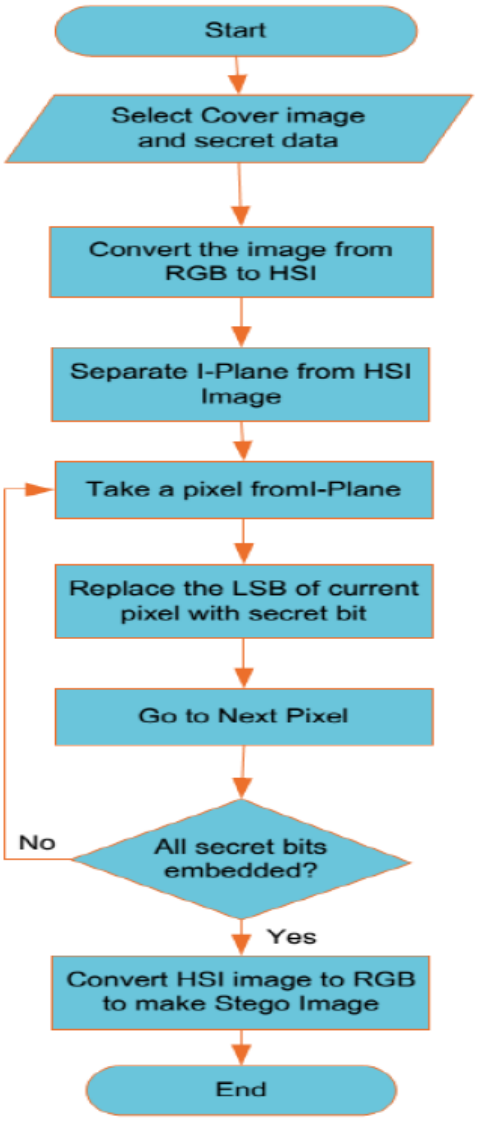

Figure 2: Embedding Algorithm Flowchart

CONCLUSION

A secure LSB technique for image steganography has been proposed in this paper using the concept of non-linear dynamic system (chaos). The chaotic system is highly sensitive to initial values and parameter of the system. The proposed algorithm provides added security to the base steganography technique. Application of separate chaotic sequence for encryption of each part of secret image provides an added security from attacks. The proposed technique uses host image files in spatial domain to hide the presence of sensitive information regardless its format. Performance analysis of the proposed technique after comparing with 3-3-2 LSB technique is quite encouraging. The proposed technique is applied to JPEG files; however it can work with any other formats. Further work includes adapting the free parameters of the logistic chaotic map using soft computing techniques as chaotic systems are highly sensitive to initial conditions.

Abstract

Designing an electronic circuit with low power and small area are two important concerns for signal processing designers. Though fast emergence of the new technologies and several reviews over signal and speech processing, the difficulty cannot be fulfilled for the hearing impaired people. Many filter bank algorithms have been discussed on the hearing aid design to extend the efficiency. The conventional design of cascaded Direct Truncation (DT) data path is mainly based on the design of Full Precision Static Floating Point. In this paper, we introduce Static Floating Point Sample Rate Converter (SFP-SRC) with Linear Phase Finite Impulse Response (LPFIR) for hearing aid applications. The Sampling Rate Conversion is done before or after the LPFIR filter with upsampling and downsampling factors. In order to increase efficiency of DSP systems, filter bank algorithms need more than one sampling rate. The proposed method provides minimum delay and excellent Signal to Noise Ratio (SNR) performance when compared to Post Truncation (PT) data path. In order to obtain better performance, many experiments have been conducted. The proposed SFP-SRC is suitable for hearing assistance applications. Hence, it is implemented on 1/3 octave analysis filter bank with umc-90nm CMOS technology at 24 KHz.

Keywords : Finite Impulse Response, Filter bank algorithms, Digital hearing aid, DSP algorithms

I. Introduction

In recent years, novel techniques of Digital Signal Processing (DSP) algorithms like Noise reduction, Auditory Compensation, Sub-band calculation, Echo Cancellation, and Speech Enhancement are applied repetitively [XVI]. DSP

N. Subbulakshmi et al

algorithms are used for implementing hearing aid devices to enhance speech precision in availability of noise [XXI]. Auditory compensation provides the solutions to the person who are severely affected from the hearing illness. Figure.1 describes the block diagram of a typical hearing aid design [XIII].

Hearing aid includes a filter bank which has a several bands and at the output a compressor to balance the loss of audibility. Several low power algorithms are implemented such as Co-efficient Decimation, Frequency Response Masking and ANSI filter. For the hearing imparedpepope hearing thresholds normalyhighfor high frequency sounds is advanced when compared to the reference speechintensities. Hearing aid does the capability of enhancing the input sounds to equivalent audiogram values. For different frequency levels, sound inputs are adjusted at to achieve the exact sounds. Various algorithms have been discussed about Non-uniform, Uniform, Interpolated FIR, ANSI S1.11and Quasi 10 ms and Octave ([III], [VII], [XI], [XXVI], [XXVII], [XXIX] and [XVIII]) for digital hearing aids. Each design has its distinct architecture with corresponding merits and demerits. Variable filter banks are discussed in [XXIX], [XXVIII] and [XII]. The Frequency Response Masking (FRM) filter banks are described in [XXV] and [XVIII] for reducing the filter complexity and group delay.

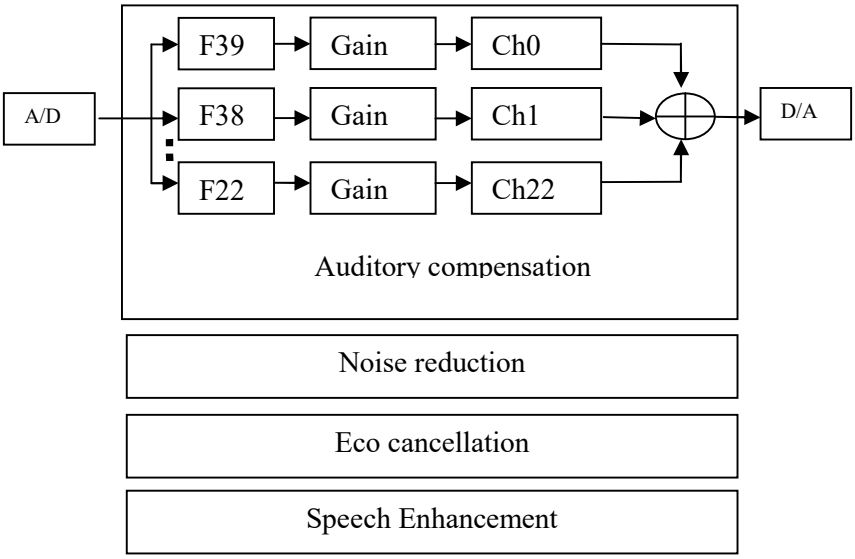

Fig 1. Block diagram of a Typical Hearing Aid [XIII]

Rapid increase of emergimg methods, more multifaceted algorithms may be incorporated in the hearing aid applications to enhance performances of the DSP circuits. Though the implementation of the DSP algorithms, to modify the complexity restricts signal processing algorithms. The fundamental blocks of filter are adder, multiplier, shifter and accumulator. Some of the DSP algorithms such as Fast Fourier Transform (FFT), Direct Cosine Transform (DCT) and the Data path of the DSP are

Copyright reserved © J. Mech. Cont.& Math. Sci.
N. Subbulakshmi et al

used in manyapplicaations. The synthesis of high level and fixed point circuits verification for analyzing the range and precision are discussed in [I], [II], [XIV], [XV], [V] and [XIX]. In the Floating Point Arithmetic (FPA) design, high precision is implemented with a large dynamic range exponents and Mantissa. Hence the floating point arithmetic is helpful for the algorithms which are dealt with unsolvable issues due its high precision.

The parallel and cascaded data path are important in the filter design. The cascaded adder-multiplier-accumulator data path is used in Linear Phase FIR filter. The cascaded data path maintains comparable operations per cycle with limited access of hardware accordingly when compared to the parallel datapath. When compared to Post Truncation (PT) method or Full Precision (FP), Direct Truncation (DT) which is cascaded is expensive and Speedy. In a digital hearing aid must consume low power usage than processor with other applications. The complicated data path has a cycle dual Multiply and Accumulator (MAC) with 24-bit for reasonable accuracy Audio signal processing. The Static Floating Point arithmetic is used to provide optimal SQNR performance.

A High precision LPFIR filter is used in [XX]. It comprises of embedded shifter with one-bit, DT adder, 16-bit DT multiplier, shifter and accumulator. The two interval 1-bit shifters are used for better hardware utilization and parallel structure of the filter data path. This filter is implemented on 18-band quasi ANSI S1.11 1/3 octave analysis filter bank. The Silicon area is diminished to 8.3%. The rest of the paper is organized as follows. Section II discusses the PEV analysis. Section III provides the proposed SFP-SRC filter bank to digital hearing aids. Section IV discusses about the results. Section V concludes the paper.

II. Experimental Study

A compact DSP for multi core systems which is fully programmable is described in [VI]. It performs light weight arithmetic-static floating point Arithmetic. Various software techniques have been extensively discussed to deminish computation complexity in the algorithm and round off noise is encountered in the proposed design. A power efficient computing platform is proposed in [XXII] for hearing aids. It consists of four processing elements. Those elements have RISC processor with various power competent accelerators. Those hardwired accelerators include truncated multiplier and static floating point for improving the SNR and diminish the hardware difficulty. This method reduces the data path, area and improves SNR reasonably than Psot truncation method. In FPA, every data manipulation normalizes its value before obtaining the results. DSP designers generally choose the fixed point arithmetic. Though, this method does not suitable for the FIR filter due to its high attenuation parameter constraints. The stop band attenuation of ANSI filter bank (for Example) is 60 dB at least. Therefore the optimal design is a combination of the floating point arithmetic and integer arithmetic [XX].

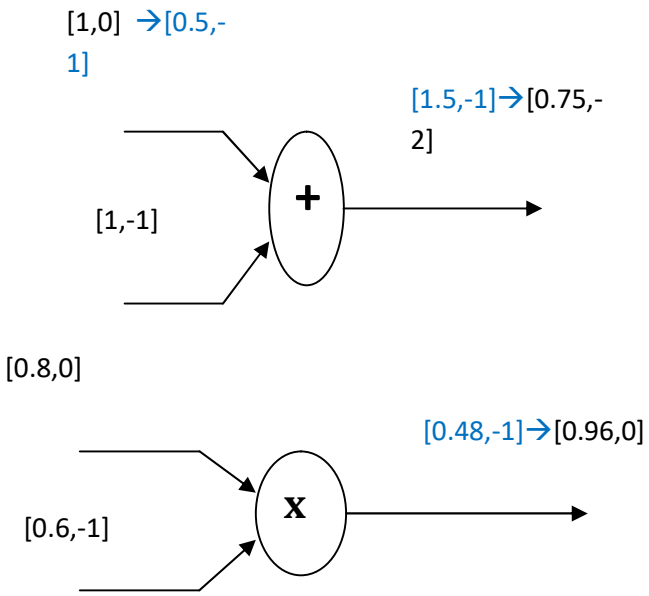

Fig 2. PEV Analysis (a)Addition and (b) Multiplication

The DSP algorithms are represented by Data Flow Graph (DFG), in VLSI signal Processing, nodes includes inputs & outputs, adders, multipliers and the data dependency occurs at in between nodes. In order to achieve high precision word length, the Satic floating point arithmetic is suitable [XX].

Peak Estimation Vector (PEV) [VI] : [M, r] of each node is evaluated in the DFG. M denotes the maximum value that cause change in the output and r is a radix point and a non-negative integer shown in Fig 2. (a) and (b).

M x 2-r = M/2 x 2-(r-1)

[M, r] = [M/2, r-1]

The PEV analysis of nodes in DFG is estimated by the following rules [VI]:

a. Addition rule:

'r' should be identical before performing the addition or subtraction operation and the equation becomes

[M1, r] + [M2, r] = [M1 + M2, r]; Add M1 and M2 by keeping r as such.

b. Multiplication rule:

The equation becomes,

[M1, r1] x [M2, r2] = [M1 x M2, r1 + r2]; Multiply M1 and M2 by adding r1 and r2.

c. Normalization rule:

Copyright reserved © J. Mech. Cont.& Math. Sci.
N. Subbulakshmi et al

M associated with radix point 'r' should be sustained as a fractional value among 0.5 to 1. If the M is divided by 0.5 then the r is added with (-1). If the M is multiplied by 0.5 the n r is added with (+1).

In Fig2., the adder has input different M values and different r values. But in the PEV analysis the added output shuld be the r value. hence it is normalized with 0.5 to 1. The first input ([1,0]) of the adder is normalisedi.e M is multiplied by 0.5 and adding -1 with the r. The normalized values becomes [0.5, -1]. The output of the adder is also normalised by 0.5. In the multiplier, there is no need to normalize the input because the multiplier output is the added cmbination of r1 and r2. Hence, directly we can get the output by multiplying M1 and M2 and simply adding the r1 and r2.

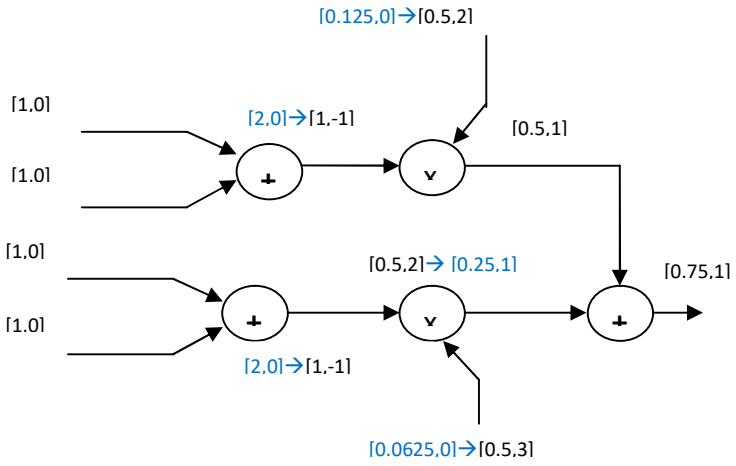

Fig 3. PEV Analysis for FIR Filter

The ouput of the multiplier is then normalized by 0.5. the final values are: [0.96,0]. Figure. 3 shows the PEV analysis of DFG of LPFIR filter. Assume that all input values are normalized to [1, 0]. Two co-efficient values h1 and h2 are considered as 0.125 and 0.0625 respectively. Initially, the coefficients are normalized as [0.5, 2] and [0.5, 3] by normalized rule. After the computation of addition node by its addition rule, the output values are normalized. Hence, [2, 0] is normalized as [1, -1]; Then using multiplication rule, the multiplication values are evaluated as [0.5, 1] and [0.5, 2]. The multiplication output [0.5, 2] is normalized to [0.25, 1]. Finally, the values [0.5, 1] and [0.25, 1] are added and hence the filter output is calculated by PEV analysis. This proposed method provides more effective bits which are stored instead of zeros in the limited word length. This shows that the coefficient value of SFP has better accuracy than fixed point arithmetic. Fig 3. shows the Direct Truncation data path for 16-bit LPFIR filter. It includes two adders and one multiplier for the data path. After applying the PEV analysis the output becomes same for all the nodes of operation.

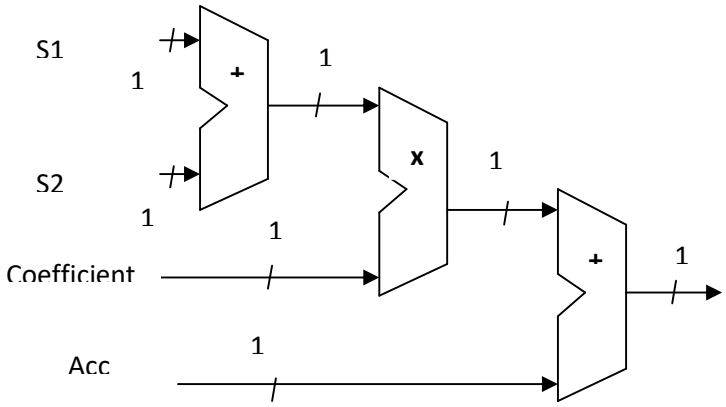

Fig 4. 16-bit Direct Truncation Data path

III. Proposed PEB Based Filter Bank

In DSP algorithms,several sub-blocks with individual sample clock rates are necessary for interfacing each block together. Sampling rate coverters are utilized in many applications such as digital audio resampling, biomedical applications, CORDIC, Software Defined Radio, etc. If the design needs m operations per cycle,then the reduction of sample rate with respect to the input signal by a factor X.

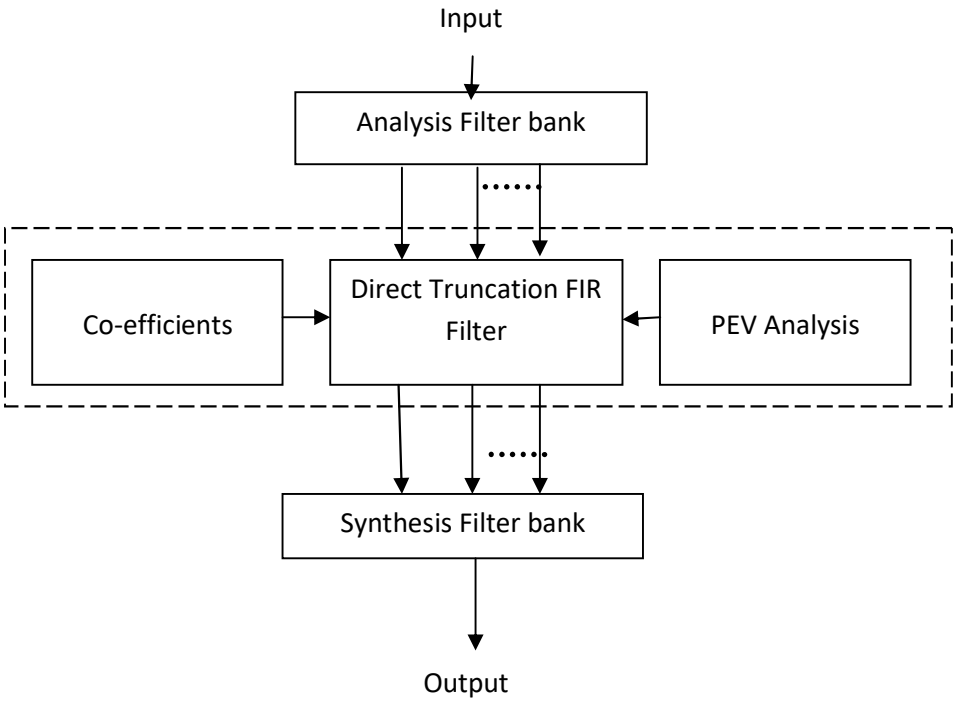

Fig 5. Block Diagram of Proposed PEVFB

Copyright reserved © J. Mech. Cont.& Math. Sci.
N. Subbulakshmi et al

The arithmetic bandwidth is reduced from its mf_s to mf_s /X operations per second. However, the sample rate converter is obtained when resampling a signal at a lower rate, in order to permit the signal to pass through a channel with limited bandwidth. Sample rate converter is connected to the LPFIR filter to improve the efficiency and consume less power consumption. This SFP-SRC filter bank is suitable for hearing aid applications. The input and output of the LPFIR filter are connected with sample rate converter. The block diagram for the SFP-SRC is shown in Fig4.

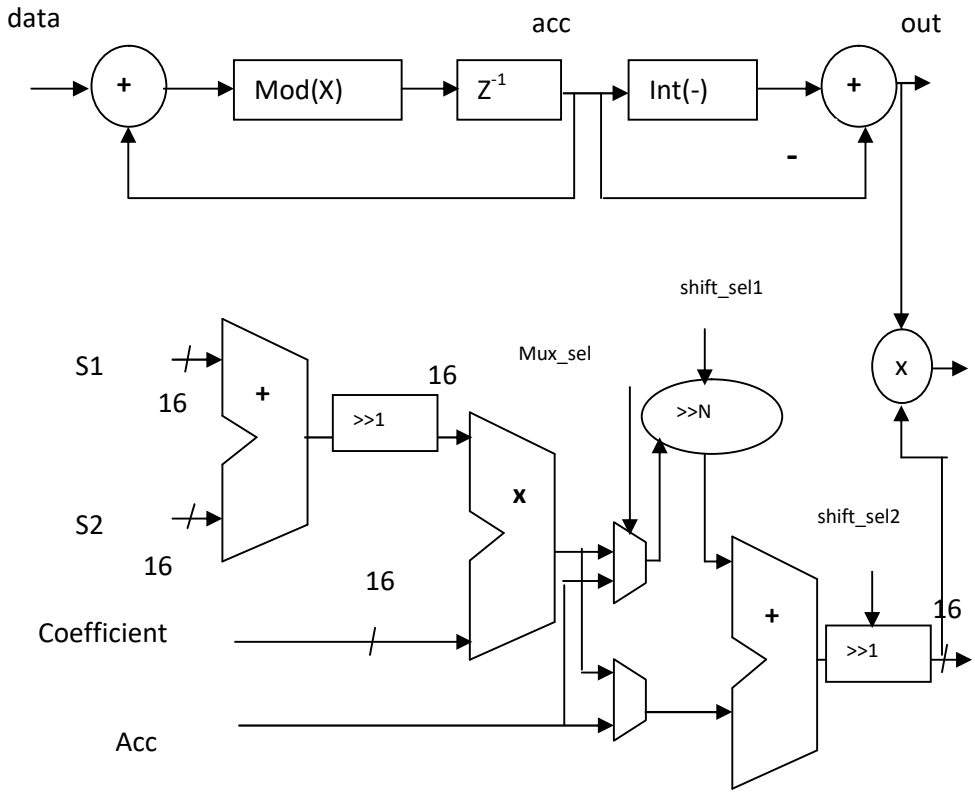

Fig 6. Proposed FIR Filter with DT

In the proposed filter design three shifters such as two one bit shifters for normalization and one N-bit shifter are inserted by the application of PEV analysis into filter deign. Along with the two adders and one multiplier, two (2:1) multiplexers are also used for the selection of the accumulator values. Multiplexer selects the input according to input select Mux_sel. S_1, S_2 are two operands of the filter. The value of the accumulator is denoted as acc. Coefficient represents filter coefficients which are predefined. The sample rate Converter produces the output value according to the input sample frequency f_{sinput} and output sample frequency $f_{soutput}$. The ratio is estimated using the formula $f_{sinput}/ f_{soutput}$. Then the output value is multiplied by the

Copyright reserved © J. Mech. Cont.& Math. Sci.
N. Subbulakshmi et al

every output of the LPFIR filter design. Then, the next output of the filter is divided by factor X then multiplied by the sample rate converter. Hence, the sample rate is reduced by half and the number of computation is also decreased due to sample rate converter. to noise ratio. The SFP-SRC technique is less complex when compared to traditional techniques. PEV analysis provides more effective bits which are stored instead of zeros in the limited word length. The sample rate is minimized using sample rate converter. The structure is designed in the MATLB tool and it is implemented in Vertex 5. The results are compared with other filter bank methods. Comparison Table. 2 shows that this proposed method is well suitable for hearing aid applications.

IV. Implementation Results

The results are implemented in the Matlab Simulink Tool and the outputs are verified in the Xilinx ISE 14.1. Table. 1 states that the proposed filter bank provides better results compared to the other filter banks. By observing the results, the area an be reduced 12% in proposed method when compared to direct truncation method. The proposed method achieved 5% of less power than direct truncation. Signal to noise ratio also provides better results by using the proposed method. Table. 2 shows performance comparison with different arithmetic. F1, F2 and F3 are the filters of ANSI filter bank. The SNR performance of the 16 bit Floating point integer data path, only the SNR performance of filters F1,F2 and F3 was best. However, worst performance in the gate count and the energy. The proposed filter bank provides better SNR performace and energy. The simulation and implementation results validate the achievement of the proposed minimum area, delay and high-precision 16-bit direct truncation SFP A–M–S–Accdatapath. Fig 5. shows the performance comparison of various filters with the proposed filter. Fig 6. shows the simulation results of 16-bit linear phase FIR Filter with PEV Analysis.

V. Conclusion

An efficient architecture Static Floating Point Sample Rate Converter (SFP-SRC) with Linear Phase Finite Impulse Response (LPFIR) for audio and speech signal processing is proposed in this paper. The basic idea behind the design of filter bank to reduce the complexity and low power consumption. This paper provides better performance in signal. This technique evaluates many combinations by conducting many experiments which results in better performance. From the results, it shows that 12% reduction in area and 5% power savings compared to the traditional methods. The proposed PEVF is suitable for hearing assistance applications. Hence, it is implemented on 1/3 octave analysis filter bank with umc-90nm CMOS technology at 24 KHz. In this paper, various filter bank techniques are reviewed based on the following aspects: Algorithms used for design, Number of sub-

DESIGN SLM OF PAPR REDUCTION TECHNIQUES OF OFDM SYSTEM

N. PANDU RANGA REDDY,
Associate Professor , Malla Reddy Engineering College (A), Hyderabad.

Abstract - Due to multiple application of OFDM signal like military HF radio links, BRAN, DAB and DVB-T and there was need to change from analogy domain data sending to digital domain data sending, also changing of single carrier to multiple sub carriers' data transmission. Orthogonal frequency division multiplexing (OFDM) plays tremendous advantages including channel conversion due it orthogonality of the sub carriers, special efficiency and robustness against ISI and ICI. One worst disadvantage of OFDM is high PAPR at the transmitter which reduces the peak power for transmission. OFDM consist of large number of independent subcarriers, as a result of which the amplitude of such a signal can have high peak values. The Selected Mapping (SLM) technique is one of the promising PAPR reduction techniques for OFDM. This technique however increases the computational and phase search complexity and PAPR reduction performance is largely dependent on the selection of random phase sequences. In this paper, a new SLM method which rotates the phase of input data after IFFT by using matrices generated from complex Hadamard code is proposed. After phase rotation, clipping technique is used to further reduce the PAPR. From simulation results, we can find that the proposed method has lower PAPR than conventional SLM combined with clipping technique.

1. INTRODUCTION

OWING to the high spectral efficiency and the immunity to multipath channels, orthogonal frequency-division multiplexing (OFDM) is a promising technique for high rate data transmission [1], [2]. This transmission technique has been adopted for a number of applications, such as the standard for digital radio audio broadcasting (DAB), the standard for digital video broadcasting (DVB), the standard for asymmetric digital subscriber line (ADSL) service over twisted-pair phone lines , and the IEEE 802.11a standard for wireless local area networks.

One major disadvantage associated with an OFDM system is the high peak-to-average power ratio (PAPR) of the transmitters output signal, where the range of PAPR is proportional to the number of subcarriers used in the system. Due to the high PAPR feature, an OFDM signal may suffer from significant intermodulation distortion and undesired out-of-band radiation [3], when it is passed through a nonlinear device, such as a transmit power amplifier.

The conventional solution to the PAPR problem is to back-off the operating point of the nonlinear power amplifier. Although simple, this approach usually causes a significant power efficiency penalty.

ORTHOGONAL Division Multiplexing (OFDM) is a technique widely used in many digital communication systems such as digital broadcastings, WLANs and 4G Mobile communication. Due to its resilience to multi path fading and high spectral efficiency it provides high and better bit rate. It also accommodate large number of sub carriers subjected to orthogonality as when compared to conventional Frequency Division Multiplexing. It utilizes multiple carriers that are modulated simultaneously. Though they overlap, owing to the orthogonality of sub-carriers they can be demodulated using correct time windowing at the receiver. OFDM is very effective against inter symbol interference and frequency selective fading providing high spectral efficiency Conventional modulation schemes such as Quadrature Amplitude Modulation (QAM) and Phase shift keying at low symbol rates are used to modulate each sub carrier. Data rates in accordance with the conventional single carrier modulation schemes in the same bandwidth are maintained. The major drawback of this system which reduces its efficiency is the distortion of the signal caused at the High Power Amplifier (HPA) of a transmitter called as Peak-to-Average-Ratio (PAPR). PAPR causes performance degradation. HPA non-linearity causes in band distortion giving rise to high BER, leading to inter channel interference.

Orthogonal frequency division multiplexing (OFDM) is the key technology which is employed in 4G wireless communication systems such as Long Term Evolution (LTE), worldwide interoperperbility for microwave access (WiMAX) and Long Term Evolution Advanced (LTE-A) . OFDM are forms of multicarrier transmission for broadband wireless communication systems i.e. it has a large bandwidth up to about 20MHz. The background behind OFDM is that it divides the frequency spectrum into subcarriers and the subcarriers are made mutually independently orthogonal to each other to avoid interference. The data in each subcarrier are transforming from serial to parallel channel for

simultaneous transmission in different channel. The Inverse fast Fourier transform (IFFT) is used to produce orthogonal data subcarriers where the input data samples are modulated either by (e.g. QAM or PSK) and after they are jointly correlated. The FFT transform the cyclic prefix time domain signal to it equivalent frequency spectrum. OFDM has significant challenge due to symbol time been less than the delay spread leading to InterSymbol interference (ISI) which is overcome by cyclic prefix or guard band concept.

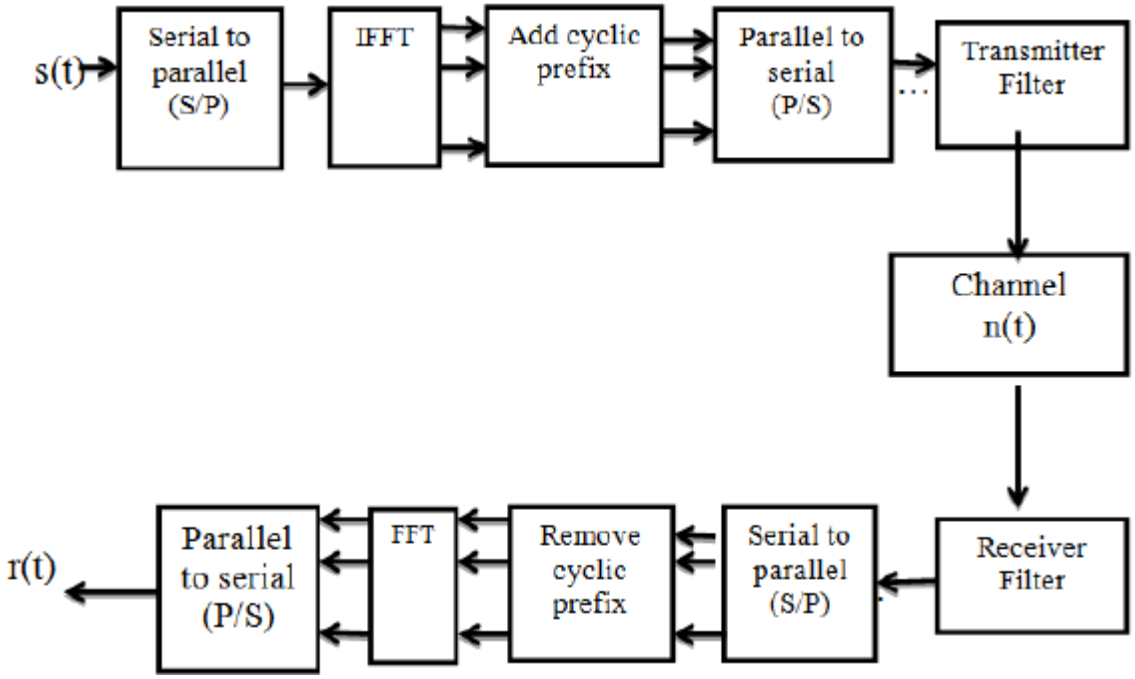

Fig -1: Block diagram of OFDM system

2. PEAK TO AVERAGE POWER RATIO (PAPR) FOR OFDM SIGNAL:

In OFDM system, the main drawback is high peak to average power ratio (PAPR).The high PAPR is significantly caused due IFFT operation where data symbols across subcarrier add up to produce high peak power value. This causes the signal amplifiers to operate into the nonlinear region leading to in band distortion and out of band radiation. The in-band distortion degrades system performances and out of band radiation causes the adjacent channel interference (ACI) due to neighbor band effect and degradation of bit error rate (BER) performance.

The peak to average power ratio (PAPR) of a continuous time signal is given by

$$PAPR = \frac{P_{Peak}}{P_{Average}} = \frac{max\ |x(t)\ |^2}{E\ |x(t)\ |^2}$$

Reduction Technique

Several techniques approaches have been proposed and implemented to reduce PAPR problem into different categories i.e. distortion and without distortion.

Distortion method includes clipping and companding whereas distortionless methods also include clipping and filtering, selective mapping, partial transmit sequence, tone injection etc.

In this section, we mainly discuss two typical techniques such as Selective Mapping and Amplitude clipping and filtering for PAPR reduction in OFDM systems.

A. Amplitude Clipping and Filtering

Amplitude clipping is one of the simplest reduction techniques for PAPR. Amplitude Clipping reduces the peak level of the input signal to a predetermined value. According to S. H. Han and J. H. Lee [1] the basic idea of this technique is to clip the parts of the signals that have high peak outside of the allowed region. The following equation below shows the amplitude clipping.

$$Y(t)=\begin{cases} -L & if\ x(t) < -L \\ x(t) & if\ -L \le x(t) \le L \\ L & if\ x(t) > L \end{cases}$$

B. Selective Mapping Technique (SLM):

The propose method for the reduction of peak to average transmit power of multicarrier modulation systems with selected mapping in 2013[7]. In selected mapping (SLM) the whole set of information symbol are loaded into the subcarrier and turn in serial and parallel after, the data block are form and then the most favorable signal with less PAPR is chosen and transmitted. The basic idea of this technique is based on the phase rotation sequence. The lowest PAPR signal shall be selected for transmission from a number of different data blocks independently.

3. PROPOSED METHOD

The common SLM method multiplies several phase rotation sequences in front of each IFFT block. This phase rotation process can be moved to back of IFFT block like as Fig. 2.Then clipping technique is carried out for further PAPR reduction.

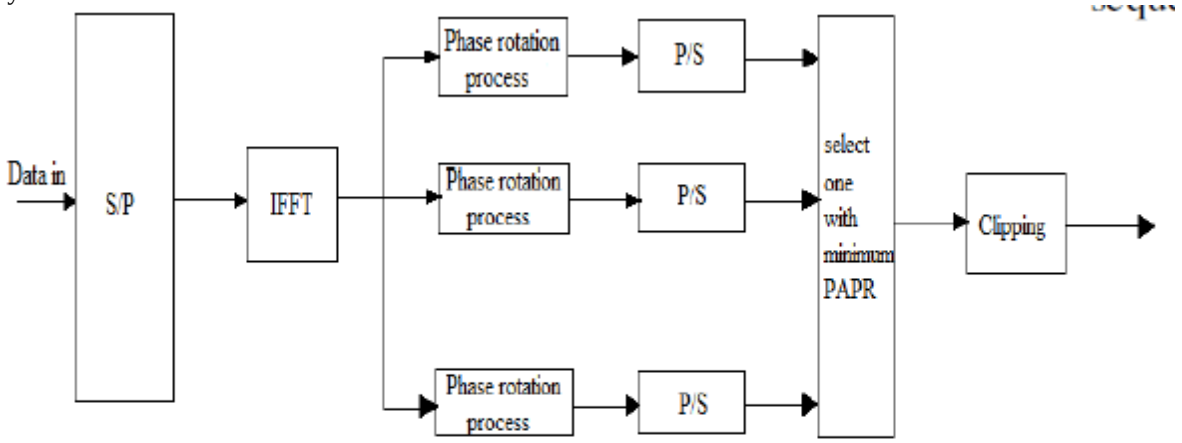

Figure 2. Proposed system.

MODIFIED SLM

The phase rotation process are different matrices generated from rows of complex hadamard matrix. They are multiplied as shown below. If we assume no over-sampling, N point DFT can be expressed like as follow matrix Q.

$$Q=\begin{bmatrix} 1 & 1 & \cdots & 1 \\ 1 & W^{1} & \cdots & W^{N-1} \\ \vdots & \vdots & \ddots & \vdots \\ 1 & W^{N-1} & \cdots & W^{(N-1)(N-1)} \end{bmatrix}$$

The phase rotation process are different matrices generated from rows of complex hadamard matrix. They are multiplied using alternate rows of 8 point complex hadamard matrix generated using[18].Each element in a row becomes a non-zero element in the matrix B. The matrix generation is given in[14].Complex hadamard matrix are used to reduce the correlation between various OFDM symbols and thus reduce PAPR much better than using random phase sequences. This is shown in figure 3.

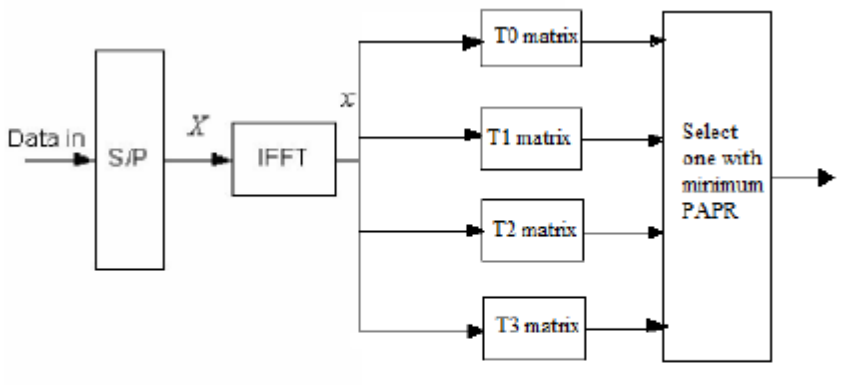

Figure 3. Modified SLM using 4 copy branches

4. PERFORMANCE ANALYSIS

In this paper, Matlab simulations are used to evaluate the peak to average power ratio reduction capability and bit error rate of the proposed method. The channel is corrupted by an additive white Gaussian noise(AWGN). In simulation an OFDM system is considered with N = 8, where N is the number of OFDM subcarriers and QPSK modulation is used for encoding the information. We have used a threshold value of 0.2 for clipping.

We can evaluate the performance of the proposed scheme using CCDF plots, which helps to measure the probability that PAPR of a certain block exceeds the given threshold. From fig. 4, it shows that PAPR of the OFDM has reduced considerably by the proposed method. We can see that with a probability of 10-2 , the PAPR of the original signal is more than 9dB, while that of conventional SLM is 7 dB, SLM technique combined with clipping is 6.8dB and the proposed

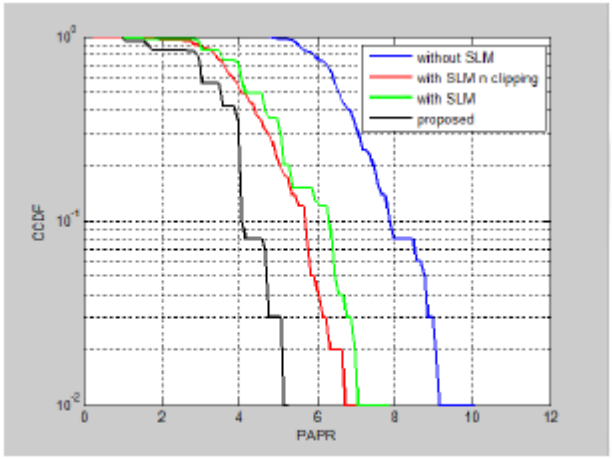

Figure 4. OFDM system using selective mapping method.

The BER curve of OFDM system and proposed scheme is also plotted. The proposed scheme maintains BER performance close to the conventional OFDM system. At the same time it serves an important role to reduce the PAPR considerably.

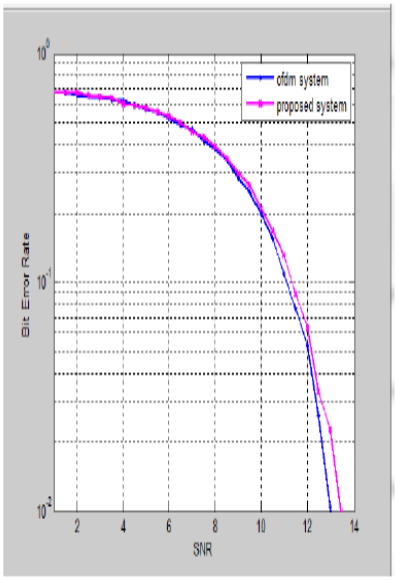

Figure 5. BER of the proposed technique for QPSK modulation ,N=8

CONCLUSION

In this paper, a new SLM method using complex Hadamard code is combined with clipping to reduce the PAPR in

OFDM. Because the SLM method can rotate the phase of input data after the IFFT process by transforming a Complex Hadamard code into several simple matrices, the computational complexity is highly reduced. The proposed method can reduce the PAPR more than the conventional SLM method combined with clipping technique and also got an affordable BER performance. scheme has a PAPR of 5.1dB.The CCDF curve has nearly 3.9 dB improvement for the proposed system.

Abstract:**Blur can be defined as undesirable transitions that occur in the original image due to various factors like the motion of the patient, atmospheric turbulence,out-of-focus camera. To retrieve the original image, we adopt algorithms in deblurring which attempts to decrease blur and acquire crystal clear image. The point spread function typically determined by the imaging systems, the entire image can be described by knowing the optical properties of the system. The process is usually formulated by a convolution equation in this proposed method. Hence it is one of the vital factors that required to be calculated. In this research work an approximate study of different image deblurring techniques is carried out and performed several experiments to evaluate these techniques in terms of performance, blur type, Peak Signal to Noise Ratio, and structural similarity (SSIM).**

Keywords:**Intrusion Detection · Point Spread Function (PSF), Image deblurring techniques, image restoration, degradation, blur**

I. INTRODUCTION

Image restoration relates to the restoration of a long-established image from degraded observations [1]. The reason for image restoration is to undo the defects which degrade an image. In situations like motion blur, it is possible to come up with a very good estimation of the accurate blurring operation and undo the blur to get the vogue image [2]. In case if the image is corrupted by noise, the best way to do is to catch up on the degradation it effected with. The work-focused here is the Gaussian blur. The purpose is to deblur the resulted degraded images by different fast deblurring techniques, such as the optimized Richardson-Lucy, the enhanced Van Cittert, the optimized Landweber, the optimized Poisson Map, and Laplacian sharpening filters. The degradation process can be observed with the following system.

The degradation process can be modelled as a degradation function h(x.y) that,together with an additive white gaussian noise from η (x,y) operates in an input image f(x,y) to produce a degraded image g(x,y).

$$g(x,y) = h(x,y) * f(x,y) + \eta(x,y) \quad (1)$$

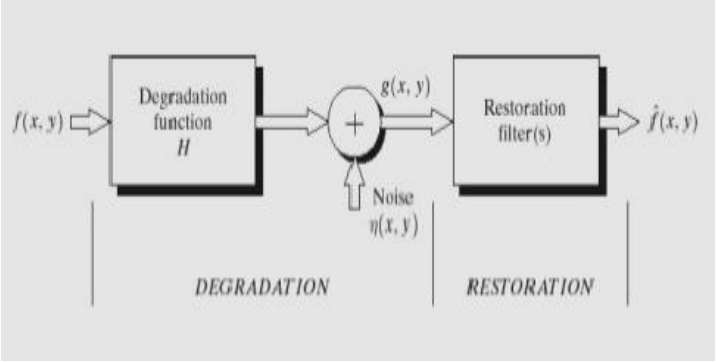

Figure 1: Degradation Model

II. BACKGROUND WORKS

Types of blur:

1). Average Blur: There are several tools used to remove noise and specks in an image. Average blur is used when noise is present over the entire image. This type of blurring can be distributed in the horizontal and vertical direction and can be circular averaging by radius R which is given below

$$R = \sqrt{g^2 + f^2} \quad (2)$$

Where '*R*' is the radius size of the circular average blurring,'*g*' is blurring in horizontal direction and '*f* ' is blurring in vertical direction.

2). Motion Blur: There are many types of motion blur. It is a device referred to between the device which is being recorded and the image. These variations can be carried over, circular movements, translations, conversions of scale, or sometimes it may be in the form of altogether. It is a filter that adds blur in a particular direction depending on the software used, [1] the movement can be controlled by angle or direction (0 to 360 degrees or (–90 to +90) and/or by spacing or intensity in pixels (0 to 999).

3).Gaussian Blur: In graphics software, this effect is mostly under-appreciation. It is used to reduce image noise. It is also appreciated in the preprocessing stage in computer-based algorithms to improve the image structure and fabricate the image at a different version of scales. The idea of Gaussian smoothing is to use this 2-D distribution as a point-spread function, and this is achieved by convolution.[5]

4). Out-of-focus Blur: When a camera images a 3-D scene onto a 2-D imaging plane, some regions of the scene are in focus and the remaining regions are out of focus. The perforation of the camera being circular the image at any point source is a small disk known as the circle of confusion whose diameter depends on the focal length, aperture, number of the lens, the distance between camera and object. Nowadays medical images are on high demand, but they are facing the problem of Gaussian and noisy blur. To overcome this, Meen Lee et al. [5] explained the research on deblurring of images based on the appraisal of PSF parameters and post-processing. The length and angle of the blur kernel are the two parameters of PSF. The deblurring interpretation is inclined by the accuracy of the estimation of the two parameters. The proposed method of PSF parameter estimation and reconstructing the image using the post-processing method.

Surveys on different image deblurring techniques were proposed by Vankawala, Ganatra, and Patel [6] about the reason for blurring on images. It may be motion blur, out-of-focus blur, camera shake, etc. Image enhancement is the other name of image deblurring which is used to decrease the amount of blur in an image. This technique is predominantly used to reduce the blur amount and convert the degraded performance of the image and it is very important to accelerate the effect of deblurring to get a good outcome. The study of image restoration techniques and research is concluded by Maheshwari [7]. But during transmission and acquisition, the Image restoration is generally used for improving the blurry image by removing the artifacts in it. The basic idea of the image restoration technique and various deblurring techniques were proposed by the author. In the field of image processing world and research, image restoration plays a vital role. It is widely used in various applications such as medical imaging. Daniel Fan and Nagy [8] explained the paper on Synthetic boundary conditions for image deblurring. the author concluded that while reconstructing a new observed image from the blurred and noisy image a boundary condition is used. Information from the new image that boundary conditions continue on edges and texture across the boundary is used in this approach. For implementing the new boundary condition an effective algorithm is used.Z. Reti [9] analyzed the topic which is based on deblurring ages blurred using discrete Gaussian. Gaussian blur is used for image degradation. The main motto is to deblur the image using discrete Gaussian. Hypergeometric series is used for this purpose a modified Gaussian blur is used. A recap of the research literature has given the parameter of various techniques. A derivative model to recover a sharp version of the image from a degraded image is presented.

Wiener filter: The Wiener filter reduces the amount of noise in an image. The inverse filtering is a restoration technique for deconvolution, i.e. when the image is blurred by a known low-pass filter, it is possible to recover the image by inverse filtering or generalized inverse filtering. However, the inverse filtering is very sensitive to additive noise. The approach of reducing one degradation at a time allows us to develop a restoration algorithm for each type of degradation and simply combine them. The Wiener filtering executes an optimal tradeoff between inverse filtering and noise smoothing. It removes the additive noise and inverts the blurring simultaneously. The Wiener filter is the Minimum Square Error optimal stationary linear filter for images degraded by additive noise and blurring. Some of the techniques where Let the case is the model described in equation (3).

$$b(x,y) = h(x,y) * s(x,y) + s(x,y) \quad (3)$$

b(x,y) is the observed blurred image, h(x,y) is the known impulse response of a linear scale-invariant system, s(x,y) is known sharp image and n(x,y) is some unknown additive noise independent of s(x, y).The Wiener deconvolution filter calculates g(x,y) and it is used to estimate s(x,y), as expressed in equation (4).

$$\hat{s}(x,y) = g(x,y) * b(x,y) \quad (4)$$

$\hat{s}(x,y)$ is an estimate of *s(x,y)* that minimizes themean square error. The weiner filter works in the frequency domain.The calculation of frequency domain version of *g(x,y)*, as expressed in equation.5.

$$G(u,v) = \frac{H(u,v)W(u,v)}{|H(u,v)|^2 W(u,v) + N(u,v)} \quad (5)$$

Where H(u,v) is the Fourier transform of h(x,y) , G(u, v) is the Fourier transform of g(x,y),W(u, v) is the mean power spectral density of s(x,y), N(u, v) is the mean power spectral densityof the noise n(x,y).

$$\hat{s}(u,v) = G(u,v) * B(u,v) \quad (6)$$

$\hat{s}$(u,v) is the Fourier transform of the estimated sharp image and B(u,v) is the Fourier transform of the observed blurred image.On an image If the three pixels in a line contain information from the same point, the digital image will seem to have been convolved with a three-point box car in the time domain. The requirements of wiener filter are as follows:

(i) The filter must be causal where this requirement is failed it resulting in a non-causal solution.

(ii) Periodic noise can be effectively removed by correcting the amplitude spectrum components altered by the noise.

However, a Wiener filter requires an accurate noise model, which may be difficult to obtain in various practical cases. In addition , a Wiener filter is also complicated in comutation.

Richardson-lucydeconvolution approach: The Richardson–Lucyde convolution or lucy-Richardson algorithm was developed by William Richardson and Leon Lucy. It is an iterative process used to recover the latent image that has been blurred by a known point spread function (PSF).In this strategy, pixels in the blurred image is represented in terms of the point spread function and sharp image. Some of the investigations based on the Lucy-Richardson algorithm can be found in [10-15]. Let X*j* is the pixel value at location *j* in the latent image, *Kij* is the point spread function (the portion of the light that comes from true location *j* that is observed at another location *i*), and bi is the observed value at pixel location *i*. The pixels in the observed image are represented in terms of the point spread function and the latent image as expressed in equation 7.

$$b_i = \sum_j K_{ij} x_j \quad (7)$$

The model assumes that x_j values are Poisson distributed.The model calculates the given x_j given the observed $b_i$andknown PSF K_{ij}. Also the model finds a recursive formula to estimate x9 as expressed in equation .8

$$x_j^{(t+1)} = x_j^{(t)} \sum_j \frac{b_i}{c_i} K_{ij} \quad (8)$$

$$c_i = \sum_j K_{ij} x(t)_j \quad (9)$$

Experimental outcome showed that the iteration converges tothe most liability solution of x_j.

III. METHOD AND MATERIALS

The image blur can be modelled by a sharp image convolving with a kernel K.

$$B = K \otimes I + n \quad (10)$$

Where *B*, *I* and *n* represent the input blurred image, noise and latent image respectively. The $\otimes$ denotes convolution operator and the deblurring problem in image are thus represented as deconvolution problem [13].Deblurring is a mixture of two sub-problems: Non-blind image deconvolution and Pointspread function (PSF)estimation. Sparse dictionary learning is a learning method of finding as parser presentation f input data in the form of a linear combination of basic elements. These elements compose a dictionary. Atoms in the dictionary need not be orthogonal[10]and the dictionary has to be inferred from the input data. By using the signal processing, the sparse dictionary learning method can be stimulated o represent the input data using as few possible components.

A. Dictionary Learning

The dictionary is usually used for Sparse representation or Approximation of signals. A dictionary is a collection of atoms, where the atoms are real column vectors of length N. A finite dictionary of K atoms can be represented as a matrix D of size NXK. Learning the dictionary adaptively from the adaptive image is the best way to choose. The algorithm below estimates the sparse coefficients of the given input blurred image.

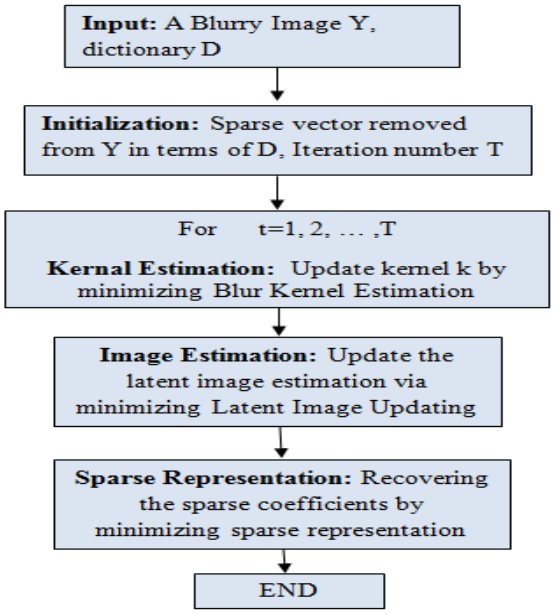

Figure 2: Methodology of Algorithm

Algorithm 1

• **Step1:** Get the blurred input image B

•**Step2:** Spilt the B into four patches asp1,p2,p3,p4.

•**Step3:** Consider first image patch p1 and find the sparse coefficient to fix K using Gaussian kernel and D as identity matrix.

$$\alpha(n+1) = argmin\|\alpha\|1 \quad (11)$$

$$s.t.\ b = (K(n) \otimes D(n))\alpha \quad (12)$$

• **Step4:** For each iteration the α value should be updated into D

• **Step5**: Take N iterations to estimating the α(n+1).

•**Step6:** Repeat the above 5 steps to all image patches and estimate the α(n+1).

B. Updating Dictionary

With the knowledge of previous algorithm using the sprase coefficient to update the dictionary of the image.

Algorithm 2

• **Step 1**: To update the dictionary, deconvolve blurred image with kernel up to last iteration using any deconvolution algorithm and get Ip.

• **Step 2**: Ip image is split into four patches.

• **Step 3**: Update the dictionary using α(n+1) and D.D(n+1) = min||Ip −D(n)α(n+1)||22. (4)

• **Step 4:** Repeat the steps 1 to 3 to all image patches and estimating the D(n+1).

C. Recovering Deblur Image

Consider antecedent algorithm to estimate the deblur kernel of the image and finally recover the deblur image.

Algorithm 3

• **Step 1:** Find the latent image patch using $Ip(n+1) = D(n+1)\ \alpha(n+1)$ (13)

• **Step 2:** Merge all the image patches of Ip.

• **Step 3**: The reconstructed image is subtracted from the blurred input image to obtain the deblur kernel.

•**Step 4**: Perform the deconvolution with the input blurred image and Deblur kernel using wiener deconvolution and Richardson-lucy deconvolution method.

•**Step 5:** Apply the regularization filter to the wiener deconvolution image and Richardson-lucy deconvolution to recover the original image.After that the RMSE, PSNR, SSIM and visual perception were analyzed for various images.

IV. RESULTS AND DISCUSSION

MATLAB R2013a (8.1.0.604)is used to simulate the deblur algorithm. The power to signal noise ratio, root mean square error, structural similarity index metric, and visual perception were analyzed for various images. It is noticed from the analysis that the deblurring was efficiently performed.experiments with blurred images by randomly generated kernel were carried out. The existing deblurring algorithms normally developed to deal with motion blur problems in which the kernels are oriented. As the camera shakes are complicated and cannot be designed well with simple blur kernels. This algorithm can recapture the latent image with more details and better contrast. The quality of the sharp image is measured to evaluate the effectiveness of different image deburring techniques. Subjective measures and objective measures are two types of measures that can be used to estimate quality. User's perception without calculating a numeric quantity through an explicit formula can be measured using subjective measures. This type of measurement is more precise because it is directly trying to accommodate different user requirements.The objective measure uses an explicit formula to calculate a numeric quantity. In the evaluation of image deblurring techniques two types of objective metrics are used, Peak Signal-to-Noise Ratio (PSNR) and Structural Similarity (SSIM). PSNR is used to measure the quality of

an image in dB (decibels). PSNR between the deblurred image and the original image measures how far the two images are equal.

$$MSE = \frac{1}{MN} \sum_{i=0}^{M-1} \sum_{j=0}^{N-1} [I_{ij} - X_{ij}]^2 \quad (14)$$

$$PSNR = 10log_{10}\left(\frac{MAX^2}{MSE}\right) \quad (15)$$

Where M is the number of rows,N is the number of columns I is the original image, X is the deblurred image, and MAX is the maximum possible intensity of the image.

Expt 1: Uniform motion blur with noise: After simulating motion blur with the blur parameters deblurring is carried out using the proposed *Sparse* method, Wiener filter, Richardson Lucy (RL) algorithm, and algorithm of Shan et. al [14]. PSNR and SSIM results reported in Table.1 for σn= 0.5 indicates how the Sparse method is superior over other methods.

Expt 2: Non-uniform blur with noise: In case of non-uniform blur removal with noise added, auspicious results are obtained, as the non-uniform kernels depict the camera shake effect, which is wearisome to remove from the single blurred image even after known the blur kernels. So this experiment is of particular interest. different non-uniform blur kernels are collected from the dataset of Levin et al. [10] which is created with the actual camera setup. In this work different deblurring techniques are compared. The following methods are tabulated after the comparison.

Table1. Comparison table of different techniques

Methods Used	Types ofBlur	Performance	PSNRValue
Wiener filter	Gaussian	Worst Result	17.06
Lucy Richardson	Gaussian	Efficient	21.02
Blind ImageDeconvolution	Motion	Efficient	26.76
Using MDF	Motion	Efficient	24.30
Using HandlingOutliers	Gaussian	Efficient	21.91
Using ASDSAR	Gaussian	VeryEfficient	31.20
Proposed	GaussianOut-offocus	VeryEfficient	38.56

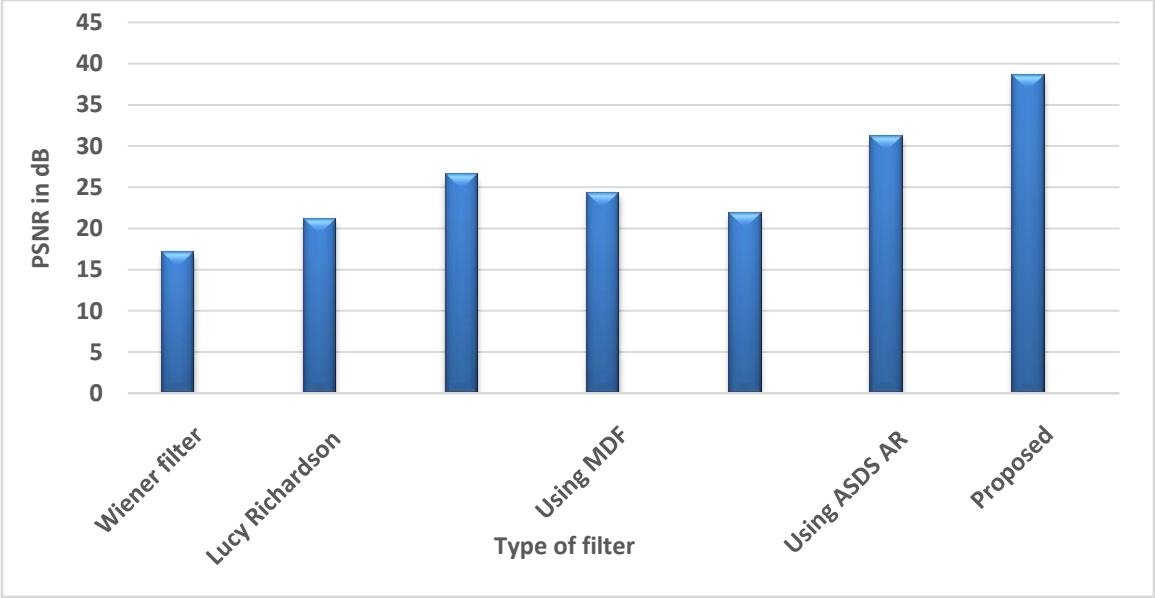

Figure 3:Comparisionof PSNR for different filtering techniques

V. CONCLUSION

The proposed method uses a simulation of an effective deblurring algorithm with dictionary learning using one single image. The technique proposed is capable to estimate blur kernels and thereby deblurred images by disintegrating the deconvolution problem into three portions deblurring and learning a sparse dictionary from the image. Experimental outcomes show that this algorithm achieves appreciative performance in terms of PSNR and SSIM results.

Mallareddy engineering college(autonomous)
srinivasvutkuri@gmail.com

Abstract:
In this a new power-saving chien search (CS) structure is proposed for parallel Bose-Chaudhuri-Hocquenghem (BCH) decoder .The CS plays an important role in identifying the areas of error in syndrome-based decoding, but incurs a huge waste of exhaustive computation power consumption. In this proposed architecture, the process of searching for the binary representation of the matrix is decomposed in two steps. The first step is accessed every cycle, but the second step is activated only when the first step is successful, this will result in remarkable power saving. Here an effective construction is presented in a two stage process to avoid an increase in the delay of the critical path. Experimental results of the proposed two-step structure for the BCH (8752, 8192, 40) code that saves 50% power consumption compared to a conventional building of the show.

Keywords:
Bose–Chaudhuri – Hocquenghem (BCH) codes, Chien search (CS), low power, two-step approach.

INTRODUCTION:

Communications and storage systems for various error correction codes are used to recover the corrupted code words, Bose-chaudhuri-Hocquenghem (BCH) code [1], [2] is the most widely used due to its powerful error correction performance and affordable hardware complexity is one of the algebraic signs. Binary BCH code is a solid-state storage such forward [3], [4] and optical fiber communication systems [5], most of the applications and the never-ending demand for high through put decoding has been running ever larger error- correction capability of different systems.Satisfying the huge computational capacity of high through put and strong error correction is inevitable, therefore, becomes more and more important power saving structure of the BCH decoding. In general, a BCH decoder to correct the bits T at the peak of the three main blocks, namely, the syndrome calculation (SC), the key-equation solving (KES) has, and Chien search (CS) [1], [2]. Receiving a code word for a given R (x) Compute syndromes SC 2T and KES (X) using the syndromes of the error locator polynomial Λ. Finally, the error is E (X) Λ sources (X) CS determined by the algorithm is based on the finding. In a parallel BCH decoder, CS main cause of power consumption and total electricity consumption [6] and can take up to a half. Numerous studies have demonstrated the ability to reduce the power consumption of CS proposed structures. Early termination of the methods presented in [6] and [7] After finding an error in the past to eliminate

redundant computations. An additional error counter is incremented when an error is found, and the counter KES down sides found in the CS is turned off matches. BCH decoder dealing with a small number of errors early in the implementation of the common and effective drug, though, when the power saving small insignificant error correction capability. [8], is a more effective method in order polynomial reduction (POR) when the error was found in the error locator polynomial of the proposed reform. Locator polynomial order one at a time, errors are detected by the decline and eventually becomes zero. POR [8] at a time, gradually power down circuitry associated with a polynomial factor makes it impossible for the CS. POR for serial BCH decoders are successful, however, because it is difficult to apply the technique of complex polynomial update parallel architecture. Further more, all of the previous power saving algorithms, including early termination, [6], [7] and the POR [8], depending on the position of the errors. For example, if faults at the end of the term of the code, as in the case of power savings is significant that in the beginning of errors. In this brief, we have a new approach, which is parallel to the CS proposed two stages of decomposition. In order to have access to each of the first step, but the first step to access the second stage will be activated only when a less successful result. The proposed two-step method [9] that is conceptually similar. The two-step approach, in general, lead to an increase in the critical path delay and delay, the losses can be solved simply by employing an efficient pipelined architecture. Unlike previous architectures [6] - [8], regardless of the error, the location of the proposed construction of the power consumption can be saved. Digital communication system for carrying the signal from the source to the destination user via a communication channel is used to transfer data. All the code words encoded, encoder, which generates a set of code word. When it becomes a code for the actual set of data encoded. Memories of errors and data corruption is a significant problem in the channels. Disorders that affect one or more of the memory cells of radiation-induced soft errors, for example, have been known to change their values. Other types of failures cause permanent damage, such as the device will no longer provide the correct data. In the event of failure to ensure that the data is not corrupted, error correction codes (ECCs) are widely used in memories [1]. To add some extra parity bits to check every memory ECCs word in such a way that errors are detected and corrected. The proposed system is basically sound channel .Parity describes the additional bits of memory for its ability to reduce data corruption. There are other costs introduced by the ECC encoding and decoding circuitry. More than one channel to transfer the data to be encoded and decoded as read from it also affects the circuit delay. In many cases, because many of the steps of the encoding, decoding speed is much more complex and ECC [1] .Traditionally single error, double error detection (SEC-DED) codes used to protect memories are limited [3]. But the data signal error was found and corrected in the proposed system for multi-byte. This point of view as well as the delay in the

performance of RS code symbols in the number of bits of memory modules and devices when the matches will be very attractive for the channel, a device that can be corrected failures. In fact, the main reason is usually used to protect the RS codes A code word for a certain polynomial coefficient of the polynomial, the generator polynomial g (x). Reed- Solomon error correcting codes (RS codes) to transmit a wide array of possible errors arising from error to restore data from a disk and data communication systems used for storage. There are two types of errors when the bits flowing from one point to another, they are subject to change because of the unpredictable interference. Change the shape of the interference signal. from 1 to 0 or 0 to more bits of data per unit of linear 1.Reed Solomon code means that the cycle has turned into a regular non-binary block code. Redundant encoder signals and message signs are included in the product using the generator polynomial. Decoder error location and intensity are calculated using the same generator polynomial. Then the correction is applied to the received code. Reed- Solomon coding, plus data storage and retrieval systems (noise channel harm) forward error correction of a type used for data transmission.

LITERATURE SURVEY:

A large number of errors, because they have the ability to correct the error correction described in this paper basically memory devices, the memory is used for the applications important to the majority logic decodable codes. However, the performance of the memory they need to have a big influence the decoding time. Technical standards, in memory devices become larger and more powerful error correction codes are needed. Euclidean geometry to overcome the problems in this paper as they use more modern codes. These codes can correct a number of errors, but usually requires complex decoders. Serially with the majority logic decoding circuitry can be implemented in a very simple, but it requires long periods of decoding. Memory, this is an important parameter for the access to the system can increase the time. Increase the size of the code, so the majority of the increase in the time of decoding the decoding logic (implemented serially), N iterations required. EG-LDPC code, the code word is used in this method (Euclidean geometry -Low Density Parity Check), there is a majority One Step Logic Decodable code. It uses the algorithm to check the code. There is nothing to check the algorithm, but code word is associated with a numerical value to be transmitted. The receiver then receives the code word at the end of the numerical values associated with the error identification is a comparison of some numerical value.There. The method is easy to implement using existing hardware. This method is more time for decoding. As well as the power consumption and the need for the region are high. One step is to identify the shortcomings of the majority of serially MLDD serial technique uses Logic decoder. [2] In this article, the author of the noisy channel (Additive White Gaussian Noise) in the presence of PSK and FSK modulation techniques Reed Solomon code (RSC) of the bit error rate (BER) on performance analysis explains. In this paper, 32- FSK (frequency shift keying), PSK (phase shift keying) modulation coded communication system is used for the simulation. In addition to the use of Monte Carlo simulation and calculation of the rate of BER MATLAB / SIMULINK is done using the tool. The results are shown using BERTOOL. In order to compare the

performance of the block length is fixed, we have taken a different code rates. After getting familiarized with the classification and characteristics of forward error correction codes, error detection and correction codes described in this section are compared to some. Hamming code - a Hamming encoder bits of parity bits are inserted into the message. The parity bits and parity bits of data to determine the different combinations to impose a fixed parity. The combinations are fixed parity check decoder. The parity bits are set according to the decoder. The combination of the binary equivalent of the error location is determined. OK, that particular bit of data that is being flipped. Hamming code in the same error code. If any of the attempted correction of double errors can be detected.

• Berger code - Unidirectional Berger code error detection code. It can only detect an error in either '1' flipped '0' or '0' flipped '1', but it means the same code. '1' are designed to detect errors with a "0", the binary equivalent of the message, then the message is sent by the number of 0s and flipped over. The invention of the '0' design '1', an error message, the binary equivalent of the number of 1s and sent along with the message, as well as when it flipped. According to the decoder to receive the binary 0s or 1s compares the number of the same design. Imbalance between the two indicates an error. It is expected to be used where the error is unidirectional.

• a valid code word in the code has always been a constant weight, constant weight code. It means that a valid code word of a fixed number of 1s. Therefore, any variation indicates an error. Multiple errors can cancel each other out as a simple but effective way of encoding it.

• Code of Ann M - An encoder message out in an M-M number of 1s in an n bit code is mapped to a word. An M-1s in the code message bits which are used to adjust the number of bits added to the number of additional M. It consists of all the M bits of the message in any 1s '1' will. It is also effective in terms of the code of coding rate.

• Erase Code - to erase the error means that you know in advance from the previous experience of its location. Erasure code is to be able to correct such errors. It is already known that this type of code is not required in the decoder circuit fault locator. Only to correct an error in the decoder is calculated by measuring the eraser.

• low-density parity check code - the low density parity check code is a linear block code. The message block is transformed into a code block by multiplying the transformation matrix. The name refers to the low density and low density transform matrix. This means that the number of 1s in the transformation matrix less. It's a lot of coding gain, but the encoder and decoder design is concerned, the best code is complicated. Mainly used for Digital Video Broadcasting.

• Turbo code - it is a convolutional code. Convolutional encoding, encoding normal. It is defined by the (n, k, l) n the number of bits input to the Turbo code, k and l is the number of output bits is the memory of the encoder. Decoding takes place in two stages. The first stage will be a hard and soft decoding step decoding. This is a very good error correcting capability, which means that there is no coding gain. The main drawback is that it has a low coding rate and high latency. Hence it is not suitable for many applications. Satellite communication latency due to distance, but also the lowest in the extra latency is too high. Hence it is mainly used in satellite communication.

• Reed Solomon code - Reed Solomon code of a nonbinary block linear cyclic code sequence. Redundant encoder signals and message signs are included in the product using the generator polynomial. Decoder error location and intensity are calculated

using the same generator polynomial. Then the correction is applied to the received code. Reed Solomon code and turbo codes, LDPC coding gain is relatively low. But it is a very high rate and low complexity of coding. Hence it is suitable for many applications, including storage and transmission.

REED-SOLOMON CODES:

A Reed-Solomon (RS) code described in a paper in 1960, Reed Solomon error-correcting code is a rst [9]. Since that time they are CD-ROM, wireless communications, space communications, DSL, DVD, digital TV application. RS encoding of the data is relatively straightforward, but the decoding of the 1960s and other major e ciency improved by Berlekamp, time consuming [2, 5, 6, 8]. RS only in the last few years, it has become possible by using the high-bandwidth data to count. Groups of bits instead of one bit at a time, that it is a gesture from the Hamming code of RS ERS. We are the groups of digits \ Call "(the \ icons" or \ Co cients ") is. If a digit is error-free in all of its bits are error-free only. For example, if an 8-bit character in a number, and the same error in three bits of impersonation we are number one is damaged. the following example is damaged two digits (but not more than two corrupted bits) that count

Original : 10110001 11011111 01001011

Corrupted
? yes no yes no

If we want to send a k digit plaintext message, RS will send n = k + 2s digits, and guarantee that the correct message can be reconstructed at the other end if there are fewer than s corrupted digits. An example of commonly used parameters: k = 223, s = 16, n = k+2s = 255, giving the ability to correct 16 corrupted digits out of every 255 digit packet. In general, the number of bits in a digit and the parameters n and s are tuned to optimize for your application. A CD-ROM can correct a burst of up to 4000 consecutive errors.

PROPOSED TWO-STEP CS ARCHITECTURE:

In the proposed architecture paraell CS is decomposed int two steps.The p-parallel CS examines p error positions at the same time, each of which generates a binary matrix of 1 x m representing a Galois field (GF) element by computing

$$Y(\alpha^{wp+i}) = \sum_{j=1}^{t} \mathrm{FFM}_{ij} = \sum_{j=1}^{t} \Omega_j A_{ij} = [\Omega_1\ \Omega_2 \cdots \Omega_t] \begin{bmatrix} A_{i1} \\ A_{i2} \\ \vdots \\ A_{it} \end{bmatrix} \quad (5)$$

Where i ranging from 1 to p. The CS will examines and determines the presence of an error when Y (αwp+i) is 1, where αwp+i is a root of the error locator polynomial.The main idea comes from the fact that the absence of errors is guaranteed if some bits ofY (αwp+i) are not equal to those of 0(m−1:1)1(0).In the GF of dimension m, the multiplicative identity element, α0 or α2m−1, is defined as 1, i.e., 0(m−1:1)1(0), more precisely In the case of GF(24), for example, no presence of errors is guaranteed if Y (αwp+i)(3:2) _= 0. Like this two-step approach is employed for early detection.This wil results in remarkable power saving.

SIMULATION RESULTS:

CS low power, depending on the size of the field of construction of the proposed two step different configurations, and error-correction capability of the horizontal factor compared to traditional construction. At the operating frequency of 200 MHz for all the

CS blocks with a 130-nm CMOS technology is, and equally probable error model [7], [8] adopted simulations power consumption. More precisely, V errors BCH (n, k, t) signals, the average bit of a distance between two adjacent errors n / V model, every bit of the code word received is from the same error occurs when the reference is corrupted.

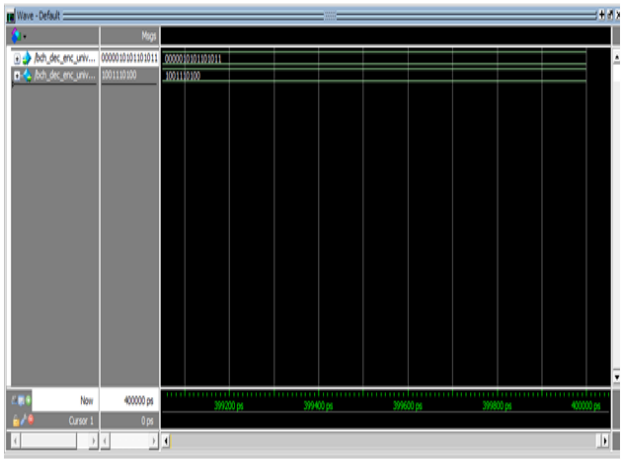

Fig: Chien search based BCH codes

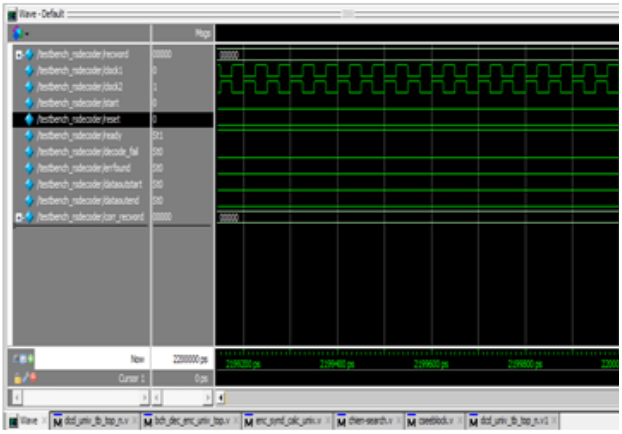

Fig: Chien search for RS decoder

SEC-RS code testbench waveforms shown in below two figures

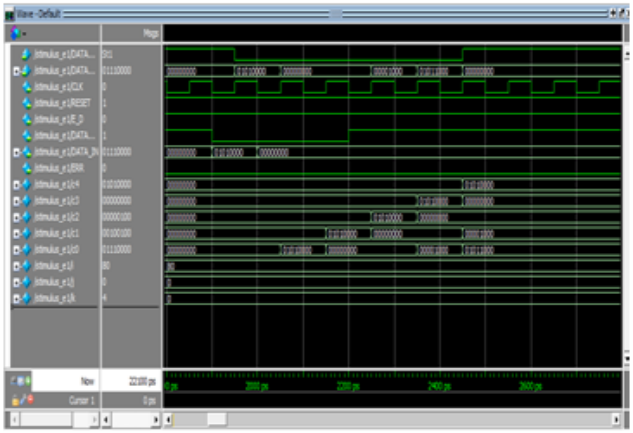

Fig. The size of the field in the first step of the bit width of 4 and shows the effect of energy saving ratio.

For fair comparison, all of the BCH codes to model the rate of 0.93 is designed and shown in Fig 8. Set the horizontal element. 4, the proposed increase in the size of the field of development becomes even more important as a result of the construction, and a small number of bits are sufficient in electricity savings increase. For example, BCH for the proposed two-step structure (8752, 8192, 40) GF (214) 49.3% power, savings over the code FFM partial opening of the first four MSBs will be processed. Moreover, Figs. 5 and 6 horizontal error correction factor and illustrate how it affects the efficiency of power saving. The horizontal element increases, the energy savings and the horizontal aspect ratio closer to 50% than the energy saving ratio of 8. It is error correction capability is almost independently shown to be saturated when. In figs. 3-6, we estimate an offset between energy savings and in spite of the simulation, a simplified energy model (9) can be used as a good

estimate. Due to the additional buffers are addressed in Section III, the proposed construction of an approximately 10% increase in hardware complexity.

CONCLUSION:

By reducing access to the second stage of the conventional CS to achieve significant

power savings is decomposed in two steps. Error operate under the same ownership, the less energy the size of the CS in the construction sector in different configurations, and error-correction capability of the horizontal factor compared to traditional construction. From the experimental results, the proposed construction of a 50% reduction in power consumption compared to the conventional horizontal CS show. Power saving horizontal factor or increase the size of the field will become more and more important. Reed- Solomon codes, such as the proposed two-step CS also applies to other linear block codes.

Abstract: Data confidentiality and encryption are essential features of modern computing. Due to its high limited size and therefore its reliability equal to that of other traditional public-key algorithms, elliptical curve cryptography (ECC) is the ultimate cryptographic method. Furthermore, the hardware acceleration of cryptographic algorithms is necessary to satisfy the raising speed demand for contemporary implementations. The core component of the residue number method is the forward converters, modulo decimal units and the reverse converters. The reverse converter is based using standard and compact adders in the current network of residue numbers. It displays substantial power usage and low speed. In-depth, it suggested a residue Montgomery algorithm for multiplying data paths among converters and between the two residue representations by evaluating the input/output conversion to/from residue representation. The design is acquired thus, we use the dual field modulator for the GF(p) and GF(2)n Montgomery multiplication, input/output conversions, mixed-radius conversions (MRC) for inputs and polynomials and exponentiation and inversion in the same hardware.

Keywords: Research in finite fields, computer arithmetic, Montgomery multiplication, parallel mechanism in arithmetic and logic structure.

I. INTRODUCTION

Throughout this era, wireless and digital interactions have rising astronomically. Hundreds of purchases exist on both the worldwide network daily. Almost all of these activities include important, sensitive details, verified transactions and authenticated users. Such specifications include a comprehensive protection system.With the rapid development of secure network communications, cryptography criteria for authentication have recently raised exponentially. Modular multiplication is a basic practice in many common architectures including RSA [1] and ECC [2, 3] for public-key encryption (PKC). Since the division process in modular reduction takes time, Montgomery [4] suggested a new methodology to prevent division. ECC is a very popular and powerful public-key encryption method for cryptographic purposes and is now very prominent in both primary and binary fields due to the smaller field size. The focus of this research will become an elliptical curve over a binary field because it is quite effective for hardware deployment due to the use of modulo 2 arithmetic.

An elliptical curve over a finite field gives a group structure used to enforce the cryptographic scheme. The activities of the company are PD and PA. Such two community operations have been merged into a lightweight hardware architecture and named PDPA. For elliptical group curve procedures, two well-known coordinate systems are often used: Affine coordinate structures and projective coordinate structures. Furthermore, the most sophisticated modular multiplication methods in Montgomery were designed for the set accuracy of operands which cannot be used for variable accuracy. Different strategies for improving the performance of point multiplication are implemented using either FPGA or ASIC implementation, including algorithm optimization and enhanced arithmetic field architectures. However, most point multiplication systems have been introduced with independent group operations, which could improve the frequency of group activities and thus decrease the

multiplication pace. Although several high-speed point multiplication strategies were described in the literature for an ECC processor, most are field-efficient. Our suggested design has a speed-area trade-off which is ideal for quicker, new, cryptography implementations. Practices including such multi-module and multi-function models have been proposed to eliminate redundancies in the hardware and therefore to mitigate power dissipation through multi-threshold voltage and multi-source stress architectures. These optimization techniques are designed for the exploration of space at the algorithm level and are specific to common numerical modules. To simplify the design level of such modulo arithmetic processes like the multiplication of units, techniques that investigate particular theoretical characteristics of the different modules of types $2n$ and $2n \pm 1$ have received comprehensive attention, amongst many others.

The VLSI design recommended in this article for the usage of RNS is the macro selection criterion for the chip memory use, which contributes to the complex implementation of main techniques. The literature survey indicates that various working conditions were suggested for the multiplication of cryptography by companies focused on polynomials to address the shortcomings of RNS schemes. The algorithm of Montgomery is one of the master areas of dual-field applications. Under key RSA word lengths, the Montgomery architecture fits well with the processing of word-size details, considering that key RSA sizes (512, 1024, 2048, etc.) often have a multiple word scale. Furthermore, the main sizes in error correction techniques are not integer multiples, therefore it indicates because, if such designs have been used in the error correction application techniques, more clock cycles would be needed to enforce them, which would result in higher power usage. This issue may be solved by implying that the system is designed at a bit level. This method is designed and applied with a view to the environment and power consumption; the next portion of the process summarizes so much about the framework suggested.

The main contributions and organization of this paper are summarized as follows: In section 2 we describe background details of Montgomery operations. Section 3 discusses the proposed work. Section 4 deliberates Results and Discussions. Finally, in section 5, we concluded the paper.

II. BACKGROUND WORKS

Encryption is performed through a public key, so then the matching private key will decrypt the encrypted document. The reliability of these algorithms depends on the hardness of the public key to extract the private key. While gradual and highly technical, asymmetric key encryption provides tremendous benefits. The main benefit seems to be that the simple primitives used will be based on well-known issues like integer factoring and discrete problems with the logarithm. Such difficulties were extensively studied and, despite years of research, their consistency was not contradicted. This may be distinct from symmetric key encryption, in which the power of the code relies on combinatory strategies. The protection of such algorithms has not been demonstrated and therefore does not rely on well-researched literary problems.

Within real-world environments, crypto-system installations must be effective, scalable and reusable. Implementations such as smart cards and mobile phones need deployment where resource consumption and power consumption are important. Such architectures should always be lightweight and low-powered. A secondary criterion is computing capacity. The degree of system reconfigurability may also be held to a minimum. This seems to be since these machines are short-lived and are typically only installed once. High-efficiency devices such as network servers, storage networks, etc. on the other side of the continuum need high-speed deployment of ECC. The crypto algorithm will never be the output bottleneck of the program. These architectures do need to be rather scalable. Running conditions can be reconfigurable, such as algorithm variables, etc. The software can be quickly reconfigured; furthermore, program implementations do not often scale the application's output. These systems need specialized equipment for speed calculations. The required clock cycles, operating frequency, and region are critical design parameters while utilizing these hardware accelerators. The clock cycles will be short and the frequency high, so that the average device latency is smaller. The region is essential since smaller areas imply that parallelism on the same equipment may be introduced, thus the device's performance.

The Correctness of RSA). Let *X*, *Z*, *Y*, *l*, *m* be plaintext, cipher text, encryption exponent, decryption exponent and modulus, respectively. Then

$$(X^{l})^{m} \equiv X \left(mod\, Y\right) \tag{1}$$

Proof. Notice first that

$$Z^{m} = (X^{l})^{m} X \left(mod\, Y\right) \tag{2}$$

$$Z \equiv X^{l} \left(mod\, Y\right)$$

$$\equiv X^{1+k\phi(Y)} \left(modY\right) (lm \equiv 1\left(mod\phi\left(Y\right)\right) \tag{3}$$

$$\equiv X.X^{k\phi(Y)} \left(modY\right) a^{\phi(y)} \equiv 1\left(modY\right)) \equiv X \tag{4}$$

The result thus follows.

Remark 1. In order to complete, this process of decryption, the approved users having the *m*, *r* and *s*, with the data available from $X \equiv Z^{m} \left(mod\, Y\right)$, makes the computation to operate at speed by taking into account two axioms

$$X_{r} \equiv Z^{d} \equiv Z^{m \bmod r-1} \left(mod\, r\right) \tag{5}$$

$$X_{s} \equiv Z^{d} \equiv Z^{m \bmod s-1} \left(mod\, s\right) \tag{6}$$

$$X \equiv X_{r}.s.s-1 mod r + M_{s}.r.r-1 mod\, s \left(mod\, Y\right) \tag{7}$$

Recently the residue number system $\{2^{y}\text{-}1, 2^{y}, 2^{y}\text{+}1, 2^{2ys+1}\text{-}1\}$ supposed to introduce both high dynamic terms with the logic of parallelism. The block diagram of RNS system based on these moduli set is shown in Figure1.

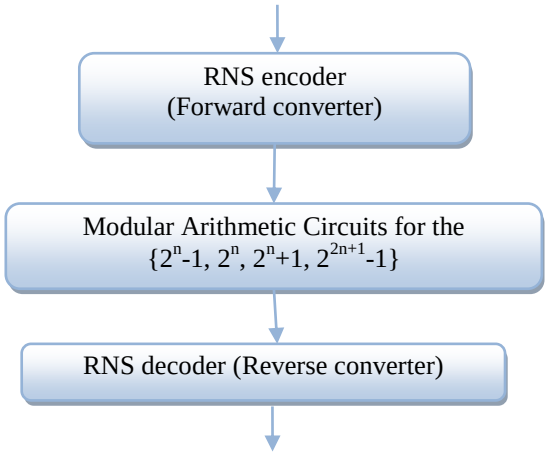

Figure 1: Block Diagram of residue number system

The first phase in constructing a converter is the collection of the module package. The collection of modules will play an important role in the dynamic range, pace, and hardware creation of the RNS. The second phase for constructing a reverse converter is to replace the variables of the module provided by modern CRT conversion algorithms.

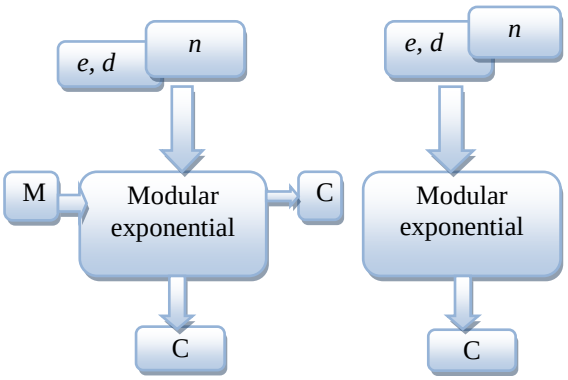

Figure 2 : The RSA encryption/decryption structure

The corresponding calculations are condensed in the third stage by utilizing mathematical characteristics and proposals. Eventually, adder elements including CSA-EAC, CPA-EAC, and Revised adders are created for final equations. Figure 2 shows the RSA encryption/decryption structure in hardware implementation. The essential of the RSA implementation is how better the modular arithmetic operations that can incorporates the modular addition, subtraction, multiplication and exponential.

III. METHODS AND METHODOLOGY

Dual-Field Modular Reduction: A final modular reduction by each modified RNS/PRNS modulus is required, for each multiplication outcome, within each MAC unit.

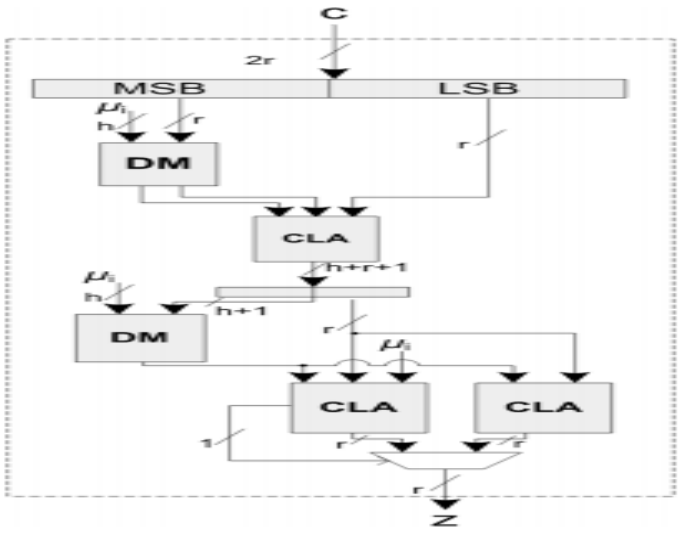

Figure 3: Connections of Dual-field modular and CLA units

Let us denote the 2*p*-bit product where its primary requirement is to modulo reduction p_i. By taking into consideration r_i and treating the term $2p-\mu_i$, in order to denote *h*-bit μ_i 2^p, the major calculation can be done which can be further be simplified as

$$z_{r_i} = \sum_{i=0}^{p-1} z_i 2^i + 2^p \sum_{i=0}^{p-1} z_{r+i} 2^i_{r_i} = G + 2^p H_{r_i} \quad (8)$$

$$= \sum_{i=0}^{r-1} m_i 2^i + \mu_i \sum_{i=0}^{h} m_{r+i} 2^i{}_{r_i} \quad (9)$$

A certain mathematical calculation extended for differential equations where a compact dual-field reduction (DMR), as seen in the figure, can be mechanized and adders, multipliers depends on modular operation are used. Nonetheless, CSKA, which would be an effective adder in terms of energy use and region usage, was implemented by CLA. The CSKA's vital latency is much lower than that of the RCA, whereas its region and electricity consumption are comparable to RCA. However, the CSKA power delay product (PDP) is smaller than the CSLA device.

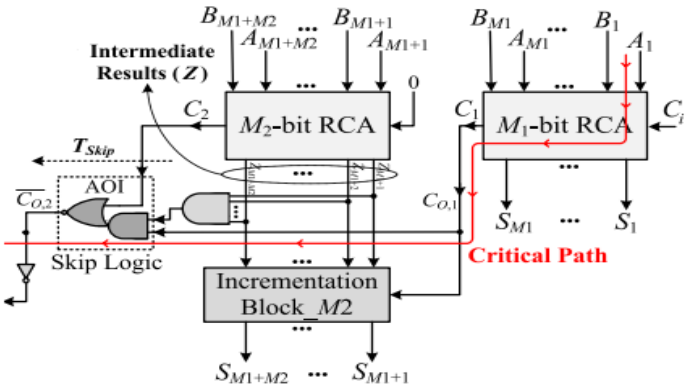

Figure 4: Modified CI-CSKA structures

In Figure 4, the modified CI-CSKA structure which can be substituted in Figure 3 by a CLA block allows us to use easier carrying skip logic. The AOI/OAI compound gates are quicker and more efficient. Remember that it is augmented in this form when the carry propagates through the skip logic. Furthermore, the completion of the carry is obtained at the output of the skip logic of even phases. The structure has a significantly lower propagation time with a slightly smaller area compared to existing areas on its own. Likewise, while the AOI gate's electric energy consumption is slightly smaller than that of the multiplexer, the proposed CI-CSKA's energy consumption is slightly higher than traditional power consumption.

IV. RESULTS AND DISCUSSION

The Montgomery architecture and modular RSA encryption was written in VHDL/Verilog and synthesized in the FF1153 speeds of XILINX ISE 14.4i (Kintex7) and XILINX ISE 12.4 products. The findings of the synthesis of the original Montgomery specification for various operand size bits are shown in Table 1-3. In the synthesis report region and frequency (minimum period) are produced. The output is measured as bit length multiplied by frequency and divided by clock cycle number.

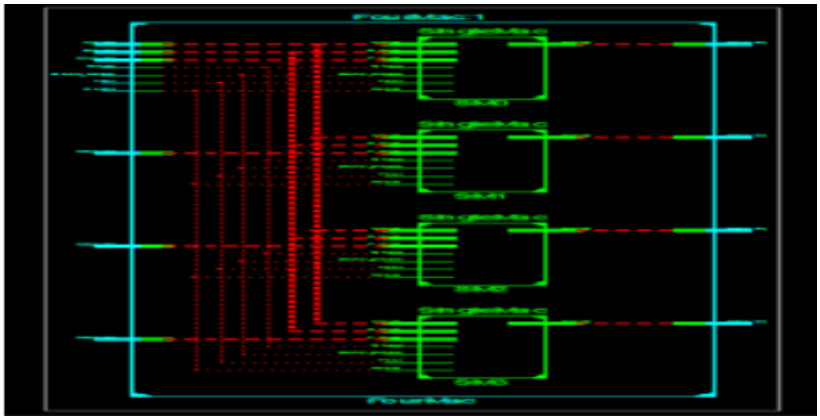

Figure 6: Technology schematic of proposed design

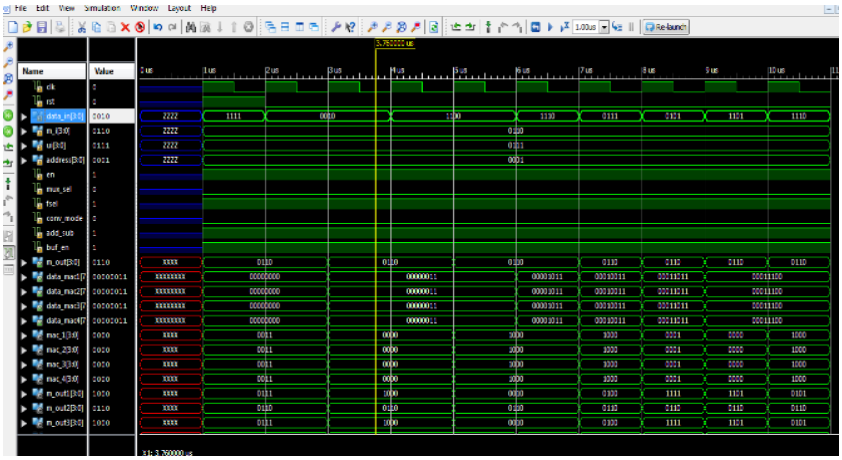

Figure 7: Simulation results of the proposed design

Table 1: Overview of logic blocks usage CSK adder for 4-bit length

Device Utilization Summary (estimated values) [-]			
Logic Utilization	Used	Available	Utilization
Number of Slices	5	960	0%
Number of 4 input LUTs	10	1920	0%
Number of bonded IOBs	14	66	21%

Delay in the path for CSK adder for 4-bit length is 9.23ns

Table 2: Overview of logic blocks usage CSK adder for 8-bit length

Device Utilization Summary (estimated values) [-]			
Logic Utilization	Used	Available	Utilization
Number of Slices	9	960	0%
Number of 4 input LUTs	15	1920	0%
Number of bonded IOBs	26	66	39%

Delay in the path for CSK adder for 8-bit length is: 9.23ns: 12.45ns

Table 3: Overview of logic blocks usage CSK adder for 16-bit length

Device Utilization Summary (estimated values)			
Logic Utilization	**Used**	**Available**	**Utilization**
Number of Slices	14	960	1%
Number of 4 input LUTs	25	1920	1%
Number of bonded IOBs	50	66	75%

Delay in the path for CSK adder for 16-bit length is: 15.23ns

Table 4: Overview of logic blocks usage CSK adder for 32-bit length s

Device Utilization Summary (estimated values)			
Logic Utilization	**Used**	**Available**	**Utilization**
Number of Slices	26	960	2%
Number of 4 input LUTs	45	1920	2%
Number of bonded IOBs	98	66	148%

Delay in the path for CSK adder for 4-bit length is: 31.23 ns

Table 5: Device Utilization Summary of 4, 8, 16, 32-Bit Carry's Skip Adder

Logic Utilization	**4 – Bit CSkA**	**8 - Bit CSkA**	**16 – Bit CSkA**	**32– Bit CSkA**
Number of Slices	5	9	14	26
Number of 4 input LUTs	10	15	25	45
Number of Bonded IOBs	14	26	50	98
Delay	8.7ns	11.3ns	14.1ns	29.8ns

V. CONCLUSION

This paper presents the design of an efficient RSA cryptosystem that uses the Montgomery algorithm for modular multiplication. With the help of dual field residue arithmetic unit, the Montgomery multiplication is done for all cases of word lengths are achieved. However, the associated DRAMM unit makes possible operations of multiplication in GF(p) and GF(2n), with the residual model. For improving the overall performance of the architecture of Montgomery and adder, the response time and critical path are decreased. The advantage of the proposed CI-CSKA achieved better results as related to other techniques.

Network Theory

Course Objectives

- To introduce basic laws, mesh & nodal analysis techniques for solving electrical circuits
- To impart knowledge on applying appropriate theorem for electrical circuit analysis
- To explain transient behavior of circuits in time and frequency domains
- To teach concepts of resonance
- To introduce open circuit, short circuit, transmission, hybrid parameters and their interrelationship.

UNIT-1: Introduction to Electrical Circuits

Passive components and their V-I relations, Energy sources - Ideal, Non-ideal, Independent and dependent sources, Source transformation Kirchoff's laws, Star–to-Delta or Delta-to-Star Transformations, Mesh analysis and Nodal analysis problem solving, Super node and Super mesh for DC Excitations.

Unit Outcomes

- Gain knowledge on basic network elements, voltage and current laws (L1)
- Apply Kirchoff's laws, network reduction techniques on simple electrical circuits with dependent & independent sources (L3)
- Solve complex circuits using mesh and nodal analysis techniques (L3)

UNIT-2: Network Theorems

Superposition theorem, Thevenin & Norton theorems, Maximum power transfer theorem, Reciprocity theorem, Millman theorem, Miller Theorem, Tellegan's Theorem, Compensation theorem - problem solving using dependent sources also, Duality and dual networks.

Unit Outcomes

- Understand significance of duality and dual networks (L2)
- Select appropriate theorem for network simplification (L5)
- Determine maximum power transfer to the load (L5)

UNIT-3: Transients

First order differential equations, Definition of time constants, R-L circuit, R-C circuit with DC excitation, Evaluating initial conditions procedure, second order differential equations, homogeneous, non-homogenous, problem solving using R-L-C elements with DC excitation and

AC (sinusoidal) excitation, Response as related to s-plane rotation of roots. Solutions using Laplace transform method.

Unit Outcomes

- Understand behavior of circuit elements under switching conditions (L1)
- Analyze response of RL, RC & RLC circuits in time & frequency domains (L4)
- Evaluate initial conditions in RL, RC & RLC circuits (L5)

UNIT-4: Resonance and Coupled Circuits

Self inductance, Mutual inductance, dot rule, coefficient of coupling, Analysis of multi-winding coupled circuits, series & parallel connection of coupled inductors.

Resonance: Introduction, Definition of Q, Series resonance, Bandwidth of series resonance, Parallel resonance, Condition for maximum impedance, current in anti resonance, Bandwidth of parallel resonance, general case resistance present in both branches, anti resonance at all frequencies.

Unit Outcomes

- Understand magnetically coupled circuits (L1)
- Determine resonant frequency and bandwidth of a simple series or parallel RLC circuit (L5)
- Determine voltages and currents in a resonant circuit (L5)

UNIT-5: Two Port Networks & Network Functions

Two Port Networks, relationship of two port variables, impedance parameters, admittance parameters, transmission parameters, hybrid and inverse hybrid parameters, relationship between parameters, interconnection of two port networks. Concept of complex frequency, driving point and transfer functions for one port and two port network, poles & zeros of network functions, Restriction on Pole and Zero locations of network function

Unit Outcomes

- Determine network parameters for given two port network (L5)
- Relate different two port network parameters (L4)
- Represent transfer function for the given network (L4)

ABSTRACT

In wireless networks, the performance of the network is inversely proportional to the distance between source and destination. Cooperative Communication (CC) technique can be used to improve the performance in such cases, wherein the intermediate nodes can be used as relay nodes. In this approach, selection of relay nodes and the path from source to destination plays a key role in the performance of the system. In this paper, we proposed a hierarchical routing algorithm for large scale cooperative mobile ad hoc networks based on mobility and link Signal to Noise Ratio (SNR). To improve the performance further we implemented cooperative communication in each hop. Simulation results show that our proposed algorithm gives better performance (average BER) than conventional routing (AODV) algorithm.

Keywords: Large scale mobile ad hoc network, routing algorithm, relay selection, mobility.

I. INTRODUCTION

Performance of wireless networks is degraded by fading, and it can be mitigated by providing diversity. Cooperative Communication is a technique which provides spatial diversity without having multiple antennas at the transmitter and receiver by forming Virtual Multiple Input – Multiple Output (VMIMO).

Cooperative Communication (CC) is implemented in large scale mobile Ad hoc networks to leverage the benefits of CC technique. Mobile Ad hoc Networks (MANET) can be a better choice than the conventional cellular system in some applications like, military and emergency search and rescue (natural disaster); where there is a need of establishing temporary communication network. Routing is the key issue in MANETs, since every node in the network having mobility so it can move freely in any direction [1].

In recent years, several routing algorithms have been proposed based on the way of establishing the path. They are based on: protocol operation, network structure, initiation of communication, path establishment or next hop selection [2, 3].

Path established based routing algorithms are categorized into three types: Proactive routing algorithms, reactive routing algorithms and hybrid routing algorithms. In proactive routing algorithms, route for every node is calculated and maintained by routing table well before it is needed. This route table is updated periodically by route update process. Proactive routing algorithms are: [4,5,6]

- Destination – Sequenced Distance – Vector (DSDV)
- Optimized Link State Routing Algorithm (OLSR)

In reactive routing algorithms, route is established only when it is needed. Therefore these routing algorithms do not need to maintain any routing information (route table) globally. Reactive routing algorithms are [4,7,8]:

- Ad hoc On Demand Distance Vector (AODV)
- Dynamic Source Routing (DSR)

Hybrid routing algorithms are a combination of proactive and reactive routing algorithms. Generally these algorithms are cluster based routing algorithms. It uses proactive routing strategy within the cluster and reactive routing strategy for cluster to cluster communication [4].

Next hop selection based routing algorithms are categorized into five groups: content based routing, probabilistic routing, Location based routing, Hierarchical based routing and broadcast based routing. In content based routing, next hop selection is merely based on query content. These types of routing algorithms (Directed Diffusion) are most suitable for sensor network architectures [9].

In probabilistic routing, a sensor node is selected randomly for the next hop by assuming, all the nodes are homogeneous and distributed randomly. In location based routing protocols, next hop relay node is selected based on the location of neighbor nodes and destination. In hierarchical routing, a set of nodes form a cluster, which helps to forward the message to the destination. Each node aggregates the message by which they reduce the overload, and hence the network lifetime is increased. In broadcast routing, every node broadcast the message if it wants to transmit (every node take decision individually) [9].

In this paper, we propose a hierarchical routing algorithm to improve the network perform. For this, we form a cluster based on the link signal to noise ratio (SNR), formation of cluster and identification of cluster head explained in algorithm 1. In this, cooperative

communication is implemented in each hop to improve the performance further.

The rest of the paper is organized as follows: description of the network given in section II, routing algorithm presented in section III. In section IV, we present the simulation results and finally we conclude the paper in section V.

II. SYSTEM MODEL

In this paper, we consider a large scale cooperative wireless Mobile Ad hoc Network (LSC-MANET) with N Nodes as shown in figure 1. Each node having 'M' radio terminals and employs Amplify and Forward (AF) relay protocol. The mobility of the i^{th} node is assumed as v^i. Every node knows its neighbor node positions by sending beacon signal periodically.

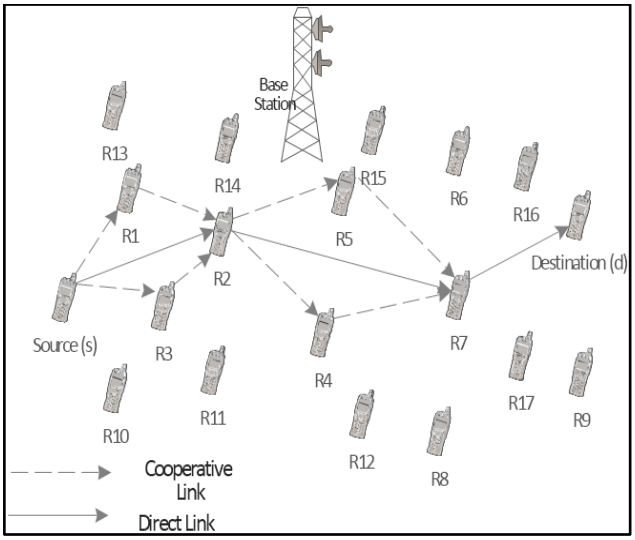

Fig. 1. Large Scale Cooperative wireless Mobile ad hoc Network.

Since every node is equipped with more than one radio terminal, each node sends the control (beacon) signal along with its node ID through setup channel, periodically for every β sec. Other nodes which are in its transmission coverage region receive the beacon signal and measure the link SNR based on Received Signal Strength (RSS) of the control signal. Node ID is useful to the received node to identify the broadcast node. Let the nodes R1, R2, R3 and R10 are in the transmission coverage area of source (s), node R1 measure the link SNR:$\gamma_{s,R1}$, node R2 measure the link SNR: $\gamma_{s,R2}$, similarly node R3 and R10 measures the link SNRs $\gamma_{s,R3}$ and $\gamma_{s,R10}$respectively for every beacon signal.

In a hop, the relay node *'j'* (destination in a hop) receives the information *'x'* from the source *'s'* through two different ways: i.e., through direct link (s → j) and through cooperative links (s → r → j). The information at the node 'j' through these two paths can be given as [10]:

$$y_{s,j} = \sqrt{P}h_{s,j}x + \eta_{s,j}$$
$$y_{s,r} = \sqrt{P}h_{s,r}x + \eta_{s,r} \quad (1)$$
$$y_{r,j} = \sqrt{P}h_{r,j}Ay_{s,r} + \bar{\eta}_{r,j}$$

and $\bar{\eta}_{r,j} = \eta_{r,j} + A\eta_{s,r}$

where P is the transmitting power, $h_{s,r}$ is the coefficient of the link from node 's' to node 'r' ($s \rightarrow r$) and $\eta_{s,j}$ is the additive white Gaussian noise of the link $s \rightarrow j$.

We assumed that, every cell site contains a global table (shown in Table I) at the base station which contains link SNRs & mobility of each node and it is accessed by every mobile node in its region. After calculating the link SNR every node updates the measured SNR in global table which is useful in the relay selection described in algorithm 1. The nodes which are not in the transmission coverage area of node 'i' its link SNR is represented by NA.

III. ROUTING ALGORITHM

Routing algorithm for the Large Scale Cooperative Mobile Ad hoc Network (LSC-MANET) is presented in this section.

Algorithm 1: Optimal Routing Algorithm

Input: Flow request from source to destination.

Output: Routing path from source to destination with each hop's relay node.

1: **while** source ≠ destination **do**
2: **if** d ϵ T(s)
3: relay node = destination
4: **else**
5: Find set of nodes which having low velocity in its transmission coverage area T(s).

$$M(s) = \{i | v^i - \min(v^j) < \theta; i, j \, \epsilon T(s)\}$$

6: Source finds the SNR of links from source node to each node in M(s) using global table.
7: The node which having the higher SNR will act as relay node for the next hop.

$$n = \arg\max_{i \epsilon M(s)} \{\gamma_{s,i}\}$$

8: forms a set of nodes which having almost equal SNR

$$SR(s) = \{z | \arg[(\gamma_{s,n} - \gamma_{s,z}) < \alpha]; z \epsilon M(s), n \neq z\}$$

9: Source use the SR(s) set as cooperative relay nodes to further improve the performance of the network.
10: **end if**
11: source node = relay node
12: **end while**

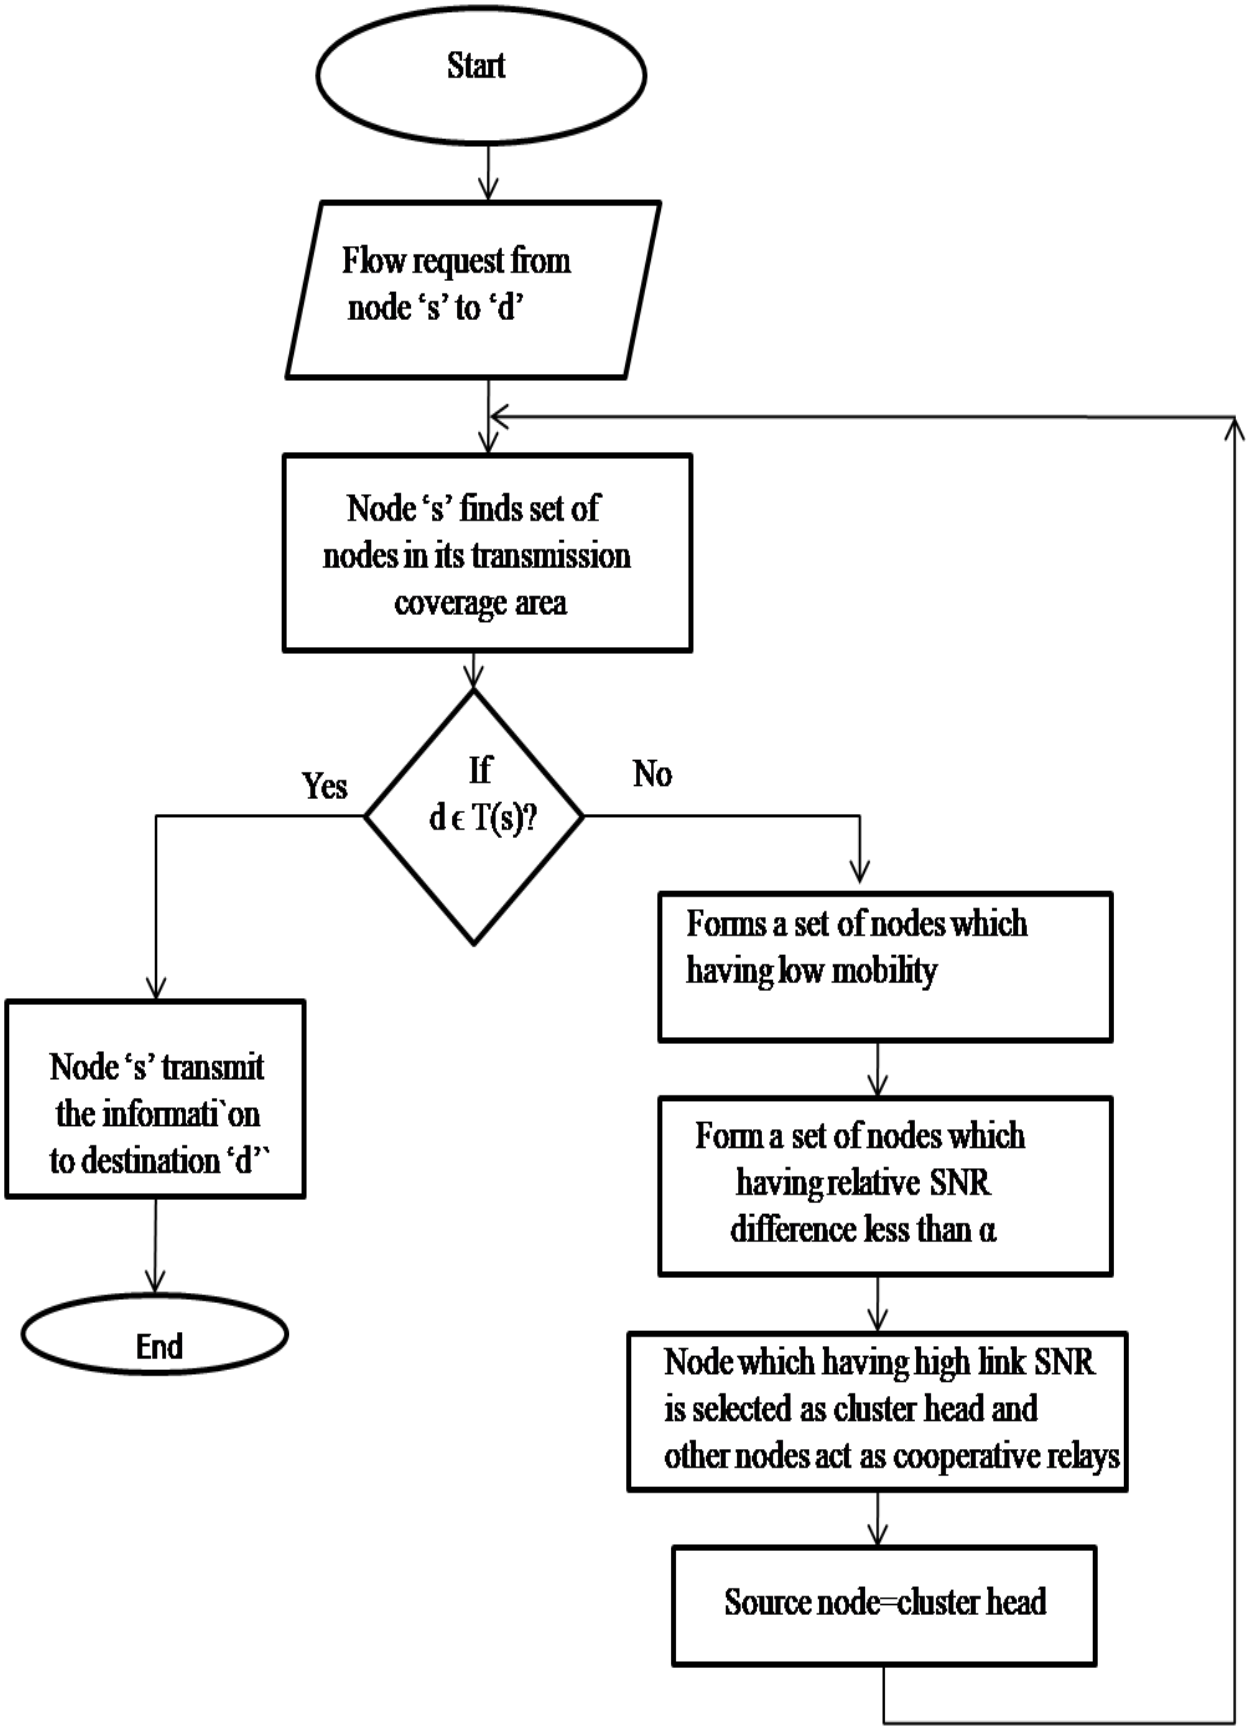

Fig 2: Flow chart for the proposed algorithm

The summary of the algorithm is given as

1) Source finds the set of nodes in its transmission coverage area T(s). It obtains every node velocity and link SNR from global table.
2) Forms a subset of step 1 which having almost low velocity.
3) Forms a subset (cluster) of step 2 which having almost high SNR.
4) In step 3, the node which having maximum SNR will be the cluster head and it will act as a source node for the next hop and other nodes in the cluster helps to transfer the information to cluster head.
5) If the destination node is not in T(s) go to step 1.

The above said algorithm is repeated periodically, so that the routing path and cooperative relay nodes are updated based on their mobility and link SNR.

IV. SIMULATION RESULTS

The simulation results of the proposed routing algorithm are presented in this section. The parameters used for the simulation listed in TABLE-II.

TABLE-II: SIMULATION PARAMETERS

Parameter	Value
Number of Nodes	50
Transmitted Power	1mW
Mobility threshold (θ)	5m/s
SNR Threshold (α)	3dB
Noise Variance	10^{-10}
Modulation	M-QAM
Path loss exponent (n)	4
Combining Strategy	MRC

Figure 3 shows the average Bit Error Rate (BER) of the network for varying node mobility. From the simulation result, we can observe that the proposed algorithm gives better performance than the AODV algorithm. The average BER of the network is increased as the mobility increases and it is improved with the number of nodes.

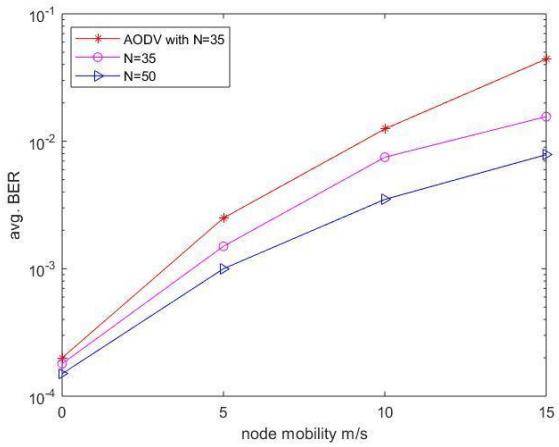

Fig 3: Average BER for varying node mobility

The average BER of the network decreases as the number of nodes of the network increases as shown in Figure 4. As mentioned in the system model, every node updates the link SNR for every β sec. The dynamic changes in the network can be captured if the nodes update for smaller intervals of time. So as β decreases, the performance of the proposed algorithm also increases.

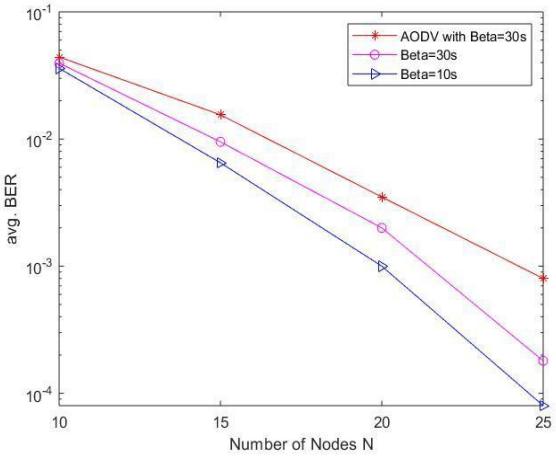

Fig 4: Average BER over Number of Nodes

V. CONCLUSION

In this paper, we proposed and analyzed a dynamic routing algorithm for large scale cooperative mobile ad hoc networks (LSC-MANET). This algorithm considers two parameters for relay selection, namely mobility parameter and Signal to Noise Ratio (SNR). It selects a set of nodes which are moving slowly, and select a node as relay from that set which having high link SNR. Therefore relay node is having relative mobility is low and SNR is high. We implemented cooperative communication in each hop to further improve the performance. From the simulation results we conclude that our algorithm gives better performance than AODV algorithm.

Abstract. Scaling of bulk MOSFETs in nanometre regime has several disadvantages. The electrical behaviour of the devices doesn't show the anticipated characteristics if scaling is done beyond certain point. But in order to have smaller devices with higher density on chips, it is necessary to avoid short channel effects (SCE) which lead to unexpected electrical features. One of the methods to avoid SCE is to have multi-gate architecture of MOSFET. This paper investigates the behaviour of double-gate MOSFETs with respect to the variation of their physical dimensions. The analyses have been done taking into notice the quantum mechanical effects due to dimensions in nanometre scale. The results obtained highlight how subthreshold and above threshold regions are impacted due to the various physical quantities that have been varied.

1. Introduction

By reducing the dimensions of MOSFETs, more number of components can be incorporated on a VLSI [1, 2] chip to have diversified applications. Adjusting short-channel effects (SCE) is the major issue during scaling down of conventional MOSFETs. There are several ways through which SCE can be lessened while reducing the dimensions of a device. There are many prominent techniques to overcome these shortcomings. Use of strain as reported in [3-5] alleviates SCE and boosts electrical integrity. Similar advantages have been found through the use of junctionless transistors [6-8].Use of multiple gates has been reported in [9-12]. The core theme of all these methods is to enable gate electric field to be more dominant in the channel region. Proper lithographic techniques are used to enable these methods.

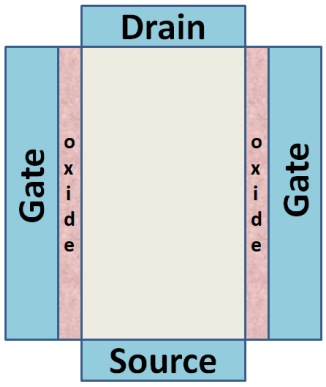

Figure 1. Double-Gate n-channel MOSFET

In multi-gate MOSFETs, there is more than one gate and all gates are maintained at the same potential through the application of gate voltage. The role of gate is to govern the electrons in the channel. Due to multi-gate, the channel electrons are better controlled [13] and exhibit superior properties than single gate transistors.

In this work the electrical behaviour of Double-Gate (DG) MOSFET as shown in figure 1 has been examined by varying the physical parameters of the device. The subthreshold characteristics denote the region of MOSFET operation when gate voltage is smaller than the required turn-on voltage. Subthreshold region determines the power consumption of the device when it is supposedly in off state. In the nanometre range, the energy levels redistribute and it impacts the threshold voltage of the given device. In our calculations we have taken into this consideration which is known as quantum mechanical effect (QM) [14].

2. Theoretical details

The potential in the channel and its charges are related through the Poisson expression written as $d^2\phi/dx^2 = (q/\varepsilon_{si})n_i e^{(\phi-V)q/kT}$ where ϕ is the potential in the channel, q is charge, ε_{si} is the silicon permittivity, n_i is the doping concentration, V is the quasi-Fermi potential, and kT/q is the thermal potential. The solution of this equation can be found using boundary conditions [15]

$$\frac{q\left(V_g-\Delta\phi-V\right)}{2kT}-ln\left[\frac{2}{t_{Si}}\sqrt{\frac{2\varepsilon_{Si}kT}{q^2n_i}}\right]=ln\beta\ \ -\ln[\cos\beta]+\frac{2\varepsilon_{Si}t_{ox}}{\varepsilon_{ox}t_{Si}}\beta\tan\beta \tag{1}$$

The drain current expression is given as [16]

$$I_{ds}=\mu\frac{W}{L}\int_0^{V_{ds}}Q_i(V)dV \tag{2}$$

The current in the linear, saturation and subthreshold regions are given as [15]

$$I_{ds,Lin}=2\mu C_{ox}\frac{W}{L}\left(V_g-V_t-\frac{V_{ds}}{2}\right)V_{ds} \tag{3}$$

$$I_{ds,Sat}=\mu C_{ox}\frac{W}{L}\left((V_g-V_t)^2-\frac{8rk^2T^2}{q^2}e^{\frac{q\left(V_g-V_0-V_{ds}\right)}{kT}}\right) \tag{4}$$

$$I_{ds,Sub} = \mu \frac{W}{L} kTn_i t_{si} e^{\frac{q(V_g - \triangle\phi)}{kT}} \left(1 - e^{\frac{-q(V_{ds})}{kT}}\right) \quad (5)$$

where μ is the mobility, C_{ox} gate oxide capacitance, W is channel width, L is channel length, V_g is applied gate voltage, V_{ds} is drain to source applied voltage and threshold voltage V_t is expressed as [15]

$$V_t = \Delta\phi + \frac{2kT}{q} ln\left[\frac{2}{t_{Si}}\sqrt{\frac{2\varepsilon_{Si}kT}{q^2 n_i}}\right] + \frac{2kT}{q} ln\left[q\frac{(V_g - V_0)}{4rkT}\right] \quad (6)$$

where $\Delta\phi$ is $\phi_m - \phi_s$, the difference of metal and semiconductor work function, t_{si} is channel thickness, and $r = \varepsilon_{si}t_{ox}/\varepsilon_{ox}t_{si}$. Due to QM effect, the increase in threshold voltage is given as [17] $\Delta V_{thQM} = (h^2 / 4qm^* t_{Si}^2)(\Delta t_{Si} / t_{Si})$ where h denotes Planks constant and additional symbols have traditional implications.

3. Results and Discussion

The calculation results are presented in Fig. 2–7. The channel length used is 1μm and oxide thickness as 1.5 nm for all calculations otherwise it has been stated.

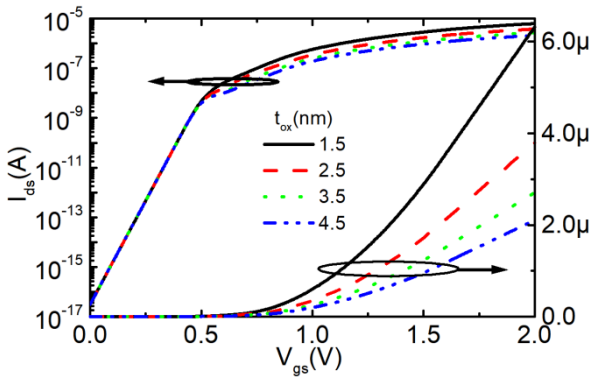

Figure 2. Drain current versus gate to source voltage for different oxide thickness.

Fig. 2 shows the variations of current with respect to applied gate voltage for different gate oxide thickness. The oxide thickness has been varied from 1.5 nm to 4.5 nm. The effect of oxide thickness variation is negligible in subthreshold region while it considerably affects the above threshold region.
In Fig. 3, silicon channel thickness has been changed to get the current variation. Here t_{si} affects subthreshold characteristics more than above threshold and it is as per the observations in [15]. The channel thickness near 5 nm contributes more to the elevation in threshold voltage arising due to QM effect.

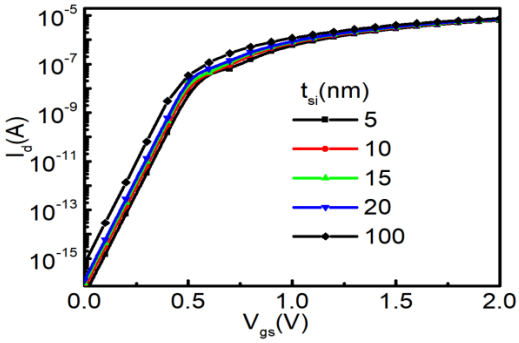

Figure 3. Drain current versus gate to source voltage for different silicon thickness..

The effect of change of channel width on the drain current is shown in Fig. 4. Current increases with width *W*. In this case, *W* has relatively more effect on above threshold area. Drain current can be increased by increasing *W*, but then it increases the size of the device.

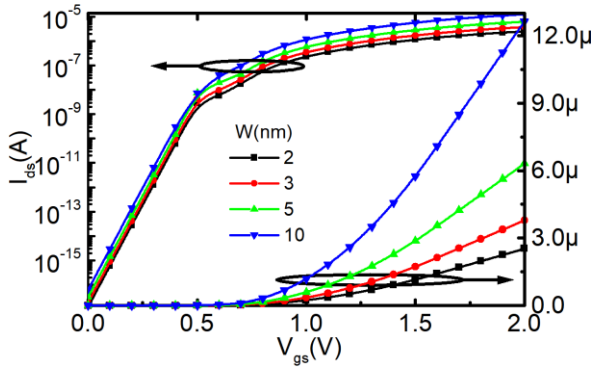

Figure 4. Drain current versus gate to source voltage for different channel width.

The outcome of altering the doping concentration can be seen from Fig. 5. Increase in doping raises the work function of silicon and in subthreshold region current increases.

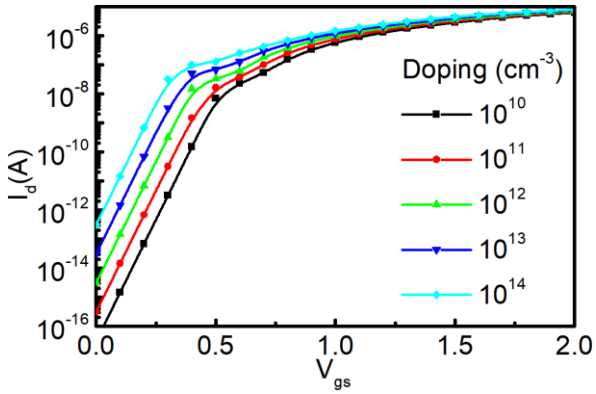

Figure 5. Drain current versus gate to source voltage for different channel doping concentration.

By changing the metal work function, desired threshold voltage can be obtained and accordingly the drain current is also affected. It can be observed from figure 6 that metal work function affects both

the regions of MOSFET operation. Threshold voltage decreases if metal work function is decreased. But one of the disadvantages is that smaller metal work function increases subthreshold current and hence the leakage current. Leakage current must be kept at minimum level. From this graph the optimum value of metal work function can be inferred.

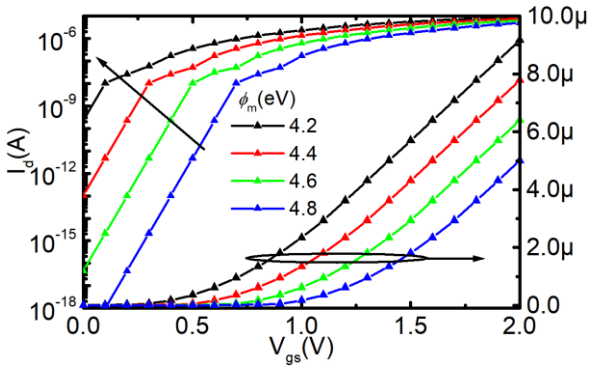

Figure 6. Drain current versus gate to source voltage for different metal work function.

The effect of mobility on current can be visualized from Fig. 7. Mobility shows more impact in the above threshold area. Therefore techniques that increase mobility may be incorporated in DG MOSFETs to increase drain current.

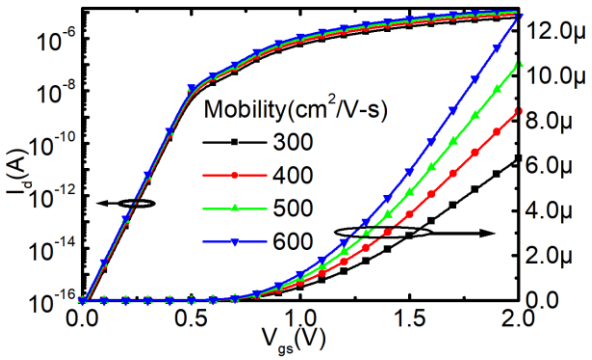

Figure 7. Drain current versus gate to source voltage for different mobility.

4. Conclusion

In this work the sensitivity of drain current of DG MOSFET for device dimension changes have been explored. It may be concluded that constraints exist for the selection of proper parameter so as to get maximum current and minimum dimension. Subthreshold current determines the off-state of the device and therefore it should be as low as possible. In the on-state, i.e., when the gate voltage is greater than the threshold voltage, larger current is expected. Selection of metal gate work function also plays very important role in the optimum performance of the device. As a future work, the effect of variation of channel length would be explored.

ABSTRACT

With the growth of internet-based applications and the explosion of consumers, cloud-based web service applications have become more common and the importance of minimizing the cost, increasing the interactivity, and management and efficient use of resources has become high. Existing methods like fixed cost per month no longer satisfy the application maintenance costs of the modern app developers. In this article, the authors propose an enhanced model for improving efficiency; maximize availability and minimizing the cost of cloud-based web applications. The authors have conducted experiments on grid dataset and analyzed the results using several algorithms on the load balancer with the multilevel optimized shortest remaining time scheduling method. The analysis clearly proves that applying a "pay as you" go mechanism will substantially reduce the cost and will improve the efficiency which resources are utilized. The results clearly suggest improvements in cost minimization and effective utilization of resources leading to effective utilization of services.

resources to the user as pay as you go manner (For example, computer systems, servers, storage and applications).

The growth of internet-based applications which are used by billions of devices in the world and the demand for cloud-based web applications are high. The service provider adds the technical infrastructural services based on the demand of users with affordable cost, minimum maintenance, shared resources, improved performance, increase the data operations parallel processing, scalability, reliability elasticity, and secured applications. In the 21stcentury cloud-based web application services pay as you manner, to meet the performance of applications by resource, network, load balancing, and Management applications. Considering web traffic at peak hours to access the services, managing the Cloud resources by performance and cost factors. In the development of Cloud-based web applications models service providers, users, designers in a service organization, the most important non-functional parameter is the development cost, maintenance cost to be minimized and optimize and provide the services to the end users.

The rest of the article is organized as follows: Section 2 deals with related work and Section 3 with the proposed method. The Sections 4 and 5 deal with experimental results and discussions, respectively. Finally, section 6 draws the conclusion.

2. RELATED WORK

2.1. Problem Definition

The objective is to provide cloud-based web applications with a minimum cost to run the services or applications without compromising on the functionality, latency, throughput, reliability, scale and other aspects. This enforces the effective use of services by the applications as well as pushes optimizations on the data center in such a way that it effectively allocates the use of resources. There are various needs and Service Level Agreement (SLA) required for the services backing the web applications during different phases of the product lifecycle i.e. development, deployment, maintenance etc. The problem focuses on delivering a mechanism to minimize the project cost during the various phases. The motivation of the cost minimization for Cloud-based web services comes from the service providers capability to control the feature set of the services provided based on the desired SLA as opted by the end user. This will enable the end user to provide the service with the desired feature set and minimum cost. The tasks, cost, load, and availability are described in Equation 1-4.

Let there will N number of DCs/Servers to process the cloud-based web applications, tasks t_1, t_2,…, t_n for allocating process:

$$tij = \begin{cases} 1 & if\ succussful \\ 0 & for\ unsucessful \end{cases} Tasks \tag{1}$$

For minimization of:

$$Total\,cost = \sum_{i=1}^{n} \left(\mathrm{C1} + \mathrm{C2} + , .. , \mathrm{Ci} , + \mathrm{Cn} \right) \tag{2}$$

subject to a load of the server where:

$$load = \frac{\text{Number of applications running on server}}{\text{Total number of applications}} \tag{3}$$

and effective utilization of services by the availability of the system:

$$availability\,of\,server = \frac{\text{No of requests over number of applications}}{\text{Total number of applica ations}} \tag{4}$$

2.2. Literature Survey

The Total Cost of Ownership (TCO) proposed by Panagiota Nikolaou in 2015, key optimization data center design, the model framework is used for availability, hardware and software resources. The performance by power single and dual channel in Web service by TCO model failure rate and cost estimated (Nikolaou, Sazeides, Ndreu & Kleanthous, 2015).

(M. Zivkovic,2011) proposed a model sequential decision for composite service request used for decisions optimal dynamic programming by backward decision structure and forward decision structure which use of cost, and response time of application. Pengcheng Xiong in 2011, proposed decision application level (adaptive feedback controller) has a robust workload based on resources on demand. Cloud computing is the Service Level Agreement (SLA) of the service provider to ensure that the quality of services by PaaS components. The web application uses multiple tiers (N-tiers), the controller, application decision maker with different levels of resources and minimizes total resource cost by managing the workload.

(Mathias, 2011) studied two replication strategy is arrival rate and response time policy, by optimizing service replication in Cloud, load replica operating cost depends on arrival rate, response time and policy. The service oriented architecture (SOA) system use service level agreement (SLA) at cost-effective, cost-saving, and balancing load multiple replicas. The service replicas have a low response time, low utilization of active replicas, control service replica utilization, the minimum number of active replicas. C. Tian in 2011, proposed optimal load balancing technique for web applications, allocation servers to maximize throughput and cost minimization. David Breitgand in 2015, proposed an Elastic Service virtual resources workload conditions, SLA virtual data centers, to manage solution quality and computation time. Service (IaaS) cloud computing, the Virtual Machine (VM) instances-based workload the user need to pay the cost, with minimum responsibility, the service is elastic, the behavior of the service is based on workload rules, optimization techniques to maximize profit.

Cloud computing has virtual scalable computing resources, Peng Zhang in 2012, proposed cost optimization to provide data services, parallel scheduling and minimize cost applications with the execution of computations cloud services. The Greedy algorithm minimizing the cost and random task. Tao in 2012, proposed a cost-effective algorithm model which optimize multiple resources based on system preference.

Farhana Kabir 2012, proposed autonomous, self-scaling, cost-effective cache for data-intensive applications, the user cost and performance considerations. Sheng Liu in 2012 proposed optimal service composition execution cost based on Quality state matrix, and execution service and the service requestor need to pay for every successful execution. Adnan Ashraf in 2013, proposed cost-effective VM multi-tier application for video applications to find an optimal solution by meta-heuristic approaches for web application. Jing Jiang in 2013, proposed an auto-scaling Cloud resource, VM for Web application providers optimized latency and SLA. Suhradam Patel in 2013, proposed a cost-minimizing by workload monitoring by grouping Virtual Machines (Wang, Shen, Di, Li & Zhou, 2013). Lijuan Wang in 2013, proposed service computing, a compositional model for data-intensive applications.

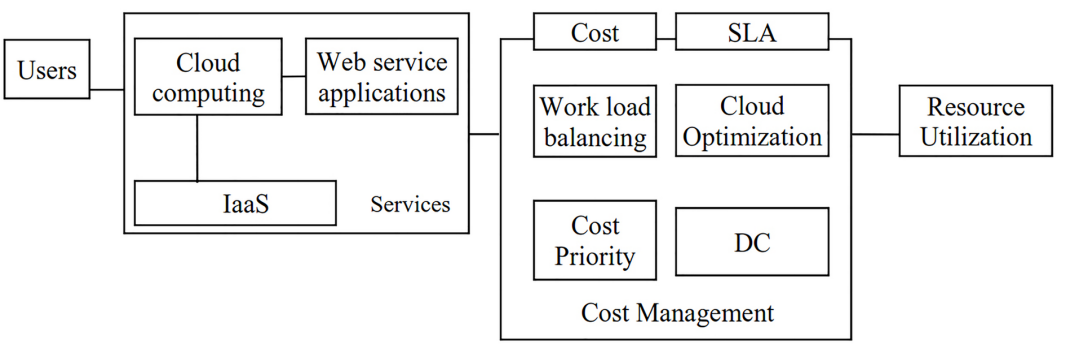
Y. M. Xia in 2013, proposed Quality optimization and redundancy removal algorithm which reduces the memory cost and improves performance (Wu & Nie, 2013). Web service is available on the Internet with the best quality of web service satisfying all functionalities. Min Yao in 2014,

used Cloud brokerage service which helps the Cloud computing by approximation and trace-based evolutions which minimize cost. Song Li in 2014, proposed Hybrid cloud computing optimization model by dynamic provision algorithm. Lu in 2014, proposed Server virtualization and game-changing technology which will maintain and high utilization of resources and reduce cost data center. Rui Zhu in 2014, proposed comprehensive cost model used for video webcast operators with many CDN networks use of ISP and CDN cloud server providers. Satish Narayana in 2014, Cloud Computing elasticity policy has optimum setup for Cloud workload. Amazon load trace control flow components for enterprise application with use of XOR and AND operators, and auto-scaling of Web services. Z. Ren in 2014, studied workload analysis of E-commerce application, and used job scheduling algorithm and proposed Fair4S, Hadoop scheduler handling for small jobs.

Waheed Iqbal (2018) proposed a pro-active auto-scaling approach used to manage the applications based on dynamic workload and probabilistic workload patterns, predictions. fog-based interval identifies application workload using URI, distributions and predicting workload by arrival rate, average response time and auto-scaling. Maria, 2018 proposed scientific instrument workflow as service (WaaS), for deployment of applications using infrastructural facilities with use of many workflows minimize the overall cost for infrastructure resource each individual workflow. The performance is analyzed Dyna, Elastic resource Provisioning and Scheduling - Multiple workflows (EPSM) approach.

Syed Aon Ali (2018) proposed a cloud, a fog-based method with use of Energy Management System to maintain electricity for a huge number of complex smart grid applications and load balancing methods. Satapathy et al. (2016) use a contiguous link scheduling, Bhateja et al. (2018) use a FOO DBMS method to optimize the query, and Satapathy et al. (2018) use load balancing to minimize the cost of cloud-based web applications.

2.3. Proposed Model and Architecture



The proposed enhanced automated cloud services consist of users, services, Management and resource utilization shown in Figure 1.

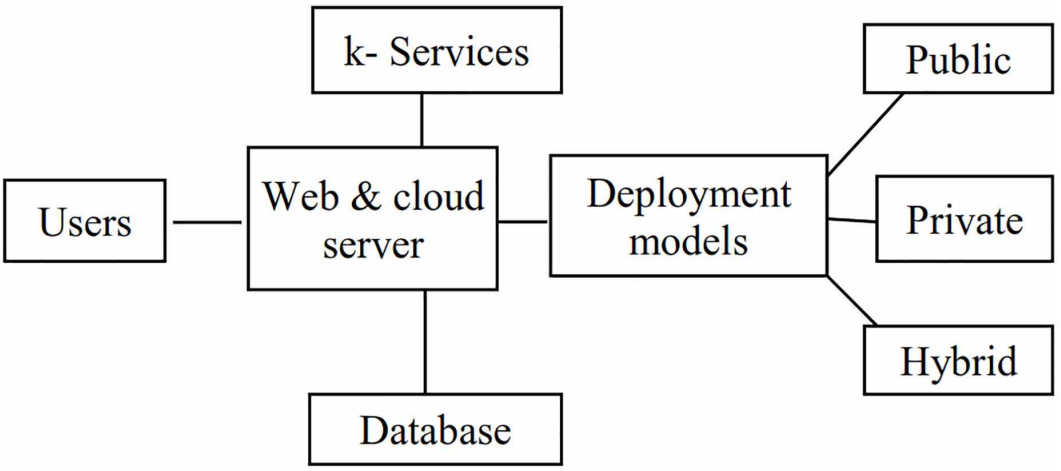
The users are the end users who can access the services pay as you manner, cloud services, and cost management with effective utilization of infrastructural resources.

2.3.1. Cloud Services

Cloud computing is an IT solution that enables end users to use resources from the cloud that are managed by the service providers and the layers underneath. Organizations are moving to cloud computing as it frees them from the management and maintenance aspects of the hardware and software and allows them to focus on their core scenarios without having to worry about other aspects. This flexibility comes at the cost of paying the service providers for the services consumed. More and

Figure 1. Web service and Cloud cost optimization model

more services are moving away from a fixed cost per month model to a "pay as you go" model which allows the end users to provision the resources on demand and deflate them once they are done with using the resources. Cloud computing model users SOA principles and operates over a faster wide area network providing high virtualization of the underlying hardware, software, and infrastructure.



IaaS service related to infrastructural services cost maximum Cloud providers, multi-unit solution resource pools. The virtual machine service used by operational cost and elastic service. Figure 2. Shows Web services and cloud deployment model has users, web cloud servers, and deployment models. The user is the clients who can access service as "pay as you go" manner. The web and cloud server which has functional services and resources in which developer deploy the applications into public, private and hybrid cloud centers.

The Cloud computing models are divided into three types SaaS, PaaS, and IaaS. There are potentially two types of pricing models:

1. **Pay as you model:** In this model, the users are charged free for specific duration hardware, software, for example up to 15 GB free for Google cloud users. And after the specified free trial period is over, the users are charged based on the consumption of the resources. If the user does not consume the resource, they can save the cost;
2. **Fixed price model:** In this model, the users subscribe to the resources and pay a flat per month price for the resources that they bought from the service provider. The price does not vary based on the consumption, but the user is charged a flat fee irrespective of the extent of the resources consumed.

The goal of the pricing models is to empower the user by providing the user with different options such as a fixed flat rate vs a variable cost based on usage. This will enable the user to select the model based on their usage patterns. If the user has a usage pattern where the usage is constant, and the SLA requirements are harder, then the user will preferably go for the fixed price model. If the user has different workload patterns during different periods of the year, then "pay as you go" pricing model might suit better which would enable the user to scale down the services provided during the "off-peak" season and scaling the same up during the high-demand and critical seasons.

Figure 2. Web services and Cloud deployment

2.3.2. Infrastructure as Service (IaaS)

The lower layer basic computing capability of system use of operating system, storage, and services in the network, including hardware servers, memory and computing power etc. Cloud provider example, Amazon EC2, VMware, Web service Elastic Compute Cloud (EC2) and Simple Storage Service(S3). And other services described in Table 1.

Cloud computing by scalability application by variant load and elasticity of cloud servers based on load. The types of cloud services are public, private and hybrid cloud services.

2.3.3. Public Cloud Services

Are designed which are not for single or group enterprise applications, these are used by the parties, pay you manner servers with storage and services. In a public cloud, the cloud service provider, the customer chooses the best service provider with affordable cost. The request of service to process the service with the use of best proposals and needs.

2.3.4. Private Cloud

Is configured and available to only authorized users not for their party and public. Services in organizations network, bandwidth, and availability. In private Cloud services infrastructure located outside, the operating system provides the services to authorized users. For example, trusted customers in organization financial services.

2.3.5. Hybrid Cloud

The organizations use Cloud model both public and private modules in financial services, cost-effective infrastructure to the user. This is the combination of public cloud for internal use and used for consolidated, virtualized and potential resources. This is financial and business solutions (Papazoglou, 2012). The services can be functional and non-functional services, for example, functional services are APIs, Menus and application services to the user whereas Non-functional like infrastructural facilities, cost of application by Quality state matrix, execution services. The quality of services described by Equation 5:

$$Qualityofservice\left(QoS\right) = F\left(cost, availability, Responsetime\right) \tag{5}$$

The Internet Service Provider (ISP) will achieve maximum profit by the quality of services, for example, network bandwidth, delay, and bit, error rate, Wireless network systems are used based on customer satisfaction. In Cloud Computing automatic control cloud system used to optimize resources using on-demand computing model. Cost effective placement algorithm is a model cloud-based environment that uses the multi-resource model by adding the resources based on demand.

Table 1. Cloud services and examples

Service	Amazon	Microsoft	Google
SaaS	Operating system, memory, services	Microsoft Azure, Office 365	Google Docs, Gmail, Google Apps
PaaS	Elastic Compute Cloud	Micro soft Azure cloud	Data center, Google App engine
IaaS	Amazon EC2, servers, storage, networking	Microsoft Azure, servers, storage, networking	Google Cloud Platform (GCP) service, servers, storage, networking

The Cloud Service Provider (CSP)s such as Amazon, EC2, and Rockspace. The demand for resources based on the cost of applications. The software as service performs running applications, monitoring communication finance the model is formulated and analyzed by aiming to study the advantages of the data access to save the cost and space. The model is used to eliminate data duplication form memory (Indrawati, Puspita, Erlita, Nadeak, & Arisha, 2018).

Cloud-based web applications require Quality of Service, the demand of customer and optimized services. SOA components, cloud services. Load balancer use of dynamic resource allocation using hierarchical balanced tree topology, if load increases, management of cloud data centers by auto scaling and the load management is shown in Figure 3.

Software service (SaaS), running applications, and monitoring communication finance. Advantages are data can be accessed, save the cost and space, elimination of duplication. To analyze and formulate the model and balance them across the instances of available multiple zones.

In cloud computing, the workload depends on the number of systems logging interactive sessions, the computing capacity, variable workload, network management. The workload can be of two types 1) predictive workload 2) dynamic workload.

2.3.6. Predictive Workload

The workload of systems can be predicted based on the current load and past load characteristics like applications, memory, network usage, and others.

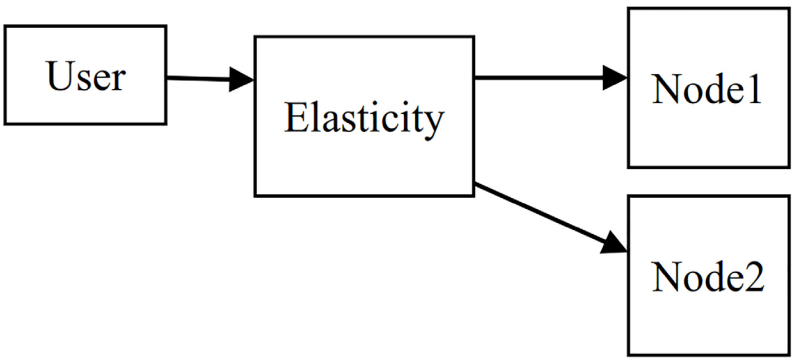
2.3.7. Dynamic Workload

Can be measured by considering the current load of the cloud-based web applications by considering the characteristics application in use, number of users, network bandwidth, scheduling, memory, DCs, and others. The submission of Machines into the systems in a cloud system which connected to proxy and virtual Node/system.

The intelligent workload management systems consist of the following components shown in Figure 4). Software applications can be identified with Data Center 2) Policy-based (Service Level Agreement): the provider promises the services based on cost and application at the time of Project assignment. 3) The client can access and identify the services 4) Performance, configuration, and Analysis and 5) secured physical and Virtual services. The above two workloads by considering the provisioning, scheduling, and Monitoring the cloud load applications.

The architecture of cloud load balancing is described here, it consists of Software applications, SLA and Middleware, operating system, servers, storage and analysis of performance and configuration, Management of services and Secured applications.

Figure 3. Load management



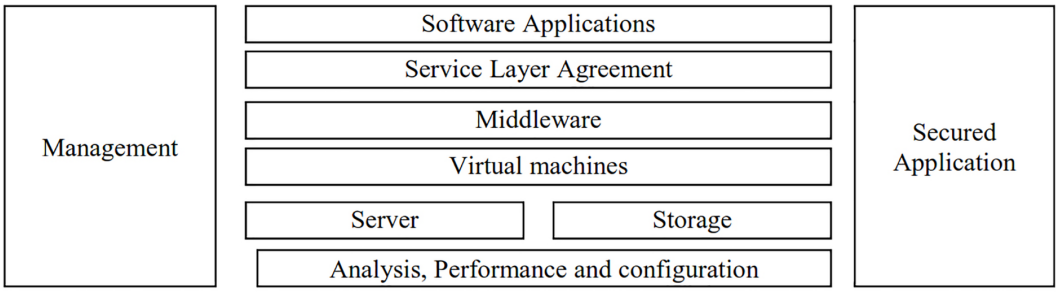


Figure 4. Cloud-based web application architecture

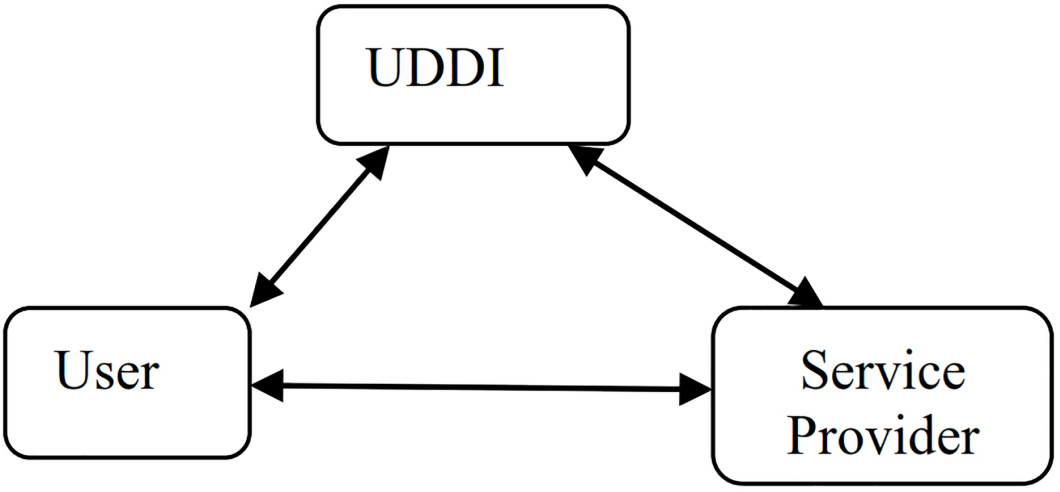
The development of applications with reduced cost by error-free quality documentation, reuse the code, and minimum maintenance of applications. In the service level agreement, the provider services to the user with SLA the quality of services Virtual systems, services provided for 24X7 time with the use of secured applications, storage systems. The Datacenters and application services, which will minimize the cost with use of Servers/ storage/Network facilities to the users based on the demand of users and workload monitoring add data centers by considering the peak hours, number of clients used, number of applications, capacity, network facilities, the response of the system. The applications are increasing the response time also increased minimize the response time by load balancing and scheduling algorithms. The load characteristics, network speed, network distance, response time, scheduling, cloud type services, hardware, the demand for services, peak load, DC, and workload management. The cloud-based web applications offer services such as cloud management, service request, applications workload management, infrastructure (virtual and physical).

2.3.8. Web Services

The growth of internet technologies, web service applications development companies has to implement right, and quality software based on user expectations. The Internet is growing the demand of use of web service applications across the worldwide. Web services are the functional services over the internet, in which a client can access the services, researchers are focused on functional services in UDDI – WSDL descriptions. The building of web-based applications uses of SOAP, REST-based models.



2.3.9. Simple Object Access Protocol (SOAP)

Use of SOA model/architecture shown in Figure 5, it has requester, provider, and UDDI registry. The service user is the client and end user who can use the functional services provided services by the provider, the service provider is the developer who can design and develop web applications and publish in registries. The heart of web service is registry, users and service providers, to improve the discovery of functions across multiple heterogeneous sources. UDDI is a registry with a pool of services.

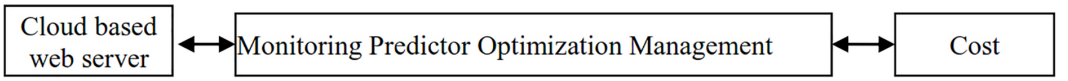
2.3.10. Restful Services

The document REST based principles used in web services, clients, and intermediates. The REST has: 1) Resource identification; 2) Resource representation; 3) Represent descriptive messages; 4) Hypermedia applications, these are linked with URI in a client-server model with message communications. RESTful services three levels: 1) architectural procedures; 2) decisions related to concepts; 3) decisions related to technology. The architecture of Restful services, in the domain the method for creates, updating, reading, deleting the resource on services (GET, POST, PUT, etc.) and involving various operations by HTTP methods. Decision-related procedures to identify the source

Figure 5. SOA model

by URI, HTTP methods used (get, put) used the same it is used in Google search engine to search the relevant queries and UDDI. The Framework and building RESTful services (Adamczyk, Smith, Johnson & Hafiz, 2011) use of technologies such as programming languages Java, PHP, Python, Ruby, Rails, HTML and others.

Web services are software components, providers ensure agreed quality of services (QoS), quality factors software engineering. ISO/IEC 25010 quality standard, models used for quality evaluations, in software and quality are functional suitability, performance, efficiency, compatibility, usability, reliability and portability (Oriol, Marco & Frranch, 2014). The service provider will assure to the client with an agreement of services by SLA.



2.3.11. Service Level Agreement

Minimum total resource cost by considering workload to optimize the service by replication of cloud data servers, the load balancing by use of replicate servers by minimum operating cost based on arrival rate, response time and policies. The SLA of Service provider, the designer must design a solution which is cost effective, cost-saving, load balancing of data centers. Service replicas, the low response time, low utilization of active replicas, control service replica utilization minimum number of active replicas. Arrival policy, response time-based policy. Balancing algorithms, replica saving arranges utilization active replica to achieve average response time, SLA, complaint. Elastic resources by adding the resources minimum subject to the minimizing the cost of web applications. The cloud-based web application service provider manages the resources based on the demand.

2.3.12. Resource Management

Web service management shows in Figure 6. The Utilization of entire system, resource, dependency matrices, and cost. The demand of cloud services, the service provider application and scaling the servers as per load and demand allocation resources, with SLA, to predict the resource management, Queuing theory, Optimal auto-scaling by collecting the data, analyze the data, utilization, management allocation, load, and DC etc. The pseudo code 1, describes the load balancing of services. The objective is to optimum load for DC and maximum availability of resources. The Load balancing equations resource utilization, expected completion, load balancing under hierarchical tree topology are described in Equations 6 to11.

Figure 6. Web service management

Load balancing let there will the N number of tasks are in the queue to access the resources in Datacenters:

$$ResourceUtlization\left(Ru\right)=\frac{Number\,of\,applicaitons\;\;running}{Total\,number\,of\,applicaiotns} \tag{6}$$

R_u: Resource utilization
A_r: Applications currently running
A_t: Total number of applications

$$Resource\,utlization\left(Ru\right)=\begin{cases}0 & if\,task\,Tij\,no\,task\,are\,running\;\;where\,Ti<0\\ 1 & The\,tasks\,running\,on\,the\,system\,where\,Ti\geq n\end{cases} \tag{7}$$

n: The number of applications

$$Expected\,completion\,time=Execution\,time+Arrival\,time \tag{8}$$

Load balancing standard deviation, the load for a DC based on Equation (6) and find the load balancing mean standard deviation is used to predict the load balancing threshold of a DC:

$$\text{load balancing MSD}=\sqrt{\frac{(\text{Average resouce utlization}-\text{resource utlizationr})^2}{\text{Total jobs}}} \tag{9}$$

$$loadbalancinglevel\left(lb\right)=1-\left\{\frac{\text{load balancing MSD}}{\text{resource utlization}}\right\}*100 \tag{10}$$

By using lead balancing level (lb) values lying between 0 and 1, if the value is zero means no load. If lb value 1 means fully loaded. Load balancing level is also called threshold.

Pseudo code 1. Load Balancing

```
Input:
Web service parameters: VMs, nodes, time allocation, availability,
demand, balance load
```

```
Output:  Balance Load
Begin
1. Web service requests time t1, t2, …, tn where web systems Ws1,
Ws2, …, Wsn
2. Web Requestprediction model, to identify key features described
in Figure 4.
3. Calculate the co-relation of elements
4. Identify the key elements cost, VMs, nodes, time allocation and
availability of Multiple servers
5. Read the load
6. Find the load balancing Mean Square SD from Equation.9
7. If (load ≤ threshold)// threshold is load balancing level use
of Equation.10
Then allocate the resources on tasks on DC
Else if (load = threshold) // the DC is fully loaded
Then balance the load by adding DC to multiple servers and Network
distribution
End if
end
```

2.3.13. Workload Management

The designer and service provider must identify the key factors, protocols, network, bandwidth, routing, and design a model based on the characteristics. Select the data workload, to analyze the jobs of types small, medium and large jobs, the priority of jobs, scheduling, and considering all the workload monitoring, to optimize scheduler policies, and optimize cost-based algorithms and predict the workload and suggest the resource utilization.

Table 2 gives the cloud application usage VMs and memory and cost. To handle the workload, EC2, grow or shrink to handle the current workload, use of data structure B+ tree fast search, memory limited, most recently used cache memory, and least recently used (limited memory). The cheap storage with the use of EC2 resident, cache $0.125 per GB month per month. A load of systems based on clients (number of users), jobs running (application usage), number of processors, queues, scheduling algorithms, and other parameters. Here we consider the dynamic workload distribution.

2.3.14. Dynamic Workload Management

Workload improves the performance, resource management, allocation of resources with the dynamic workload. The changes of workload are analyzed by Workload analysis with use of Map-reduce work. The Optimize job scheduling methods with the use of map-reduce in Hadoop. Examples are Google, Facebook, Twitter, and Yahoo.

Web services can process the requests simultaneously to a maximum number of concurrent users. Video streaming application, video encoding, compression, bit rate, frequency. The cluster video encoding, virtual machines (EC2), quality of service utilization 95 to 99%. In a multi-tier web

Table 2. Cost of Cloud applications

Price per Hour in ($)	Virtual Machine (EC2)	Memory
0.08	1	2GB
0.32	4	7.5 GB
0.64	8	15 GB

application, the delay, load, capacity, admission control, prevent server overload, load prediction, predictive functional load, and reduces the machines. Grid dataset used for experimental analysis using R language which sample Grid dataset 10580 records and 12 parameters from (Grid Datatset, n.d.), summarized in Table 3., and Figure 7. Gives the number of users waiting on the queue of processes and number of applications are executing on processors the waiting time, as applications are increasing the waiting time is also increasing. Figure 8 describes the number of users requesting applications waiting time of the process is also increasing and it reaches the maximum value.

Delay, performance and cost share VM resource to improve performance, share the application to multi-web applications. For example, in video transcoding, the number of frames, bit rate, and bits used per second. Sharing of multiple concurrent streams data to improve VM utilization. And automatic adjustment and adaptability of cost, load distribution, adjust load conditions. The CPU utilization to load the jobs in memory utilization of networks and provides an approach to reduce the physical nodes.

Web applications quality by maximum throughput, server utilization, load balancing, network cost, minimize resource utilization worst case optimize to integrate new optimization which overall cost by minimizing the individual costs by load balancing, scheduling, and effective utilization of resources. The final balance to minimize the cost, balance server load. The pseudo code 2. Describes load distribution will improve the performance. The maximum utilization of services, if the load is accepted then proceed, otherwise update the system with DC, all the systems are updated based on demand and usage.

Pseudo code 2. For Load distribution

```
Input:  Request of services in a server system (DC) load
Output:  load distribution
Begin
Step 1:  Initialize the variable
```

Table 3. Grid dataset

Parameter	Description	Measured in
JobID	Counter, t_1, t_2,..t_{ij}	Sequence number
SubmitTime	In seconds	Milliseconds
WaitTime	In seconds	Milliseconds
RunTime	Runtime measured in wallclock seconds.	Time
NProcs	number of allocated processors- DCs	Number
ReqNProcs	requested number of processors	Number
ReqTime	requested time measured in wallclock seconds	Milliseconds
Status	job completed = 1, job failed = 0, job cancelled = 5	Integer
UserID	string identifier for the user	String
GroupID	string identifier for group user belongs to	String
ExecutableID	name of the executable	Filenameid
QueueID	string identifier for queue	String

```
Step 2:  Read the requestsTasks(T_ij)
Step 3:  Read the load resource utilization using Equation.6
Step 4: While (Maximum utilization) do
If (Load balance is with utilization)// Pseudocode 1. Load
balancing
Then load accepted yes.
else
Update the parameters and add DC based on load level threshold
using Equation.10.
end if
Step 5: All the system update and systems load distribute
dynamically   based on demand and distribute load to multiple
servers using   network balancing.
end while
end
```

The pseudo code 3. Describe the demand of web services (DC), if demand if high allocate the resource, based on demand allocate the resources, number of machines, number of applications, capacity and finally based on demand to allocate the DC for load distribution.

Pseudo Code 3. Find the demand cost of the web server (DC)

```
Input: Demand, load
Output: Based on demand add DC and load balancing
begin
Step 1: Initialization of parameters
Step 2: For each utilization
Step 3: Being calculate the demand
if (demand high)
then
Allocate the resource add DC
else  if (demand == average)
then the allocation is based on average demand
else
Allocate the resource based on demand.
end if
Step 4: The number of Machines, and the number of applications,
Memory   machines (MB), Capacity, CPU demand.
Step 5. If (new DC is added based on load)
Function load distribution()// Pseudo code.2 Load distribution
Optimize the cost of DC by load balancing and scheduling
algorithms
described in Table.4
Step 6. Find the load distribution
end
```

3. EXPERIMENTAL RESULTS

Load Balancing Performance Parameters with various algorithms like Random allocation, round-robin allocation, and weighted round robin. The application grid dataset which consists of sample 10580 and 12 parameters are shown in Table 3. Experiments are conducted using R Language, jobs are

running, submission time, waiting time of runtime of applications, a number of allocated processors, requested processors etc. the experiments conducted using R language and found that the users are increasing and applications are increasing the waiting time is also increasing shown in the Figure.7, the number of tasks (t_{ij})are executing waiting time reach to maximum when applications are reached to maximum load in the Figure.8, the Maximum utilization of processes according to demand and load adding the DC to distribute the load. In Table 4. Describes the load balancing algorithms for selecting parameters.

The models can be used for workload predictions, Static, Round robin, Minimum-maximum, Dynamic Loader, Honeybee, Ant colony optimization and Optimized Multi-level Shortest Remaining Time First and others. Workload predictions and management of DC and load balance will improve the cost of servers.

The users or the customers who can use the web and cloud applications. The specific applications like e-commerce, finance, insurance, transport etc. The infrastructural use facilities such as the hardware, storage, networking and server configurations. The optimum utilization of resources, high availability of resources, management of service with optimized cost. Figure 9. represents load balancing applications. Network load balancing is shown in Equations 6 to 11:

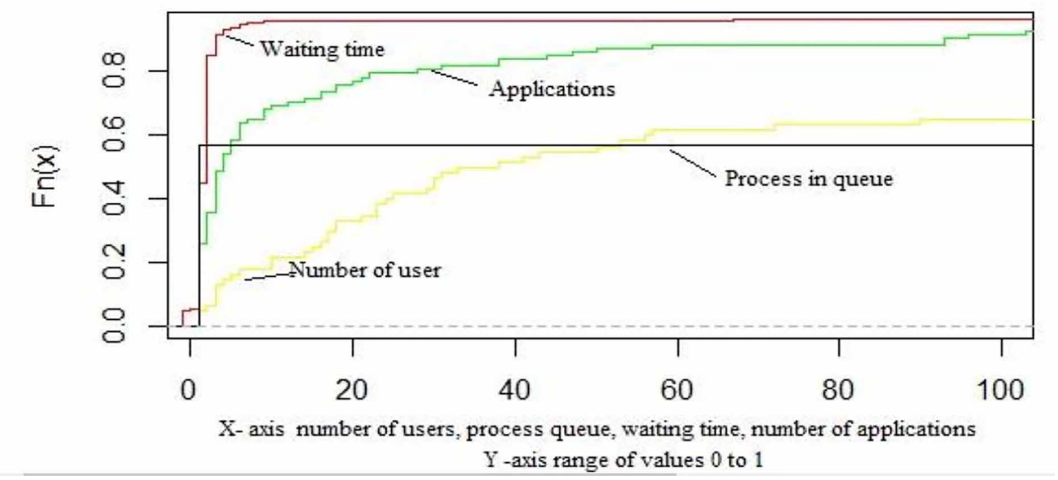
$$Network = Number\,of\,Active Transactions * \frac{total\,transactions}{weights} \tag{11}$$

The systems which handle the load as per user requests and available services, based on load adding the servers (DC) number of servers used for experiments are 12 and optimum utilization of servers by using the following. Load balancing where the list connections servers with a smaller

Table 4. Load balancing algorithms comparisons

Load Balancing/ Parameter	Random Allocation	Round-Robin Allocation
Nature of systems (DC)	Static	Dynamic
Overhead of processors	More overhead	Less overhead for round robin
Resource utilization	Less utilization of resources because randomly allocate the resources	The resource utilization is more because resources are allocated dynamically
Processor	Little trashing	No thrashing
Preemptiveness	Nonpreemptive	Preemptive by Shortest job First / Non-Preemptive priority can be decided
Predictability	Less for the static approach	weighted round robin designed for dynamic load balancing based on demand
Adaptability	Less because of deterministic allocation space	More because of flexibility to add the space based on demand
Reliability	Less because memory is fixed	More because memory is based on runtime requirement
Response time	More	Less
Availability	Less	More
Central/ distributed systems	Central	Distributed

Figure 7. Grid dataset the jobs are in queue number of users and applications are increasing the waiting time also increases



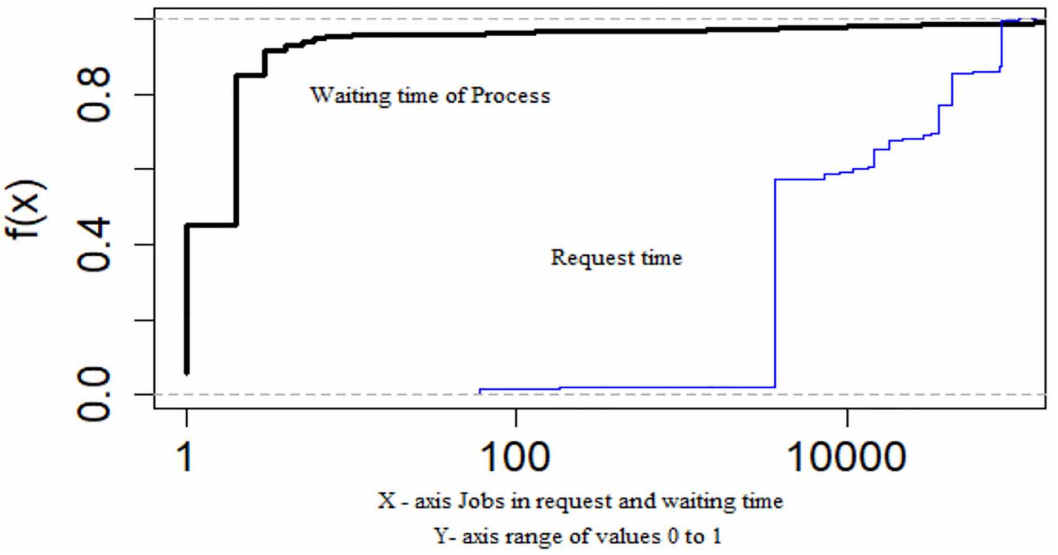


Figure 8. Grid data request time of the job (Task T) and waiting for jobs the number of process waiting time as request time waiting time reaches to the maximum

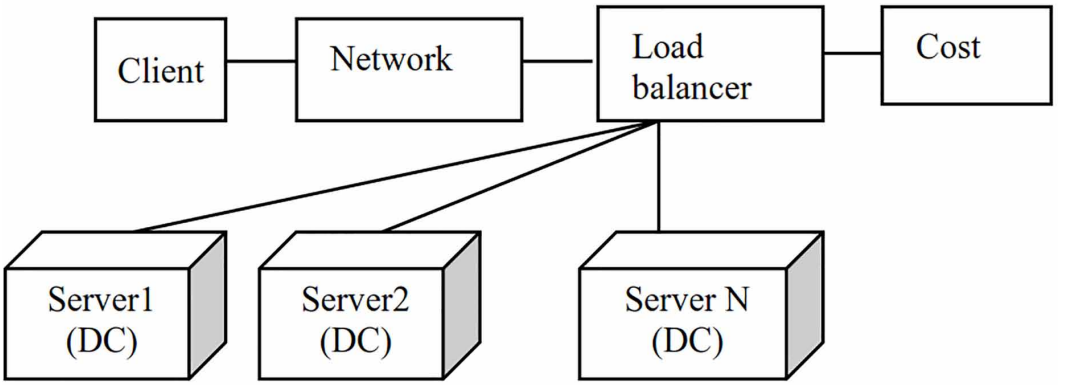


number of outflow routes. Weighted least connections each server to load the weights each server load across weights, Use round robin, and weighted round robin, equally time (Grid Dataset, n.d.).

3.1. Cost Management

The goal is automatically to adjust the load balancing with the DC-based on demand and Demand cloud resources, data-intensive applications. Read the input parameters nodes, resources, demand and applications etc., find the load of the current server (DC), if the server is balancing workload proceed with the load, not means assign resources applications to the system, find the load of the servers, if more load means and add the DC and distribute the load and update the system information.

Figure 9. Load balancing of systems

Use of job scheduling algorithms minimize the waiting time and maximize the available, and load balancing helps to minimize the cost of web-based application. The pseudo code. 4 describes cost minimization of systems here we have used 10 data centers as infrastructure as service. For example, Elastic Compute Cloud (EC2), Simple Storage Service (S3).

Pseudocode 4. Cost minimization algorithm

```
Input:  nodes, resources, demand, resource demand, current
database
Output:  Nodes (n) new database-1(if not available)
Cost plan - migration table Migration = false
Begin
Step 1:  Initialize the variables
Step 2:  Read the data,
Step 3:  For each node
Compute Load of the server using Equation 10.
Step 4:  if(load is more based on demand)
then
add the DC
migration = true;
else
execute the load on the same server
endif
Step 5:  if(migration is true)
then
current new demand
update demand
if(n>0)
then
// resource is free
return the resource
Step 6: Find the total cost using Equation 14.
end if
```

```
end if
end
```

The total cost of applications including the development cost, infrastructural cost, manpower, maintenance cost of systems and applications. Cost = ∑(cost of all things), a cost that includes development cost, development cost, service cost, and maintenance cost. The cost can be minimum, average and maximum depends on the requirements and infrastructural facilities and demand applications. The total cost is described Equation 14 and performance is by query request and delay (latency) by Equation 12. The response time to be minimized by using multi-level queue shortest remaining time algorithm:

$$Performance = querytime - latency \tag{12}$$

Time of request within latency(delay), an independent, self-scaling, cost-effective cloud cache, runtime user cost, auto configuration, resource management, scaling, workload.

The query time is by Equation 13. Which use of optimal nodes, optimal storage, predicted workload and data access based on the parameters the query response time is calculated. This will improve the performance latency miss, latency fast and the query execution time:

$$\text{Query Time} = \frac{OptimalnodeXnodes}{dataaccessfast} + \frac{optimalstroage}{slowaccess} + \frac{Predictedload}{\text{Data miss}} \tag{13}$$

The predicted load is computed by using Equation 14. Which predicted query by multiplying the data size:

$$PredictedLoad = predictedquery * Datasize \tag{14}$$

The availability is system is by invocations requests over total invocations. Estimate service errors, whole system all servers Mean time to Failure (MTTF), Mean time to Recovery (MTTR), throughput, availability input, and server will process.

Cost estimation of Web and cloud services including the data centers, estimation of maintenance, availability of services by FTS (Fault Tolerance System), MTTF model, faulty components, replacements, disk, CPU etc. predicted cost by Equation 15:

$$TotalCost = \sum \left(development\,cost + infrastrucure\,cost + services\,cost + maintanance\,cost \right) \tag{15}$$

Utilization of server by Equation 16:

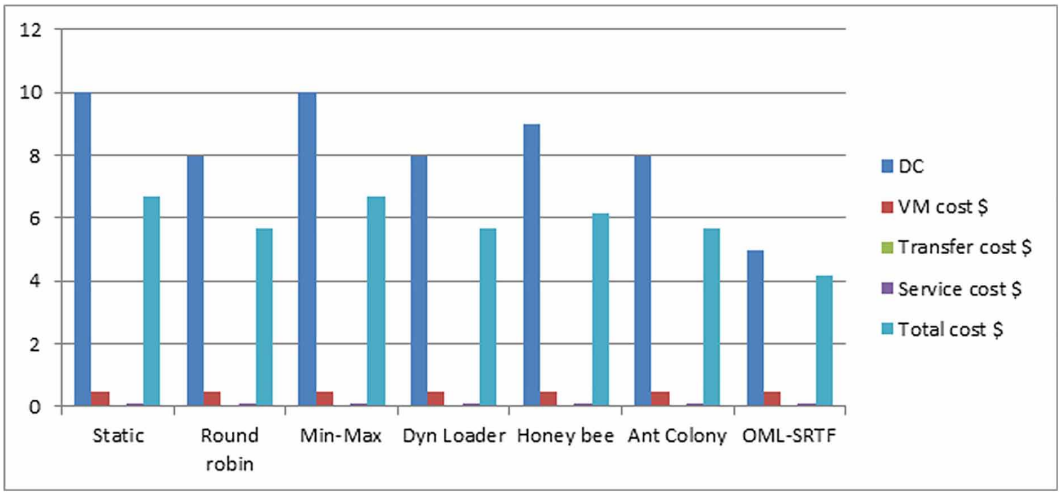
$$\text{Utilization of server} = \text{Number of servers} * \frac{\text{No. of server components predictedload}}{\left(\text{MTTF} + \text{MTTR}\right)} \tag{16}$$

Estimate the server errors whole system all servers, with MTTF, MTTR, and utilization.

In the Web service applications, the user requests the application server and a request processed by the application server by executing functionality and further operations to communicate to the database server. The virtual systems use of IaaS service with scalable, web application at operational

cost, the proposed cost-effective solutions are shown in Table 8 which improve the results of cost optimization, load balancing helps to effective utilization of resources, optimized Multi-level Shortest Remaining time first will reduce the average waiting time. Figure 10 shows the cost optimization of various load balancing and scheduling methods.

4. DISCUSSIONS



The goal is improve the quality of web services and reduce the cost of applications, by minimizing failures with use of best practices (Swami Das, Govardhan & Vijaya Lakshmi, 2016; Ebert, Dumke, Bundschuh & Schmieterndorf, 2005) in development of web applications, reduce the cost and improve the utilization of services, the quality improvement by internal process view as skilled employees as a result minimize the fault rate, and external view optimization of cost of applications, with accuracy product and services.

The customer satisfaction to services the develop use of best practices deployment, and maintenance of cloud-based web applications, this by planning, monitoring and management and improving the efficiency of components with best techniques are discussed below. These methods are also used to minimize the overall cost of the Cloud-based web application:

1. Minimize the defects in code;
2. Functional correctness improvement;
3. Cost management and optimization by minimizing the maintenance cost(rework) including detection and repair of faults and error in a web application;
4. Optimum strategies at all levels including high-speed networks;
5. Inspections, preventive measures and risk management in software development;
6. Portability and adaptability of applications, and systems;
7. Several jobs with available resources, servers and workload and software and hardware, analyze the application using benchmark dataset and tools.

Cost optimization in internet applications, the proposed method is a model using load balancing, effective utilization of resources (i.e. infrastructural) and scheduling algorithms. The user internet

Figure 10. Comparative study of cost optimization using load balancing and scheduling methods. X-axis scheduling method and Y-axis cost of Cloud services

uses functional services like banking, etc. Internet applications play an important role in economics and services (Weintraub & Cohrn, 2015; Van de Bossche, Vanmechelen & Broeckhove, 2015).

The advantages and disadvantages of Load balancing are listed in Table 5.

5. CONCLUSION

The use of cloud-based web applications increasing rapidly, the cloud service IaaS and deployment models public, private and hybrid. Providing infrastructural, platform and software services. The demand to use the services, based user requirement of services, that adds the Infrastructural, platform and software services. There are various factors influence the cost. whereas design, development, and maintenance of software, the software services, where data centers(nodes) are heavily loaded with many tasks, as considering the load constraints, and resource importance, high availability (I/O operations), and maximum utilization of resources, subjected to minimizing the overall application. The proposed enhanced model architecture which is well suited for cloud-based web applications design deployment and minimizing cost and effective utilization of resources by considering the demand, cost, resource utilization, applications, quality of services, management applications, analysis of workload management, load balancing(like static, dynamic workload) with example random allocation and round-robin dynamic allocation, and use of cost minimization algorithm (Pseudo code 4), with grid dataset consists of 12 parameters with sample of 10580 records. The experimental results conducted R language and result in the number of users increases, the applications are increasing, the processes in the queue, the waiting time is also increasing. The designer will use load balancing, and scheduling (Multi-level shortest remaining) algorithms will improve the performance shown in Figure 7, and Figure 8. Table 4 describes the load balancing comparisons, Table 5 describes various scheduling methods advantages and disadvantages are discussed. Table 6 describes the scheduling models and finally optimized multi-level CPU scheduling – load balancing will be best solution., Table 7 shows a sample of 1559 records of Grid dataset, number of processors, average waiting time, an average of maximum execution time, minimum execution time, maximum execution time computations. Table 8 shows the cost optimization of load balancing, effective utilization of resources and scheduling algorithms. Figure 10 shows the comparative study of load balancing- scheduling algorithms among these Optimized Multi- queue shortest Remaining time method got improved results. The suggestion to improve the cost minimization and effective utilization of resource with a user of best practices such as application load balancer with use of scheduling methods. The network load balancers used

Table 5. Load balancing details

Scheduling	Pros	Cons
Static	Load at complete time	Not handle throughput
Round robin	Fixed quantum CPU burst	Longest task time
Minimum-maximum	Small task better completion	Starvation
Dynamic Loader	Work distortion at runtime use FTS	Check the node
Honeybee	Increase throughput minimum Response time	High priority
Ant colony optimization	Faster information, minimum span, independent task, and intensive computation	Network overhead for a long time and no clarity in ants
Optimized Multi-level shortest remaining time First	Faster information and minimization of response time for many tasks, Better performance	Needs to sort the jobs based on the shortest remaining time - priority

Table 6. The cost of applications using various scheduling methods

Scheduling	Service Utilization Cost	DC Cost	Maintenance Cost	Load Balancing	Effective Utilization
Static	Fixed cost	more	Increased	Manually	Manually
Round robin	Variable cost	Less	Decreased	Dynamically	Dynamically
Minimum-maximum	Fixed	More	increased	static	static
Dynamic Loader	Variable	Less	Increased	Dynamic	Dynamically
Honeybee	Fixed/ variable	More	Increased	Static/dynamic	Manually/ Dynamically
Ant colony optimization	Fixed	More	Increased	Manually	Manually
Optimized Multi-levelShortest Remaining Time First	Variable	Less	Decreased	Dynamically	Dynamically

Table 7. A sample of 1559 records of grid dataset, number of processors, average waiting time, an average of maximum execution time, minimum execution time, maximum execution time

Processors	Record Job Count	Average Waiting Time (ms)	Average Execution Time (ms)	Maximum Execution Time (ms)	Minimum Run Time of One Record (ms)	Maximum Run Time of One Record (ms)
1	368	3.73	2.3	65161	1	60
2	841	46.94	8.3	1058	2	305
4	220	2.29	1.45	559	3	313
8	110	2.89	2.69	4	2	10
12	2	3	114.5	210	23	212
16	16	3.06	5.06	7	2	9
24	2	3.5	31	35	31	38

to minimize defects, functional correctness, and the maintenance cost to be minimized. In the future, IoT controlled the Hybrid load balancing algorithms will be used for mixed attributes.

Table 8. Cost optimization by load balancing, scheduling, and effective utilization

Scheduling	Load Balancing and Effective Utilization	Virtual Machine	Communication	Per Hour Cloud Service Cost	Total Cost in $
		VM Cost in $	Data Transfer Cost $	Fixed Cost	Total Cost $
Static	10	0.5	0.06	0.08	6.68
Round robin	8	0.5	0.06	0.08	5.68
Minimum-maximum	10	0.5	0.06	0.08	6.68
Dynamic Loader	8	0.5	0.06	0.08	5.68
Honey bee	9	0.5	0.06	0.08	6.18
Ant colony optimization	8	0.5	0.06	0.08	5.68
Optimized Multi-level Shortest Remaining Time First	5	0.5	0.06	0.08	4.18

M. Swami Das is working as an Associate Professor in CSE dept, MREC, Hyderabad. He completed B E(CSE) in 1998 from CBIT, (affiliated to Osmaina University), Hyderabad, and M Tech (CS), from JNTU Kakinada in 2002, and Purusing Ph D in JNTUH Hyderabad. He has 17 years of Experience in Teaching, Industry and Research. His research interests are Web services, Cloud computing and Data mining.

A.Govardhan, Rector (Pro Vice-Chancellor) and EC Member at JNTUH, India. He did his B.E(CSE), from Osmania University in1992, M Tech (CS) from JNU, New Delhi, and PhD from JNTUH in databases in 2003. He has 24 years' of experience in Teaching, research and administration. Served and held several Academic & Administrative positions including, Principal (JNTUHCEH), Director (SIT), Director of Evaluation, Principal, Head of the Department, Chairman and Member on several Boards of Studies of various Universities and Students' Advisor. Recipient of 32 International and National Awards including A.P. State Government Best Teacher Award 2012, Bharat Seva Ratna Puraskar, CSI Chapter Patron Award, Bharat Jyoti Award, Int'l Intellectual Development Award and Mother Teresa Award for Outstanding Services, Achievements, Contributions, Meritorious Services, Outstanding Performance and Remarkable Role in the field of Education & Service to the Nation. Past Chairman of CSI Hyderabad Chapter. Member on the Editorial Boards for 12 Int'l Journals. Member of several Advisory Boards & Academic Boards, a PC Member for 75 Int'l and National Conferences. Has 2 Monographs Published in USA, 10 Book Chapters in Springer. Guided 81 Ph.D theses, 1 M.Phil, 135 M.Tech projects and published 525 research papers at International/ National Journals/ Conferences including IEEE, ACM, Springer and Elsevier. Organized 2 Int'l Conf, 20 Workshops & 1 Refresher Course. Delivered more than 100 Keynote addresses and invited lectures. Has 24 years of teaching and Research experience. He is a member in several professional and service oriented bodies. Areas of research include databases, data science and information retrieval systems.

D. Vijaya Lakshmi, working as a Professor and Head of the Dept of IT, MGIT, Hyderabad. She received a Ph.D. from JNTUH, Hyderabad, is a member of MEACSE, IJCAR. She is holding Games and Sports Committee Convenor, Presiding Officer in Women Welfare Cell, MGIT. She is guiding four research scholars in JNTUH Hyderabad. Her research areas include image processing, web services, data mining and security. She has more than 20 years' experience in teaching, research and administration.

Locality—Aware Scheduling for Containers in Cloud Computing

G. Charles Babu, A. Sai Hanuman, J. Sasi Kiran and B. Sankara Babu

Abstract The cutting edge scheduler of containerized cloud administrations considers load balance as the main rule, numerous other imperative properties, including application execution, are ignored. In the period of Big Data, applications advance to be progressively more information escalated and subsequently performed inadequately when conveyed on containerized cloud administrations. With that in mind, this paper means to enhance the present cloud administration by considering application execution for the cutting edge compartments. The more explicitly, in this work we fabricate and break down another model that regards both burden equalization and application execution. Dissimilar to earlier examinations, our model edited compositions the predicament between burden equalization and application execution into brought together steaming issue and after that utilizes a factual technique to effectively settle it. The most difficult part is that some sub-issues are amazingly unpredictable (for instance, NP-hard) and heuristic calculations must be formulated. To wrap things up, we actualize a framework model of the proposed planning procedure for containerized cloud administrations. Exploratory outcomes demonstrate that our framework can fundamentally support application execution white safeguarding generally high burden balance.

Keywords Cloud computing · Load balance · Containerized cloud administration · Safeguarding · NP-hard

1 Introduction

The previous couple of years have seen a developing number of versatile and sensor applications that depend on Cloud support. The job of the Cloud is to enable these asset constrained gadgets to offload and execute a portion of their register serious undertakings in the Cloud for vitality sparing and additionally quicker preparing. Notwithstanding, such offloading to the Cloud may result in high system overhead which isn't reasonable for some portable/sensor applications that require low idleness. In this paper, we propose a territory mindful burden-sharing method that permits edge assets to share their remaining task at hand so as to keep up the low inertness necessity of Mobile-Cloud applications. In particular, we examine how to figure out which edge hubs ought to be utilized to impart the remaining task at hand to and the amount of the outstanding burden ought to be shared to every hub. Our trials demonstrate that our region mindful burden-sharing procedure can keep up low normal start to finish idleness of portable applications with low inertness variety while accomplishing great use of assets within the sight of a dynamic remaining task at hand.

Objectives

- To examination prescient investigation of territory mindful storage tier information obstructs over Hadoop;
- To plan area mindful burden part taking in versatile distributed computing;
- To structure toward territory mindful planning for containerized cloud administrations;
- To examination territory mindful booking for holders in distributed computing.

2 Literature Review

2.1 Structuring Your Paper

LaValle et al. [1] the term "Enormous Data investigation's alludes to an extensive scale answer for overseeing mammoth datasets in a parallel domain. Hadoop is a biological community that forms vast datasets in appropriated processing situation. The biological community is additionally classified into four sub-ventures, for example, HDFS, MapReduce, YARN, and Hadoop Commons. The Hadoop Distributed File System (HDFS) is a spine of biological system, which helps putting away and handling substantial datasets. As of late, HDFS is moved up to heterogeneous capacity level condition that adapts to information square handling over various capacity gadgets for example Plate, SSD, and RAM. The square position strategy dispatches information squares to the gadgets without figuring I/O exchange parameters and territory points of view. In addition, HDFS chooses arbitrary Datanodes that could

profranganathang@gmail.com

be situated into the following rack having longer way than neighborhood rack. This expands the information square handling dormancy and results in a colossal postponement for reproduction the board in heterogeneous capacity level. To determine this issue, we propose a prescient examination that fabricate a territory mindful capacity level hub outline and anticipate the most adjacent accessible capacity level for square occupation preparing. The test assessment delineates that the proposed methodology diminishes information square exchange time overhead, copy exchange time overhead and diminishes hub ways to an ideal availability over the bunch.

Cloudera [2] in this paper, we propose a system for security safeguarding redistributed medication revelation in the cloud, which we allude to as POD. In particular, POD is intended to enable the cloud to safely utilize different medication recipe suppliers" medication equations to prepare Support Vector Machine (SVM) given by the logical model supplier. In our methodology, we configuration secure calculation conventions to enable the cloud server to perform generally utilized number and division calculations. To safely prepare the SVM, we plan a safe SVM parameter choice convention to choose two SVM parameters and develop a safe consecutive negligible enhancement convention to secretly invigorate both chose SVM parameters. The prepared SVM classifier can be utilized to decide if a medication substance compound is dynamic or not in a security safeguarding way. In conclusion, we demonstrate that the proposed POD accomplishes the objective of SVM preparing and concoction compound order without protection spillage to unapproved parties, just as exhibiting its utility and productivity utilizing three certifiable medication datasets.

Kala Karun and Chitharanjan [3] cloud-helped Internet of Things (IoT) gives a promising answer for information blasting issues for the capacity imperatives of individual items. Nonetheless, with the influence of cloud, IoT faces new security challenges for information commonality between two gatherings, which is presented without precedent for this paper and not as of now tended to by customary methodologies. We research a protected cloud-helped IoT information overseeing technique to keep information classification when gathering, putting away, and getting to IoT information with the help of a cloud with the thought of clients increase. The proposed framework novelly applies an intermediary re-encryption plot, which was proposed in \cite{XJW15}. Henceforth, a protected IoT under our proposed strategy could oppose most assaults from the two insiders and untouchables of IoT to break information classification, and in the interim with consistent correspondence cost for re-encryption against gradual size of IoT. We further demonstrate the technique is handy by numerical outcomes.

Abbas et al. [4] Information spillage is the coincidental revelation of delicate data through relationship of records from a few databases/accumulations of a cloud information distribution center. Vindictive insiders represent a genuine danger to cloud information security and this legitimizes the emphasis on data spillage because of maverick representatives or to pariahs utilizing the qualifications of authentic workers. The exchange in this paper is confined to NoSQL databases with an adaptable construction. Information encryption can lessen data spillage, however, it is illogical to scramble huge databases and additionally all fields of database records. Encryption restricts the tasks that can be carried on the information in a database. It is along these

profranganathang@gmail.com

lines, basic to recognize touchy reports in an information stockroom and focus on endeavors to secure them. The limit of a spillage divert presented in this work evaluates the instinctively evident intends to trigger cautions when an insider aggressor utilizes unreasonable PC assets to correspond data in various databases. The Sensitivity Analysis dependent on Data Sampling (SADS) presented in this paper adjusts the exchange offs between higher effectiveness in recognizing the dangers presented by data spillage and the exactness of the outcomes gotten by testing vast accumulations of reports. The paper gives an account of trials surveying the viability of SADS and the utilization of specific disinformation to confine data spillage. Cloud administrations distinguishing touchy records and decreasing the danger of data spillage are additionally talked about.

Tsuruoka [5] with the appearance of distributed computing, an ever-increasing number of individuals will in general re-appropriate their information to the cloud. As a basic information use, secure watchword look over scrambled cloud information has pulled in light of a legitimate concern for some specialists as of late. Be that as it may, the majority of existing looks into depend on a perfect suspicion that the cloud server is "interested however genuine", where the list items are not checked. In this paper, we think about an all the more difficult model, where the cloud server would most likely carry on unscrupulously. In view of this model, we investigate the issue of result confirmation for the protected positioned catchphrase seek. Not the same as past information confirmation plans, we propose a novel obstacle based plan. With our cautiously formulated check information, the cloud server can't know which information proprietors, or what number of information proprietors trade stay information which will be utilized for confirming the cloud server's rowdiness. With our methodically structured confirmation development, the cloud server can't know which information proprietors' information are installed in the check information support, or what number of information proprietors' confirmation information are really utilized for confirmation. All the cloud server knows is that when he carries on untrustworthily, he would be found with a high likelihood, and rebuffed truly once found. Besides, we propose to enhance the estimation of parameters utilized in the development of the mystery confirmation information cradle.

3 Methodology

The predictive analysis consists of two phases, i.e., (i) Storage-tier summary container and (ii) Predict the most nearby Datanode.

The storage-tier summary container collects all the Datanode and storage media information, i.e., computing capacity and storage-tier devices with volume statistics. Moreover, the media predictor performs training sessions over the dataset and predicts the most nearby Datanode with available storage-tier media as seen from Fig. 1.

profranganathang@gmail.com

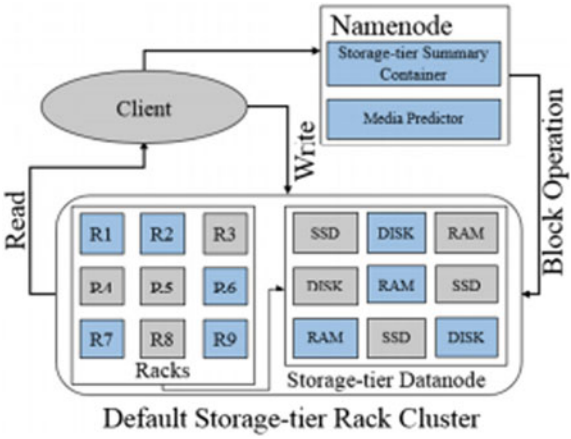

Fig. 1 Storage tier predictive analysis over HDFS cluster

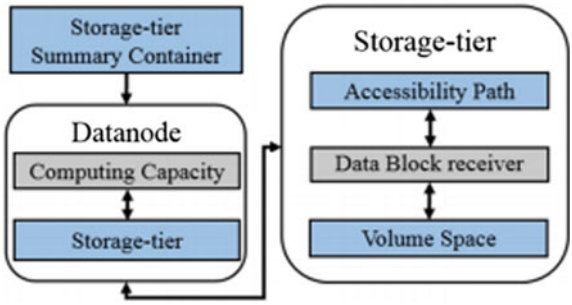

Fig. 2 Storage-tier summary architecture

Storage-tier Summary Container

The summary container consists of Datanode information, i.e., CPU, storage media, accessibility time, 1 MB data block receiving time and volume sizes of each storage (Fig. 2).

4 Results

Environment

The biological community comprises of Intel Xeon processor with 8 CPUs, 32 GB memory, and capacity gadgets, for example, 1 TB Hard plate drive and 128 GB Samsung SSD. Notwithstanding that, we use Intel center i5 with 4 Core, 16 GB memory and capacity gadgets for example 1 TB Hard circle drive and 128 GB Samsung SSD. We introduce 5 virtual machines having virtual box 5.0.16 as observed from Table.

profranganathang@gmail.com

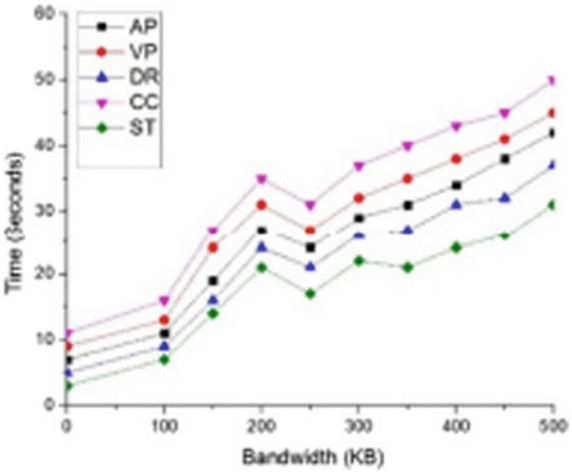

Fig. 3 Storage-tier summary container message collector

The exploratory dataset comprises of:

(i) 250 arbitrary SSD word check information squares of 64 MB (40 GB size),
(ii) 250 irregular DISK word tally information squares (40 GB size) and
(iii) 250 arbitrary RAM word check information squares (40 GB size).

Storage-tier Summary Collector

The collector fetches event traces of computing capacity, storage-tier I/O, Accessibility Path timestamp, Datablock receiver timestamp and Volume Space statistics over container. The message length varies between $0.5 \leq \text{size} \geq 5$ KB and consumes a resource between $0.2 \leq \text{Bandwidth} \geq 500$ KB/s. The summary container stores 2.7 GB of log information over 120 GB data blocks as observed from Fig. 3.

After generating container messages, we perform prediction simulations over three "250" random data blocks. In the first hour of simulation, we observe that predictor detects pattern of "109" SSD data blocks, "78" DISK data blocks and "63" RAM data blocks. In the second hour of simulation, we use "500" random data blocks and analyze that predictor observes pattern of "211" SSD data blocks, "192" DISK data blocks and "97" RAM data blocks. In the third hour of simulation, we evaluate "750" random data blocks and evaluate that predictor observes pattern of "322" SSD data block, "219" DISK data blocks and "109" RAM data blocks as observed from Fig. 4.

The media predictor depicts locality-aware nearby Datanode statistics with available functional media. The predictor lists processing timestamp, accessibility timestamp, and completion timestamp of data blocks over respective storage media. As a result, we calculate locality-aware path and observes that proposed processing, node, and storage-tier approaches are 39.1, 54.7, and 22.9% efficient than default data block processing. This reduces storage-tier latency, node latency, and overall processing latency as observed from Fig. 5.

profranganathang@gmail.com

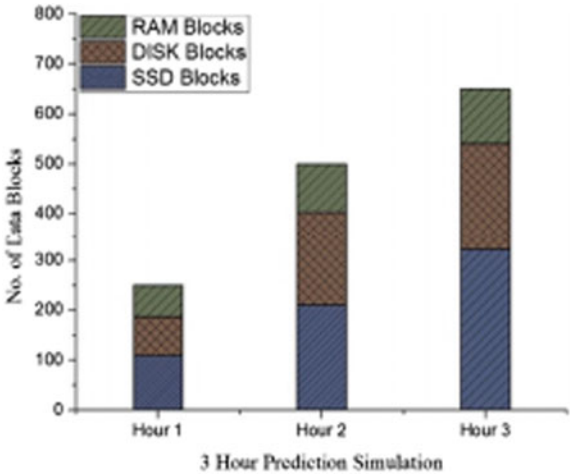

Fig. 4 Storage-tier media block job prediction

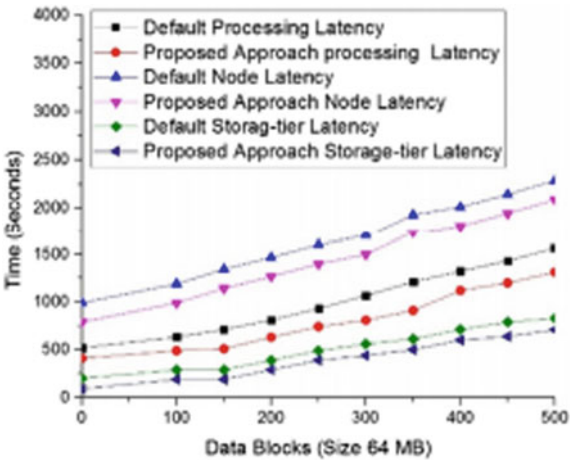

Fig. 5 Latency optimization over HDFS cluster

5 Conclusion

In this paper, we think about the issue of burden-sharing to deal with runtime elements in a Mobile-Edge Computing (MEC) condition. Our inspiration depends on the dynamic property of the outstanding burden in MEC alongside the low idleness prerequisite for a considerable lot of the present portable/IoT applications. The Edge Cloud stage that has been proposed to give computational loading backing to versatile applications faces extra difficulties in taking care of outstanding burden elements since the hubs in Edge Clouds are ordinarily associated by WAN with high system inertness and constrained transmission capacity. We propose a region mindful burden-sharing method that permits edge hubs to share their outstanding task at hand

profranganathang@gmail.com

to different hubs to meet the low dormancy prerequisite of the versatile applications on account of remaining task at hand increments. Our heap sharing system enables hubs to

(1) Intelligently decides if to share their outstanding burden to different hubs,
(2) Selectively picks which hubs the outstanding burden ought to be imparted to, and
(3) Determines the amount of the remaining burden ought to be shared. Our trial results dependent on a genuine Twitter's follow demonstrate that our territory mindful burden-sharing strategy can keep the general dormancy of versatile applications near the applications' ideal objectives just as better use assets even on account of dynamic outstanding task at hand.

A Comparative Analysis of Parallel and Distributed FSM approaches on Large-scale Graph Data

S. Ajay Kumar, Pellakuri Vidyullatha

Abstract— Graph Mining has an explosive growth or increasing use of graphs in generating graph databases of real-world applications. It contains either a single large-scale graph or set of small size graphs. A Graph is used for complex dynamic modeling objects and they are often changing in nature i.e. it may increase or decrease in their size. Frequent subgraph mining plays a vital role in data mining, with an objective of extracting useful knowledge is presented in terms of repeated structures. Graph mining is used for the chemo-informatics, Bio-informatics, sentiment analysis, social human behavior analysis, financial network analysis, web analysis, wired and wireless networks. In this paper, we describe in detail survey on frequent subgraph mining algorithms, which are helpful for retrieving knowledge from complex dynamic objects. There are different types of large-scale parallel and distributed frameworks used for performing graph partitioning, FSM based on Apriori and pattern growth strategies, and large-scale graph processing techniques to achieve load balancing memory scalability, partitioning, load balancing, granularity and technical enhancement for future generations.

Keywords: Graph partitioning, frequent subgraph mining, Apriori, pattern growth, parallel framework.

1. INTRODUCTION

Nowadays, one of the most challenging issue to be faced by government, business, scientific, and social network communities is to mine valuable information [1]. Most of the domains, there have been a success for the data that takes in terms of entities and along with their attributes, because the relationship between the entities can be helpful. A Data Mining is an analysis step in the way of Knowledge Discovery in Databases (KDD) and it should be in different forms, i.e. recurring patterns of transactions to complex patterns of transactions which are interrelated. It aims to extract the attractive patterns and knowledge from the huge amount of homogenous or heterogeneous data which is being collected within the business and the experimental world.

Basics of Graphs: A Graph is an efficient and suitable method to model the data in complex databases. It serves as an imperative data structure in various areas including social network, bioinformatics and web applications etc. In this model, a relationship should be in terms of nodes and edges, where a node acts as an object and an edge will is to make the relationships between the nodes. Graph modeling which helps us to deal with the problems that were not solved before and find the similarity between graphs is essential.

As communication networks are graphs, in which each node is a protein and each edge describes the way of an interaction, there are two possible methods to measure the similarity between the graphs. First make a pair-wise comparison among the vertices and/or links in two networks and compute an overall similarity score for the given two networks from the similarity of among the components, it requires time quadratic in terms of its edges and vertices, and it is computationally possible even for large-scale graphs and it totally neglects and defects the network shape, considered them as the collection of nodes and edges instead of graphs. In this, if they share most of the common substructures or subgraphs then we can consider two networks are similar and to solve subgraph isomorphism problem is an NP-complete, in this, the time taken for execution is expensive because this problem increases exponentially with problem size. To speed up the subgraph isomorphism with the help of novel graph canonical labelling and different types of heuristics approaches were developed.

Modern graph datasets follow two magic words i.e. “Large and Evolving”, here term large means that vertices and edges available in that graph are in terms of millions and billions. Evolving in these graphs is not static frequently, changing with addition and/or deletion of nodes and/or edges [2]. In dynamic graphs, if an insertion of subgraph that leads to more number of subgraphs and it may not be the desired subgraph, becoming the targeted subgraph pattern, removal of a single node may result in the changes of most recently required subgraph available in the current graph into non-targeted subgraph or subgraph of the targeted subgraph. Next challenge is if a graph dataset is combined into a single entity or split into more units, i.e. it may be a single connected component or disconnected. These kinds of graphs will offer different performance with different algorithms before

Revised Version Manuscript Received on March 08, 2019.

Pellakuri Vidyullatha, Associate Professor, Department of Computer Science & Engineering, KLEF, Vaddemswaram, Guntur Dist, Andhra Pradesh, India.

selecting the proper algorithm and choosing data set type is also very essential. FSM is a critical and crucial problem in data retrieval or mining domain. The aim of the FSM is to identify possible subgraphs will occur in the input graphs more frequently than a given user-defined threshold [3]. It is also called frequent pattern mining or frequent subgraph discovery. It has significance in intra disciplinary areas, such as protein structure analysis, transportation systems, sentiment analysis, defense and security, wireless networks, financial network analysis, and sentiment analysis. The structures relevant information is gathered from the above applications are simple trees.

Apart from the graph analysis, FSM is essential in intra-disciplinary areas, such as privacy-preservation, protein function prediction, image processing, classification, clustering, and graph indexing. FSM in a social network is required to identify the way of social media communications. In spite of getting useful information, finding the FSM will probably provide, it may be sensitive data such as web-click graphs, trajectory graphs, mobile phone call graphs, and, release directly the FSM will cause substantial concerns on the users' privacy those who are participating in the data.

The remaining paper is described in the following strategy. In the next section, gives a review of different graph partitioning approaches. Section 3, deals with the various frequent subgraph mining techniques using Apriori-based and patterns growth methods those will be helpful for solving the FSM in small-scale graphs to large-scale graphs they depend on the candidate generation approaches and the frequency counting. Section 4, we present the parallel and distributed frameworks for finding the FSM on large-scale graphs. Section 5, discuss the conclusions and future scope.

2. GRAPH PARTITIONING APPROACHES:

Unstructured meshes are illustrated as undirected graphs and they follow the sparse matrix data structures. Various algorithms are operating on these graphs usually involve the iterative application of the same basic processing at each and every node of the graph, and each node will do a small amount of work. Unstructured mesh types of problems may be implemented on a parallel and distributed-memory computer, the graph must be divided into multiple subgraphs and each subgraph is associated with one processor. Then after, all of these subgraphs should be of very nearly equal size subgraphs or equal numbers of vertices for achieving an efficient load balancing, and the edges to be connected to the subgraphs is minimized for avoiding unnecessary communication or connection among the processors.

Let G is an undirected graph from G_1 to G_n. In this, $G_i=(V_i, E_i)$ is a tuple where V is a collection of non-empty vertices $V=\{v_1,v_2,\ldots,v_n\}$ and E is a collection of non-empty edges $E \subseteq V \times V$, such that each and every edge $e \in E$ belongs to the pair of vertices (v_1, v_2). Suppose, Graph $Gs = (V_s, E_s)$ is acts as a subgraph of $G =(V,E)$, indicated as $G_s \subseteq G$, iff $V_s \subseteq V$ and $E_s \subseteq E$. In this, bunch of graphs in G and user-mentioned support threshold is S_{min}, then G_s is said to be frequent only if it is a subgraph of at least S_{min} graphs. The support$(G, G_s) = \{G_i | G_s \subseteq G_i \cap G_i \in G\}$ denotes the supporting graphs of G_s. A subgraph G_s is frequent if $|support(G, G_s)| \geq Smin$. Suppose F denotes the collection of all FSMs and frequent subgraph $X \in F$ is said to be maximal only if it is not having the frequent supersets where M is a group of possible maximal FSMs and which is helpful to identify the maximal FSMs as connectivity is a valuable information which is collected from the connection between the nodes and permits for removing the mining disconnected combinations. The graph partitioning (GP) problem follows the NP-complete, it is also called the min-cut problem and defined as splitting the given graph into smaller chunks or blocks. Graph Partitioning can be implemented in two ways i.e. vertex based partitioning and edge-based partitioning.

For graph mining, good partitioning on large graphs is crucial because of several reasons. One of the best GP is the vital pre-processing step is to follow the divide-and-conquer algorithms, in this graph is divided into roughly same sized dense subgraphs, the same algorithm is applied on it and combines the intermediate results in the final phase. Another type of partition is to reduce the size of cross-partition edges that decreases the length of communication among the different machines at a large scale.

Large-scale graph partitioning challenges are multi-level paradigm, quality graph partitioning, and load balancing. There are various graph partitioning algorithms [4] that will use different techniques to overcome the above challenges.

There are two types of Graph partitioning techniques: 1) Static Partitioning 2) Dynamic Partitioning. Static Partitioning is further classified as serial partitioning and parallel partitioning whereas dynamic partitioning is further classified as distributed and clustered Approach. Figure1 shows the classification of algorithms depends on the implementation of graph partitioning strategies.

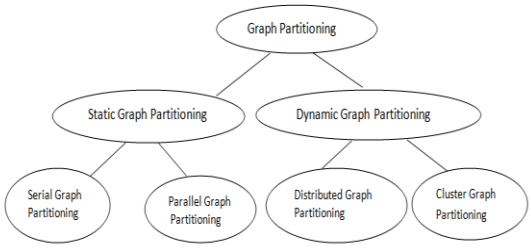

Figure1. Classification of Graph partitioning strategies

2.1. Non-Adaptive or Static Graph Partitioning:

Static partitioning is an essential way of multi level computations. Here, split a node into various m-disjoint subsets using the first stage of multi-phase calculations, in which they are active and the subgraph contains only those nodes in the first subset and its connected edges are partitioned. The subgraphs are calculated nodes are locked, it will not be changed further and accordingly, the next nodes which are available in the second subset will be appended to the subgraph. In this phase, the nodes which are from the second subset are easy to vary the subdomains and these free vertices which are allotted to the identical subdomains as their

locked neighbors. Though the next iteration of partitioning is over, the subdomains which are calculated from the second subset nodes are blocked, the third subset nodes and edges are added to the subgraph, it is further partitioned for the third iteration and the similar process is to be continued for m iterations, which gives a multi level partitioning result.

Serial Graph Partitioning: METIS is an irregular graph and which is consists of sequential programs for graph partitioning, divides the large meshes, and computes the fill-reducing orderings of sparse matrices will results in quickly produce good quality graph partitioning. METIS related algorithms are depended on the multilevel k-way, multilevel recursive-bisection, and multi-constraint partitioning approaches developed in the University of Minnesota Digital Technology Center (DTC) labs and is freely distributed.

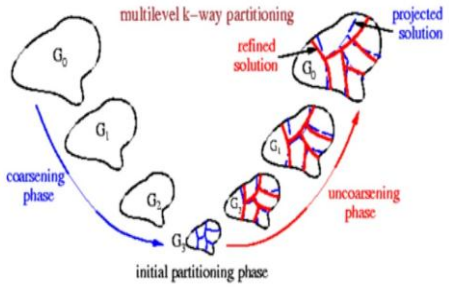

Figure2. Phases of Multilevel graph partitioning

Multilevel graph partitioning has three levels or phases that they are graph coarsening, initial partitioning, and uncoarsening. In the first phase i.e. Graph coarsening, a consecutive in sequence tiny graphs is computed from the input graph, every consecutive graph is to be built from the earlier graph by combining for a maximal size set of neighboring pairs of nodes and it should be continued until the size of the graph will have been reduced to less number of nodes. In the second phase, a partitioning of the coarsest, the smallest graph is to be identified, it is very small and which executes quickly. In the third phase, the partitioning of the smallest graph produces a useful larger graph by allocating the bunch of vertices which are combined to get the same partition as that of their relevant collapsed node. After completion of the projection step, it should be modified with the help of different heuristic methods to repetitively move the nodes between partitions till the that types moves will enhance the performance of the GP solution. Therefore, the uncoarsening phase is completed only if the partitioning solution given graph is obtained on has been projected all the way to the given graph.

METIS use modern strategies to consecutively decrease the size of the graph and refine the graph partitioning during the uncoarsening phase. At the time of coarsening, METIS applies the algorithms is simple to identify a good quality partition at the coarsest graph.

Parallel Graph Partitioning: There are various issues when the graph partitioning is performed in parallel implementation [5]. The large-scale graph data could not be computed in a consecutive manner because the memory is not enough to allow the partitioning that can be resolved on enormously concurrent implementation and a group of workstation clusters. To partitioning the very large-scale graph data in parallel graph partitioning algorithms for parallel implementation large size memory is needed.

Parallel graph partitioning is focused on geometric, spectral, and multilevel partitioning approaches. Geometric graph partitioning algorithms are easy to parallelize whereas multilevel partitions and spectral partitions are very complicated to make parallelize. The parallel asymptotic runtime is identical to which it performs a parallel matrix-vector multiplication on a randomly partitioned matrix, because of that the given graph is not properly scattered among the processors. Initially, the input graph is partitioned and distributed among the processors and the parallel asymptotic run times of multilevel partitions and spectral partitioning diminish the performance of a parallel matrix-vector multiplication on a good partitioned matrix and these partitioning approaches need to parallel well partitioning of the input graph.

2.2. Dynamic Graph Partitioning

Most of the static graph partitioning strategies is not give good quality of input graphs. But the dynamic graph partitioning will give the quality of input graph partitioning, including low edge cut that's the way the parallel adaptive graph partitions will run considerably faster than static partitions and it can be applicable to the scalable graphs and real-world applications.

Dynamic graph partitioning is not possible to do in a single memory because it has the aspect of radically increasing graph nodes and it may be billions of nodes, for this reason, it uses the distributed memory system concept which helps to place graphs in various machines and processing. For dynamic partitioning of a given large-scale graph, it requires load balancing, clustering and few heuristic techniques which obtain good results. Some of the other dynamic partitioning approaches are the parallel graph partitioning or streaming graph partitioning for the complex networks and spinner technique for scalable graph partitioning for cloud networks.

Most of the parallel geometric partitioning approaches will not affect the execution at the initial distribution of the graph, which will be helpful for the partitioning algorithm i.e. a rough partitioning is a faster geometric approach. Rough partitioning is useful for the reallocation of the graph before performing the spectral partitioning or parallel multilevel. This approach considerably enhances the concurrent efficts of the additional correct partitioning task.

Parallel graph partitioning [6] is decisive for achieving preeminent results in the circumstance of dynamic GP, in this, the input graph is shared earlier among the processors and it is the necessity of repartitioned as a consequence of adaptive nature of underlying computation. In a dynamic GP approach, if one processor is used for repartitioning of the given large-scale graph will generate a severe bottleneck problem that should be negative impact measurability. The widespread approach is to perform on the large graph that uses the

simultaneous computational systems to compute the algorithms and graph dataset is shared among the machines and different concurrent computation techniques will be useful to handle these types of graphs. There are various computationally efficient and good quality algorithms are used for graph partition problem, but the results are may or may not be optimal, such as spectral bisection method, Kernighan-Lin algorithm, and multilevel graph partitioning, however, these techniques are not scalable to the graph data with large sets. One of the eminent techniques is the graph stream partitioning for large scale distributed graphs is to accept the graph datasets sequentially from the disk onto a cluster heuristics techniques. In most situations, it is identified as impracticable for the distributed system, in which graph data is performed in a parallel way.

In distributed graphs, a distributed memory system was helpful for online query processing over large-scale graph which may be a billion nodes. For organizing the large-scale graph on distributed systems, segregate into more partitions and each and every partition is stored in one processor without any conflicts or overlapping. Dynamic multi-phase graph partitioning will cause major effects on load balancing and inter-process communication in distributed graphs. To maintain the consistency in this environment, fulfill the load balance constraints and minimize the inter-process communication.

3. FREQUENT SUBGRAPH MINING

FSM is used to calculate all the possible subgraphs which occur in the input graphs most frequently than a given user-defined threshold. It is generating the candidates and the task of candidate generation is done either in a depth-first or breadth-first strategy. From the generated candidate subgraphs, the frequently occurring subgraphs are found i.e. support counting. There are two issues of given FSM, first it is to generate the candidate subgraphs without including the duplicates and second is to calculate the eminent processing approaches that produce the necessary and desired frequent subgraphs or candidate subgraphs. FSM is used to check the isomorphism checking strategy. The best candidate subgraph generation technique will produce the candidates and it avoids the duplicate candidates.

Every FSM should follow the three characteristics that they are:

Graph Representations: A graph is described as an adjacency matrix or adjacency list and difficult to find the isomorphism testing using adjacency matrix and adjacency list. Canonical labelling describes a unique code for a given graph and it makes possible to check isomorphism because it makes sure that given pair of graphs is isomorphic, then their corresponding canonical labelling is same.

Subgraph Enumeration: Enumeration is a task of calculating or counting subgraphs one by one. Graph enumeration to be done by using either join operation or extension operation. With single join operation, multiple candidates are identified and with many join operations single candidate which can be duplicated. With extension operation, it can restrict nodes which include to the newly introduced edge.

Frequency Counting: Frequency counting for graphs can be done using either embedding lists or recomputed embedding.

3.1. Categorization of Frequent Subgraph Mining Algorithms: There are three major challenges of subgraph generation process that they are infrequent subgraphs, isomorphic subgraphs, and the subgraphs that do not available in the graph database. FSM algorithms use various strategies to reduce and eliminate these issues or challenges. Grouping the similar approaches depends on their nature of the given input graph data which may be small-scale graphs to large-scale graphs.

There are possible ways to find out the frequent subgraph mining search strategy i.e. either using Breadth First Search (BFS) or Depth First Search (DFS) approach. The algorithms basically depend on the input correctness then one is to accept the exact graph for a certain group of graphs as input and another is an uncertain set of graphs as input. In this, an input may be a bunch of small graphs or a single large graph as input. After multiple FSGs are identified then it will produce a complete set of FSGs or a partial set of FSGs.

Apriori-based Approach: The basic scheme of this frequent substructure mining algorithms [15] is to combine two size-k frequent sub structures and to produce (k+1) size candidate graphs, searching for frequent graphs and starts with the small size and continues in a bottom-up approach. In this, isomorphism testing is an expensive i.e. NP-Complete problem, test the false candidates or false search efficiency is minimized.

Apriori-based FSM approaches are further classified as follows: Suppose given graph is a large single graph then GREW and HSIGRAM algorithms are used. If the type of the graph input is a graph database then it uses the AGM algorithm. Suppose input is a set of graphs then FARMER, FSG, FFSG, ISG, and SPIN algorithms are used. If the input is a dynamic graph then it uses Dynamic GREW. Finally, the given input graph is an uncertain set of graphs then we use MUSE, MUSE-P, WMUSE, and UGRAP algorithms.

GREW [7]: It is a sparse matrix representation of a static graph and uses repetitive merging for subgraph candidate generation. It follows a greedy search strategy. The aim of the GREW is to calculate maximal independent set of a graph, which is collected from the FSM so as to calculate the frequency which missed many interesting patterns. GREW is efficient for large-scale graphs and for finding non-trivial patterns which allow the maximum portion of the input graph.

HSIGRAM : It is an adjacency matrix representation of a static graph and uses the iterative merging for subgraph candidate generation which follows a breadth-first search strategy. The aim of the HSIGRAM is to calculate the maximal independent group of a graph, which is built from the FSM embeddings to evaluate its frequency.

AGM [8]: It uses adjacency matrix representation of a static graph and uses the vertex extension for subgraph candidate generation which follows a breadth-first search strategy. It is used to find the FSMs using graph database as input, which is gathered from the frequent subgraph so as to

assess the Canonical labelling. It increases the substructure size iteratively one vertex at each step.

FARMER: It uses trie structure representation of a static graph and uses the level-wise search (ILP) for subgraph candidate generation which follows a breadth-first search strategy. FARMER is to find the FSM using a group of input graphs and it not efficient for most of the output generations.

FSG: It uses adjacency-list way of a static graph and uses the one edge extension for subgraph candidate generation which follows a breadth-first search strategy. FSG aim is to identify the frequently connected subgraphs using the bunch of graphs as an input, which is to be the frequent subgraph and estimate the Transaction identifier (TID) lists and it follows NP-Complete approach.

FFSG [9]: It describes the matrix adjacency representation of a static graph and uses the merging and extension for subgraph candidate generation which follows a DFS strategy. FFSG is needed to calculate the FSMs using graphs as input, which is cumulated from FSM so as to find the sub-optimal canonical adjacency matrix tree and it follows NP-Complete approach.

ISG: It uses Edge triplet representation of a static graph and uses the edge triplet extension for subgraph candidate generation which follows a breadth-first search strategy. ISG is to compute the maximal FSM using the input of a set of graphs and it is build from the FSM for evaluating the Transaction identifier (TID) lists and it follows the NP-complete approach, each and every FSM supports group of transaction identifiers.

SPIN [10]: It is the adjacency matrix representation of a static graph and uses the join operation for subgraph candidate generation which follows a breadth-first search strategy. SPIN is used to find the maximal FSM using a set of graphs as input, to evaluate the Canonical spanning tree and non-maximal graphs are to be found but needs an entire database scan. It works efficiently for compressing a huge number of FSM to a very small number of maximal subgraphs and allows large scalability to large graph databases.

Dynamic GREW: It is a sparse matrix representation of a dynamic graph and uses the iterative merging for the subgraph candidate generation which follows the depth-first search strategy. In this, FSM is constructed from dynamic patterns in FSM to collect the suffix trees and it needs more burden to identify dynamic patterns.

MUSE [11]: (Mining Uncertain Subgraph patterns). It follows the adjacency matrix representation of a static graph and uses the Disjunctive normal forms for subgraph candidate generation which follows a DFS strategy. The main aim is to find the FSMs use the input as an uncertain set of graphs, which is constructed from frequent subgraphs for evaluation of the DFS coding scheme. It found that the given sub-graph pattern is an output or not. Various pruning techniques are helpful to decreases the complexity of verifying subgraph patterns. MUSE is an accurate, efficient algorithm for massive uncertain graph databases. MUSE algorithm is further enhanced by MUSE-P and WMUSE (Weighted MUSE) algorithms as per application requirements.

Pattern Growth Approach: The basic idea of a pattern Growth FSM algorithm is to extend the frequent graph keep on including the new edge, in every feasible position and it uses edge-extension technique, the problem with this approach is that relevant sub-graph is identified the number of times. To overcome the problems of Apriori-based algorithms, many pattern growth strategies use the depth-first search technique.

Pattern growth FSM approaches are further classified as follows: Suppose the input graph is a single large graph then SUBDUE, GBI and SEUS algorithms are used. Some situations, the input graph is a set of graphs then we use CloseGraph, Gaston, gSpan, MOFA, MSPAN, JPMiner, TSP, RP-GD, and RP-FP algorithms.

SUBDUE: It uses the adjacency matrix representation and uses the level-wise search for subgraph candidate generation which follows a greedy search strategy. SUBDUE is to gather the minimum description code length and it uses very less number of patterns.

GBI : It uses the single large static graph as an input and which follows a greedy search strategy. The isomorphic test is exact for GBI.

SEUS : It uses the single large static graph as an input and which follows a depth-first search strategy. The isomorphic test is exact for SEUS.

CloseGraph: It basically follows the adjacency list representation of a static graph and uses the rightmost extension for subgraph candidate generation which follows a depth-first search strategy. The CloseGraph aim is to compute the depth-first search lexicographic order and it required a lot of time for failure detection.

Gaston: It uses hash table representation of a static graph and uses the extension for subgraph candidate generation which follows a DFS strategy. Gaston is used to find the embedded lists and interesting patterns may be lost.

GSpan: It uses the adjacency list representation of a static graph and uses the rightmost extension for subgraph candidate generation which follows the depth-first search strategy. GSpan performs the depth- first search lexicographic order and frequent graphs generated can't be scalable.

MOFA: It uses the adjacency list representation of a static graph and uses the rightmost extension for subgraph candidate generation. It is to identify the depth-first search lexicographic order and frequent graphs produced may or may not be exactly frequent.

MSPAN: It uses adjacency list representation of a static graph and uses the rightmost extension for subgraph candidate generation which follows depth-first search strategy. MSPAN follows the depth-first search lexicographic order.

JPMiner : It follows the adjacency list representation of a static graph and uses the rightmost extension for subgraph candidate generation. It is to examine the DFS lexicographic order, to evaluate the frequent jump patterns and sometimes there may be less number of jump patterns.

TSP : It is the adjacency list representation of a dynamic graph and uses the rightmost extension for subgraph

candidate. The aim of the TSP is to find the depth-first search lexicographic order, to find the representative graphs and time for summarizing the pattern is more than for mining.

RP-GD: It uses the adjacency list representation of a static graph and uses the rightmost extension for subgraph candidate generation. The aim of the RP-GD is to find the depth-first search lexicographic order, and frequent graphs generated can't be scalable.

RP-FP: It uses the rightmost extension for subgraph candidate generation which follows a depth-first search strategy. It is used to find the depth-first search lexicographic order, and time for summarizing the pattern is more than for mining.

4. PARALLEL AND DISTRIBUTED FRAMEWORK FOR GENERATION OF LARGE SCALE FSM:

We describe a framework for processing and generating large scale frequent subgraph mining with parallel and distributed approaches on a cluster. Scalable graph processing consists of five phases that they are reading the data, pre-processing, partitioning, computation and writing data, in each phase handle the errors effectively. Graph processing architecture will be one of the graph programming models such as Distributed Architecture, Share-Memory Architecture, and Heterogeneous Architecture. For the implementation of this framework, we need to use the following aspects, they are MapReduce, Hadoop, GraphLab, Giraph, and GraphX techniques.

MapReduce Framework: MapReduce [12] is a programming framework used for the processing and generating a huge volume of data in a distributed manner. It provides an efficient user interface for handling the data distribution, replication, and load balancing. It performs three abstract functions i.e. map, shuffle, and reduce. The raw data is used for reading and processing to the output (key, value) pairs is done by map function. The output of the map function is forwarded to the reducers propagated through the more secure network so that the pair with the identical key is to be grouped together done by the shuffle function. The key-value pair with the identical key is to be processed as output, key and value pair is done by reduce function. In this MapReduce iterative program which runs on several MapReduce tasks, then the output of the current task should be the input of the next task.

Hadoop: Hadoop provides a scalable idea to store and process the data sets with a huge amount in distributed and parallel fashion. It is an open source implementation of the MapReduce programming model and for its file management which follows the Hadoop Distributed File System (HDFS). Various tools which are used on top of Hadoop such as Hive, PIG, Spark, HBASE, iMapReduce [13], Scoop and Flume. Because of the accuracy, big graph mining, efficiency, scalability simplicity, and fault tolerance using Hadoop.

GraphX: It is a data model which contains the property graphs and immutable collections. It was developed on top of the Apache Spark [14], represents transformation on graphs and each and every operating action creates a new graph. It is apache spark API for graphs and graph parallel computations which intends to execute the large-scale graph algorithms proficiently. The immutability condition will clarify the abstraction and helpful for fault tolerance and reuse of data. It consists of unordered tuples or key-value pairs which are represented as unstructured data. In this, a key may be null and not be unique, and value might be a random object. The unordered data collection view is important for processing the raw input, graph computation results are to be evaluated. This framework uses a programming abstraction method is said to be Resilient Distributed Graph (RDG) interface, it constructed on Spark's in-memory storage abstraction i.e. Resilient Distributed Datasets (RDD). It follows the directed adjacency structure with user specified attributes connected to each and every vertex and edge, and they are treated as RDGs.

Giraph: Apache Giraph [15] is the most popular and powerful open-source platform for the parallel and distributed environment. It uses Map-only Hadoop jobs to coordinates the vertex-centric workers and it takes help of HDFS for storing and processing graph datasets. It has a faster input loading time compared to Pregel and it inherits the benefits and deficiencies of the Pregel vertex-centric programming method.

GraphX, Giraph, and GraphLab parallel frameworks provide good results when compare to conventional frameworks, thus one of the above-mentioned frameworks can be adopted for identifying FSM in a large scale graph data and implemented further using either R language or Python.

5. EXPERIMENTAL RESULTS:

Time complexity analysis of the PFSG-Miner is to divide the analysis of the FStG algorithm is on master processor and PFSG algorithm is on the slaver processors in parallel environment. All the experiments have been conducted on a Downing 4000L platform at Gansu Computing Center. The platform contain 48 2.2GHz CPUs and 24 2.2GHz Core 2 CPUs. It has 14 146G Ultra30 SCSI hard disks. In order to reflect the effectiveness of the algorithm, compare this algorithm with the gSpan and FFSM algorithms. The

gSpan and FFSM execute on single processor, while this algorithm will run on four slave processors at parallel phase.

The experiment chooses real data and simulation data. The real data is DTP (therapeutic program developmental) which provides the collection of compounds. The compounds in DTP can be divided into 3 datasets, which include CA (active confirmed), CM (moderately confirmed) and CI (confirmed Inactive). Figure 3, Figure 4 and Figure 5 shows the running results of PFSG-Miner, FFSM, and gSpan on different datasets.

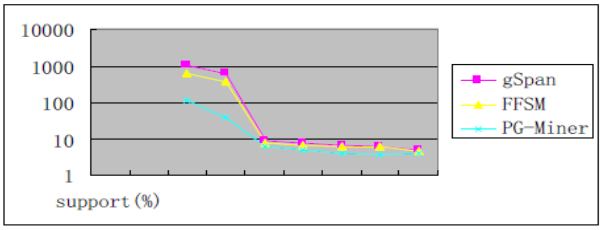

Figure 3: CA Data Set

5. CONCLUSION

In this paper, we present a comparative analysis of the several FSM algorithms with their merits, demerits, behavior, and application in a parallel and distributed environment. FSM is useful for multi disciplinary areas like bioinformatics, chemo-informatics etc. where digging of iterative patterns among the huge collection of networks. Based on the various graph partitioning algorithms, we have classified graph partitioning approaches into static, dynamic, distributed and parallel implementations. The algorithms have been classified depends on the Apriori and Pattern growth approaches. Generally, the existing algorithms focus only on static graph datasets. Still, most of the research work was not done on the complex dynamic or evolving large-scale graphs for mining pattern. If it applies on distributed and parallel implementation will also save the more processing time.

Generating Highlights of Cricket Video using Commentators and Spectators Voice

Mohammed Inayathulla, C Karthikeyan

Abstract*: Videos are one of the important and richest sources of data on internet. In this growing world of digital technology video summarization will be handy in analysing the video data. Recently Natural Language Processing has attracted more researchers to work to meet the current emerging challenges. Among the various issues, video summarization got more focus and in this regard, many applications and works have been evolved. Video Summarization is the process of creating a small video describing the actual video within short duration(s). The paper focuses on generating highlights of a cricket video by analysing the voice of commentator and spectators. The experimental results have shown good performance when compared with human generated summary.
