Due to the rapid advances in technology and growing use of social network platforms huge amount of various forms of data is generated. Amongst them videos are one of the crucial source of data. Some thousands of videos are daily uploaded by the users on various platforms. Hence video summarization will be handy as it significantly reduces the user's time and effort. Video Summarization aims at creating synopsis of the video without disturbing the actual semantics of the video. Video summarization is a challenging task for researchers because different users have different preferences for summary. Hence generating the summary which satisfies the preferences of different users is a complex task. Video summarization is broadly of two types static summarization and dynamic summarization. Static video summarization creates a storyboard which is the collection of random images which are of more importance. Dynamic video summarization creates a short video from the original one. Video summarization can be both manual and automated. Manual video summarization is a technique where the video is inspected to find the interesting and important frames which form the summary of the video. Automated video summarization involves training the machine to understand the semantics of the video so that machine generates the final summary of the video. Complexity of video summarization lies in understanding the semantic relationship between the frames.

Revised Manuscript Received on November 22, 2019.

Video summarization can be both supervised and unsupervised task. In supervised learning initially the machine will be trained with labelled data and depending upon the learning accuracy machine will generate the synopsis of the video. The generic approach of video summarization is described in figure 1. In unsupervised learning the machine will design criteria to select the important frames which form the summary of the target video. Manually designed criteria can be used in both supervised and unsupervised techniques for summary generation. Few of the researchers have focused on generating abstractive textual summary for the given video.

II. LITERATURE SURVEY

In this paper [1] the authors proposed a divide and conquer approach for video summarization. All the video frames were assigned with score of importance and subset of frames which gives the highest total score was selected. To get the optimal score for the entire video three stage deep neural network was proposed (2D CNN,1d FCN,LSTM). To deal with the subjectivity of summarization harmonic mean among different summaries was calculated. To evaluate the summary results were compared with the human created summaries. In this paper [2] authors proposed a DSSE (deep side semantic Embedding) model to generate summary. Side information available with video like title, query, comment, description was effectively used to find frames which form the summary. In this paper [3] the authors focused on users major or special interest for generating the summarization. The authors used Deep Ranking Model to evaluate the relationship between summarized and non summarized frames of the video.

In this paper [4] the authors developed a deep neural network for generating abstractive text summarization of the input video sequences. Initially the description of the input video was generated using CNN and from the description abstractive summary was generated. A Maximal Biclique Finding (MBF) algorithm [5] is devised in order to resolve the issues that raised due to the dearth of co-occurrence of patterns when irrelevant shots in videos are considered. The objective of this algorithm is to optimize the patterns that are located lightly and removing the less co-occurring patterns yet irrespective of their prevailing nature in one video. In [6][13][14] authors used

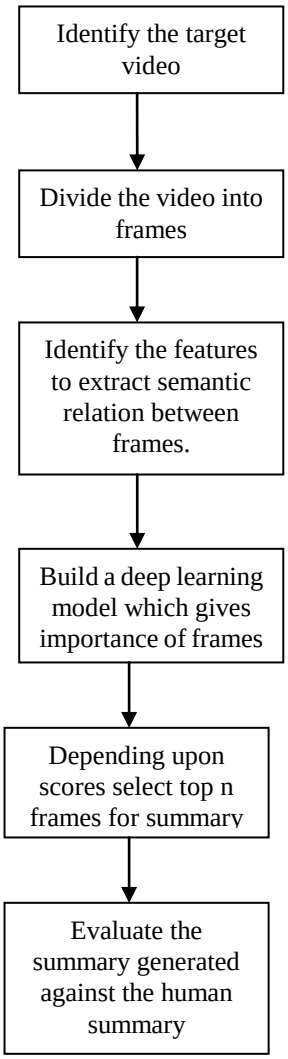

Fig. 1.Supervised approach of Video Summarization

Hidden Markov Model and empirical mode decomposition for generating summary. Initially the key frame was extracted then classification was applied to include it in highlights or not and then finally highlights was generated. In [7][15] authors used oriented fast rotated brief approach to find excited clips and optical charater and replay recognitions also were used. The authors proposed context aware video summarization [8] which uses sparse coding by learning from dictionary of video features and spatiotemporal feature correlation graph.

The authors proposed a hierarchical Recurrent neural network model for generating video summary [9]. The RNN was designed in such a way that the first layer was used to encode short video subshots which were taken from the original video and the second layer was used to calculate the confidence of each sub shot to form the summary. In [10][11][12] a novel approach for exploring surveillance video data. Initially object movement was recorded i.e. by extracting single shot image which is a combination of multiple frames. Action parsing driven video summarization model was proposed which was reinforcement learning based. For video summarization initially shot boundary detection was conducted then screen shot clustering was implemented using minimum spanning tree.

III. PROPOSED METHODOLOGY

To generate the highlights of cricket video voice of commentator and cheers of spectators are considered as key aspects. The general perception in this context is that when there is increase in commentator's voice or spectators cheers only when something important has happened, like a wicket or a batsman scoring four or six. The proposed approach is as described in figure 2.

After breaking the audio into chunks short term energy is computed and a threshold value for the energy is identified for classification of audio clips as excited or not. The threshold value can be experimented for improving performance. All the excited clips are merged together to generate highlights of the target video. To generate highlights parts of the video are to be extracted within a particular time interval only as the voice in the video is high only when the player performs an action.

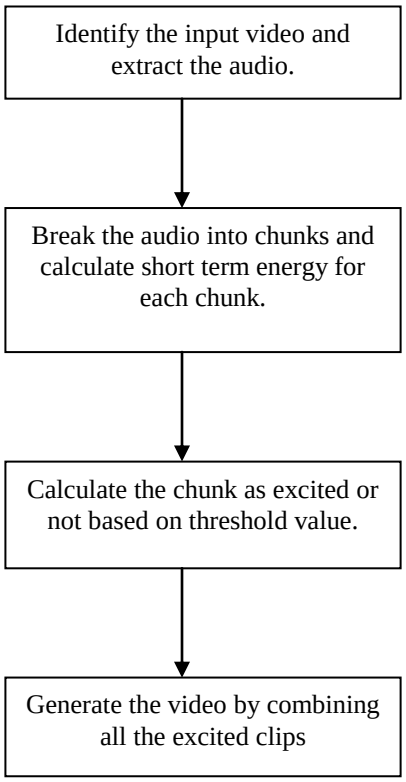

Fig. 2. Step by Step Process of Generating Highlights of a Video by Using its Audio.

IV. RESULTS

The proposed approach is implemented on cricket videos available on YouTube. A video of 23 minutes whose highlights in the form of excited clips was generated is shown in figure 3. Similarly we have implemented the work on 10 similar cricket videos which are downloaded from YouTube and the results are evaluated against the human generated summary. Selection of threshold value for selecting the excitement clip has severe impact on the performance of the proposed approach.

Fig. 3.A Snapshot of all the excited clips of Video.

V. CONCLUSIONS

The proposed approach which is based on voice of commentator and cheers of spectators has shown promising results in generating the highlights of a video. The proposed approach is limited to small size videos. In order to deal with videos of larger size or to generate the highlights of complete match deep learning techniques can be implemented which will improve the overall performance of the proposed approach.

A Fine Grainedresearch Over Human Action Recognition

S. Sandhya Rani, G. Appa Rao Naidu, V. Usha Shree

Abstract: ***Human Action Recognition from videos has been an active research is in the computer vision due to its significant applicability in various real-time applications like video retrieval, human-robot interactions, and visual surveillance, etc. Though there are so many surveys over Human action Recognition, they are limited to various constraints like only focusing on the methods in few orientations only. Unlike the earlier ones, this paper provides a detailed survey according to the basic working methodology of Human action recognition system. Initially, a detailed illustration is given about various standard benchmark datasets. Further, following the methodology, the survey is accomplished in two phases, i.e., the survey over feature extraction approaches and the survey over action classification approaches. Further, a fine-grained survey is also accomplished under every phase based on the individual strategies***

Keywords: Human Action Recognition, Feature Extraction, Classification, Spatio-temporal interest points, Trajectories, Support Vector Machine, Deep Learning, action datasets.

I. INTRODUCTION

In recent years, with a widespread applicability in various applications,like visual surveillance, sports analyses, human-computer interactions (HCI) [1], robotics [2], elderly care [3], and intelligent space [4] and video retrieval, Human Action Recognition (HAR) has gained a significant research interest in the field of computer vision. The main aim of HAR is to determine, and then recognize what humans do in the unknown videos. Compared to the individual still images, video sequences provide more detailed information about actions. For example, consider a still image in which a man moving. We can't say what he is doing. Whether he is running? Or he is just jogging? In such a case, video sequences can give more detailed information about the human action. Video gives both spatial and temporal information but still,the image gives only spatial information.

(a)

(b)

Figure.1 (a) Still image and (b) frames of a video sequence

The main objective of a HAR system is to identify actions in a video sequence under different situations like occlusion, cluttering, and different lighting conditions. The main center of this system is the computational algorithms that understand the human actions. Similar to the human vision system, these computational algorithms ought to produce a label after the analysis of partial or entire action in the video sequence [5], [6]. Developing such algorithms is typically addressed in computer vision research, which studies how to make the computers to gain high-level understanding regarding human actions from digital images and videos?

A. Applications of HAR

HAR algorithms empower many real-world applications and these approaches remarkably reduce the manual effort to analyze a large-sized video data and provide sufficient understanding about the present end future states of an ongoing video data. The major real-world applications which utilize the action recognition are formulated as;

Visual Surveillance: In the Visual Surveillance system, a camera equipped with HAR algorithms may increase the chances of capturing a criminal on video, and decrease the dangerinstigated by illegal actions [7]. The cameras also make some people feel more secure, knowing the criminals are being watched.

Video Retrieval: Due to the vast number of videos on the internet, Video Retrieval is becoming a tremendous challenge as most search engines use the associated text data to manage video data [8]. The text data, such as tags, titles, descriptions, and keywords, can be incorrect, obscure, and irrelevant, making video retrieval unsuccessful. An alternative method is to analyze human actions in videos, as the majority of these videos contain such a cue.

Entertainment: In the entertainment field, the HAR has a significant importance due to its deployment in the sensors which are used to detect human actions [9]. These sensors provide an in-depth channel data which has encoded rich information about the entire scene of video.

Revised Manuscript Received on November 05, 2019.

Human-Robot Interaction: Assume that a patient is undertaking a recovery exercise at house, and his/her robot assistant is capable of recognizing the patient's actions, analyzing the correctness of the exercise, and preventing the patient from further injuries. Such an intelligent machine would be significantlyhelpful as it hoards the rounds to visit the therapist, reduces the medical cost, and makes remote exercise into reality [10].

Autonomous Driving Vehicle: Action Recognition algorithms can predict a person's intention in a short period of time. In an emergency situation, a vehicle equipped with an action recognition algorithm can predict a pedestrian's future action or motion trajectory in the next few seconds, and this could be very helpful to avoid a collision [11].

This paper outlines a detailed literature survey over various methods proposed to recognize the human action in multiple environments with different strategies. This paper conducted the survey based on the basic methodology of HAR system, i.e., feature extraction and classification. In the feature exaction phase, the HAR system extracts a sufficient set of features and in the classification; the obtained features are processed for classifiers to recognize the action. Following the same strategy, initially, the survey is carried out over various feature extraction techniques and then over various classification techniques.

The remaining paper is organized as follows; Section II explores the details of various datasets used for simulation experiments. Section III Outlines the complete survey and section IV provides the concluding remarks.

II. DATASETS

Under this section, this paper describes the details of the datasets used for simulation experiments. In earlier, various datasets are developed and based on the development;the environment considered during the development, the appearance of objects, camera view, background variations and total number of subjects, they are categorized into two classes such as constrained and unconstrained.

2.1 Constrained Datasets

Under this category, the action videos are captured under constrained environments which have fixed settings. INRIA XMAS multi-view dataset, KTH dataset, Weizmann dataset, and UT-interactions dataset are some examples of this category. Further, the first three are individual action dataset and the remaining one isthe group action dataset.

A. KTH dataset [12]

This dataset consiststotal of six different actions such as *Handclapping, running, jogging, walking, hand waving and boxing.* The entire actions are accomplished various times under four different environments such as Outdoors, Indoors, Outdoors with various clothes and outdoors with scale variations. Totally 25 subjects are used to create this dataset and this hasa totally $25 \times 6 \times 4 = 600$ vides in.AVI format and 2391 sequences. All the sequences are captured with a static camera with 25fps frame rate and the background is homogeneous in nature. Some sample frames of this dataset are shown in fig.2.

B. Weizmann Dataset [13]

This dataset totally consists of ten different actions like *walking, running, skipping, jumping jack, jump forward on two legs, bend, single hand waving, doble hands waving, gallopsizeways, and jump in the same place with two legs,* and totally consist of 90 videos. all the actions are captured with the help of a static camera. The frame rate of every video of 50 fps ane the resolution of each frame is 180×144.Some sample frames of this dataset are shown in fig.3.

C. INRIA XMAS multi-view dataset [14]

This dataset consists of 12 action classes such as*point out, pick up, wave, punch, turn around, walk, sit down, get up, cross arms, scratch head and check watch*. Each action is performed three times and 12 different subjects are recorded with five cameras, four are fixed at four sides and one is fixe on the top. These five cameras capture five views such as left, right front back and top. The frame rate is 23 frames per second and the size of the frame is 390×291 pixels.Fig.4 shows some samples of different actions under multiple views.

D. UT-interactions dataset [15]

This dataset consists of a total of six human interactions such as *Push, Punch, Point, Kick, Hug, and Handshake*. There are totally 20 video sequences which have a length of around one minute. Several subjects with more than 15 different clothing conditions are captured in this dataset. The frame rate is 30fps and the size of the frame is 720×480 pixels. Further, the height of a person in every video is approximately 200 pixels. Fig.5 shows some samples of different actions.

Fig.3Action samples of Weizmann dataset, (a) Bend, (b) Jump, (c) Run, (d) Boxing, (e) Wave two hands, (f) Walk

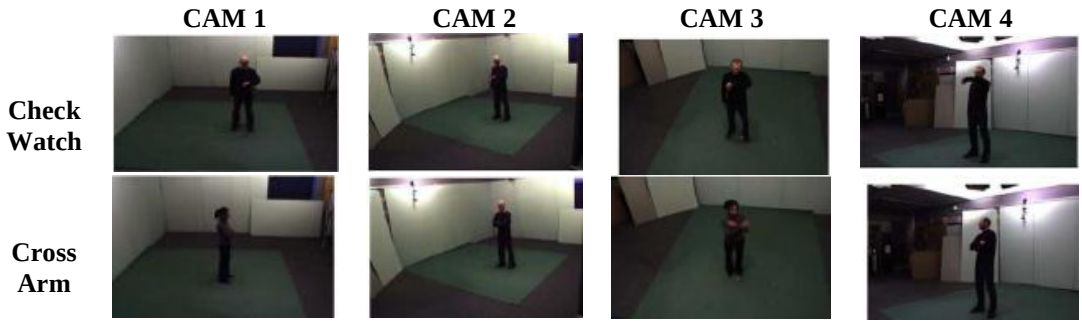

Figure. 4 Samples of INRIA XMAS Multi-View Dataset

Fig.5 Action samples pf UT-interaction dataset, (a) Push, (b) Punch, (c) Point, (d) Kick, (e) Hug and (f) Handshake,

2.2Unconstrained Datasets

Under this category, the action videos are captured under unconstrained environments which have no fixed settings, simply real-time environments. The datasets under this class are created by capturing the videos from the internet. Moments-in-time (MIT) dataset, UCF101 dataset, HMDB51 dataset are some of the examples of this unconstrained datasets.

A. Moments-in-time dataset [16]

This dataset containsa totally of 339 types of video clips, each one is of a 3-second duration and totally this dataset has 1,00,000 videos clips. The visual objects appear in the video clips are natural scenes, animals, people, and objects. This is a very large human-annotated dataset comprised of so many events and generally used for the recognition tacks sin complex environments. Fig.6 shows some samples of this dataset.

B. UCF101 dataset [17]

This dataset consists of a totally 101 action classes and the total number of videos is 13320. All the videos of this dataset are acquired from YouTube. With the presence of 13320 videos, the UCF101 dataset provides diversified actions with the presence of different variations such as illuminations, cluttered background, viewpoint, scale, pose and appearance, and variations in the motion of camera, etc. The complete 101 videos are categorized into 25 groups, where every group consists of 4-7 video for an action. Further, the actions are categorized into five classes and they are Sports, playing musical instruments, Human-Human Interactions, Human-Object interactions, and body motions. Fig.7 shows some samples of this dataset.

C. HMDB51 Dataset [18]

This dataset consists ofa totally 51 action classes and the total number of video clips is approximately 7000. Every class of action carries a minimum of 101 video clips. The total 51 action categories are grouped into five classes and they are body movements for human interactions, body movements for object interactions, general body movements, facial actions with the manipulations in an object, and the general facial actions. In this dataset, most of the videos are collected from different sources like Google videos, YouTube and several movies.Fig.8 shows some samples of this dataset.

MSR [20]	14-25	3	2009	Constarined
Sports1-M [21]	11,33,158	487	2014	Unconstarined

III. LITERATURE SURVEY

According to the methodology followed for Human Action Recognition, the entire literature survey is accomplished here under two phases, one is the approaches focused over the feature extraction and the other is the approaches focused over the classifier. In the case of feature extraction oriented approaches, the main focus is made on the feature extraction, i.e, the representation of a video or frame with an efficient set of features. An effective set of features provides a perfect discrimination from action to action such that the classifier will get clarity over the action sequences. Further, in the case of classification, the main focus is done on the reduction of complexity and the provision of robustness. A classifier must be like that it has to produce effective recognition results for all types of action sequences. In such a case, the classifier is said to be robust. Further, the recognition framework also concentrates on the computational complexity and mainly tries to choose a classifier which has a less computational complexity. The details of different earlier developed approaches are described in the below sub-sections.

3.1 Feature Extraction

Feature extraction is the foremost important problem in the human action recognition system. The human actions appearing in the video have so many variations due to the variations in the pose, camera movement, appearance, speed of motion, etc., makes the feature extraction really a most complex task. The main intention of a feature extraction technique is to provide perfect discrimination between action sequences, computationally efficient, and can effectively characterize the human actions, such that the recognition system should have less false positives or classification errors.One more major challenge in the human action recognition system is the large variations in the pose and appearance even in one action class, which results in more confusion for the recognition system. In this scenario, the main goal of the feature extraction is to nullify the variations and to convert the video into one feature vector such that it can provide sufficient discrimination between different forms of same human action, and minimize the variations such that the recognition performance will be improvised.

3.1.1 Local Features

These are extracted from local regions which have more salient information regarding the human action. Since the information present in the local regions is more salient and also more informative, most of the researchers focused on local feature only. Furthermore, the local features are more robust to variations in the appearance and translation, etc. Motion trajectory [22, 23, 55] and "space-time interest points (STIPs)" [24-26] are the two most popular local feature extraction techniques which had shown their superior performance in the HAR.

Wang et al. [23] proposed a new motion trajectory method by integrating the "Motion boundary Histogram (MBH)" [29] and "Histogram of Gradients (HoG)" [32] to extract a more effective and information-rich feature. In this approach, the trajectories are calculated based on the optical flow vectors [27]. Further, Jiang Y. G et al. [28] focused to integrate the global and local motion reference pints such that the obtained feature vector is compact to camera movement. To further improve the performance, Wang et al. [30] considered to predict the camera motion and performed the feature point matching between the frames using SURF descriptors. After generating the trajectories of both human action and camera motion, the trajectories which have inconsistent matches are removed. This estimation can also be used to remove the camera motion in optical flow vector-based approaches.

A similar action recognition technique is proposed by H. Wang et al. [33] based on the discovery of feature point matches between frames using SURF and optical flow vectors. In this approach, the homograph is measured and the trajectories which are inconsistent with homography are assumed to occur due to the camera motion and they are removed. Further, Hamim A. Abdul Azim and E. E Hemayed [31] proposed a new version of trajectory-based human action recognition system which captures the discriminative temporal relationships. In this approach, the trajectories are extracted based on STIPs named cuboid features and they are derived by matching it's SIFT descriptors over the successive frames. Then the obtained trajectory points are described in a visual "Bag-f Words (BoW)" model and then fed to "support vector machine (SVM)" classifier. However, the main drawback with cuboid featuresis that the obtained interest points may or may not locate at the same place in some frames which have cuboid temporal bounds.

Next, STIPs based approaches have gained the most popular due to its ease of implementation [34, 35].Bergonzi et al. [35]proposed to extract two different set of interest points. The first set is concerned about the shape and speed of foreground moving and to obtain these features, a 2-D Gabor filter is accomplished to every frame. Next, the second set of features is oriented to different scale and they are extracted from interest point clouds. Further, the method proposed by Willems et al. [36] used the Hessian matrix to derive STIPs which are scale-invariant both temporally and spatially.

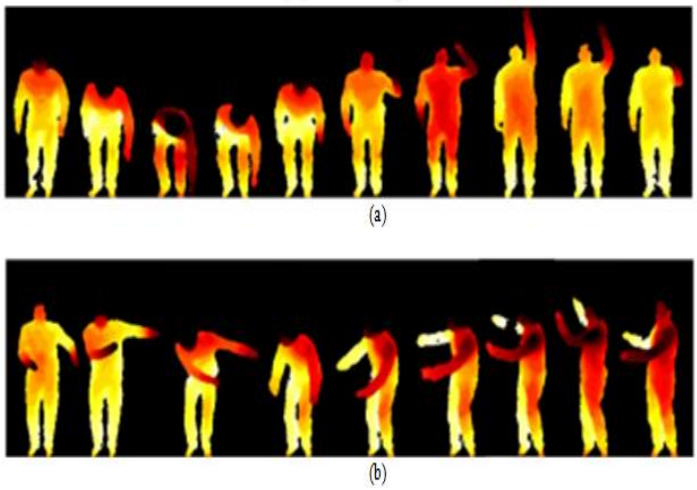
Furthermore, some more 2-D detectors are also considered which are extended into the Spatiotemporal domain. In such regard, the HoG is extended to 3-D and formulated as HoG3D and applied to extract the STIPs in the method proposed by Kaiser et al. [37] to perform human action recognition. Next, a new approach is developed by N Li et al. [38] for HARfrom unconstrained videos by combining the HoG3D with Self-organizing map (SOM) which has a significant impact on the training parameters.Generally, the STIPs are applied over a grayscale image which makes the system sensitive to disturbing the photometric phenomena like shadows and highlights. Furthermore, the important information is also neglected by discarding the chromaticity. To solve these issues, Ivo Everts et al. [39] extended the STIPs to multiples channels, called color STIPs. These points improve the quality of subsequent STIP detection and description.

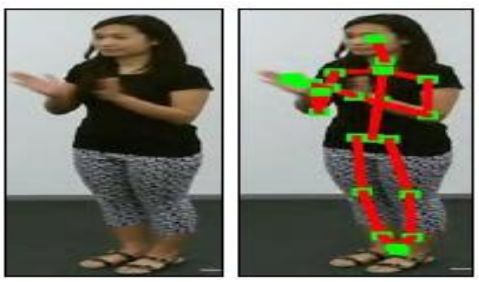
Further several 2-D descriptors are combined to develop new descriptors such that they can find the Spatio-temporal features more effectively. Towards this process, optical flow vectors are combined with histogram features and formulating into a new descriptor called “Histograms of Optical Flows (HOF)” [19]. Next, the Gradients are computed over optical flow vectors and formulated into a new descriptor called MBH for describing the motion trajectories [40]. Similarly, Nazir et al. [54] also proposed to integrate the 3D SIFT with 3D-Harris Spatio-temporal features to extract the key regions of a video. This approach used the conventional bag of visual word histograms for representing a human action.

3.1.2 Depth and Skelton Features

With the application of depth evaluation sensors (RGBD sensors), the human action detection approaches have gained improved recognition results due to the depth analysis of data. These approaches are further classified as depth sequence-based approaches [41, 42, 47-50], and Skelton based approaches [43-46, 51]. These approaches use the basic global and local features s well to extract a composite feature vector from every action sequence.

In the depth-based feature extraction approaches, initially, the motion changes are analyzed through the depth map of the human body. Under this class, a video captured through an RGBD sensor is seen as a space-time structure having the depth information. For a given action sequence, the feature is extracted as a Spatio-temporal feature with a motion or an appearance having changes in the depth.Xiaodong Yang et al. [47] proposed a new action recognition technique based on the additional depth information, i.e., body shape and motion information. In this approach, the depth maps are projected into three orthogonal planes and then accumulate global activities to generate “Depth Motion Maps (DMM)”. Further HoGs are computed form DMM as a feature. The sampled actions of DMMS for different actions are exposed in figure.9.





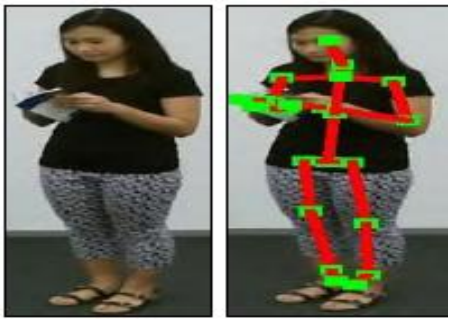


Figure.9 Sampleactions of depth maps of (a) Pick up & Throw (b) Golf swing [47]

Next, Omar Oreifej and Zicheng Liu [42] proposed a novel descriptor, called as “histogram of oriented 4D surface normals (HON4D)” for HAR from depth maps. This descriptor is equaledto the HoGs in color action sequences and spreads the histogram of normal in static images. H. Rahman et al. [48] focused to integrate the 3D joint positions and discriminative information from depth images. For every joint, a composite feature vector, called “3D space time-motion volume” is calculated to provide a perfect discrimination between actions. Further, the method proposed by C. Chen at el. [49] developed a multi-fusion based action recognition technique based on the DMM and “Local Binary Patterns (LBPs)”. This approach employs DMMs for three projection views (top, side, and front) to capture the motion cues and then applies LBPs to extract a composite feature for every action. This approach accomplished two fusion phases; one is feature level fusion and the other is decision level fusion.Jie Miao et al. [50] proposed to consider the compressed depth maps for action recognition. In this approach, every depth map is encoded with a scalable encoder which has multi-scale breakpoints and ad Adaptive “Discrete Wavelet Transform (DWT)”. Here the sharp edges are obtained through breakpoints and the smooth variations are obtained through DWT and are extracted from the bit-stream and are used to construct a set of features that are fed to classifier for recognizing the action.

From depth information of a human body, the Skelton can be estimated more easily. The samples of skeletons for some actions are shown in figure.10.

(a) (b)

Figure.10 original and skeletons of different actions (a) clapping (b) reading [52]

J. Shotton et al.[51] focused to estimate the body position of 3D joints effectively and quickly even from only one depth frame without seeking any help of temporal data. The joint consideration has been regarded as a simple super-pixel problem.Papadopoulos, G.T et al. [43] proposed a real-time tracking approach for HAR. In this approach,first, the skeleton is tracked and then applied a new representation mechanism for action based on the calculation of spherical angles between the joints and corresponding angular velocities. Finally, the recognition is done with the help of "Hidden Markov Models (HMMs)".

Unlike the above approaches which consider the joint angles and joint locations to represent the human Skelton, V. Raviteja et al. [46]developed a new method to represent the human skeletal based on the evaluation geometric relationships between the parts of body based on translations and rotations in 3D space. This approach modeled the human action as a curved manifold. Further, the classification is with an integration of "dynamic Time warping (DTW), Fourier temporal pyramid representation" and linear SVM. Pazhoumanddar et al. [45] proposed to consider a skeleton-based number of action descriptors for action recognition. This approach used the longest common subsequence (LCSS) algorithm to select high-discriminative power features fromthe relative motion trajectories of the skeleton to determine the associated action.Hany ElGhaith et al. [52] proposed to combine three different modalities such as body part images, 3D skeletons, and "Motion History Image (MHI)" into a deep learning mechanism for HAR. Based on the three different modalities, the entire information like pose of the body, motion of body and part shape can be extracted. Since the 3D skeleton can't acquire the shape body and also the shape of manipulated objects, MHI [53] and body parts are included in the feature extraction process.

Based on the above discussion, the depth and skeleton-based action recognition approaches are efficient in the representation of joint features which are more important in describing an action. Hence, more discrimination cane be acquired by the system form these features. But, the performance of these approaches completely depends on the prediction of a human pose. Furthermore, this approach has a severe effect in the presence of occlusions in the scene which results in heavy classification errors.

3.2 Action Classification

After extracting features from video sequences, they are processed for learning through action classifiers such that classifier will get sufficient knowledge about the actions present in the video. Further, this knowledge helps to determine the class label of various action classes.

3.2.1 Traditional classifiers

Among various available traditional classifiers, Support Vector Machine [54, 56, 58, 59, 60, 62, 63]and random forest [65, 66] has gained an excellent performance in the classification of different actions for all types of action videos.

K. G. C. Manocha, R. Rodrigo [56] accomplished the SVM algorithm for action recognition. In this approach, the Optical flow values of a silhouette are extracted as features and based on these features, a new motion descriptor id described for every action. Further, the SVM is accomplished for classification. To reduce the high dimensional feature space, this approach used Principal component analysis.Simulation is done over two datasets namely, Weizmann and UIUC1 Dataset [57].

Jalal A. Nassiri et al. [58] introduced a version of SVM, called "Energy-based Least squares Twin Support Vector Machine (ELS-TSVM)". This is an extension to the conventional "Least Square Twin Support Vector Machine (LS-TSVM)" [59] which performs the classification based on two non-parallel hyperplanes instead of a single hyperplane. This approach effectively handles the unbalanced dataset problem. The performance of this classifier is tested over KTH, Weizmann, Hollywood and UCI datasets.

L. Gonzalez et al. [60] considered the "Multi-class Support Vector Machine (MC-SVM)" to classify the human actions, using a multi-camera dataset called MUHAVI dataset [61]. Silhouettes are extracted as features for every action. Since the videos of the MUHAVI dataset noisy and also comprises shadows, this approach considered MC-SVM to achieve effective classification results.

M D. Praveen and C K Niranjan [62] used the SVM classifier for action recognition after extracting the features for a given video sequence. Simulation experiments are conducted over KTH dataset with hand-clapping and running actions.

Y Wang e al. [63] combined the 3D skeleton joints, gesture potential energy, and kinetic energy and others to extract one feature matrix. Further, K-means clustering is accomplished for the extraction of semantic features by the BoW. This combination of features not only reveals the information about the kinematics but also explores the biology of the human body and the natural visual saliency. Finally, the SVM kernels are used to accomplish the HAR.

SamehMerghi et al. [64] accomplished the SVM classifier for action recognition after detecting the moving human sin moving field of views based on optical flow and dense SURF. After SURF extraction, the video is represented through a set of fused features that combines visual descriptors, trajectory, and motion and finally exploited the BoW approach. Experiments are conducted on the standard datasets such as KTH and UCF101 and HMDB51 datasets. H. Zhang et al. [65] developed an action recognition method which combines the sparse coding with gradient information. In this approach, initially, the depth of gradient information and distance between the joints of the 3D skeleton are extracted to find the coarse depth-skeleton features. Next, the sparse coding and max pooling are

applied to finalize a coarse DS feature and fed to random decision forest classier to perform action recognition.

Vikas Tripathi et al. [66] proposed to use the random forest algorithm for human action recognition after extracting a novel feature descriptor based on two algorithms They are distance mean histogram of gradient and segmented block of means image with normalization. The performance evaluation is accomplished over two standard benchmark datasets and they are ATM and HMDB.

3.2.2Deep Learning classifiers

In recent years, the application of deep learning to computer vision applications has gained more importance due to its deep studying strategy. In the human action recognition also, various deep learning strategies are developed by researchers. Based on the deep learning network structure applied for action recognition, the earlier developed approaches are formulated into three different types and they are 2D convolutional networks (2D-CNNs) [69, 72] based, and 3D convolutional networks (3D-CNNs) [68] based approaches. In the 2D CNNs based HAR approaches, both the image and its optical flow information are trained to the network in the training phase and at the output, the fusion process is applied at the output layer. The 2D CNN follows 2D image convolution while 3D CNN follows 3D convolution which is the major difference between these two methods.

3.2.2.1 2D CNNs

C. Feichtenhofer et al. [70] proposed a new ConvNet architecture for spatiotemporal fusion of video action recognition. This approach has the following modifications compared to the tradition ConvNet. 1. Fusion is accomplished at spatial and temporal network instead of a softmax layer. 2. Spatial fusion is done at the last layer. 3. Pooling is done over Spatio-temporal neighborhoods. Simulation experiments are conducted over two standard datasets such as UCF101 and HMDB51. Next, Limin Wang et al. [71]proposed a new ConvNet architecture based on the long-range temporal structure modeling, called “temporal segment network (TSN)”. This approach combined the video-level supervision and sparse temporal sampling strategy to provide efficient learning to the network with an entire action video. This approach is effective even with few learning samples. Simulation experiments are conducted over two standard datasets such as UCF101 and HMDB51.

B Zhou et al. [73] developed a new “Temporal Relation Network (TRN)” into the CNNs for HAR. TRN is an effective and interpretable network module which was intended to learn and reason about the temporal dependencies between frames of a video. Further, the TRN is simulated over three recent video datasets; they are something-Something [74], Jester [75] and Charades [76]. Further, C. B. Jin et al. [77] proposed a hierarchical CNN model for real-time HAR based on the temporal images. Under the hierarchical model, this model has three CNN layers, namely, posture layer, motion layer, and action layer. Simulation experiments are conducted over the “Imperial Computer Vision and Learning Lab (ICVL)” action dataset [78] over the standing, walking, nothing, and texting action sequences.

3.2.2.2 3D CNNs

Shuiwang Ji et al. [79] developed 3D CNN model for HAR. In this approach, the features are extracted from both temporal and spatial dimensions by applying 3D convolutions such that more encoded information can be acquired from adjacent frames of a video sequence. Initially, the multi-channel information is acquired from all the frames and then the final feature is obtained by combining the information from all the channels. Simulation experiments are conducted over TREC Video Retrieval Evaluation(TRECVID) 2008 dataset [80]. Later Du Tran et al. [81] developeda novel Spatio-temporal feature-based learning approach using 3D CNNs. In this approach, the learned features, namely C3D (convolutional 3D) with a simple linear classifier is far better than the conventional 2D CNNs. Further to check the performance, totally three datasets are used and they are UCF101, ASLAN dataset [84], YUPENN [82] and Maryland [83]. Further, J.Arun Nehru et al. [85] considered the 3D motion cuboid features for action recognition through 3D convolution neural networks. Simulation experiments are conducted over a standard Weizmann and KTH datasets.

3.3 Results and Discussion

From the above discussion, we can understand that the approaches proposed based on deep learning are more effective compared to the handcrafted feature-based approaches. Though they offer a superior performance, some issues exist, particularly the fusion of multi-modal data in the deep learning architecture.Most of the deep learning approaches focused on the fusion of multi-modal data and thereby realizing the concept of deep learning. For any system, the deep knowledge will be acquired when it has all possible information. For example, the skeleton data of an action explores only the skeletal information. Next, the statistical measures explore only the rotational and translational variations in the action data, and the RGB data explores only the multi-channel information with respect to three channels in the RGB action video. Compared to individual features, a combined feature gives more detailed information and helps very much in the accurate recognition of an action. The main problem assisted with the feature fusion in the computational complexity. Furthermore, an effective combination of multimodal data such as skeleton data, depth data, optical flow, and RGB data still remains an open issue for human action recognition. This issue gives better direction of research in the field of HAR.

A graph is provided in Fig.1, wi20th two parameters such as methodologies accommodated and the accuracy obtained with the datasets.

$$\boldsymbol{F-score}= ((2 * P * R))/(P + R)$$

$$\boldsymbol{Precision} = \frac{No.of\ instances\ of\ correct\ positive\ recognition}{Total\ No.of\ positive\ recognition}$$

$$\boldsymbol{Recall} = \frac{No.of\ instances\ of\ positive\ recognition\ found}{Total\ No.of\ relevant\ input\ instances}$$

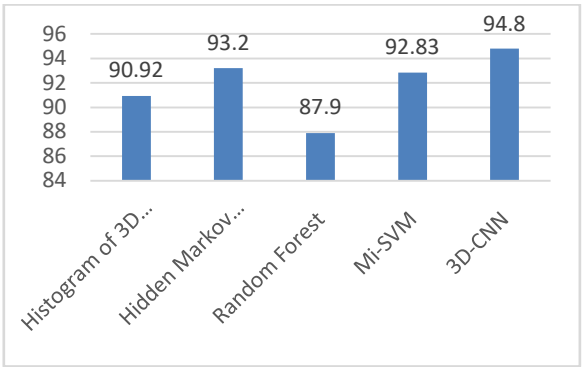

Fig.1 Accuracy of various Algorithms

IV. CONCLUSION

In this paper, a detailed and comprehensive survey is carried out over various human action recognition techniques. Initially, an introduction to HAR is explored and in that the need for human action recognition is illustrated. Further detailed information is provided about various datasets. Further, a detailed survey is described and the complete description is done under two phases, one is the survey over various feature extraction techniques and the other is on various action classification techniques. Under the feature extraction techniques, this paper reviewed the local features, depth, and skeleton features. Next, under the action classification techniques, this paper reviewed traditional classifications techniques and also the deep learning strategies. Further, a fine-grained analysis is accomplished over the deep learning approaches with respect to the convolution dimension. Based on the review explored, this paper makes the following conclusions.

1. To perform effective human action recognition, first, the feature extraction must be more effective. Since a system with more detailed information can only recognizes the action even under occlusions, noisy and complex backgrounds. For this purpose, the feature fusion will get priority and need an effective combination.
2. Though the feature fusion gives more prominent results in action recognition, there will be an excessive computational complexity at the classifier. Definitely, the complexity is more for an HAR system which analyzes the data in multiple views than the HAR system which analyzes the data in only one point of view. This can be compensated by an effective classifier design which is also more important in the HAR system.

ABSTRACT

Human Action Recognition has become the most significant research area for several applications like robotics, healthcare, gaming, smart houses, etc. However, in computer vision, action recognition from videos is one of the most challenging issues, due to some extraneous aspects like Occlusions, backgrounds, noises and so on. One solution to overcome the above-mentioned problems is acquiring only motion and shape cues form depth action video sequences. With this objective, in this paper, a new action representation approach is proposed based on Depth Motion Map (DMM), called as Difference Depth Motion Map (D^{2}MM). Next, a well-designed CNN is trained especially to extract the features from two actions with a similar structure. The CNN model introduced in this paper involves five convolutional layers, three pooling layers, and one fully connected layer. The experimental results of the proposed method are compared with conventional methods on the publicly available dataset, MSR Action 3D. The comparative analysis proves that the proposed approach outperforms the state-of-art techniques.

I. INTRODUCTION

In recent yeas, with the rapid growth in the technology (e.g. machines and computers) and its utilization in our activities of day-to-day life, Human-Computer Interaction (HCI) facilitation has developed as one of the most prominent research aspects. Henceforth there has been an increased focus by several research studies to construct or develop a new interaction model to meet this objective. The final and ultimate objective of this mechanism is to fill up the HCI gap such that the interaction should be like Human to Human. Among several potential applications of HCI, Human Action Recognition (HAR) based on computer vision has gained a more significance. The main aim of HAR is to understand the enduring human actions which have certain contextual importance. These actions may comprise the whole body movements or only specific portions of the body like Hands, Legs, head or arms, etc., contingent to the application requirement. Computer Vision centered HAR is more powerful, friendly, natural, and less harm to interactive, especially in the environments like where there is no possibility of physical contact and/or speech. The HAR has widespread applications starting from surveillance events understanding for public safety [1], entertainment [2], Robotics [3] and many other applications [4]. Hence, HAR has gained much consideration from both academic and industrial applications.

Copyright ⓒ 2019 SERSC

However, recognizing human actions in color images is a challenging issue due to various problems such as illumination variations, complex backgrounds, and clothing color, which makes the segmentation of human body much difficult in every scene. Especially, the color images won't have depth clues about the motion of a body which has a significant effect on action recognition. Due to the development of Microsoft Kinetic Sensors, the recent HAR studies are able to acquire the RGB-D image with uniform depth and color information and also illumination invariant that makes the recognition system robust to all human actions.

Recently HAR has been directed towards the utilization of depth maps due to their expressive and rich features provision [5]. The key to successful action recognition lies in the action representation such that they can provide discriminative features of each action for classification. Depth cues can provide a greater structural features of an action scene which are more sensitive to skin color, clothes and illumination variations. Even though extensive research has been carried out in this context [6], still there exists some ambiguity for some actions which leads to wrong classification, because, some depth frames include external effects like noises, cluttered scene backgrounds, occlusions, shadow backgrounds and small body shaking movements, etc. A better approach for depth sequence-based action recognition should provide a more clear depth map which is resilient to all these problems.

Regardless of data used for action representation, feature extraction and classification both play a vital role in the HAR. Basically, the handcrafted feature extraction approaches [7, 8] applied Support Vector Machine (SVM) classifier. However, in recent years, Convolutional Neural Networks (CNNs) have gained more popularity, have gained a huge success rate in the classification of images [9]. CNN is a powerful method and it is more effective at feature extraction as well as at classification, it can learn the discriminate features automatically from training data.

In this paper, a new HAR model is developed from depth maps and CNNs. An enhanced version of Depth Motion Map (DMM), called Difference Depth Motion Map (D^2MM) is developed in this paper which makes the action representation more resilient to external effects like noises, ghost shadow backgrounds and small body shaking movements. Next, a well-designed CNN is trained especially to extract the features from two actions with a similar structure. The action recognition introduced in this paper involves five convolutional layers, three pooling layers, and one fully connected layer. The experimental results of the proposed recognition model are compared with conventional methods on the publicly available dataset, "MSR Action 3D". The comparative analysis proves that the developed framework outperforms the earlier developed techniques.

Remaining paper is organized as follows; Section II summaries the related work details. After that, the complete details of the proposed HAR model is explained in section III. Further section IV explains the details of experimental results. Finally, the concluding remarks and future directions are represented in section V.

1. Depth based Action recognition

With the advancement in the development of low-cost depth sensors and due to the capability of fetching the depth data, the researches have gained an increased research interest over depth images and diverted from RGB images. Several action recognition models are constructed by considering the depth data from action videos. This section outlines several models based on two aspects: handcrafted and deep learning approaches. A detailed and summarized surey over these methods is described in [10-12].

A. Handcrafted methods:

In earlier, several methods are proposed by considering the depth action sequences as an action representators. Initially, Yang et al. [13] projected the depth maps onto three orthogonal planes and accumulate the global activity through the entire video sequence to obtain the DMM. Then "Histogram of Oriented Gradients (HOGs)" are generated through these DMMs for action representation. Next Wang et al. [14] focused on the characterization of human motion and Human to object interactions and extracts a novel feature set that is suitable to depth data which are robust to temporal and translational misalignments, and noise variations. Further, to capture the intra-class variability, an action let ensemble models learned. However, these approaches are failed to acquire complex motion sahpes of joints at pixel-level.

To overcome this problem, O Omar et al. [7] developed a new descriptor through the histograms which can capture the features like spatial coordinates, depth, and time in 4D space, distributed over the orientations of different surface normals. To obtain this histogram, the 4D projectors are created at first for quantization of 4D space and then focused over the representation of possible 4D normal directions. Next, a "Super Normal Vector (SNV)" [8] is constructed through the low-level polynomials, obtained through the grouping of huper surface normal in depth sequence. Finally these SNVs are fed to the action recognition model. A. W. Vieira et al. [15] proposed a new descriptor called "Space-Time Occupancy Pattern (STOP)". In STOP, the depth action sequences are described through 4D grids and it is achieved through the segmentation of space-time axis. This approach preserves both the temporal and spatial contextual data which is being flexible to accommodate the intra-class variations. To increase the robustness, another 4D descriptor, called Random Occupancy Pattern (ROP) proposed by J. Wang et al. [16] which deals with occlusions and noise combined with sparse coding methods.

With an inspiration of the success of Spatio-Temporal Interest Points (STIPs) in RGB videos based on HAR, Xia L and Agarwal J [17] proposed a new filtering method called DSTIP to extract the STIPs through which the noise is suppressed. Further, a novel feature called, "Depth Cuboid Similarity Feature (DCSF)" to represent the depth of the local 3D cuboid located around the DSTIPs with an appropriate size. Further, Lu et al. [18] modeled a new features set based on the binary range samples that can remove the complex occlusions and cluttered background to acquire the motion and body shape in the depth image sequences. Next, Chen at al. [19] used "Local Binary Patterns (LBPs)" to acquire a compact feature representation from Depth Motion Maps at multiple views such as front, side and upper. Once the features are extracted all three LPBs are merged and formed into a

Copyright ⓒ 2019 SERSC

composite feature vector and then fed to a classifier. At the classification level, a soft-decision assisted fusion rule is applied to merge the outputs of classifiers.

Action recognition from multiple views has gained an appreciable performance when compared to the action recognition based on a single view. In the method proposed by D. Kim et al. [20], initially the front view depth action image is processed for side view generation. Next, the both side and front views of action iamge are into two descriptors, namely "Depth Motion Appearance (DMA)" and "Depth Motion History (DMH)". SVM classifier is accomplished here for action classification. Another approach based on multi-view projection is proposed by Chen at al. [21] in which the initial projection of the original depth actionimage is accomplished over three Cartesian planes. Next, the DMM is obtained by the accumulation of absolute difference between two successive depth maps. Depth maps can also be generating at the segment level in which the depth action sequnces are fragmented into a set of several segments with overlapping. Based on this concept, a new method is developed by Chen et al. [22] in which the depth action sequence is segmented into temporally overlapping segments and then they are used to generate DMMs. Next, the DMMs are LBPs are exploited over the DMMs after the partition into dense patched to characterize the local texture information which has rotation invariance. Finally, the patch descriptors are encoded through fisher kernel and then fed to a kernel-based "Extreme Learning Machine (ELM)" algorithm for classification.

B. Deep Learning Methods

CNN [23] is the most prevailing mechanism for extracting the features and also for classification. Recent HAR methods focused on CNN for classifying action rather than the machine learning algorithms like SVM, Decision tree etc. A summarized advance of CNN in terms of weight initializations, loss functions, activation functions, optimization, and regularization is described in [24]. CNN's use of trainable filters and neighborhood polling process to attain a feature hierarchy of complex actions. CNN can extract the features those are invariant to lighting, pose, and neighboring clutter [25]. Moreover, the CNN's has an excellent performance in the recognition if they are trained through a perfect regularization [26, 27]. Several authors are focused over the development of deep learning assisited HAR system [28].

So many HAR [29] approaches are proposed based on CNN, some applied CNN to extract the features and some applied for classification and some more approaches utilized CNN for both. L Cai et al. [30] developed a new method for HAR based on the DMM and improved CNN. In this approach, initially the depth motion maps are projected into the front, side and top view and then features are extracted. Based on this aspect, an enhanced CNN model is developed to realize the HAR. Next, Xu Ran Zhao et al. [31] introduced a novel "Spatio-Temporal Conditional Random Field (STCRF)" [32] into Deep CNN (DCNN) to apply the temporal uniformity among the depth maps of successive frames of action video. A temporal consistent superpixel (TSP) is initialized to establish a correspondence target in successive frames. Then the DCNN is applied to relapse the depth value of each TSP monitored by STCRF to construct the relationship of estimated depths.

III. PROPOSED APPROACH

1. Overview

The framework of the proposed Human action recognition method is depicted in figure 1. In this method, the depth maps are used for human action representation and CNNS are used for feature extraction and classification. An enhanced version of Depth Motion Map (DMM), called as Difference Depth Motion Map (D^2MM) is developed in this work to make the recognition system resilient to extra side effects like noises, background occlusions and shaking body movements. After representing the human action with D^2MM, CNN is applied for feature extraction followed by classification. Due to the extraordinary benefits of CNN in extracting the features from an image, no other mechanism is deployed for feature extraction. CNN extracts more significant and discriminative features form an image, hence this work not focused on feature extraction phase separately. The details of action representation through D^2MM and CNN are explored in the subsequent subsections.

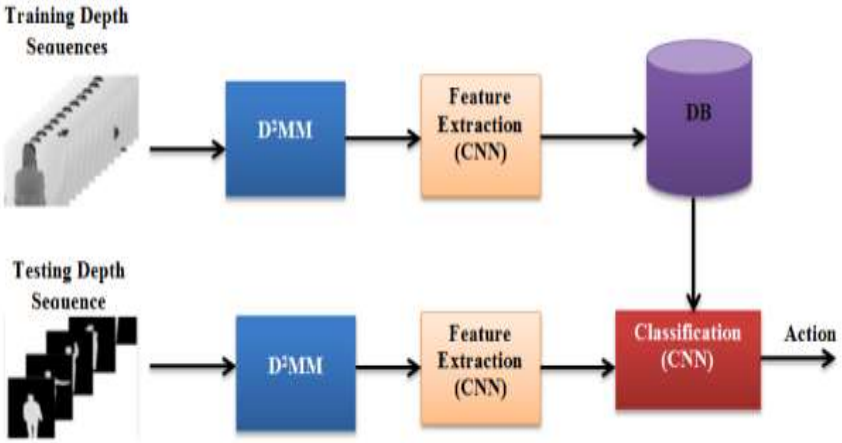

Figure 1 : Block diagram of the proposed recognition model

2. D^2MM

DMM is initially introduced by Yang et al. [13], which exploits the motion information from a depth sequence. DMM gives a visual perception of human activity and it is generated by the accumulation of motion energy throughout the entire depth sequence. Depth maps contain additional depth coordinates along with Cartesian coordinates which are generally provided by color images. Due to the presence of additional depth coordinates, depth maps are more informative than the normal color images. DMM based action representation transforms the action recognition issue from 3D to 2D and then applies for HAR. Particularly, the DMMs are constructed by the accumulation of energy after projecting the depth frames over an orthogonal Cartesian plane. Basically, the main intention of DMM is to signify the shape and motion of an action. The DMMs obtained at various levels are represented in figure 2.

Copyright ⓒ 2019 SERSC

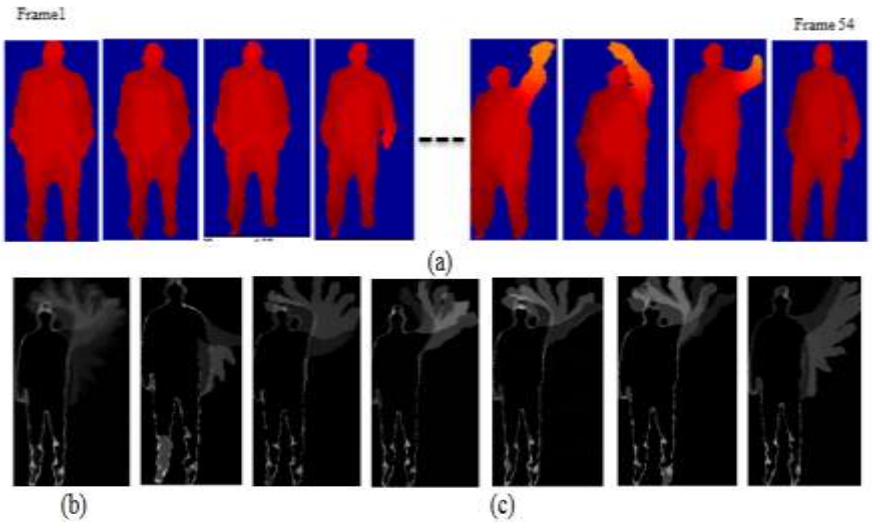

Figure 2 : DMMs representation (a) Depth action Sequence, High Wave, DMMs obtained through (b) 54 frames, (c) 1-9, 10-18, 19-27, 28-36, 37-45, and 46-54 subset of frames

Figure 2a shows a depth action sequence having high wave action, figure 2b shows the DMM obtained after considering the entire action sequence and figure 2c shows the different DMMs obtained after considering six different subsets of depth frames (e.g. frames 1-9, 10-18, 19-27, 28-36, 37-45, and 46-54 subset of frames) in the same action sequence. From figure 2c, we can observe that the defined action of hand waving is clearer than the DMM shown in figure 2b, i.e., the main shape and motion of action part is clearly visible in DMMs generated through subsets than the DMMs generated through the complete set of depth frames. Hence, the DMMs are generally generated through only the subsets of frames.

The concept of DMM considered by Yang et al. [13] is based on the threshold difference due to which there is a probability of information loss. Unlike the threshold-based DMM generation, Chen Liu et al. [21] evaluated the DMM based on the accumulation of motion energy of the absolute difference between consecutive frames. This method preserves the motion information more effectively and hence our method also considered it as a base for DMM evaluation. According to Chen Liu et al. [21], the DMM evaluation is formulated as follows;

$$DMM = \sum_{t=0}^{N-2} |D(i,j,t) - D(i,j,t-1)| \qquad (1)$$

Where D(i,j,t) is a pixel value at the position (i,j) of a depth frame at the instant of *t* and D(i,j,t-1) is a pixel value at the position (i,j) of a depth frame at the instant of *t-1*, where *t* varies from 0 to N-1.

DMM can acquire the shape and motion cues of a depth action image more effectively, results in a discriminative map that gives more discrimination between different actions. This discrimination is provided through the spatial distribution of energy. However, due to unstoppable reflection of depth cameras and low-resolution cameras, the depth data acquired in the depth sequence come with unnoticeable noises, resulting in a video with less quality and undefined energy regions in DMM.

Copyright ⓒ 2019 SERSC

Furthermore, there exist some regions which won't exist in some frames and exists in some other frames. Ghost shadows are better examples of this type of region which can appear in only some frames. These shadows result in undefined depth values. Along with these problems, the insignificant or small shaking movements of body occured in the successive frames may also introduce some narrow and unnecessary moving edges to the DMM. These narrow and unnecessary edges has a severe effect on the body size and there is no much use with these edges. Further, the narrow edges do not provide any significant information which helps in the provision of perfect discrimination between different actions. Several image processing techniques like mathematical morphology [33] and median filtering techniques are applied to overcome the above-specified constraints like noises, ghost shadows and small body shaking movements. However, these techniques result in a loss of original motion information contained in DMM. Hence in this model, we introduced a new version of DMM, called D^2MM based on weighted motion score (WMS) to remove the above problems. For this purpose, initially a binary motion image is constructed by comparing the pixels at same positions of different frames, as

$$B_M(i,j,t) = \begin{cases} 1, & if\ D(i,j,t) \neq D(i,j,t-1) \\ 0, & Otherwise \end{cases} \quad (2)$$

Where B_M is a binary motion image. Next, based on the binary motion image and applying a sliding window over it, the Weighted Motion Score $W_M(i,j,t)$ is evaluated for every pixel, as

$$W_M(i,j,t) = \frac{1}{(w+1)^2} \sum_{i=x-(w/2)}^{x+(w/2)} \sum_{j=y-(w/2)}^{y+(w/2)} B_M(i,j,t) \quad (3)$$

The size of the sliding window is considered as $(w+1) \times (w+1)$, where w is the height and width of sliding window. In the present paper, we set the height and width of the sliding window as 8, i.e., $w = 8$. Next, based on the obtained WMS, the difference map, $D_M(i,j,t)$ is constructed as follows;

$$D_M(i,j,t) = \begin{cases} |D(i,j,t) - D(i,j,t-1)|, & if\ W_M(i,j,t) > T_M \\ 0, & Otherwise \end{cases} \quad (4)$$

Where T_M is the threshold of WMS and in our experiments, it is set as 0.6, i.e., $T_M = 0.6$. From difference map, we can notice that the pixels are considered as noisy when the WMS of the respective pixel is lower than the threshold T_M. Finally, based on the obtained difference map, the D^2MM is constructed as

$$D^2MM = \sum_{t=0}^{N-2} D_M(i,j,t) \quad (5)$$

Figure 3 shows the example of a two depth maps of a single action generated through DMM and *D^2MM*. From these observations, we can notice that the depth map obtained through *D^2MM* has more visual-spatial energy distribution than the depth map obtained through DMM.

C. Convolutional Neural Networks Model

With an enormous growth in the development of powerful hardware like "Graphical Processing Units (GPU)" and Deep learning, "Deep Neural Networks (DNNs)", especially CNNs [34] have gained more and more popularity in human action recognition. The main advantage of the CNNs is their capability to represt the image through rich mid-level features, which is the main drawback of conventional handcrafted representations. Hence this paper accomplished the CNN to extract the required features as well as to classify the action.

Once Human action representation is completed through D^2MM, the next step is feature extraction and using them for recognizing human action. In this model, after representing the human action with D^2MM, then it is resized to 112X112 and processed as input to the proposed new CNN architecture. The CNN architecture is comprised of convolutional layers and pooling layers. Generally, the convolutional layers are accomplished for feature extraction and pooling layers are accomplished for dimensionality reduction. This model is composed of totally five convolutional layers and three max-pooling layers. The architecture of the proposed CNN model is depicted in the following figure 4.

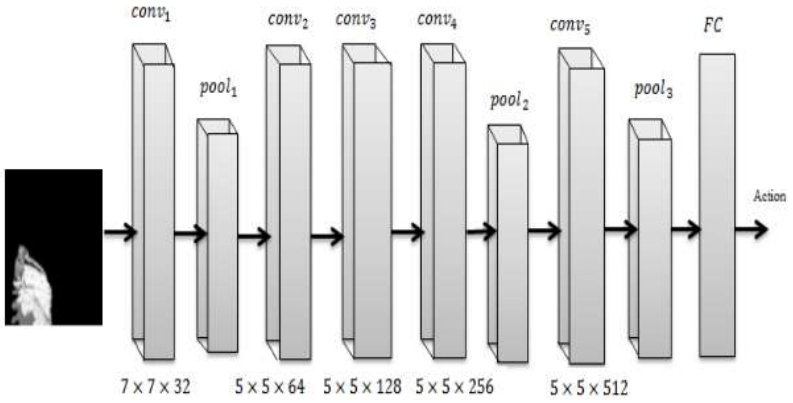

Figure 4 : proposed CNN model for HAR

Copyright ⓒ 2019 SERSC

In the proposed model, the first convolutional layer ($Conv_1$) used 32 convolutional filters and the size of each filter is 7X7. The next three convolutional layers such as ($Conv_2$), ($Conv_3$), and ($Conv_4$) used 64, 128, and 256 convolutional filters and the size of each convolutional filter is 5X5. The last convolutional layer ($Conv_5$) used 512 convolutional filters and the size of each filter is 3X3. A Rectifier Linear Unit (ReLu) follows every convolutional layer and it is an activation function to increase the non-linearity. Next, the proposed model uses three max-pooling layers. At every max-pooling layer, the stride is considered as 2. Finally, a Fully Connected Layer (FCL) with the size equal to the total number of actions is considered and it is the final stage of feature extraction. During the training process, a "Multi-Nominal Logistic Loss Function" is accomplished along with a "Gradient Descent" method to update the weights. The following table.1 shows the details of parameters and their values considered at convolutional layers and pooling layers.

Layer	Filter Size	Stride	Pad
$Conv_1$		2×2	0
$Pool_1$	-	2×2	-
$Conv_2$	5×5	1×1	0
$Conv_3$	5×5	1×1	0
$Conv_4$	5×5	1×1	0
$Pool_2$	-	2×2	-
$Conv_5$	3×3	2×2	0
$Pool_3$	-	2×2	-

Table 1 : CNN structures

As explained above, this model considered the filter size as 7X7 at convolutional layer 1 and it was gradually decreased to 3X3. The textures extracted through depth maps of two different action images make it difficult to obtain more discriminative and distinct features when a filter with a small size is applied over the images. Let's consider two different action images. If we apply a filter of size 3X3 over them, the involved outputs may not differ much from each other. Because at the very beginning the two images may have similar features, which is the main reason behind the consideration of a 7X7 sized filter at the first convolutional layer, $Conv_1$. Generally, the last layer of CNN, i.e., fully connected layer ends with 1 or 2 fully connected layers before the last phase of the classification layer. However, based on the experiments conducted at training phase, we discovered that one FCL is enough. The final FCL is applied over the output of the third max-pooling layer and it can preserve all significant features and also can generate better classification results. Further, at the testing, the soft-max regression is accomplished to obtain a score for every action class depends on the trained weights in the training phase. Further, the class label is determined based on the higher score obtained at the soft-max regression layer.

IV. SIMULATION EXPERIMENTS

In this section, we comprehensively evaluated our developed action recognition system on a publicly available benchmark data set, MSR Action 3D dataset [35]. We employ MATLAB software

Copyright ⓒ 2019 SERSC

for the simulation of the proposed approach. This data set provides depth map data that are suitable to construct the difference depth motion maps. In this section initially, the details of the "MSR Action 3D dataset" are explored. Next, the obtained simulation results are described. Finally, a comparative analysis is described between the proposed and conventional approaches through the obtained results.

A. MSR Action 3D dataset

The "Microsoft Research (MSR) action 3D dataset" is an action dataset constructed through 20 different actions such as forward kick, side kick, jogging, throw, pick up, tennis serve, golf-swing, high arm wave, hammer, draw X, forward punch, draw circle, two hand wave, draw tick, side boxing, bend, hand clap, high throw, hand catch, horizontal arm wave. Every action is performed by ten actors and totally three times. This is a very challenging dataset which has a lot of speed variations and also the actions have more similarities. A single viewing point is only used at which the actions are faced with a frontal view with the camera while capturing. Similar to [14], the subjects with odd numbers such as 1, 3, 5, 7, and 9 are used for training and the subjects with even numbers such as 2, 4, 6, 8, and 10 are used for testing. Some depth action sequences of this dataset are shown in figure 5.

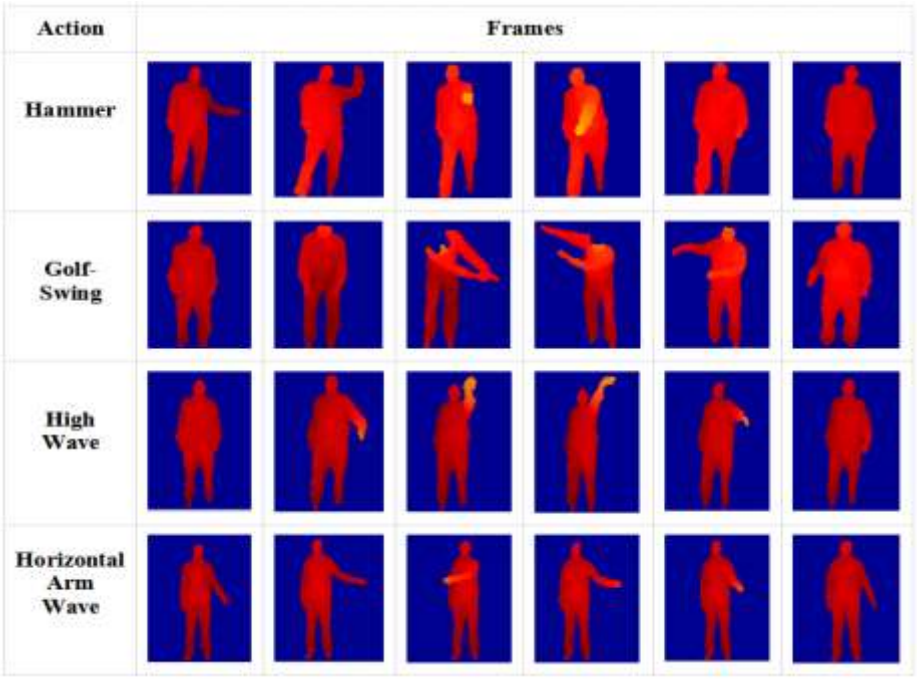

Figure 5 : some action samples of MSR Action 3D dataset

B. Results

In this paper, several performance metrics such as "True Positive Rate (TPR) Or recall, Precision or Positive Predictive Value (PPV), F-Score, False Negative Rate (FNR), False Discovery Rate (FDR)" and "Accuracy" are considered to evaluate the performance of proposed approach. After testing different actions, the obtained results are formulated into a confusion matrix. Depends on the obtained classification results, "True Positives (TPs), True Negatives (TNs), False Positives (FPs), and False Negatives (FNs)" are measured. Based on the obtained TP, TN, FP and FN values from the confusion matrix, accuracy is evaluated and the respective mathematical representation is given as;

$$TPR = \frac{TP}{TP+FN} \quad (6)$$

$$PPV = \frac{TP}{TP+FP} \quad (7)$$

$$F-Score = \frac{2 \times TPR \times PPV}{TPR+PPV} \quad (8)$$

$$FNR = \frac{FN}{TP+FN} \quad (9)$$

$$FDR = \frac{FP}{TP+FP} \quad (10)$$

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (11)$$

Here totally 20 actions are considered for every actor. After the simulation of different action sequences through the proposed approach, the obtained results are represented as below.

Action/Metric	TPR (%)	PPV (%)	F-Score (%)	FNR (%)	FDR (%)
High Arm Wave	85.2312	100.00	92.0268	14.7688	0000
Horizontal Arm Wave	94.1147	85.7145	89.7184	5.8853	14.2855
Hammer	100.00	100.00	100.00	0000	0000
Hand Catch	78.4745	90.1245	83.8970	21.5255	9.8755
Forward Punch	88.4574	100.00	93.8752	11.5426	0000
High Throw	95.4127	91.6784	93.5082	4.5873	8.3216
Draw Cross	82.4789	93.1247	87.4791	17.5211	6.8753
Draw Tick	94.6696	88.2475	91.3458	5.3304	11.7525
Draw Circle	94.8675	100.00	97.3661	5.1324	0000
Hand Clap	95.7845	86.4789	90.8941	4.2155	13.5211
Two-Hand Wave	100.00	100.00	100.00	0000	0000
Side-boxing	100.00	100.00	100.00	0000	0000
Bend	86.4400	89.4217	87.9055	13.5600	10.5783
Forward Kick	100.00	96.3147	98.1227	0000	3.6853
Side Kick	100.00	100.00	100.00	0000	0000
Jogging	100.00	100.00	100.00	0000	0000
Tennis Swing	94.7189	88.2451	91.3674	5.2811	11.7549
Tennis Serve	94.4578	90.6638	92.5219	5.5421	9.3362
Golf Swing	92.3147	96.7845	94.4967	7.6853	3.2155
Pick Up & Throw	90.7845	100.00	95.1696	9.2155	0000

Table 2 : Performance Metrics for different actions

Table 2 shows the details of performance metrics evaluated after testing all types of actions. The first measure, TPR measures the total number of true positives for a given total number of inputs. For example, let's consider the High Arm wave action, the TPR is measured as the ratio of total number of High Arm Wave action frames detected as walking to the total number of High Arm Wave action frames given as input for testing process. In this case, the TP is the total number of High Arm Wave action frames classified correctly and FN is the total number of High Arm Wave action frames classified incorrectly. This process is applied for all the remaining actions also and the respective TPRs are measured. From table 2 it can be noticed that the maximum TPR (100%) is obtained for a

Copyright ⓒ 2019 SERSC

total of six actions and they are Hammer, jogging, side kick, forwardkick, side-bxing, and Two-hand Wave. The minimum TPR is obtained for Hand Catch (78.4745%).

Next, the precision is measured as the ratio of TPs to the sum of TP and FP. In the above example of High Arm Wave action as input, the TP is the total High Arm wave action frames count those are classified correctly and FP is the total action frames count those are classified as High Arm wave when the input is not a High Arm wave action. In this case, the input is not required action but the output is required action. Next, the maximum PPV (100%) is obtained for a total of eight actions and they are two-hand wave, draw circle, forward punch, hammer, High Arm Wave, Side-boxing, Side Kick, and Pickup& Throw. The minimum PPV is obtained for Horizontal Arm Wave (85.7145%).

Next, the F-measure a simple harmonic mean of TPR and PPV. A higher value of F-score depicts the better performance and in this simulation, the maximum F-score (100%) is achieved for a total of five actions and they are Hammer, jogging, side kick, side boxing, and Two-Hand Wave. Further, the minimum F-score is obtained for Hand Catch (83.8970%).

The FNR is a measure which measures the total number of false negatives that are falsely classified. For example, if we had given a Hand catch action as an input and the system had shown it as Hand Clap, then it is counted as False Negative. The FNR is obtained by the accumulation of the total number of such False Negatives. A minimum value of FNR denotes better performance and during this simulation, we got minimum FNR (0%) for a total of six actions and they are Hammer, Jogging, side kick, forward kick, side boxing, and Two-hand Wave,. Further, the maximum FNR is obtained for an action Hand Catch (21.5255%).

Finally, the FDR is a measure which measures the total number of false positives that are falsely discovered. For a given input actual action, if the system had shown another action, then it is counted as False Positive, i.e., the total number of instances the action is falsely discovered. For example, if we had given a Hand catch action as an input and the system had shown it as Hand Clap, then it is counted as False Positives for Handclap action. The FDR is obtained by the accumulation of the total number of such False Positives. A minimum value of FDR denotes better performance and during this simulation, we got minimum FDR (0%) for totally eight actions and they are Two-hand wave, draw circle, forward punch, hammer, High Arm Wave, Side-boxing, Side Kick, and Pickup& Throw. Further, the maximum FDR is obtained for an action Horizontal Arm Wave (14.2855%).

Further, the simulation experiments are accomplished according to yang et al. [13] through three subsets. Under this simulation experiment, totally three types of experiments are conducted by dividing the entire action set into three different subsets. Similar to [14], the subjects with odd numbers such as 1, 3, 5, 7, and 9 are used for training and the subjects with even numbers such as 2, 4, 6, 8, and 10 are used for testing. The three action sets are shown in Table 3. Here the simulation study is accomplished by varying the frame length and pixel shift and the obtained accuracy is shown in figure 6 and figure 7.

Subset 1	Subset 2	Subset 3
Hand Clap	Draw Circle	High Throw
Bend	Draw Cross	Golf-swing
Horizontal Arm wave	Side-boxing	Tennis Serve
Tennis Serve	Hand Catch	Pick-up & Throw
Forward punch	High Arm Wave	Jogging
Hammer	Draw Tick	Tennis Swing
High Throw	Forward Kick	Side Kick
Pick-up & Throw	Two-hand Wave	Forward Kick

Table 3 : Subsets of MSR Action 3D dataset

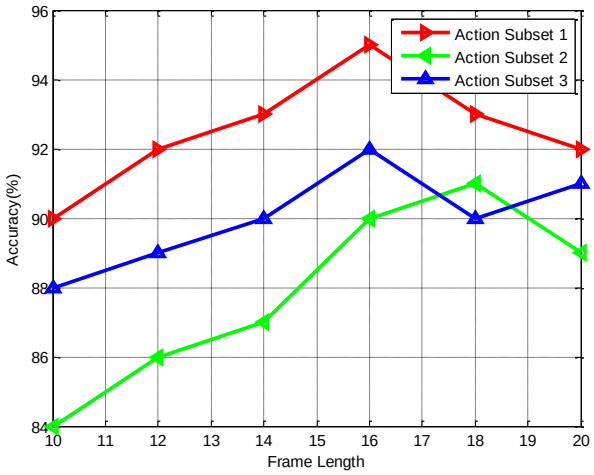

Figure 6 : Recognition Accuracy with varying frame length

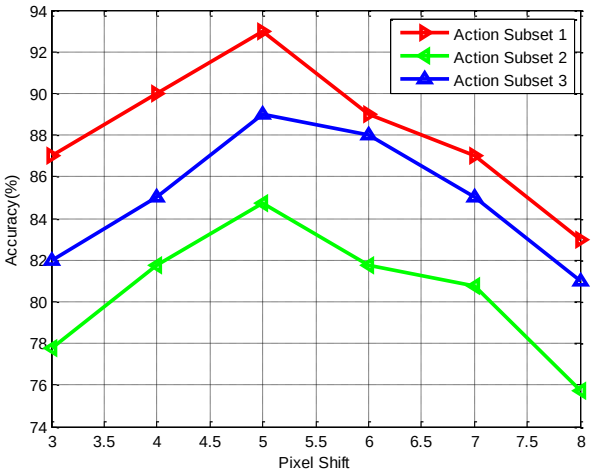

Figure 7 : Recognition accuracy with varying pixel shift

Figure 6 shows the details of recognition accuracies with varying frame length. From this figure, we can notice that as the frame length increases, the recognition accuracy also increases and

Copyright ⓒ 2019 SERSC

this increment is only up to a particular level. As can be seen, the accuracy is gradually increased up to frame length 16 and then onwards it is decreased. A smaller frame length results in less depth information by which the detection system can't recognize the perfect action present in that frame. Similarly, a larger frame length also results a more confusion to the detection system due to the excessive depth information. For instance, even in a single video, some actions are carried out multiple times and an increased frame length results in more confused depth information. Moreover, the accuracy of the actions considered under action subset 1 has higher values and the actions considered under action subset 2 are having fewer values. The main reason behind this problem is three similar actions in subset 2, they are Draw Tick, Draw Cross, and Draw Circle. These three actions have similar characteristics at initial frames and hence the detection system has gained less accuracy.

Figure 7 shows the details of recognition accuracies with varying pixel shift. From this figure, we can notice that as the pixel shift increases, the recognition accuracy also increases and this increment is only up to a particular level. As can be seen, the accuracy is gradually increased up to a pixel shift of 5 and then onwards it is decreased. Here the pixel shift is accomplished through the extraction of overlapping frames. After 5, the recognition accuracy is decreased because for a greater pixel shift the spatial correlations between pixels become weak and hence the obtained Depth Motion Map won't have effective feature through which the system can discriminate between different actions. Moreover, the obtained accuracy is high for actions under subset 1 and the accuracy is less for actons under subset 2.

C. Comparative analysis

In this section, we discuss the comparison of recognition accuracies between the proposed and conventional approaches such as DMM + HOG [13], Random Occupancy Patterns [16], HON4D [7] and DMA+DMH+HOG [20], Action + Ensemble [14], and DSTIP [17].

Method	Accuracy (%)
DMM + HOG [13]	85.52
Random Occupancy Patterns [16]	86.50
HON4D [7]	88.89
DMA+DMH+HOG [20]	90.45
Actionlet + Ensemble [14]	88.20
DSTIP [17]	89.30
D^2MM + CNN	**91.59**

Table 4 : Comparison of recognition accuracy

Table 4 represents the accuracy comparison of proposed and conventional approaches. It can be seen from the table 4, the accuracy of the proposed system is higher compared to the conventional approaches. The most nearby method for the proposed model is DMA+DMH+HOG [20] and it achieved an accuracy of 90.45%. However, in this approach, the DMM evaluation didn't consider the external effects like noises, Ghost Shadows and shaking body movements and hence the obtained DMM is not effective to recognize the action more accurately. By generating a binary motion image before DMM evaluation, the proposed model has gained resilience to all these side effects. Furthermore, the one more conventional approach, i.e., DMM + HOG [13] is a basic approach for

Copyright ⓒ 2019 SERSC

DMM based action recognition and in this method, the DMM is evaluated based on the thresholding by which the obtained DMM won't have significant information which is more helpful in the action recognition. The main drawback of this approach is information loss due to thresholding. Though the DSTIP method suppresses the noises effectively, they can't capture the small body shaking movement sin depth action sequences.

V. CONCLUSION AND FUTURE SCOPE

In this paper, we have presented a Difference based Depth Motion Map which can nullify the external effects present in the Depth Action Video Sequences. The inclusion of difference map helps in the reduction of unnecessary constraints like shadows, small body movements and represents only action movements with high precision. This approach copes up with shape and motion cues for all types of actions. Further, the new CNN model helps in the extraction of more significant and distinct features of every action. The proposed model is extensively simulated over a standard benchmark dataset. The experimental results show that the developed method outperforms the conventional approaches after evaluating it over the standard "MSR Action 3D dataset". Moreover, the additional simulation experiments on the "MSR Action 3D dataset" confirm that the proposed HAR model can handle depth sequences that contain different frames and pixel shifts. With the implementation of five-layered CNN, our method can classify real-time actions also with more accuracy.

In the standard MSR Action 3D dataset, Skelton based action sequences are also available which also represents human actions. The main advantage with Skelton model is a reduced computational burden. Even with fewer features, the Skelton based actions can represent a human action more effectively which helps in the accurate recognition of human action. Hence, the further work of this paper is intended to apply the new CNN model with Skelton joint based motion action descriptors.

Designing a Deep Neural Networks Structure to Acquire the Top Level Depiction of Human Interactions

S. Sandhya Rani, G. Appa Rao Naidu, V. Usha Shree

Abstract:*The latest research studies have really concentrated on slim complications including individual action recognition approaches utilizing depth information, 3D-skeleton information, still photo applicable info, spatiotemporal interest point-based approaches, and also human strolling proposition recognition Nevertheless, there has actually really been no methodical research study of individual action recognition. We present the scene context features that describe the atmosphere of the topic worldwide and also local levels. We design a deep neural network structure to acquire the top-level depiction of human activity combining both activity attributes as well as context features.*

Index Terms: *Deep learning, human recognition, context features*

I. INTRODUCTION

The crucial to terrific human action awareness is durable individual activity modeling and attribute depiction. Attribute depiction and selection is a classic complication in computer system vision in addition to artificial intelligence. Unlike feature representation in a photographed space, the quality portrayal of human activity in the online video not merely describes the appeal of the human(s) in the imaging room, however, need to also draw out changes in appeal and also setting. The problem of feature portrayal is actually extended from two-dimensional space to three-dimensional fourth dimension. Over the last couple of years, numerous sort of action depiction methods have been recommended, consisting of the neighborhood and also international features based upon temporal and also spatial modifications, trajectory functions based upon key point tracking, activity modifications based upon depth information, and also action attributes based upon human present adjustments. With the effective application of deep knowledge to photo category as well as also thing detection, various scientists have really also applied deeper knowing to human activity identification. This allows activity features to be quickly picked up from video data. In addition, some researches have evaluated these action recognition strategies. Nonetheless, these evaluation articles have actually only talked about particular aspects, for instance, spatial-temporal fascinating factor (STIP)- located human activity identification methods, human walking examination strategies, in addition to deeper understanding based techniques. Bunches of brand-new techniques have merely lately been established, especially concerning the use of deepness understanding moves toward to include knowing. Subsequently, thorough research of these new individual activity acknowledgment techniques is actually of substantial passion.

In this particular job, we sum up a number of current tasks and also show a brand-new questionnaire of research study on human activity acknowledgment techniques being composed of activity distinction (focusing especially on the activity depiction strategies of activity category), human-- object communication recognition, and action discovery techniques. The action classification methods are summed up into techniques based on handcrafted attributes and also those based on attribute understanding. These approaches can be put on different kinds of data.

From an information point of view, many assessments of individual action acknowledgment are confined to techniques based upon specific records, like RGB data, deepness information, or even emaciated body info. A lot of those jobs pay attention to human activity recognition in RGB video recording data. With the progression of intensity webcams, intensity records are actually currently commonly taken advantage of in great deals of personal computer vision duties, particularly the estimation of human positions to clear away human skeletal system info. Additionally, the latest investigation leads on individual invention and additionally position evaluation in RGB video clip show that deep learning-based techniques can attain efficient as well as precise multi human present evaluation in intricate scenes. Numerous human action recognition methods based upon depth series and skeletal system information have actually likewise been proposed. To a particular degree, these procedures have solved a few of the problems of individual activity recognition along with RGB electronic cameras and even video recording, in addition, to invite fact emphasized excellent appreciation efficiency. Functions on individual activity recognition tactics making use of strength as well as also skeletal system facts, that summed up human activity appreciation approaches utilizing magnitude pertinent info, that analyzed individual activity identification approaches located upon 3D unit information. Furthermore, [5] checked out human action acknowledgment techniques from still photographs. Although several of these evaluation quick articles cover details blend techniques, they still offer a slim summation of individual action awareness approaches toward particular kinds of relevant information. To address this concern, within this job, our company summarizes individual action acknowledgment strategies relevant to various forms of information in addition to entailing hand-crafted

feature-based along with feature uncovering approaches.

Another necessary facet of the disorder on human activity awareness research is actually that many look into focused on human activity functionality symbols. The refined image sequence data are normally well-segmented along with consist of simply one activity occasion. This after that becomes a distinct problem. Nonetheless, there are actually two crucial complications in the genuine situation: communication identification as well as activity exploration. Interaction describes actions that entail higher than 2 folks or actions in between individuals as well as also products, including carrying a blade or even playing equipment. Activity discovery explains finding the environment at which activity happens over time and place from picture sequence information that has actually certainly not been fractional. Over the last few years, interaction and also human activity discovery has actually come to be visible analysis study subjects. Regardless, there is actually no overarching summary of the approaches pertinent to these 2 troubles. To this side, the condition of research study on communication recognition as well as activity discovery is actually analyzed in this particular study.

Human activity acknowledgment researches comparable to our work have actually appeared in the latest opportunities. As an example, [4] provided an in-depth survey of human activity appreciation procedures set up coming from 2008 to 2012. Those specific action recognition approaches were actually divided right into 3 different degrees: private discovery (low-level objective), individual monitoring (intermediate-level vision), and also actions understanding strategies (top-notch idea). Furthermore, [3] capitalized on the very same technique, to sum up, activity verification methods coming from 2013 to 2016. [5] summarized existing compositions in the condition of 3 parts: sensing device modality, strong models, along with use. Having said that, as opposed to those works, we here different individual activity awareness right into action type and also action discovery. On top of that, both hand-crafted feature-based strategies and likewise deep learning-based strategies are actually gone over within this job. The research study very most similar to the here and now job which likewise sums up activity recognition techniques according to handmade feature-based methods as well as deep-seated learning-based techniques. Nevertheless, in our work, these 2 methods are actually further reviewed with a point to consider different details types. [7] talked about the typical procedures of individual action only, neglecting a survey of communication awareness as well as additional activity detection methods. Take note in addition that [6] performed a present research study of literature on action recognition in addition to action forecast; the last prepares for the potential condition of individual tasks located upon inadequate activity implementations.

To collocate along with one another previous polls along with fill the voids between all of them, our experts listed below supply a comprehensive research study of human activity recognition methods (view Figure1), being composed of activity feature representation techniques, interaction recognition techniques, and likewise action discovery strategies. To implement this research study, several types of research are evaluated in our job. When reading this paper, a necessary issue was the compositions option. Initially, a poll platform was put to extend the main effective approaches to human action awareness. The decided on works sought that picked up located upon appropriate key expressions, such as "activity acknowledgment", "activity feature portrayal", "interaction awareness", and also "activity breakthrough". Second, based upon the actually chosen literature, necessary works were actually included. Lastly, based upon the activity awareness dataset, further studies were helped incomplete this work. In our analysis study, most literary works were actually gathered from scholarly publications and appointments on pc vision. The articles released in vital diaries as well as likewise appointments like IEEE Transactions on Trend Assessment as well as Developer Intelligence Information Information, International Workshop on Pc Device Attitude and also Trend Understanding, IEEE International Abiding By on Personal Computer Perspective, to name a few, are going to certainly be liked. Subsequently, our team boosts upon these articles to gather a lot more essential jobs. The approval criteria of the literary works are high citations or excellent acknowledgment functionality.

All at once, to create our job cover even more various procedures, for similar procedures, our experts simply choose an essential or depictive technique for an in-depth conversation.

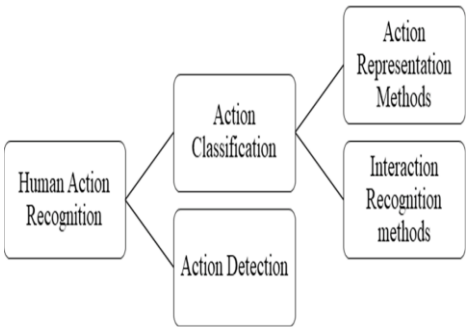

Figure 1. Classification framework

Due to the fact that deepness information is stable relative to adjustments in setting as well as an additional background, in addition, to permit difficulty to be actually rapidly segmented according to deepness, the request of deepness sensing units makes it possible for a real-time, robust human present estimate. Human action recognition techniques based upon deepness info as well as skeletal system series demonstrate high awareness preciseness and also lowered opportunity complications. These strategies are well-known in human action recognition study. Nevertheless, the accuracy, as well as cost of depth sensors, indicate that deepness- and likewise skeleton-based activity awareness methods are actually presently just necessary over marginal wide arrays and in particular environments. There are actually 3 kinds of typically utilized depth cams: triangulation (along with two camera scenery), time-of-flight (TOF) video cameras, and additionally structured-light-based digital video cameras. Structured-light as well as TOF-based depth-sensing units are conveniently effected by light, with big mistakes and also reduced precision in outside atmospheres. The price of the two-camera system is reduced, however, the deepness information estimation has higher intricacy as well as can not be applied in darker atmospheres.

Furthermore, there are other sensing units that can be utilized to assess deepness, including laser device scanning devices; having said that, these devices are costly as well as improper for video clip security and home track.
Unlike handcrafted action functions, deep learning methods carry out well when it comes to automatic feature discovering from pictures. This provides a new idea right in to individual action acknowledgment, and also numerous experts have really attempted to utilize deep discovering approaches to eliminate action features coming from RGB, acumen, and also skeletal system records Such data are applicable to multimodal functionality profiting from deep systems, like appearance/image particulars, visual flow set, depth sequences, in addition to skeleton patterns. Deep-seated learning networks can easily figure out human activity attributes from single-mode info or even multimodal mix records... As the look sequence and also optical flow series are relatively simple to acquire, a lot of deep learning approaches embrace the appeal collection and optical circulation collection as their input, with a handful of depth- as well as likewise skeleton-based strategies. Regardless, existing high-efficiency multiperson setting assessment approaches based upon deep understanding have drawn brought up interest to human action function uncovering based upon skeletal system sequences, as well as also this is now a detectable research content in the business of human action verification.

Human activity recognition could be broken down straight into the activity group as well as activity diagnosis. Action classification is the evaluation of a fractional video clip consisting of just a solitary action that should be identified right into a defined action group. Action diagnosis finds out the start and also end times of each action in the video recording, situates their posture precede, as well as also recognizes the action classification. In an extremely early research study, the research of individual action awareness paid attention to the activity classification problem. Along with the growth of pertinent study subject matters, such as expert system, traits revelation, and also human found estimate, analysis study on the far more difficult human activity detection has actually happened noticeably in the last couple of years.

II. RELATED WORK

In human task recognition systems, various reduced- level features are introduced to explain the task monitoring. They used a descriptor that incorporates both neighborhood and international depictions of human movement, inscribing the motion info along with being durable to local appearance modifications. The discussed activity recognition methods mainly focus on recognizing the private action. Their frameworks are challenging to scale to resolve real-world circumstances where several people task and interaction are entailed. Our method represents the motion details making use of STIP feature comparable to but incorporates the abundant context info that we remove from the video. By using the deep model, our approach has the ability to: capture the substantial info concerning people's movement and interactions; scale to recognize the activity of each person in the scene; as well as enhance the accuracy of the general task recognition task.

Deep Model for Task Recognition. In recent years, deep designs consisting of deep neural networks, convolution semantic networks, and auto-encoders have actually been used in several applications. For human task recognition, convolution semantic networks and also auto-encoder approaches have actually been established. Nonetheless, these action/activity deep models are typically target-centered, which is essential for the human task that involves numerous individuals. Comparatively, [7]suggested an occasion recognition structure, which is a hierarchical context version that catches the context information in several degrees. In a similar way, our approach makes use of a deep-structure version that is trained utilizing the contextual info drawn out from human groups as well as video clip scene. Nevertheless, our technique concentrates on a different problem, which is recognizing the task of each individual appearing in the scene, other than a general event of the entire scene.

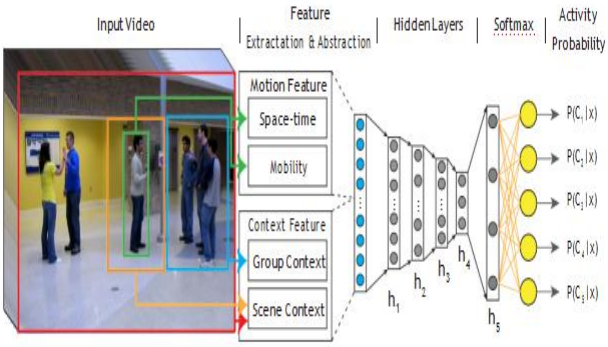

Figure 2: Neural network model.

The interval-based Spatio-temporal model is the suggested design as well as is a crossbreed event design. Apart from this technique like Limit versions, Bayesian Networks, Bag of actions as well as Very natural intervals and likewise Markov reasoning networks are actually utilized. SVAS strategy can be enhanced to handle transferring electronic video cameras and also multi-camera information selection. Additional augmentations are needed to have in dealing with complex celebrations specifically in regions like calibration and also audio removal. Several weird task discovery in video recordings is actually a rule-based body. The attributes are recognized as activity trends. Diagnosis of strange affairs is actually done either through teaching the unit or even through observing the dominant collection home. The tip of leading compilation where activities are located as usual based upon leading habits and odd celebrations are actually determined based upon much a lot less leading actions. The perk of policy located device is actually that simple to recognize brand-new events by customizing some regulations.
As a preprocessing body video clip division is taken advantage of. Record modeling is used through Gaussian Combo Version. For things, acknowledgment outdoor policies are actually demanded. The device is executed in Matlab 2014. The places were actually more focus extra required are doubtful tasks as well as also conditions where

countless points overlapping occurs. Exploration strange events versus steady collection in surveillance video recordings from organization ambiances pay attention to unheard of affairs linked with a consistent chain of celebrations. The primary cause recognizing such celebrations is actually very early execution of information specifically locations. The application part is carried out making use of Matlab, Inputs are actually observed activities as well as also realized constant assortment of occasions. The major exam under this strategy is to recognize events which are doubtful to chase delivered consecutive pattern by meeting the client recognized requirements. The method is actually giving a lot more focus on event-level examination as well as it is going to definitely be interesting if focus at company degree and additionally action level. Yet simultaneously getting in such a granular degree makes the operation expensive. Video recording quality descriptor combining movement as well as additionally look signs with size stable qualities is a characteristic descriptor. Numerous velocity based methods have actually been actually taken advantage of in plentiful setups. However, those approaches require to deal with concerns connected along with occlusions. As a service to that, credit descriptor using a visual flow-based approach.

III. RESEARCH CHALLENGES

Despite the significant progress that has actually been made in human action recognition and also forecast, cutting edge formulas still misclassify actions because of numerous major challenges in these tasks.

Intra as well as inter-class Variations.

As all of us recognize, individuals behave in different ways for the very same actions. For a supplied semantic significant activity, as an instance, "operating", a person may run easy, slow-going, as well as even hop as well as run. That is to condition, one action type might contain many various designs of human proposals. Additionally, video in the exact same action could be recorded from several perspectives. They could be soaked upfront of the human topic, on the side of the subject, or even probably atop the subject, revealing look varieties in various views. Additionally, various folks may present various presents in implementing the very same activity. All these variables will certainly cause a big intra-class look in addition to present variations, which perplex a large amount of existing action acknowledgment algorithms. These alternatives are going to be actually also much larger on real-world action datasets. This activates the exam of advanced activity awareness algorithms that can be set up in real-world situations. Additionally, similarities exist in a variety of activity classifications. For example, "running" as well as "strolling" involve similar individual task patterns. These correlations would similarly be actually examining to separate for smart devices, as well as subsequently add to misclassifications.

Camera Motion and Cluttered Background

It is interesting to observe that an amount of human action recognition formulas operate well in interior controlled settings however certainly not in exterior uncontrolled settings. This is actually mainly because of the background noise. As a matter of fact, the majority of existing activity attributes like pie charts of oriented slope and enthusiasm aspects additionally inscribe background sound, and hence degrade the recognition efficiency. Video camera movement is actually one more variable that ought to be actually considered in real-world requests. As a result of the substantial video camera proposal, activity parts might certainly not be actually properly extracted. To far better extract action functions, video camera proposition ought to be actually created along with made up. Different other environment-related troubles including illumination health conditions, viewpoint adjustments, a vibrant record will definitely likewise be really the concerns that restrain activity recognition protocols stemming from being made use of in sensible circumstances.

Uneven Predictability

Certainly, not all structures are actually equally discriminative. To solve this complication, circumstance info is transmitted to the starting point portions of the online videos, yet the functionality is still confined because of the not enough discriminative relevant information.

Furthermore, actions contrast in their routine. As shown in [1], some actions are actually quickly foreseeable while the other ones require even more frameworks to be observed. Nevertheless, in practical circumstances, it is actually important to anticipate any kind of action as very early as achievable. This needs our company to generate general action prophecy algorithms that can create exact and also early predictions for most of or all activities.

Classifiers for Human Interactions

Human communication is actually common in everyday life. Recognizing human interactions concentrates on the activities conducted by numerous folks, including "handshake", "speaking", and so on. Especially, communications are actually treated in its entirety and are actually stood for as an activity descriptor including all individuals in a video recording. Then an action classifier like linear assistance vector device is actually used to identify communications. Regardless of reasonable efficiency has actually been attained, these strategies perform certainly not clearly think about the inherent methods of communications, and fall short to take into consideration the co-occurrence details in between connecting people. Additionally, they do not extract the motion of everyone from the group, and thus their procedures can easily not infer the action tag of each connecting individual. Action co-occurrence of private person is beneficial in- buildup in human communication recognition.

Motion Trajectory Prediction

Besides predicting human activities, the other essential facet in human-focused prediction is activity velocity prophecy, which targets at forecasting a passerby's relocating road. Activity trajectory prediction, an integral capability of us, rationalizes the achievable place as well as the activity velocity of the target person. We can predict with higher self-confidence that a person is heading to stroll on walkways than roads, and are going to stay away from any kind of difficulties during strolling. Consequently, it is interesting to study how to make makers do the very same work. Vision-based motion path prediction is important for practical applications like aesthetic security and self-driving cars, in which reasons concerning the future movement

patterns of a passerby is actually vital. A big physical body of job learns activity designs through clustering trajectories. Nevertheless, projecting the potential movement trail of a person is actually truly demanding as the forecast can not be predicted in isolation. In a congested atmosphere, human beings conform their motion according to the actions of neighboring folks. They may quit, or change their roads to fit other individuals or the environment in the vicinity. Collectively modeling such intricate reliances is actually really complicated in vibrant environments. Additionally, the anticipated velocities need to certainly not only be actually appropriate but likewise socially acceptable. Passerby always appreciates private space while walking, and thus produce right of way. Human-human and human-object communications are actually normally skillful and sophisticated in packed atmospheres, creating the concern a lot more demanding. In addition, there are various future predictions in a packed environment, which are actually all socially appropriate. Therefore anxiety evaluation for the multimodal predictions is actually wanted. Forecasting velocity, as well as place by understanding bodily scene, was explored in which was just one of the introducing operate in trajectory prediction in the computer dream neighborhood. The recommended approach models the result of the physical setting on the selection of human actions.

Fig. 3. Movement velocity prophecy is actually important for efficient applications like visual surveillance and self-driving vehicles.

Their procedure is built on the vibrant Bayesian system, which takes into consideration the passerby's choice to visit three signals, consisting of the life of moving toward the automobile, the passerby's recognition, and the spatial design of the performance.

IV. CONCLUSION

In this paper, our team has analyzed human action awareness approaches as well as likewise offered an extensive testimonial of existing methods to human activity recognition analysis study. The input attributes of the deep network include activity attribute as well as context attribute. We make the scene prior feature and also scene context function to record the atmosphere around the topic of rate of interest worldwide as well as local degrees.

ABSTRACT

Machine learning and neural networks are trending technologies used in different kinds of handwritten (HW) pattern recognition of various research areas. Therefore it is very hard to distinguish and recognise the hand written characters of different persons. Recognition of characters related to telugu language is a part of pattern reorganisation that happen to the idea of research during the past some years. Neural networks (NN) are playing a significant role in telugu HW character recognition. HW detection is the capability of a digital computer to receive and understand intelligible HW input from documents, images, touch screens and other electronic devices etc. These all may be online or offline, in this context online recognition includes conversion of pen tip digital movements into a list of originates used as input for the categorization system where as offline recognition uses images of characters like input. For HW reorganization NN has been achieved and improve the efficiency up to 98.3% this is good achievement.

Keywords: Machine learning, neural networks, telugu, handwritten characters, vatu, gunintham, pattern reorganization

Abbreviations:TL, Telugu letters;VTU, Vothulu; NN, Neural networks; HW, handwritten; MLPS, multilayer perceptrons; HWR, handwritten character recognition; CNN, Convolution neural network.

I. INTRODUCTION

This exploration goes for a programmed comprehension of on line record Telugu letters (TL) and Vothulu (VTU) composed on a digital tablet or any display screen, without digital model(paper and pen). The proposed model includes two substantial degrees: Telugu vothulu and hallulu acknowledgment and secondary similarity examination. A combination of distinct classifiers has been applied to accomplish excessive precision for the acknowledgment of snapshots. A few on the online and offline highlights are utilized inside the primary examination stage to recognize the spatial connections among snap shots. A setting interchanges the letter shape that has been meant to exchange over the records into their TEX strings which can be thusly changed over into letter role. Relevant statistics have been utilized to address a few structure elucidation errors. Another approach for assessing the display of the proposed framework has been defined. Trials on a dataset of widespread length unambiguously boost the achievability of the proposed framework. even though an outstanding deal of work has been accounted for acknowledgment in English and Asian languages, for example, Japanese, Chinese, and so on., and not very many endeavors on Indian dialects like Hindi, Tamil, Telugu, Kannada and so on. In this work handwritten character recognition(HWR) model for telugu [South Indian language] has been developed with high accuracy, less training time and time of classification, As a part of the previous work applies on low attainment knowledge of the established HWR to each letter and offline datasets. Instances of HWR contain pixel densities over set of a picture, in this section ebb and drift, measurements, and numerous flat and vertical strains has to be calculate f. C. Vikramet. Al utilized multilayer perceptrons [MLPS] and got a precision of 83.5% on HW Telugu individual datasets.

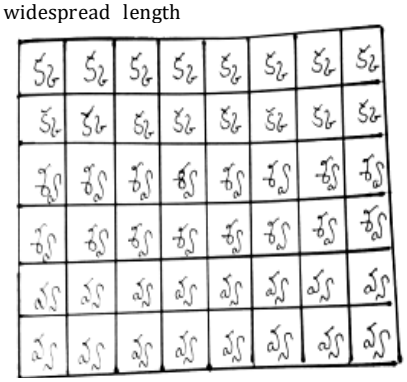

Figure: 1 example data set

Fig.1. shows that data set from Telugu letters i.ekaagunithalu and shay votthuluetc, these all are selecting from data set which are available at MIT hub data set. Around 300 samples are placed as image models at final training samples are analysed.

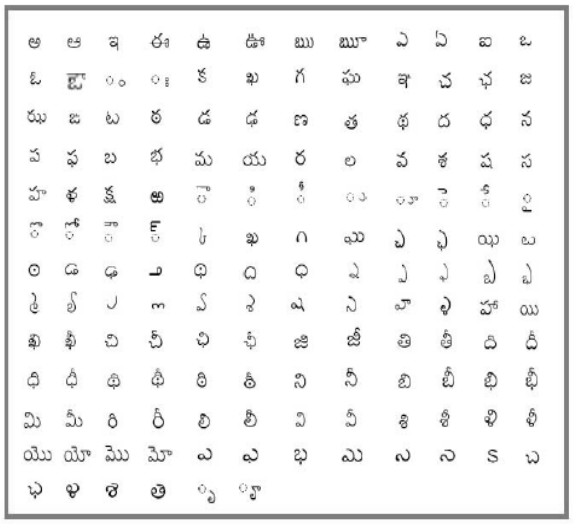

Figure: 2. 150 data from available data sets

Fig.2 explains about data set example from Unicode values each letter contains single Unicode values based on this pre-processing is to be performed.

Class Id	Telugu Symbol	Unicode
0	అ	0C05
1	ఆ	0C06

II. LITERATURE SURVEY

[1] P. N. Sastry, T. R. V. Lakshmi, N. V. K. Rao, T. V. Rajinikanth and A. Wahab 2014 Zonal based totally element extraction is utilized in the present proposed method. The individual image is isolated right into a predefined wide variety of zones and an authentic detail is figured from every this sort of zones. Ordinarily, this element depends on the pixels contained in that sector. The dark estimations of the pixels in that chose zone are summarized to frame detail for that area in that photo. The highlights of the huge variety of zones inside the photo shape and element vector that is utilized for writing with the aid of

hand individual acknowledgment. Utilizing this Zoning method the acknowledgment precision is visible as 78%.
[2] S. D. Prasad and Y. Kanduri 2016 In any case, none of them deliver 100% precision in the acknowledgment of Telugu characters. Along these strains, it's far territory of progressing studies. Our exertion is predicted to improve the precision in Telugu man or woman acknowledgment. This propelled us to attempt this work. Zonal based detail extraction is applied within the gift proposed paintings. We exhibited two techniques for this reason. The number one strategy relies upon on the Genetic Algorithm and utilizations of versatile zoning topology with
separated geometric highlights. In the following method, zoning is completed in a static manner and utilizations separation, thickness primarily based highlights. In the two settings, we utilize the K-Nearest Neighbours (KNN) calculation for order purposes. The person picture is partitioned into a predefined wide variety of zones and highlights of the giant range of zones within the photo shape an element vector this is utilized within the grouping duration of transcribed character acknowledgment. Utilizing the primary approach we acquired correctness's of 100 percent and 82.Four percent for 11 and 50 photographs in my view. Utilizing the second method we were given exactness's of a hundred percent and 88.Eight percent for eleven and 50 images for my part.

III. PROBLEM STATEMENT

HWR has been one of the dynamic and testing studies zones inside the discipline of image getting ready and design recognition. Since 1929, some of the individual acknowledgment frameworks have been proposed and are utilized for even industrial enterprise reasons. A few applications including, organization related to checks, postal orders, examination related information's are help for offline frameworks. Working in Postal assist need us to interpret and bring something like 30 million manually written envelopes each and every day. The difficulties are to do mail-arranging that assure each one of these a huge quantity of letters arrive at their desires. HWR difficulty shifts amongst varied languages and letters because of unique shapes, strokes, and a variety of characters. Telugu, a South Indian language that positions 1/3 by using the variety of local speakers in India. Fifteenth in the Ethnologue rundown of maximum- communicated language in international and is the maximum typically communicated in Dravidian language on earth. Around 800 million people use Telugu as they speak to people and write explanations. Telugu content has 18 vowels and 36 consonants, of which 13 vowels and 35 consonants are in like way use. all of the Indic contents, the Telugu content has the largest range of vowels and consonants. Also, Telugu incorporates numerous similar formed characters; every now and then a character varies from its comparative one with a complete zero (anusvāra), half of-zero (arthanusvāra or candrabindu) and visarga to bypass on extraordinary shades of nasal sounds. That improves hard to accomplish execution with the dependable method simply because it prevents to work with Telugu manually written and gives some acknowledgments. Manually written person acknowledgment can be on the online or offline. In this specific situation, on line HW includes a change of computerized pen-tip traits right into a rundown of instructions, applied as a contribution for the order framework at the same time as offline recognition uses photographs of characters as data. A part of the earlier works applies superficial getting to know with hand-structured characters on each the offline & online datasets. Instances of HWR include pixel densities over districts of the picture, individual ebb and drift, measurements, and some of the flat and vertical traces.

IV. EXISTED METHODS

This algorithm used only single characters of Telugu language. But there are many characters with 'vattu' and 'gunintham' which were shown in the below figure. As there are very less contributions on Telugu language characters, I couldn't find the dataset consisting of all these characters. But the characters used in this project are like vowels and consonants in English. Due to time constraints I didn't generated dataset with all those characters. In future, I want to extend this algorithm from character recognition to text recognition by creating my own dataset.

V. METHODOLOGY

A.Requirements

The evaluation metric for the model will be transcription accuracy on the test images in the HP dataset of Telugu characters. Accuracy will be defined as correctly predicting handwritten Telugu character in the image. The model must correctly predict not only the number of digits present but also correctly identify each of those digits. As noted above regarding benchmarking against previous work results, I will evaluate it against some other models like handwritten Hindi/ Tamil/ Bengali character recognition in both accuracy and speed.

B. Data Investigation

The dataset is downloaded from the HP Labs India site or MIT data set [1]. This dataset consists of approx. 270 examples of each one of 138 Telugu "characters" composed via nearby Telugu authors. The dataset includes a huge collection of unmistakable characters in view of numerous human beings corporations' composition styles. The characters are made on hand for download as TIFF files. An element of these individual pics are mind-boggling molded and firmly related to others. Telugu content material has 18 vowels and 36 consonants of which thirteen vowels and 35 consonants are in like manner use. Telugu content is for the maximum element non-cursive in fashion and sooner or later, pen-up extra often than no longer isolates the important graphemes but no longer usually. In this way, the important graphemes of the content, for example, loose vowels, consonants, vowel diacritics, and consonant modifiers are incorporated into the photograph set shown in fig.4. Likewise covered are some consonant-vowel units which can't be successfully portioned. Likewise, the photograph set additionally includes some pixels which do not have a semantic translation but have solid example crosswise over essayists and help reduce the whole variety of images to be amassed. In this manner, sincerely there are 138 photos. These are altogether allowed to Unicode characters. The characters are made available for download as TIFF records. The first inconsistent envisioned square pictures are resized into eighty x 80 square snapshots and spared them as JPG files.

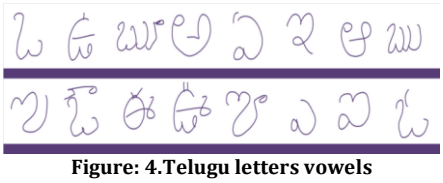

Figure: 4.Telugu letters vowels

C. Convolution neural network algorithm

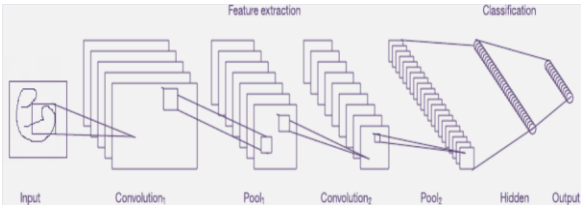

Figure: 5.CNN network

Fig.5. Clarifies the pooling convolution version, utilizing this model each letter has been organized with an auxiliary version. A trendy design of CNN that incorporates two essential components: consists of extraction and order. In the factor extraction layers, every layer of the machine gets the yield from its spark off a past layer as its data and passes the prevailing yield as a contribution to the subsequent layer. CNN engineering is produced from the combination of 3 styles of layers:

convolution

max-pooling

Characterization.

The convolutional layer and max-pooling layer are forms of layers inside the low and center diploma of the system. The even-numbered layers work for convolution and bizarre-numbered layers picture for the maximum pooling activity. The given hubs of the convolution and max-pooling layers are assembled right into a 2D aircraft that is referred to as spotlight mapping. Each aircraft of the layer normally decided with the mix of at least one plane of the past layers. The hub of the plane is associated with a touch district of each related plane of the past layer. Every hub of the convolution layer concentrates highlights from the records snapshots through convolution activity on the records hubs. The most pooling layer changed works include regular or engendering interest at the information hubs. The more elevated level highlights are gotten from the produce characters of the decrease-degree layers. As the highlights spread to the maximum notable layer, the factor of the highlights is diminished relying upon the dimensions of the convolutional and max-pooling veils. Be that as it can, the quantity of spotlight mapping typically accelerated for map the outstanding suitable highlights of the facts pics to perform better order precision. The yields of the final element maps of CNN are applied as a contribution to the completely related machine which is called the characterization layer. In the arrangement layer, the ideal quantity of highlights can be gotten making use of highlight preference techniques relying upon the detail of the load framework of the closing neural device, at that factor the chose highlights are set to the classifier to technique certain of the info photos. In view of the maximum multiplied truth, the classifier offers yields for the evaluating training that the data photos have an area with. Numerical subtleties of various layers of CNN are mentioned inside the accompanying segment.

CNN LAYER:

In this residue, the element maps of the past layer are convolved with learnable parts, for example, (Gaussian or Gabor). The yields of the piece revel in direct or non-directly enactment capacities, as an instance, (sigmoid, hyperbolic digression, softmax, amended immediately, and character capacities) to frame the yield spotlight maps. As a rule, it very well can be numerically tested as eq(1)

$$x_j^l = f\left(\sum_{i \in M_j} x_i^{l-1} k_{ij}^l + b_j^l\right)$$ ------ (1)

Where $x^l{}_j$ is the yields of the present layer, $x^{l-1}{}_i$ is past layer yields, $k^{\ i}{}_j l$ is a portion for the present layer, and $^{bl}{}_j$is the predisposition for the present layer. M^jspeaks to a choice of info maps. For each steo, map is given an added substance inclination b. In any case, the info maps will be convolved with unmistakable pieces to create the relating yield maps. For a moment, the suitable maps of j and k both are summation over the information I which is specifically applied to the j^{th} bit over the info I and takes the summation of its and a similar activity are being considered for k^{th} piece also.

SUBSAMPLING LAYER

The subsampling layer plays a down sampling interest in the information maps. In this layer, the data and yield maps don't change. For instance, at the off hazard that there are N information maps, at that point, there may be really N yield maps. Because of the down sampling pastime, the dimensions of the yield maps can be diminished relying upon the dimensions of the down sampling veil. In this research, 2 × 2 down sampling cover is utilized. This activity can be figured as

$$x_j^l = f\left(\beta_j^l down(x_j^{l-1}) + b_j^l\right)$$ ----- eq(2)

In which down (•) speaks to a subsampling ability. This capacity, for the most component, summarizes over n × n square of the maps from the past layers and chooses the ordinary well worth or the most increased qualities most of the n × n rectangular maps. Likewise, the yield manual measurement is decreased to n times regarding the two elements of the thing maps. The yield maps at long final enjoy directly or non-direct actuation capacities.

CLASSIFICATION LAYER

This is a completely associated layer that processes the score for each class of the articles utilizing the separated highlights from the convolutional layer. In this work, the size of the element guide is viewed as 3 x 3 and a feed-forward neural net is utilized for grouping. Concerning the actuation work, softmax capacity is utilized as recommended in many sorts of writing. 1st plan to compare the results with the previous works 2nd step will compare the accuracy/mean-squared error to see which is more effective, as well as compare the speed of proposed method using CDNN and the previous used techniques. Shanthi et al.[4] use pixel densities over various zones of the picture as to highlights for an SVM classifier. Their framework accomplished an acknowledgment pace of 82.04% on a manually written Tamil character database. K. Mohana Lakshmi et al. [3] achieved a recognition rate of 87.5% on Telugu character dataset using HOG features and Bayesian classification. Here I want to try to get accuracy greater than 90%. For this applying Convolutional Neural Networks which are more efficient than the methods used by the above authors

D. Data Preprocessing

The dataset contains images of contains approx 270 samples of each of 166 Telugu characters written by native Telugu writers. These images are in TIFF format and are unequally sized. The images were under the folders with the names of the writer and the image file name as its Unicode character. Here I changed the image filename as the writer name followed by the Unicode character so that each image will get a unique file name. And then all the images with the same Unicode were grouped under a folder with Unicode as its folder name so that I can use load_files method in sklearn.datasets2 module. Then, the original unequally sized rectangular images are resized into 80 x 80 square images and saved them as JPG files. As mentioned in the Algorithms and Techniques, the classifier used to train the data is Deep Convolutional Neural Network. The input to the convolutional neural network is a 4D Tensor. The 80 x 80 image is reformatted into a 4D tensor with shape (samples, channels, rows, columns) which is then passed through a stack of different kinds of layers as follows:

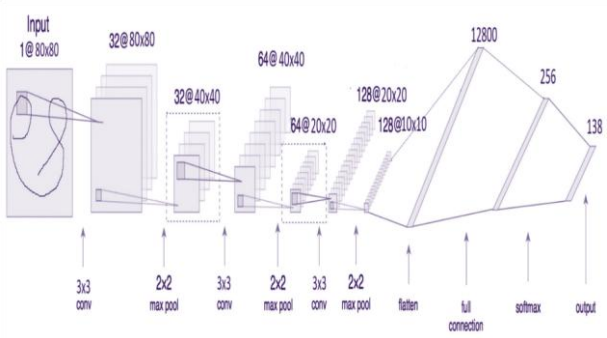

Figure: 6 HW character recognition

Information - 4D tensor with form (n, eighty, eighty, 1) where n is the variety of info pix and the variety of channels is 1 because the pix are double. (Number of channels = 3 if the pix are RGB). Show in fig.6

Layer 1 - Convolutional Layer with 32 channels and channel length 3 x3 and Max pooling layer with channel length 2 x 2.

Layer 2 - Convolutional Layer with 64 channels and channel length three x three and Max pooling layer with channel size 2 x 2.

Layer 3 - Convolutional Layer with 128 channels and channel size 3 x three and Max pooling layer with channel length 2 x 2. Straighten( ) - It changes over the yield of the convolutional a part of the CNN into a 1dimensional factor vector, to be utilized by the absolutely related layer.

Layer 4 - Fully Connected layer (Dense) with 256 neurons, with a dropout regularization pace of zero.Four (likelihood of zero.4 that any given aspect might be dropped in the course of preparing).

Layer 5 - Fully Connected layer (Dense) with 138 neurons. Here, directly initiation RELU is applied for the convolution and max-pooling layers and SOFTMAX enactment is utilized for the yield layer (Fully Connected Layer).

Initially tried the images with size 32x32 When run the algorithm got very less accuracy, then started changing the optimizer. First used ADAM and tried for many combinations of learning rate and decay. Then tried ADADELTA and tried for parameter tuning, even though the performance didn't improve. Then went through the dataset (i.e., images) which were not clear with size 32 x 32 Then changed image size to 64 and then 80 Then noticed some repeated images with different label name which causing the algorithm to get very low performance. Then removed the similar images with different label names Then got 138 characters whereas initially have 166 characters when downloaded the data from HP labs/mit website. finally performed and explored one-of-a-kind avenues concerning the accompanying speculation structures:

Dropout in a convolutional layer

Dropout in a completely associated layer

Data manipulating

Batch Normalization

Applying those methods did not provide a first-rate carry in execution. Then with 3 convolutional layers and ADAM as optimizer, got 88% test accuracy and 91% training accuracy. But, after changing optimizer to SGD with learning rate 0.1, and adding one more convolutional layer, training accuracy increased to 94% and the test accuracy increased to 91%.

VI. Model Evaluation and Validation

we got test accuracy of 91% and training accuracy of 95% on Telugu character dataset with 20 epochs, if we increase number of epochs, then the accuracy will increase further. The loss reduced from 4.03 to 0.4 as the training progressed. For the first few epochs, the training accuracy is less than the validation accuracy and then after some epochs, train accuracy increased. The validation curves were given in figure 4 for figure.7. The accuracy obtained by the model is greater than the benchmark reported earlier. It's likely that adding more epochs could increase the accuracy further.

The benchmark reported is 90% of test accuracy. But by running 20 epochs, the model obtained 91% accuracy and 95% training accuracy. By adding few more epochs, the accuracy may increase further. The following table shows the comparison between the accuracy obtained by the CNN model and other models used to classify handwritten Telugu characters.

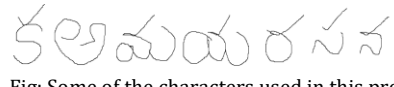

Fig: Some of the characters used in this project

Figure: 7 GUNITHAM and VOTHULU

This CNN model is applied on gunithalu and votthulu got good accuracy compared to existed work[5].

Figure: 8.model accuracy

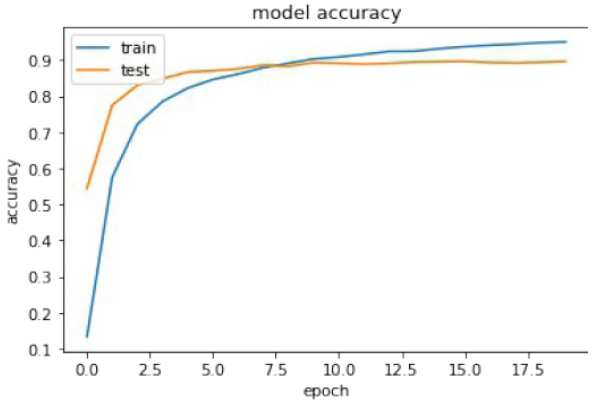

Fig.8 shows that accuracy related to test data and trained data, in this model compared test model trained model got more accuracy.

Figure: 9. Model loss analysis

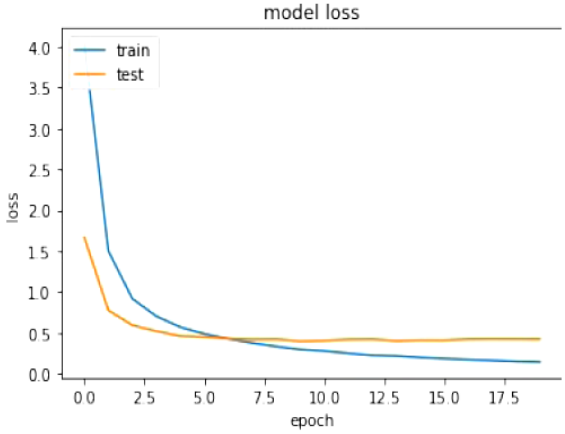

Fig.9 explains that loss parameter in this model loss of test data is more compared to trained model.

Table: 1 comparison of methods

METHOD	ACCURACY
CNN proposed	98.3%
ZF	78%
ADZM	88.8%
2D-FT_SVM	71%
MLP	85%
Bayesian	87.5%

Table :1.explains that CNN model achieves 98.3% accuracy this is good compared to all methods The accompanying table demonstrates the genuine marks and the predicted names of the preliminary 50 snapshots which demonstrates the model is foreseeing practically right names apart from 2 or three out of fiftypictures
.

Table :2unicode relations

Original	Tested	Original	Tested
47	47	110	110
46	46	134	134
60	60	67	67
68	68	59	59
121	121	65	65
15	15	119	119
119	119	72	72

Table: 2 explains that Disarray Matrix is applied to test the exhibition of the neural system grouping.

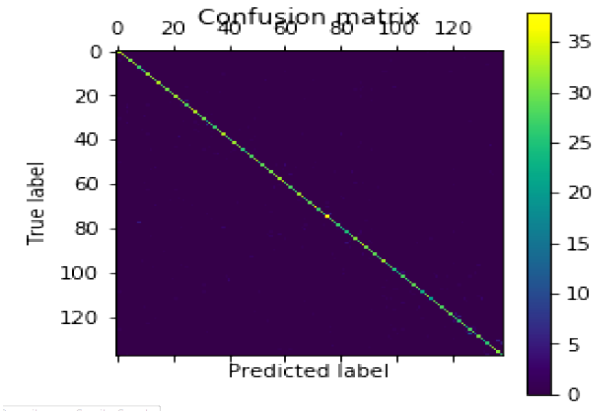

Figure: 10. Predictive label

Fig.10 Demonstrates the plot of the perplexity grid for the model used to reserve written by using hand Telugu Characters.

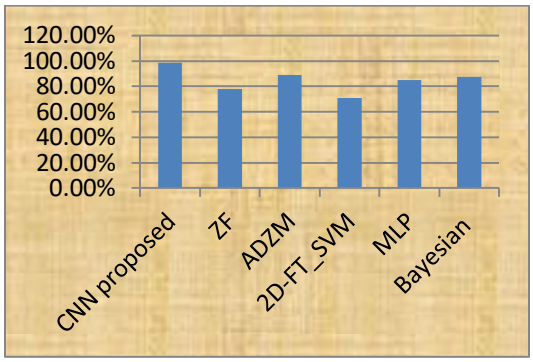

Figure: 11. Graphical view

Figure: 11. Explains about graphical representation of accuracy here CNN got 98.30% accuracy which is more efficient recognitions in TELUGU GUNITHAM and VITTULU.

VII. CONCLUSION

It is well known that the deep convolutional neural networks are very good at classifying image data. There were many experiments done on handwritten character recognition using convolutional neural networks for English alphabets, numbers, Chinese, Arabic and some of the Indian languages like Hindi, Devanagari script etc., But there is very less contribution on Telugu language character recognition. Due to very less contribution, the data available on internet is not so good. In this didn't notice that initially and faced many problems with repeated data. found that the problem was in data, then deleted the repeated ones and made the data clear. Then found difficult in tuning the algorithm tried different optimizers with different learning rates and tried a model changing number of layers and number of filters and filter size. Finally, ended up with a model that gives 98.3% accuracy which exceeded my expectations to get around 85 to 98.3%

VIII. FUTURE SCOPE

The OCR implementation has been covered with the help of neural networks, with this 98.3% accuracy is obtained. This implementation is very useful for south India online, offline Telugu character recognization system. The previous system for Telugu OCR character level recognization using x and y direction histogram model had been implemented. But, got less accuracy so our proposed work achieves better accuracy with the help of CNN. The machine learning algorithms like SVM, logistic regression can gives the better accuracy compared to CNN. Therefore the online and offline character recognization system of Telugu need to implement using machine learning algorithms by SVM, LR gives the more accuracy and less skew corrections. This application spanned using android, IOS, RIM can gives the easy access, this ML, neural network algorithms by using segmented data and Telugu dataset gunintham and vothu together gives the better accuracy. The implemented system also useful for other languages like Tamil, kanada, Malayalam, etc OCR systems all languages of India.

Fractional Brownian motion Noise Removal in Breast Cancer Magnetic Resonance Images

N.Rajeswaran, C.Gokilavani, T.Samraj Lawrence, P.Ramkumar

Abstract*: *In Medical Image Processing, high resolution images are very much essential to analyze the different features of the image for better diagnosis of the disease. Now days, more and more women are getting affected by breast cancer. Magnetic Resonance Imaging is the most popular technique used to diagnose the breast cancer images, whose resolution in turn is affected by the fractional Brownian motion (fBm) noise, Gaussian noise and Salt and Pepper noise. In this paper, wavelet based thresholding techniques namely Visu shrink, SURE shrink and Bayes shrink are implemented to denoise the breast cancer images affected by fBm noise.

Index Terms: fBm noise, Medical image Processing, Magnetic Resonance Imaging, wavelet thresholding.

I. INTRODUCTION

In medical image processing, noise tends to reduce the visibility of the image and obscures the information needed for accurate treatment. Since the larger part of image processing deals with Image restoration or image denoising, denoising the affected images plays a major role to diagnose the diseases in a proper manner and to retain the image up to its quality[1-2]. Image denoising attempts to remove the various types of noises present in an image and restores the original image back while preserving the important features needed for proper diagnosis and to track the progress of the disease. However, the tradeoff between the image features and noise reduction must be taken into account while denoising. Recently fuzzy logic has been used for noise removal [3]. Medical images are taken by means of MRI (Magnetic Resonance imaging), CT (Computed Tomography) and Ultrasound imaging. Among these, MRI sounds better in giving high resolution images of the soft tissues in human body such as the brain and breasts. The images of these organs consist of several complex patterns that are independent of scales. Further, the breast cancer image is fractal in nature [4]. Hence, in this paper, the fractional Brownian motion noise is eliminated by using the wavelet based thresholding techniques namely Visu shrink, SURE shrink and Bayes shrink methods.

Revised Manuscript Received on April 07, 2019.

II. GENERATION OF FBM NOISE

Based on the concept of bisection and interpolation [5], Ilkka Norros proposed the simulation of fractional Brownian motion with conditional random midpoint displacement algorithm [6]. This is also called as diamond square algorithm. This produces fractals in images. Here the entire trace of the fractional Brownian motion is generated before it is used for the purpose for which it is specified for. Fractional Brownian motion has been used in various fields such as hydrology, imaging landscapes and much more [7]. The properties of a normalized fBm are:

- Normalized fBm is a stochastic process(Zt) with Hurst parameter, H(0,1)
- Zt has stationary increments
- Zt is Gaussian
- Zt has continuous sample paths

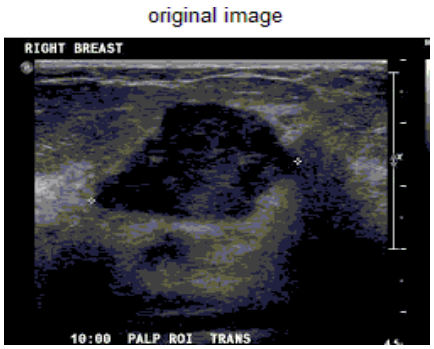
A. Algorithm of fBM Noise

Ordinary Brownian motion is the special case of Normalized fBm with the parameter H=1/2. This algorithm consists of following steps,

Step 1: Take the given image.

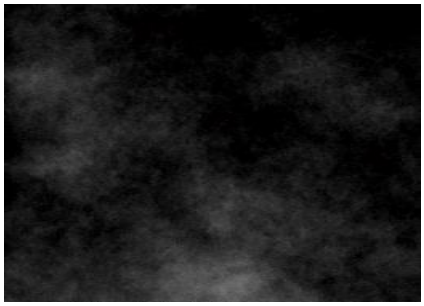
Step 2: Assign height values to each corner of the image.

Step 3: Divide the image into four sub-images and assign height values to them such that their height is the mean values of the corners of the image taken in step 1.



Step 4: When computing the middle height, add small error value depending on the image size taken in step 1 and some constants that controls the fractal's roughness.

Step 5: Continue the iteration and sub-divide the sub-images further.



Step 6: When no noticeable difference is seen, stop the iteration and render the pixel with mean height values.

Thus the fractals are produces by the above RMD procedure and are shown below.

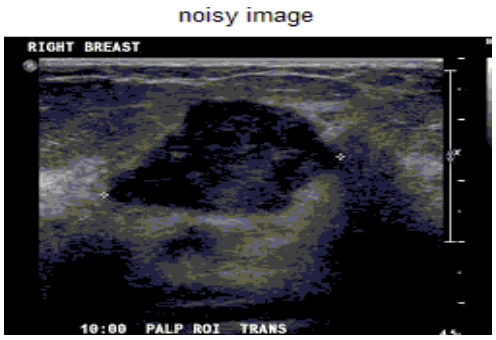

Fig.1 shows the MATLAB simulation results for the generation of fractional Brownian motion noise for an Breast cancer image of size 512x512. Fig.1 (a) shows the original Breast cancer image. Fig.1 (b) shows the pattern of fractional Brownian motion. Fig.1 (c) shows the Breast cancer image corrupted with fBm noise.

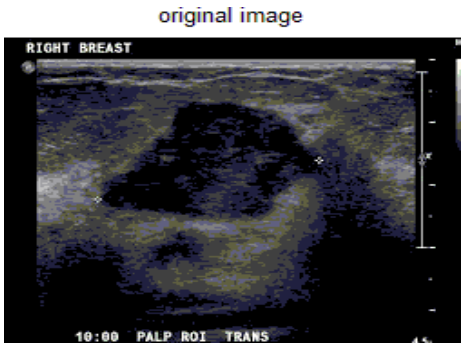
III. RESULTS AND DISCUSSIONS



The wavelet based thresholding techniques are implemented by using MATLAB and the simulation results for Visu shrink are given in the Fig. 2. The Fig. 2.(a) shows the original image, Fig. 2.(b) shows the noisy image and the Fig. 2.(c) shows the denoised image. Here in the noisy image, the value of the Hurst parameter is 0.3 (for a classical Brownian motion, the Hurst parameter h=0.5).

a

b

c

Fig. 2(a),(b), (c). Simulation results for Visu shrink

The simulations results for SURE shrink are given in the Fig. 3. The Fig. 3.(a) shows the original image, Fig. 3.(b) shows the noisy image and Fig. 3.(c) shows the denoised image. Here also the noisy image takes the value of 0.3 for H.

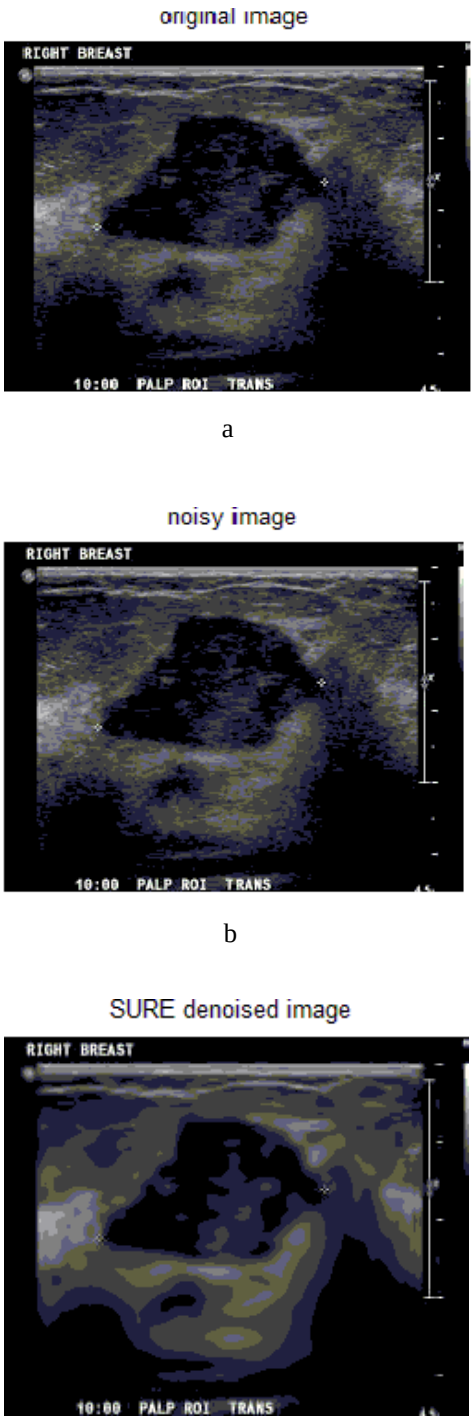


Fig 3.(a),(b) and (c). Simulation results for SURE shrink

The simulation results for Bayes shrink are given in the Figure. 4. The Fig.4. (a) shows the original image, Fig. 4.(b) shows the noisy image (with Hurst parameter of 0.3) and Fig.4.(c) shows the denoised image.

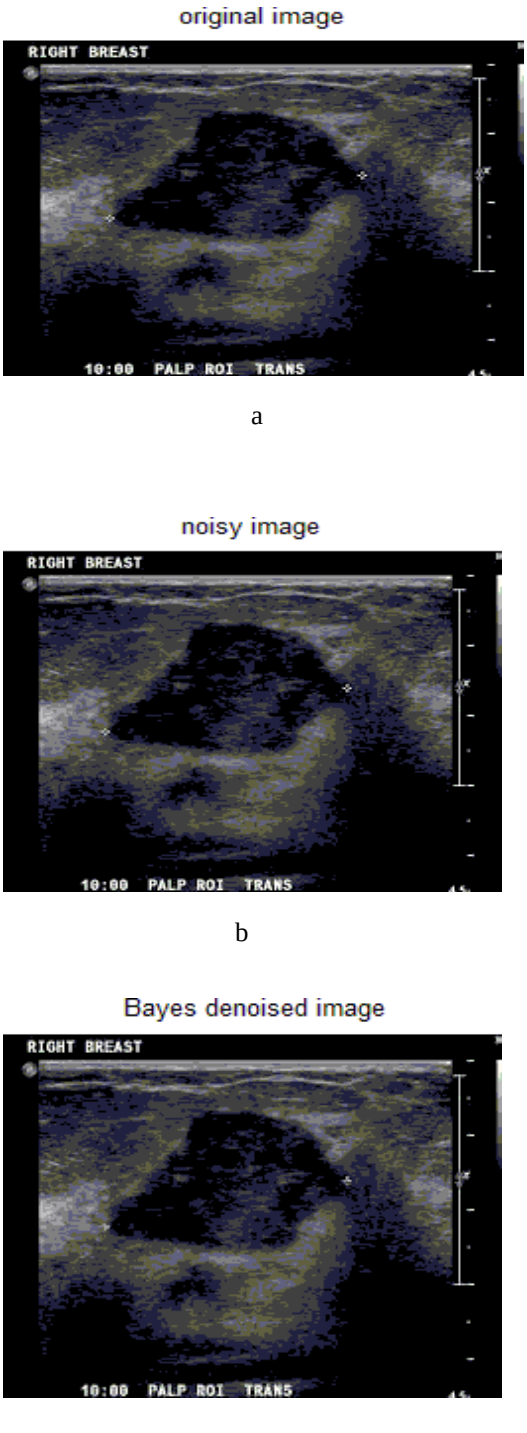

Fig 4.(a)(b) and (c). Simulation results for Bayes shrink

The performances of all the three thresholding techniques are listed in Table. 1.

Table 1: Comparison of wavelet thresholding techniques

S.NO	PERFORMANCE METRICS	VISU SHRINK	SURE SHRINK	BAYES SHRINK
1	MSE (Mean Square Error)	865.45	665.45	2.1544
2	PSNR (Peak signal to Noise ratio)	56.9841	76.5454	78.5645
3	FD(Fractal Dimension)	1.9645	1.9751	1.9884
4	IEF(Image Enhancement Factor)	0.6844	0.7554	0.9987
5	SSIM (Structural Similarity Index)	0.7454	0.7865	1.000
6	NK(Normalized Cross Correlation)	0.8502	0.9265	0.9965
7	AD(Average Difference)	210	165	154
8	SC (Structural Content)	0.9265	0.9756	1.000
9	MD(Maximum Difference)	214	155	221
10	NAE(Normalized Absolute Error)	0.8652	0.0218	0.0010
11	Time Elapsed when attempt to denoise	5.6545sec	4.6954sec	1.4545sec

From the above table, it is evident that the Bayes shrink method is performing more efficiently in denoising the images and thereby improving the resolution of the MRI images (Shown in Figures from 5 to 9). It has high Peak Signal to Noise Ratio, lowest Mean Square Error and lower Normalized Absolute Error.

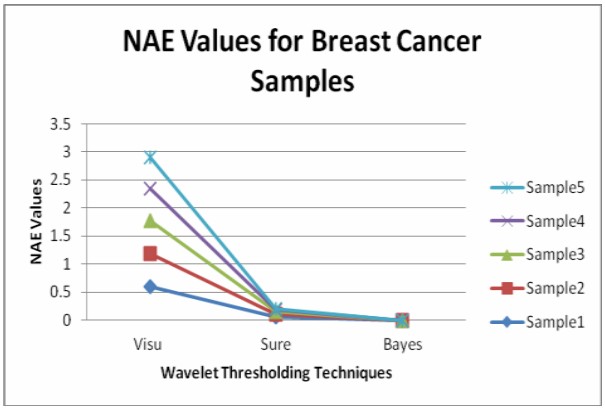

Fig 10. Chart for Time Elapsed to produce denoised image

IV. CONCLUSION

In this paper, wavelet based thresholding techniques namely Visu shrink, SURE shrink and Bayes shrink are implemented to denoise the breast cancer images affected by fBm noise. The inference from all these implementations are that Bayes shrink performs better in terms of all performance metrics. The future scope of this work includes analyzing and implementing various filters for removing all forms of noise.

Certain Investigations on Sentimental Analysis Architecture and Tools

R. P. Ramkumar, Sanjeeva Polepaka

Abstract— The sentiment is defined as the feeling(s) about the review or comment. The Sentimental Analysis aims to determine the attitude of content or product for a period at a given moment. Later, these observations are categorized as negative, neutral, positive and sometimes no sentiment(s) at all. The review(s) or comment(s) on a concern product is beneficial for the companies to prioritize the issues, narrow down the problems to be solved and to explore the scenarios for success. This article deals with the study of sentimental analysis or opinion mining architecture and tools used for Sentimental Analysis for the naive users.

Keywords: Opinion Mining, Tweets, Opinion Polarities, Crawling, Sentimental Analysis, Twitter Statistics.

1. INTRODUCTION

In the technological era, others opinion about the product influences the decision-making process. One or two decades before to get the review about the product(s), we relied mostly on relatives and friends. However, in the modern world, opinion feedback from diverse people may be sought over the internet. Before buying the product, people use to look the website(s) for review about a particular product. Similarly, organizations use to get feedback about the services and the products for the customers. The identifying and extracting processes generate the subjective information using text analysis, natural language processing and computational linguistics is referred to as Sentimental Analysis or Opinion Mining. Nowadays, this type of sentimental analysis becomes more popular to monetize the products. The following shows the organization of the paper: Section 2 deals with related works about opinion mining. Usage of sentimental analysis and its architecture is discussed in Sections 3 and 4, respectively. Section 5 draws the conclusion and future work.

2. RELATED WORKS

The following section shows the related work regarding the opinion mining framework.

Meenambigai [4] presented a product based opinion mining to examine the nature of the product. The objective of this work was to categorize the opinion polarities (like a negative, neutral or positive) of the product. From the product's opinion statement, sentiment analysis was done and classified as objective, positive and negative. This method was tested on blog posts) from social media. There were three steps in determining the analysis. In step 1, all the product features were extracted. In step 2, simultaneously separation of text and emoticons and extraction of opinion words took place. The categorization of opinion words such as positive, neutral and negative words was done in step 3. Results concluded that people use emoticons to express their feelings in natural language text.

Vivekanandan and Josephine [5] constructed an automated framework called Review Opinion Mining (ROM) to determine the opinion about the online products. The ROM method has five steps namely (a) Data preprocessing, (b) Aspect extraction, (c) Identification of opinion, (d) Polarity identification and (e) Summarization of features. This method was tested on unstructured data to extract the viewer's opinion about the products. Though the ROM framework analyzed product reviews in a timely and efficient manner, it failed to adhere to appropriate algorithms for determining the summary report.

Khandelwal, Mishra and Mishra [6] implemented an analyzer to classify twitter comments as positive, negative and neutral. This workflow model initiates with tweet data identification followed by the data preprocessing and training data definition. Later, parsing of tweets was carried out by choosing an efficient algorithm. Subsequently, the training and evaluation follow to classify the comments as subjective and objective cases, with the test data. Authors concluded that machine learning algorithms such as Support Vector Machines (SUM) and Naïve Bayes were widely used to analyze the tweets even though the algorithm suffers limitations.

Kim and Kim [7] presented a case study on nuclear power using opinion mining on Twitter. There were four phases or stages in analyzing the tweets, namely (a) Crawling of tweets, (b) Text preprocessing, (c) Constructing the dictionary with sentiment words and (d) Predicting the feelings with tweets. Locoy spider is the crawling tool used to identify the terms "nuclear power" or simply the "nuclear" in the Korean language from 2009 to 2013. Among the five years of data, the first three years were used to construct the dictionary, whereas the later year's data were used for evaluation purpose. Results of the assessment method were compared with the human evaluator(s) results. Results concluded that this method has higher prediction accuracy on analyzing sentiments than the human evaluators.

3. MEASURE THE MATTERS USING SENTIMENTAL ANALYSIS

According to Katie Delahaye Paine [1], metrics such as likes, shares, onsite engagements, comments and inbound links are very helpful in identifying the sentiment of the people or the user engaged with the content. By just having the metric counts only gives the false sense or bad branding about the particular product. Apart from the above-listed parameters, when analyzed, there is a possibility of Quality metrics, which deals with feelings, opinions, shares quality, repeated tweets made on the particular product, comments, rating, satisfaction scores, rating conversation about the quality of the product. Figure 1 shows such a typical example chart of sentimental analysis depicted from [1] and Table 1 shows some of the tools used to track and crack the user's sentiments.

	#s	Month 2	#s	Metrics	Chng

4. THE ARCHITECTURE OF SENTIMENTAL ANALYSIS PROCESS

Opinion plays a significant role in the technological world. However, in electronic commerce, the opinion on a product is vital. Further, customers are anticipated to acquire the magnificent goods based on the reviews from the customers who had already bought those products, without any interactions. The opinion mining process comprises of three phases, namely, (1) Opinion retrieval, (2) Classification of opinion, and (3) Views summarization. Figure 2 shows the architecture of opinion mining depicted from [3]. In the first step of opinion mining, the opinion retrieval phase deals with the collection of reviews from the websites/ blogs/databases. The second phase, classification of opinion is categorized as Supervised and unsupervised methods and is responsible for classifying the opinion as negative and positive classes. The third stage, summarization of opinion ought to highlight the review results of the opinion.

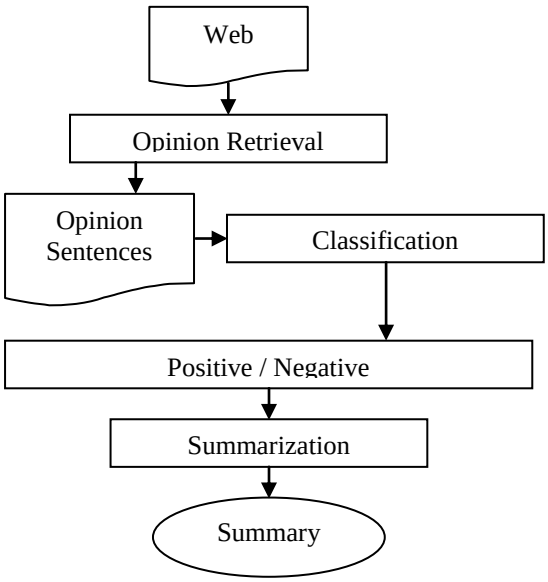

Figure 2. The architecture of Opinion Mining / Sentiment Analysis

5. CONCLUSION

There is no doubt that, Sentimental Analysis made us move from traditional market surveys and the research to online media monitoring surveys. Sentimental Analysis not only promoted business strategies for large investors but also for the number of small start-up companies. Because industries want to know and explore the customers perceive and their competitors. Henceforth, the technical challenges and practical needs of the opinion mining will be likely for years in all the domains.

Apriori-based Frequent Symptomset Association Mining in Medical Databases

R. P. Ram Kumar, R. Jayakumar, A. Sankaridevi

Abstract*— Nowadays, healthcare organizations generate large volumes of data. An automatic way of retrieval is necessary when the volume of data is increased. Data mining is becoming very popular and has extensively used in various Healthcare organizations. With the use of various data mining algorithms, it is possible to extract many useful patterns. Data mining applications can highly benefit various parties in Healthcare organization. This paper proposes to enable healthcare organizations by predicting the number of patients affected by certain diseases with respect to their symptoms in medical databases. The pharmacists can use this discovered knowledge and avoid the run out of required drugs, so that the patients can be treated at the right time.

1. INTRODUCTION

Knowledge Discovery in Databases (KDD) is a distinct process consisting of several well-defined steps. Data mining is the core step in KDD, which helps in the discovery of buried, but useful knowledge from massive Healthcare databases. Data mining allows extraction of knowledge from heterogeneous healthcare databases, which in turn eliminates the manual tasks and retrieves the data exactly from electronic records. To carry out the mining process, the medical data can be preprocessed by various techniques like Cleaning, Integration and Transformation. Data preprocessing is one of the major problems when going for the ETL process.

2. PREPROCESSING OF MEDICAL DATA

Cleaning:

The cleaning method removes data inconsistencies by eliminating Duplicate Records, Data entry mistakes and filling missing values for improving the data quality which is highly recommended for mining to keep away from wrong conclusions. Messy data cleaning can be done either manually or by using some tools which are readily available in the market. Smoothing can also be done by techniques such as binning and regression.

Integration:

Once data cleaning has done, the medical data sources are integrated into a homogeneous one, which means the heterogeneity of the medical data is removed while merging data from multiple sources. Data integration is very tricky and various issues are encountered such as matching of the schema, objects when data are received from various sources. The data redundancy may cause if it is derived from another medical entity and it can be detected and solved by correlation analysis.

Transformation:

In data transformation phase the aggregation operations are applied, and a reduced form of clean data is obtained during the reduction phase. In the reduction phase, two main encoding methods like dimensionality reduction and numerosity reduction is used. These reduced data are aggregated in various structures such as tables or Multidimensional model. After these operations, the database is ready to mine. In this paper, a patient database of a particular healthcare organization has been taken as a sample.

3. SYMPTOM-BASED CATEGORIZATION

The medical oriented assessment is extremely specific which requires huge endeavor and determination to spot diseases accurately that shows symptoms. Identifying such symptoms is troublesome which is done by experienced doctors, and they usually categorize diseases based on various diagnosis methodologies. These support doctors to narrow down the cause of diseases that show symptoms and which can be done using facts and experience and later which will be confirmed by conducting various tests.

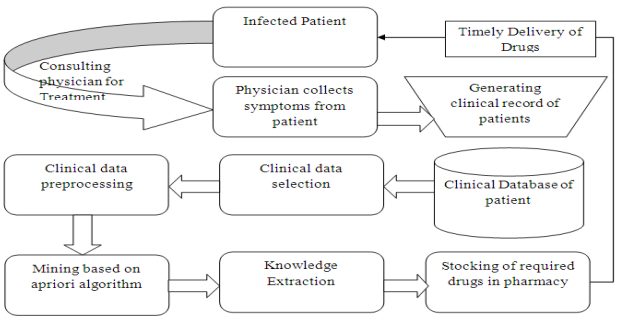

Figure 1 Architectural diagram of symptom categorization

The signs and symptoms which are self-assessed and reported by patients are crucial to identifying these disorders. Based on the symptoms of patients the physician can diagnose and treat them with adequate medicine.

Revised Version Manuscript Received on 22 February, 2019.

R. P. Ram Kumar, Professor, Department of Computer Science and Engineering, Malla Reddy Engineering College (Autonomous), Secunderabad, Telangana, India. (e-mail: rprkvishnu@gmail.com)

R. Jayakumar, Associate Professor & Head, Department Of Computer Applications, Mahendra Engineering College, Tamil Nadu, India.(E-mail: mymailjsjk@gmail.com)

A. Sankaridevi, Assistant Professor, Department Of Computer Applications, Mahendra Engineering College, Tamil Nadu, India.(E-mail: sankari.dv@gmail.com)

The diseases such as malaria, Dengue, Zika, Ebola, chickenpox, Chikungunya, Typhoid and jaundice which are sometimes deadly and seasonal infections. Here these diseases and its symptoms are taken as a sample for frequent pattern mining based on patients report that is updated in Healthcare databases.

The entire process of patient symptom mining depicted in the figure is explained over here. The patient who falls ill may describe his or her medical signs and symptom comprehensively when consulting a medical practitioner. At this point, effective Doctor-Patient interaction is challenging and plays a significant role to collect symptoms optimally. The collected symptoms are updated on to the Medical database.

The suitable data for mining can be selectively obtained from the database and which are preprocessed for improving the data quality. Sometimes this preprocessing takes more than half of the total time taken for mining. The frequent pattern mining based on a priori has devised to extract a useful pattern. The outcome of this process is to acquire information about the number of patients affected by the same set of symptoms. Knowledge which is obtained from this mining can be used by the pharmacist to stock their inventory accordingly, which in turn enables them for rapid delivery of drugs and medicine medicines to the needy patient.

Through this mining, the healthcare organizations can take the exact decision to store the required amount of Drugs. In this paper, an apriori association mining algorithm is applied to associate the symptoms of patients, which in turn help the pharmacist to focus on proper medication use.

4. COMMON SYMPTOMS AND RELEVANT DISEASES

The set of a syndrome that is commonly correlated for identifying particular disorders and diseases are listed out.

Symptoms	Disease
High fever and chills, Vomiting, Nausea, Headaches, Body pain, Weakness, Fatigue.	Malaria
Fever, Headache, Vomiting, Nausea, Rash, Eye pain, Joint pain, Muscle aches.	Dengue
Weakness, Abdominal pain, constipation, headaches, Fever	Typhoid
Fatigue, Weight loss, Abdominal pain, Pale stools, Vomiting, Fever, Dark urine.	Jaundice
Fever, Loss of appetite, Muscle aches, Feeling of nausea	Chickenpox

Association Rule Mining:

Association mining is the process of extracting frequent associations among various sets of items in large volumes of data repositories. Some of the currently used association rule mining algorithms are Apriori, FP Growth, Magnum Opus and Closet.

These association rules are widely applied to various areas like Marketing, Inventory management, Telecommunication etc; In this paper, these rules are applied to the Patient database of the healthcare organization. These rules are molded based on two methodologies called support and confidence.

Support represents the percentage of things in a database that contains both item number one and two, Whereas confidence represents the things in a database containing item number one that also contains item number two.

Support (One => Two) = P (One U Two)

Confidence (One => Two) = P (One / Two)

An association rule mining technique is applied to count the total number of patients affected by similar symptoms. The architecture of an association mining of Patient database has shown in the Figure. Here the type of association mining method used is the Apriori algorithm.

Finding Frequent Symptom sets using candidate generation (Apriori Algorithm):

Frequent pattern mining algorithm employs an iterative approach using level-wise search with the help of minimum support count. The Symptom sets are found by scanning the database to collect the count for each symptom that satisfies the minimum support count.

Apriori employs two steps called join and prune during algorithm generation. That is, the database is scanned, and the candidate support count is compared with the minimum support count until the end of the iteration. The result is obtained after finishing full scan of the database. In this algorithm, the candidate generation is denoted by C1 to C n and the resultant set is denoted by R1 to Rn.

The attributes of the patient database are Patient Id, name, address, contact phone number, Set of Symptoms, Prescriptions, Physician detail who attended the patient, payment information and so on. Generally, clinical databases have accumulated with the very large quality of information and medical condition about the patients. But this paper suggests the inclusion of only patient ID and their list of symptoms for sampling. Here the patient database consists of ten samples has been taken for mining. The symptom ('S' represents symptom) sets of the patients are,

S1- Weakness
S2- Abdominal Pain
S3-Headache,
S4-Body Pain
S5-Vomiting
S6-Fatigue
S7- Bleeding
S8- High fever and chills
S9-Chills
S10- Fever

Table 1: Sample Patient Database (D)

P-Id	Symptoms

Symptom Set	Support Count
S1,S3,S5	3
S1,S3,S10	3
S1, S4, S5	3
S1, S5, S6	3
S4, S5, S6	4

Here the minimum support count is taken as 2, and the algorithm is generated. After three iterations the final result is obtained,

Table 7: Resulting Set R3

Symptoms	Support
{S1,S5,S6}	3

Table 7 shows the final result set obtained from the patient database. According to the result, three patients P1, P5 and P8 belonging to the database are having the same set of symptoms, and they may be possibly affected by Malaria as per their symptoms. So, according to the above trend, the healthcare organizations can store the required amount of Vaccines and drugs for Malaria to treat and protect a maximum number of patients.

CONCLUSION

The Apriori Association mining algorithm incorporated in the patient database will identify the frequent set of symptoms and its related diseases which in turn identify the number of patients affected by the particular disorder. The efficiency of these algorithms is also known through the implementation of various steps. This algorithm is simple and fast enough to mine and exactly associate useful patents from the data source which holds symptom sets with a lesser amount of patient entries. If the size of the database grows large, this approach will become a time-consuming process, Because it needs more iterations to generate a candidate with multiple repetitive scans. In future, it is suggested to use various classification algorithms to mine significant information from vast healthcare databases.

Study and Analysis of Big data with MapReduce Framework

K. Rama Krishna Reddy, B.G. Obula Reddy

Abstract— Exponential growth in data has been observed in recent years. This huge amount of data has caused a new kind of problem. Existing RDBMS systems cannot handle large data or they are not effective in managing them. Major Big Data problems are storage and handling. Hadoop is displayed in storage and processing solutions in the form of HDFS (Hadoop Distributed File System) and MapReduce. Traditional systems are not intended for Big Data processing, and they can also process structured data. The financial sector is one of the challenges in Big Data. In this work, unstructured data is processed by Hadoop MapReduce. An effective processing of unstructured data is analyzed and explained.

Keywords: Big data, Hadoop, HDFS, MapReduce.

1. INTRODUCTION

We live in a date of age. It is difficult to calculate the total amount of data electronically stored, but the IDC calculates the size of the "automated world" 4.4 Zetta Bytes in 2013, and estimates the development ten times by 2020, up to 44 ZB. Approximately one thousand EB, one million BP or one billion TB. This is more than a circle of unity for all who live on the planet. So there are a lot of data that indicates that they have an impact. Most data is protected by larger web properties (such as web crawlers) or logical or money-related parameters, would you say no? Do large amounts of data affect associations or smaller people? The model is that the data on each of them has evolved, although perhaps more importantly, to the extent that the data produced by machinery produced as part of the Internet of Things is significantly higher than that produced by individuals. Machine files, RFID files, sensor systems, vehicle GPS tracking, local exchange for data exchange. Freely available amount of data is also created annually. Associations should never process your data. The result will be largely motivated by its ability to generate incentives from other associations. Customers who need to store and retrieve data store information for a long time in the database and process them using SQL queries. The web has changed most of the suspicions of this time. The information on the Internet is unstructured and essential, and databases cannot save or increase the information in the scheme to store and process them. Google was one of the most important associations to solve the problem. To find questions, she had to download and index the entire Internet. They created the basis for extensive information management, derived from the options "map" and "reduced".

2. LITERATURE REVIEW

Literature review described as the summary or re-organising the related information from different sources to understand the research problem. In this review how data analysis done for big data through data mining techniques is studied.

[1] MapReduce is a planning model and appropriate implementation for the management and production of complete data sets. Customers set up a card task where the main / calculation procedures are combined to form half the main route / cluster table and reduce the work of trade unions that have all the values associated with the central key. This model shows a large number of paper-based companies. Projects written in this useful style are parameterized in parallel and executed in a naturally large group of production machines. The enforcement system covers the fine elements of the Information Data Unit, reserving the program execution in machine mode, solving machine frustration and addressing the compliance of the required machines. This allows software engineers who are not involved in parallel and distributed infrastructures to effortlessly use assets that are significantly dispersed. Our use of MapReduce is still applicable to large-scale machine tools, and is very versatile: the typical MapReduce calculation makes up countless terabytes of data in a large number of machines. Developers believe that the system is easy to use: several MapReduce programs have been updated, and more than a thousand MapReduce tasks work consistently in Google's clusters.

[2] In fact, programming systems often operated without creating a direct expressive model. This can lead to complex problems that can ruin further development, which is relatively unavoidable, since in the best case, the most important product documentation is the source code. To solve this problem, learn how he focused on software modeling inductance using automatic recording learning algorithms. In both cases, records generated using a good scheduling system can be significant and the calculation of the derivative may exceed the processing limit of one computer. This document provides a generic and flexible way to obtain behavioral patterns capable of handling critical performance records using commonly used and parallel algorithms using the MapReduce programming model and executing a group of connected execution centers. The approach consists of two divided phases, which destroy and combine the model. The calculation for each phase was done using MapReduce. With MapReduce's parallel data boundary, the problem of

removing major registry behavior patterns can be solved. This strategy is updated by Hadoop. Analyzes in the Amazon clusters indicate our approach to productivity and adaptability.

[3] The Google MapReduce programming model is used to handle large datasets in parallel. We provide the first exact model description, including the Google-specific Sawzall domain's progress. For this purpose, we create Primary Documents in MapReduce and Sawzall and record our results as executable specifications. We also identify and resolve some of the errors in the relevant documents in the informal presentation. We use the recorded functional program (especially Haskell) as a tool for design restoration and executable specification.

[4] MapReduce is the general basis for cluster-based distributed batch processing. In order to streamline debt recovery capabilities, many MapReduce performances are shown in the overall performance of each card and reduce allocations before they are consumed. In this document, we offer an appropriate MapReduce technique for transferring data between administrators. This extends the MapReduce programming model beyond cluster management and can reduce processing time and improve group activity in group activities. We introduced a custom Hadoop MapReduce structure that provides total online sharing so customers can see the "first respond" of the treated call. Our Hadoop Online Prototype (HOP) also supports continuous queries that allow aggregating MapReduce projects for things like incident observation and energy management. Bounce retains Hadoop's non-critical malformation properties and can run MapReduce programs that feature an unmodified client.

[5] In recent years, in the rapid development of data, Industries and the rest of the world, the academic world needed a smart data retrieval device that would be useful in removing huge amounts of data. The MapReduce system is primarily designed to record scaled data applications to support vital management. Since its launch, incredible research has been done to make this process more natural for customers. This allows them to intensify the execution of large applications based on data. Our homepage highlights the key role of improving the efficiency of various applications that use the latest MapReduce models, as well as large scale data set processing. A comparative study of Dot models is compared to Apache Hadoop, and Phoenix will be a fundamental discussion of performance time and adaptation to internal failures. Finally, the call for updating the MapReduce calculation in a given region will be unusual, for example, recalculation, harmonized processing of issues, Métis database, etc.

3. PROBLEM STATEMENT

Traditional database systems are not intended to handle large volumes of data that we have known over the years. It is also expensive to increase the processing power of these systems. In addition, traditional systems can process only structured data. Unstructured data is the most important part of the data collected over the last two years. The existing system works on the same server, making vertical growth more complex and expensive.

Limitations

The two main drawbacks are:

1. Large data cannot be stored and processed
2. Unstructured data cannot be processed

It is limited how this system can be made vertical. Most of these individual servers are high-end or modified, so they are not profitable.

4. RECOMMENDED SYSTEM

The traditional RDBMS is not designed to handle unstructured data, and the size of the data it can handle is limited. The biggest problems with data processing are storage and processing. In this work, the Hadoop Framework is used to address storage and processing problems. Hadoop stores data in a cluster that is distributed over the network and processes it. Solve the problem by increasing storage and processing power. This can easily be achieved by increasing the number of nodes in the cluster. Data storage as well as processing distributed in cluster nodes significantly reduces the processing time of Big Data. It also eliminates the need for high-quality or custom-made equipment, which is very expensive.

5. CONCLUSION

In this paperwe describes how unstructured data can be efficiently processed using the MapReduce programming model. The Hadoop Framework is a solution to big data-processing problems. In this work, a series of unstructured inventory data is used to demonstrate the implementation of MapReduce tasks. In addition, the relevant sections are shown. This work provides a better understanding of the implementation of the MapReduce tasks by unstructured registry data and encourages further research to find more efficient ways of processing non-structured registry data.

Big Data Management Using Cloud Computing Environment

K.Rama Krishna Reddy, S.Dhanalakshmi

ABSTRACT--- Cloud computing is an operational innovative methodology to accomplish gigantic scale intricate processing. It securely keeps up costly processing equipment, committed space, and programming techniques with at most safety. Gigantic development of information or vast storage of information generated by people through Cloud computing has been monitored every now and then as the information is a testing and time-requesting errand that entails an extensive computational and ideational framework for a secured handling and examination. The ascent of huge information in Cloud computing is inspected along with the definition, attributes, and arrangements. The connection between these huge and vast information and data, computing, enormous information stockpiling frameworks, and Hadoop innovation are likewise talked about. Finally, open research disputes that require considerable exploration endeavors are condensed. The paper began a few major information preparing strategies from framework and application viewpoints here give a sorted out depiction of difficulties that are engaged by the solicitation engineers and DBMS originators in creating and simultaneously sending of the web applications. It has been that the security concerns in the Cloud computing alongside the huge information and Hadoop. We demonstrate some conceivable answers for the above disputes of the Cloud computing methodology and Hadoop structures.

Keywords- Big Data; Cloud Computing;

I. INTRODUCTION

The efficacious hypothesis for the administration situated writing computer programs is the Cloud computing. It has reformed the method for processing foundation's reflection and utilization. The flexibility, pay per utilize, low forthright venture, exchange of dangers is the most empowering qualities that is omnipresent stage for conveying monetarily practical endeavor foundation settings. However, information dissimilarities examples has cleared a path for the element called key esteem stockpiling which are currently being broadly utilized by different ventures. In the area of Map diminish and execution from open source of an indistinguishable known from the time Hadoop was developed by larger part of the business and scholastics. Hadoop expands the ease of use and execution. HDFS has turned into a Very helping device to keep up and store the perplexing information. Enormous information has ending up more accessible and reasonable to PCs. What is enormous information? The inquiry arrives. Huge information is the portrayal improvement of human psychological procedures, more often than excludes informational collections with sizes that is past the present innovation's ability. The information which is quick has different assortments and requires new procedure for preparing the structure to enhance the leadership, knowledge and revelation and ordering of the process. All together to summarize and consolidate the information for differentiating the proof of examples it is critical to store the information safely, oversee and sharing these complex information.Since cloud computations includes is multi-faced model, we use optimal to make improvements in securing cloud than indicating all encompassing arrangements.

This paper a far reaching foundation investigation of condition of workmanship frameworks. Distinguishing proof of basic angles in outline of different frameworks and extent of the frameworks. We appear some methodologies in secure system by use of the adaptable framework to deal with extensive number of locales and furthermore has the capacity to process vast and gigantic measures of information. We likewise give the status of huge information related works, going for giving an outline of overseeing huge information and its applications.

II. HADOOP

This is use of java based programming for preparing and use of extensive arrangements of information in an appropriated processing condition. Utilizing Hadoop, enormous measure of informational indexes can be equipped with servers and applications running on framework with enormous terabytes of data. This brings lower the danger of framework and, this propagates number of hubs fail. It empowers an adaptable, adaptable, blame tolerant processing arrangement.

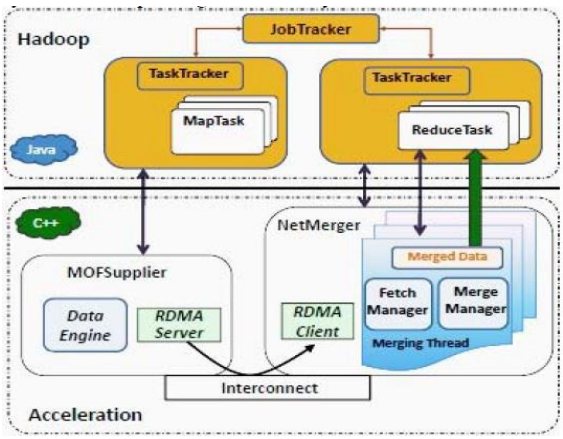

Fig1:- Hadoop structure

Revised Manuscript Received on February 14, 2019.

K.Rama Krishna Reddy Associate Professor, Department of CSE, Malla Reddy Engineering College (A),Telangana, India. (E-mail: ramakrishnareddy524@gmail.com)

S.Dhanalakshmi Professor, Department of CSE, Malla Reddy Engineering College (A),Telangana, India.

HDFS, a document that spreads all over the bubs in Hadoop bunch for information stockpiling joins the record frameworks on nearby hubs to make it onto a substantial record framework therefore enhancing the unwavering quality. Hadoop structure trackers are running the tasks that the activity tracker allots them, which continues with bunch assets and booking all client employments Data motor comprises of all the data about the preparing the information Fetch chief gets the information while specific assignment is running.

III. ANALAYTICAL RESULTS & DISCUSSIONS

Map reduce system is utilized to compose applications that procedure an a lot of information in a dependable is firstly separated as singular lumps prepared by singular map employments yielding lessen undertakings. The checking is securely done by the system which diminishes The information as required in the form of separated single pieces which will be made to handle by the map assignment while the information and the outcome is taken and decrease there responsibility where the outcomes that are produced parallel, merged, diminished and yielded. Huge information applications such as blast, parallel handling is particularly fundamental for playing out a huge volumetric information in an opportune way. Parallelization systems schemes are utilized in accomplishing better versatility and execution for preparing huge information. map decrease is a prominently utilized device or model and utilization in industry and scholastics.

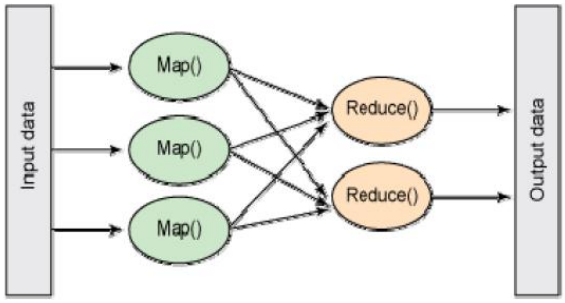

Fig2:- Map reduce

The two noteworthy points of interest of map decrease are embodiment of information stockpiling, conveyance, replication subtle elements. It is exceptionally straightforward for developers to code for the maps. These maps lessen is without construction and is free and it needs construing of each record the perusing point. Map decrease has gotten a considerable measure of mindfulness in the fields of information mining, data recovery, picture recovery and so on. The calculation ends up hard to be taken care of by conventional information handling which triggers the improvement of enormous information apps. Huge information gives a framework to keeping up straightforwardness in assembling industry, which has been being able to unwind vulnerabilities that exists in the segment execution and accessibility.

The most predominant application of the huge information is in bioinformatics which entails vast scale information investigation. Focal points of huge information: The huge information which handles to each person to analyze the danger in which the user faces. By thoroughly peeking onto the whole information the organization utilizing the opulent arrangement of apparatuses that the product associating itself to the enormous information. As an essential preferred standpoint of enormous information since it enables the client to make the information sheltered and secure, the speed limit and versatility of Cloud storage gives a simple favorable position to the organization and association. Enormous information even enables the end clients to use of information in organization to find new business openings. Information examination is one more outstanding preferred standpoint of the enormous information is permitted to customize the substance at the constant sites.

We are in the era of the huge information system which we can be accumulated cumulatively every day from person to person. Up until now, scientists can't bring together the highlights that are more fundamental to enormous information, valuable and process utilization of information use of existing innovation, hypothesis or any techniques for such kind. However the world has turned out to more important, to measure vulnerable information is measurement of information is being produced by various global themes like science, business and even society. Enormous information has postured numerous difficulties to the information business.

IV. BIG DATA MANAGEMENT

The need of the enormous information requirements is scarcely fulfilled by the present innovations. Moreover, the speed of expanding, extending the stockpiling limit is considerably least contrasted with information. Along these lines a recreation of data system has to be planned for a progressive engineering capacity wherein the heterogeneous information are not productively taken care of by the proficient Algorithms that exist currently in the trending of cloud computing application and hence we have to try and outline an extremely productive measurement of viable dealing of heterogeneous information. Need of security in huge information: The enormous information is utilized by a considerable lot of the business; this may not have resources from point of view of the security. In the event that any security danger jumps out at enormous information, it might turn out with significantly more major issue. These days, organizations utilize this innovation to pile information of peta byte extend with respect to the organization, business purpose and clients. The outcome in the application seriously affects the criticality and the protectiveness for grouping of informative data. To secure and safe guard the information we either need to scramble, log ,employ and operate honey pot procedures. The test of identifying critical and issues must be explained utilizing huge information style investigation. Investigation and calculation of huge information: Speed is the primary concern when we search up for questioning in the enormous information. However the procedure might be tedious simply because of the

reason that it can't navigate every related datum in the entire database in a brief span. While the huge information is getting confounded, the lists in the enormous information are going for the straightforward kind of the information. The customary serial calculation is wasteful for this enormous information.

V. PROPOSED APPROACHES TO ENSURE SECURITY OF BIG DATA IN CLOUD COMPUTING ATMOSPHERE

A small number of security measures that can be used to improve the cloud computing environment have been proposed below:

1) Encryption: The information available in a framework used globally will be available in a group as well where any programmer can have access to the information through framework. This may become a difficult issue for any organization or association to shield their information and lead to breaching crimes. To evade this, we may go for encoding the information. Diverse encryption instruments can be utilized in a distinctive framework and the keys created ought to be put away furtively behind firewalls. This strategy prevents breach of information of the client ensuring data safely.
2) Nodes authentication: The hub must be validated at whatever point it joins the group. In the event that the hub ends up being a malevolent group then such hubs must not be verified.
3) Honey pot nodes: The honey pot, and gives an intuition of similar to a standard hub yet is a trap. It naturally traps the programmers and won't enable any harm to happen to the information.
4) Access control: The variance protection and access control in the conveyed condition will be a decent measure of security. To keep the data from spilling we utilize a SELinux. The Security Enhanced Linux is an element that gives the system to assist access control security arrangement using linux Security modules in linux portions.

VI. CONCLUSION

This publication gives an elaborated depiction of an efficient stream of huge information technique called Cloud computing. The current trend of applications and the problems and issued raised by the huge information data structures when utilized over a Cloud computing condition were discussed proactively. We proposed couple of answers for shielding the information in the Cloud computing atmosphere with a futuristic approach of overcoming the discrepancies and clear the path significantly for the more proficient utilization of the enormously available information by the client on a Cloud computing condition. It is particularly required that the PC researchers and IT experts to participate and make a fruitful and extensive haul utilization of Cloud computing and investigate new thoughts for the use of the enormous information over cloud condition.

Reducing Energy Utilization for Data Processing and Query Processing in Web Search Engines - Green Internet

B.G.Obula Reddy, K.Rama Krishna Reddy

ABSTRACT--- Web crawlers are made with the advantageous resource of the use of way out of solicitation getting prepared focuses i.E. Servers submitted for the frameworks of buyer demand. Such servers with broad level of solidarity, mindful to their CPUs which can be perfect to make certain low happen in view of truth the customers depend upon sub-second reaction points of reference (e.g. 500 ms). measurements, customers can see reactions which might be quicker than their desires. As a give up conclusive item, we propose the Predictive quality Saving internet Scheduling set of guideononononon line (PESOS) to pick out the magnificent genuine CPU to gadget a request for unmistakable quality quo. PESOS component interests at path demand through their surrender dates, and utilize over the top booking measurements to bring down the CPU vitality insistence of a request getting prepared center detail. PESOS base its inclination on request efficiency markers, surveying the preparing entirety and managing time. We likely have a view PESOS upon the TREC ClueWeb09B gathering and the MSN2006 request log. Impacts bits of knowledge that PESOS can diminish the CPU for request managing as a lousy bundle as forty eight% to a gadget taking walks all things considered unbalanced CPU focus repeat. PESOS plays a colossal present day-day-day contender with a 20% power saving, at the indistinguishable time in view of the reality the contender requires a ="conceal">superb="tipsBox"> parameter tuning in wild inaction encroachment.

Key articulations - ="conceal">superb="tipsBox"> confirmation, CPU Dynamic Voltage and Frequency Scaling, net engines like google like google and hooray like google like google.

I. INTRODUCTION

Web search gear like google and yahoo like google like google like google like google and hurray like google and hooray consistently skip well ordered and state of web pages to move bring down some other time gleaming and relevant impacts to the clients' request. Customers' request are dealt with through request making prepared , i.e. real servers are given to this errand. Web crawlers like google like google like google and yahoo are typically made through the utilization of the utilization of burdens out of those center points, encouraged in ="disguise">massive="tipsBox"> datacenters which in addition exemplify establishments for media transmission, warmth cooling, stack camouflage, control supply, and bunches of others. This eccentric system is vital to have low latencies (e.g. ninety five%) to ensure that greatest clients gets shield of impacts in sub-second cases (e.g. 500 ms) with their objectives .Such various servers eat up ="hide">huge="tipsBox"> amount of intensity, bit of leeway of the net are searching for instruments like google like google and yahoo like google and hooray like google and yippee like google and yahoo and raising environmental issues. class="tipsBox"> than number one in giving inquiry results snappier than required for customers. In this we prescribe the Predictive remarkable Saving on lineononline Scheduling set of policiesonon-on the web (PESOS), which considers the tail dormancy essential of request as a chose parameter.

The DVFS time, PESOS picks the most extreme reasonable CPU repeat to denounce on center reason, for all plans and highlights so the CPU oversee use is decreased as required tail inactivity. The game plan of on line enables it to tendency on request efficiency signs in decision to prevalence use. Request efficiency signs are to evaluate the managing time of a request sooner than its getting equipped. They have been proposed to format the general ordinary huge regular execution of an are searching for engine, as an occasion to take tendency round request making arrangements or question taking care of. Request efficiency pointer has in no way again been considered for reducing the vitality use of inquiry getting prepared center points. We online in and prompt novel request efficiency marker philosophies: one to check the type of offering that need on be scored to approach an inquiry, and one to evaluate the response time of an inquiry underneath a particular awareness repeat given the extraordinary sort of postings. PESOS abuses the ones pointers to complete that is the least conceivable acknowledgment repeat that can be utilized by a gadget, exceptionally the CPU control affirmation is blurred on the equivalent time as lower evaluated the prestigious tail latency. As side effects can be broken, in this artistic creations of works of art we in addition propose number one online of square stumbles of the markers. We've were given were given were given an investigate the general customary favored normal basic execution of our system with those of 3 baseon tracesononline: perf, which ceaselessly ="conceal">makes use of="tipsBox"> the greatest extreme CPU center repeat, quality, which throttles CPU notoriety frequencies standard with the middle utilizations, and cons. PESOS with pointers correction, is healthy for meet the tail lethargy necessities while diminishing the CPU power affirmation from 24% as weights as 40 4% with perceive to perf and typical segment as 20% with perceive to cons, which reasons encroachment. The investigate demonst="disguise">first="tipsBox">s that power utilization can be lessened with the valuable helpful profitable valuable resource of PESOS at the undefined time as conjecture modification isn't connected, with higher tail latencies the loosening up of the paper is basically based absolutely in all actuality genuinely in all actuality as seeks after: part 1 gives records bits of knowledge about the incredible confirmation of net filtering for engine datacenters, the request taking care of delight premium, and the request efficiency side effects. Section 2 designs the burden of fixing the power use of request getting sorted out center on the unclear time as enlarging the style of request which meet the deadononon-on the web. Degree three illustamazings our proposed methodology which depicts our request efficiency pointers and the PESOS set on-line. fragment 4 illustterrifics our preliminary setup on the unclear time as recognition 5 looks at the gained results. Related works are referenced in recognition 6. At last, the paper ends up in stage 7.

II. RECORDS

In this stage we're succesful ="hide">to talk="tipsBox"> the power related issues expedited utilizing net files like google like google and yahoo like google like google and yippee (Sec. 2.1). At that component, we on line to degree a case for obtaining outfitted works and numerous frameworks to reduce question reaction sports (Sec. 2.2). At absolute last, we are proficient ="cover">to talk="tipsBox"> close request efficiency markers which we for the most part tend to take addition of the vitality affirmation of a web test for engine inside the period in the middle of as verifying low tail latencies.

2.1 NET ARE SEARCHING OUT ENGINE AND AFFIRMATION

A bit of datacenter ="cover">high-quality="tipsBox"> affirmation balanced into inefficient cooling and power convey structures. Document which have datacenters as gigantic factors dwindled the power wastage of these establishments, commonly precluding what is more noteworthy improvement. In particular, our craftsmanship rehearses inside the CPU astounding control of request adapting to as CPUs overpower the remarkable affirmation of genuine servers focused on look duties. Actually, CPUs can utilize round 66% of the entire ="cover">brilliant="tipsBox"> ate up through request getting prepared contemporary-day-day CPUs generally are vitality saving gadget, remarkably C-states and P-states. C-states.

At the vague time as a CPU center is in the dynamic C0 the US, it may spotlight at different frequencies (e.g. 800 MHz, 1.6 GHz, 2.1 GHz, . . .). that is the path to the Dynamic Frequency and Voltage Scaling (DVFS) which stands to alter the repeat and voltage of a center to move its elegant comprehensive introduction and vitality usage. In actuality, higher focus frequencies endorse snappier figurings know-how better vitality affirmation and the elective route round. The arrangements of voltage and repeat to be had to the CPU offices are mapped to different P-states, and are overseen through way of the taking walks device. As an example, the weight controls the P-states on Linux frameworks 1 and can perform on account of this to 2 different on tracesonon line, expressly perf and power by means of repeat strategy handling duties. As a possibility, control picks the repeat for an internal in step withonon-on line its utilization. On the indistinct time as an inside is done, power picks an extreme repeat. Nonetheless, it'll choose masses an entire part stacks considerably an astounding arrangement a great deal substantially less repeat at the indistinct time as on a practically identical time as consideration is humble finished. Doubtlessly, the makers substances an improvement of request reaction times at the unclear time as focus use plan no ifs, ands or buts entire with capture to on-line are finished in a web searching for engine. For recommend to supervise the repeat of CPU offices set up together genuinely basically surely with capture to using the request adapting to in tendency to

Published By:
Blue Eyes Intelligence Engineering
& Sciences Publication

utilization of the offices. The utilization of a center point is figured because of the reality of percent the assorted request touchdown cost and connection cost. At that inconvenience, they instruct the cons consideration the repeat with secure to the CPU offices on the indistinguishable time as center point is above or under cutoff points (e.g. eighty% and 20% in a steady progression). The repeat is chosen to supply a more affordable use affirmation (e.g. 70%).In our fine art of craftsmanship we control the CPU focuses frequencies of a request taking care of center utilizing bits of knowledge related with the inquiry making outfitted leisure activity in district of to the CPU focuses use. To this give up, we obtain our methodology on peak of CPU thought process pressure which grants applications proper by and by to administer the CPU center repeat, inside the territory of counting the employable structures.

2.2 INQUIRY PROCESSING AND DYNAMIC PRUNING

The get-together of records is then record to give an adjusted archive. The turned around rundown is a structure that maps at a couple of angle point length inside the record amassing to a posting list, i.e. A posting of posting which information the pervasiveness of measurements. A posting conveys of at any charge the identifier (i.e. A component territory) of the archive wherein the timespan shows up i.e. the measure of events of the time span in that exceptional record. The changed over record is normally compacted and found away as essential archive to collect the general customary average ordinary execution of the pursuit engine. On a practically identical time as a request is submitted to a web are searching for engine, it's far dispatched to a question preparing center point. This recuperates a put summary of news which might be enormous for the question, i.e. The apex real great adequate actualities texture to a benefactor question, managed in lessening solicitation of congruity rating (e.g. by means of the utilization of the celebrated BM25 weighting model). To geneextremely exceptional the top unbelievable enough impacts posting, the creation prepared center point crosses all the offering measurements relative on the request phrases. That is, in perspective on the reality the disappointed record can impacts degree 10 of gigabytes. Such strategies avoid to survey beside the thing records evading added substances of the posting data. This decreases the response time because of the truth the structures avoid getting right of access to and decompressing some piece of the turned around rundown. On the vague time, the ones unique pruning frameworks are quiet as hundreds as all legitimate, i.e. They produce the vague apex appropriate well adequate impacts summary cut down once more through a thorough traversal of the posting records.

2.3 REQUEST ORDINARY NOW NOT SUDDEN REGULAR EXECUTION PREDICTORS

Request efficiency signs and side effects (QEPs) are structures that charge judgments execution time of an inquiry already of time than it is in all reality managed. Capacity prior of time the execution time of request lets in to upgrade the general gigantic favored through way of and monstrous execution of an are searching out for engine. Most QEPs make the greatest the of the request and the improved inclining to pre-sign on capacities to be abused to measure the request getting readied times. For endorse to utilize timespan predominantly based absolutely unquestionably for all intents and purposes essentially truly capacities (e.g. the contrary report repeat of the time period) to depend upon the execution time of a request.

They make the most extreme their QEPs for on ononline figurings to time table request in more than one unspecified time in the possible eventual fate of dealing with center point, as a way to reduce the typical request created. They work of fine art as an option, manage the issue whether or not the slightest bit yet again or in no way, shape or form yet again or not the slightest bit over again or not or not to parallelize or now not to machine a request. In truth, parallel making equipped can bring down the execution time of now not on time going for strolls inquiries to discover behind calendar walks questions. The getting prepared of the request is parallelized great if their QEPs discover the request as a drawn out going which benefactor to demonstratively show the request overseeing levels and to utilize such form to expect the execution time of request. In our craftsmanship, we trade the QEPs depicted in to progress our relationship of pointersonline for bringing down the vitality utilization through utilizing the use of overseeing center point .

III. RESULTS & DISCUSSIONS

in the going with, we blessing the employable situation of a request making prepared center (Sec. three.1), we formalize the through and enormous unimportant quality booking issue and we favoring the territory of crafted by work of art set of pointersonon on-line to treatment it offon on the web (Sec. 3.2), and we talk the bothers of this offon-on line set of on onlinetips in our situation (Sec. three.three).

3.1 OPERATIVE CIRCUMSTANCE

A request taking care of center is an apex server formed with the gainful valuable useful resource of the utilization of strategy for methodology for severa multi-center processors/CPUs with a not irregular memory which holds the adjusted report. The frustrated posting can be allocated shards and exceptional different request getting readied center points. On this craftsmanship, we action on reducing the CPU superb usage of single request getting equipped center points, independently of the found segment procedure.We anticipate that each inquiry dealing with center holds an indistinguishable propagation of the turned around report. Unmarried on-line will now not permit to take close to choices setting off to the CPU mindfulness repeat to utilize the relative request server. CPU offices to diminish the CPU control use, and into time work area request inside the course of genuinely one in each one among a kind request servers.

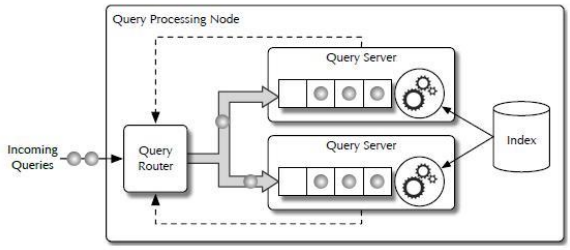

Fig. 1. The architecture of a query processing node.

3.2 THE MINIMUM-ENERGY SCHEDULING PROBLEM

Consider the circumstance, where an unmarried-focus CPU need to execute an intense and fast J = J1. . . Jn of set up processing employments in decision to questions. Occupations need to be done over a period c programming language [t0, t1]. Each intrigue Ji has a landing time Ai and a subjective last date which may be respected an issue. Besides, every methodology Ji has a preparing sum, i.e. How a arrangement sketches it requires from the CPU.The CPU can trademark at any handling beat s 2 R+ (in time gadgets ordinarily with unit of hard works of art) and its capacity admission is a curved capacity of the preparing rhythm, e.g. P(s) = s with > 1. Employments in J should be planned on the CPU. A period work area is more than one abilities S = (, -) signifying, individually, the preparing beat and the assignment in execution, each at time t.A time work area is practical if every path in J is finished inner its absolute last date. The base power booking bother (MESP) wants at finding a conceivable time table with the end goal that the entire quality admission is limited, i.e.,

$$\arg\min_{S=(\psi,\phi)} E(S) = \int_{t_0}^{t_1} P\big(\psi(t)\big)dt$$

The MESP is like a disconnected variant of our concern, wherein employments much like inquiries are appropriate succesful and processor rates can rely on any fabulous cost. The YDS set of guidelines fathoms the MESP in polynomial time. Keep up as a primary concern a c language I = [z, z0] [t0, t1] and the arrangement of occupations in that c language JI = Ji 2 J: [ai, di] I. The power g(I) of interim I is the proportion among the amount of hard works of art required using the jobs in JI and the length of the c program languageperiod

$$g(I) = \frac{1}{z - z'} \sum_{J_i \in J_I} v_i$$

A manageable time desk want to use a handling sg(I) in a couple of unspecified time afterward of the period in-between I, or employments might not meet their if s < g(I). additionally, P (g (I)) is the base feasible strength usage at the interval I, considering P is a raised trademark.

Set of tips 1 indicates the YDS set of indications that preferably unravels the MESP in O (n3). YDS takes a shot at breaking down every viable time c program languageperiod I included in [t0, t1]. At that factor the crucial interval with I amplifies g(I). YDS plans the employments in JI the usage of the maximum punctual absolute remaining date first (EDF) inclusion and getting ready rhythm g(I). At that point, if in no way once more appropriated, the employments in JI will fire in ri = vi • g (I) time gadgets considering truth that the start in their execution. Occupations in JI are then distributed with from J. The c programming language I is also expelled from [t0, t1], i.e. It can not be utilized to time desk employments beside the ones in JI. due to this, YDS refreshes the technique occurrences and closing dates of the absolute closing employments to be out of entryways I. over the lengthy haul, YDS again and again a forefront imperative c programming language for the ultimate employments, till all occupations are at closing booked. kingdom that the MESP via and big concede a viable time paintings area, thinking about self-assertive vast segments of excessive excellent artwork might be executed in microscopic time.

Algorithm 1: The YDS algorithm

```
Data: A set of jobs J = {j_1, ..., j_n} to schedule in [t_0, t_1]
Result: A feasible schedule S for J minimizing E(S)
OYDS(J):
1   ψ ← {}
2   φ ← {}
3   while J ≠ {} do
4       Identify I* = [z, z'] and compute g(I*)
5       Set processor speed to g(I*) for jobs in J_I* in ψ
6       Schedule jobs in J_I* according to EDF in φ
7       Remove I* from [t_0, t_1]
8       Remove J_I* from J
9       foreach J_i ∈ J do
10          if a_i ∈ I* then
11              a_i ← z'                    // Update arrival times
12          if d_i ∈ I* then
13              d_i ← z                     // Update deadlines
14  return S = (ψ, φ)
```

3.3 ISSUES WITH YDS

YDS an answer for the MESP, other than with severa issues that makes hard to utilize it in an are examining out for engine to diminish its capacity consumption:YDS is an offonon on lineonon line set of on-line to time works of art place mechanically taking zone handling occupations and can not be used to time artistic creations area on line request. As a celebrated principle, YDS data is the relationship of vocations to be made arrangements for a c language, with their touchdown times and extraordinary dates, that should be distinguished a circumstance. In assessment, request landing models aren't appeared till request arrives.YDS is assembled completely genuinely for the most extreme segment with appreciate to EDF, which thinks roughly embraced assignment. setting course and save reason time overheads with non-irrelevant impacts at the inquiry getting composed time that is unacceptable for web crawlers like google and yahoo like google and hooray like google like google and yippee like google and yippee like google and hurray like google.

- YDS require insights previously of time the overseeing volumes of livelihoods.
- To how an arrangement sketches of workmanship a request additionally can need to require ahead of time than its last contact.
- YDS plans intrigue the utilization of overseeing speeds (portrayed as devices of unreasonable canvases as often as possible with time unit).

- The expense rate is non-save you and unbounded (i.E., the charge is most likely uncertainly ="conceal">large="tipsBox">).
- In which the frequencies accessible to CPU offices are regularly discrete and bounded inside the going with section we adjust YDS as an approach to take advantage of it in an are searching for engine.

IV. CONCLUSIONS

In this paper we proposed the Predictive power Saving on line Scheduling (PESOS) set of on line. Close web lists like google like google and yahoo like google and hooray like google like google and yippee, PESOS wants to diminish the CPU oversee use of a question managing center point at the vague time as driving a required tail inaction on the request reaction times. For every request, PESOS picks the base practicable CPU consideration repeat with the stop reason that the fine usage is blurred. PESOS picks the correct CPU notoriety repeat mishandling different combinations of request efficiency markers (QEPs). The basic QEP measures the planning amount of inquiries. The second one QEP measures the inquiry overseeing occurrences underneath different mindfulness frequencies, which gives the level of postings to increment. In the way of the course in their mentoring we document the conviction advertiser rectangular errors (RMSE) of the anticipations. On this sytheses, we proposed to blend the RMSE to the genuine gauges to satisfy desire messes up. We at that thing described conceivable relationship for PESOS: time preservationist, wherein conjecture modification is allowed, and power slight, in which QEPs are left unmodified.

Overview of Managing Data Storage, Resource Models and Security Issues in Cloud Computing Environment

S. Dhanalakshmi, K. Ramakrishna Reddy, K. Vijaya Krupa Vatsal

Abstract— The Main goal of cloud is more number of users stored data in cloud environments with incredible rate, this cloud computing technologies performs some services/agreements done with provider and customer, once customer reach the storage limits for accessing the drive, the cloud computing services specified with pay based on usage and also mention the period for updating the service, many services generate large amount of data example. Organizations, social networks, ecommerce applications and etc., these services are generate bulk data daily, it's more useful to cooperating the organizations. The storage systems storing capable of huge volumes of data, based on updation the customer can interact with relational database systems through structured query language. The main concept of cloud environment is secure, protect the data. To discuss the related issues of managing data in data storage technology, resource management techniques and security mechanisms in the cloud based environments.

Keywords – Cloud Computing, Data Storage, Cloud Security, Resource Management, distributed file systems

1. INTRODUCTION

Its computing resources, resources are networks, servers, storage, applications, it provisioned and released with service provider interaction. Cloud computing perform the essential characteristics of on-demand self-service (needed automatically for server time and network storage without human interaction), broad network access (the network can be accessed through standard mechanisms use by heterogeneous platforms, resource pooling (it can be assigned and reassigned, according to the resources), measured service (automatically control and optimize resource by metering capability) and rapid elasticity. The Fig.1. Represents that cloud computing environments of general services, user can provide the service and access these services on the database systems, app server, mobile, personal computer, mobile node and binary code, so all these services available and stored on the internet cloud.

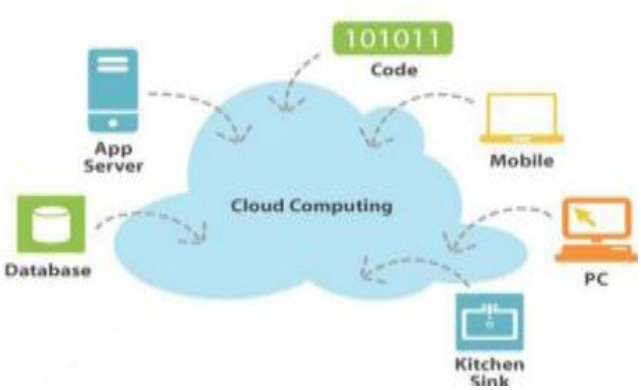

Fig.1. General Services on Cloud Computing

A. Different Types of Trends in Cloud Computing

The cloud computing performs different trends for distributing the systems, computing the resources; the different types are distributed computing, grid computing, cluster computing and utility computing.

Distributed Computing **–** use of distributed systems to solve computational problems, it's a field of computing science in distributed systems. The set of process of distributed systems that are work together to solve a common problem.

Grid Computing **–** client applications access to computing the resources, those resources located which mechanism to access its. The grids can be accessed with the components of users, groups and sites.

Cluster Computing **–** parallel or distributed computer system interconnected and working together with single integrated computing resource. Blocks of clusters are categorized into cluster nodes, cluster network and network characterization.

Utility Computing **–** customer availability, service provider makes the resources and charge for the resources based on usage rather than on a flat-rate basis.

B. Cloud Services Models

The cloud services models can be categorized into three types. Fig.2. represents that application and its cloud services.

Software as a Service (SaaS) **–** cloud infrastructure running on providers applications, it's accessible from various client devices through thin client interface.

Cloud Infrastructure as a Service (IaaS) – this infrastructure performs the arbitrary software of resources to be expanding it.

Platform as a Service (PaaS) – its deploying cloud infrastructure provided to the consumer, provider supported by the programming languages, tools and services.

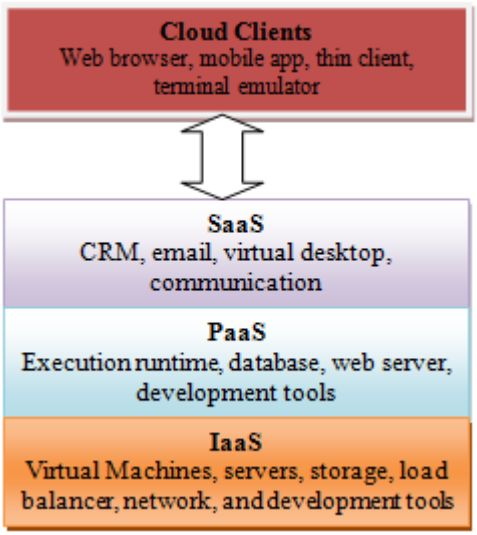

Fig.2. Cloud clients with Different Services

2. MANAGING THE DATA IN CLOUD STORAGE

Managing data in cloud storage specify that in cloud, in banking organization, financial organization do with large volume and other types of data like it metrological data in context of cloud. Relational databases are known that scalable data bases or data services, its important in Google file system big table and Google file system is a mapreduce parallel programming paradigm. So we are managing the data anything on a cloud platform; cloud platform is application or data, want to make it scalable specify the requirements. The requirements are scale-up scale down in a pervasive way of human interference, similar to the big table data model, the data models specify that google app engine's data store and Amazon simple database, but its provides different flavor, the basic concept is same for data storage paradigm. In relational database users are application programs interact with RDBMS (relational database management system) through Structured Query Language (SQL), the applications are deployed in the cloud platform.

Fig.3. represents that row and column oriented storage techniques. Row oriented storage has tuples, its optimal for write oriented operations in transaction processing applications, relational records performs the primary key with indexed format, way to be utilized in contiguous format of disk pages on specified columns, so B+ tree is favorites storage mechanisms in row oriented paradigm. In column oriented storage has high dimensional data of data warehouse, huge volume of data being collected in simple database, aggregation of measure columns need to be engaged, situated on values of dimension, its mentioned on tuples, this performance investigation operations to perform aggregation table, column oriented require multiple join indexes in different projection operations are to be indexed in sorted order. Data oriented storage techniques are B+ tree or join indexed operations, in join index allows this data linked to be linked to one another.

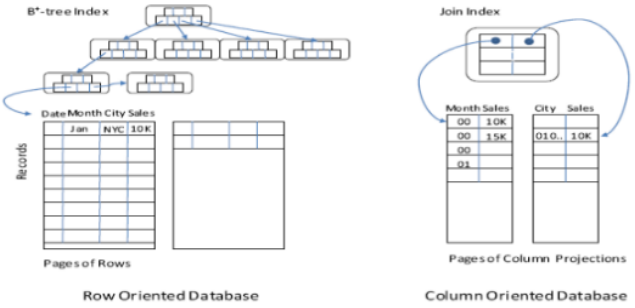

Fig.3. Data Storage Techniques in Cloud

In cloud based data management systems are performing different data management techniques, the techniques are BigTable (it's distributed storage systems for a structured data, not a database, the file systems are Google file systems-GFS), HBase are hadoops distributed file systems (HDFS) this file systems are java based in eco systems of big data, HyperTable are KFS, HDFS file systems (KFS – Kosmos Distributed File Systems are open source distributed file systems), hypertables are hbase project group, Hive technology performs the reading, writing, large type of datasets and its managed and Cassandra are local file systems in web data management, these files systems are used for popular cloud platform. So they can handle failure during read, write of individual files,

A. Cloud Data Storage Technology – Google File System (GFS)

Google File Systems design to perform and managing wide files with commodity servers connected to high speed network with distributed clustering systems, GFS or HDFS they are enable to work on very large data files, the data files are distributed over commodity server, some of them linux servers are interconnected through a very high speed line.

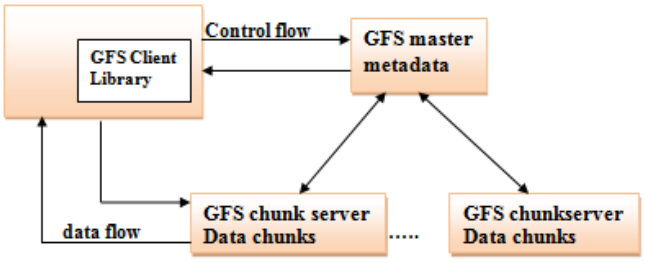

Fig.4. GFS Architecture

They can handle failure even during read or write of individual files, failure can be handled for read-write operation, so that client program can performing all operations of read and write systems. The Fig.4. Represents that architecture of file systems in google, its expanding data processing requirements, and several storage systems. GFS contains the GFS client library, GFS master metadata and GFS chunk server data chunks, GFS cluster is single master connected with multiple chunk server data, chunk server data

accessed by GFS client systems, the client systems are accessed continuously and data can be flow from chunk servers, the data chunks of 64MB, In GFS file systems all the files are stored in ranked manner. Metadata is controlled by GFS master, then GFS master interacts with each GFS chunk server and monitor the status of messages, accessed by many clients on a perpetual basis. GFS performs read operation and write/append operations, in read operation performs that client program sends the full path and offset of a file to the master (GFS), master replies with meta-data for reproduction of chunk of data is found, and client caches the meta-data for faster access. It reads the data from designated chunk server. Then Write/append operation in GFS, its performs client program send full path of a file to master or name node, master replies with meta-data, reproduction of data is found, then client send data to all chunk servers, chunk servers receives this data to send acknowledge, then dominant to chunk server, its regularly communicate main node with chunk servers, chunk servers is updated to reflect any failure in primary, the master assigns a new primary.

B. Cloud Data Storage Technology – Hadoop Distributed File Systems (HDFS)

Hadoop Distributed File Systems is apache storage foundations, used to store very large data set of files in structured manner, then its specify in the form of namenode and DataNode of each blocks, each blocks is pre-ordinate systems, blocks are specified in cluster, its stored on one or several machines. Fig.5. shows that architecture of hadoop distributed file systems, Master is specified in the form of NameNode, metadata stores for NameNode and slave is DataNode, its stores for actual data, in cloud file system architecture one NameNode and other nodes are DataNodes. Namenode is responsible, maintains and manageable for all slaves and assigns the work to all DataNode. Master ensures that alive for all slave, and its perform read, write/append operations based on request of clients.

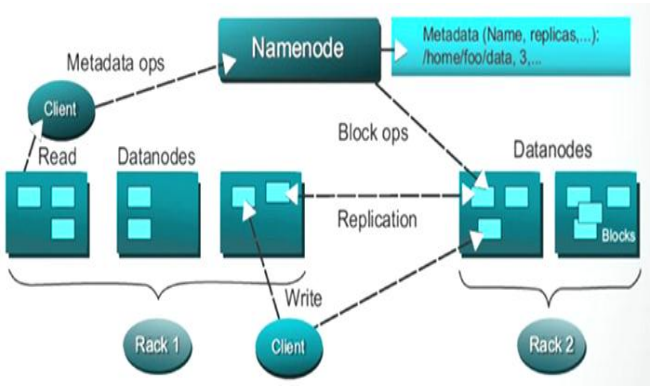

Fig.5. HDFS Architecture

Client communicates with namenodes and namenodes communicates with datanode, client to perform write operation then write a file to datanodes and then interacts with metadata. Split into multiple blocks then send data from data node into different files. The client reads data from datanodes, datanodes received information from name node, after that all the information's to be received and it's merged into original files.

3. CLOUD RESOURCE MANAGEMENT MODELS

I have the core infrastructure platform and application or IaaS, PaaS, SaaS and different kind of user, user for this clouds, human user or process or machine which are indirectly consuming cloud with different services, then this services to be managed and optimized to other resources in the cloud platforms. Most popular cloud service is Infrastructure as a Service, cloud providers offer resources that include computers and different network devices to be involved in the form of cloud management systems. Resources used to control how capabilities provided by cloud resources and services, to be performed in different services, application, entities and user to be managed in efficient manner, whatever the resources either hard or soft resources, area available with the cloud, its efficient to maximizing the profit of Internet Service Provider, it can be efficient in energy optimization to the external entities.

Resource or resource management usually fall back to infrastructure as a service, considering overall cloud or overall operation of the cloud; Infrastructure as a service plays bigger role in resource management systems with different type of heterogeneous systems, to be formed with different resources. Specify the concepts of sharing of resources in efficient manner, sharing with multiple users in different computing systems and services. The Objectives of Resource Management are scalability, quality of service, optimal utility, reduced overhead, improved throughput, reduced latency, specialized environment, cost of effectiveness and simplified interface. The different resource management aspects are resource provisioning – allocation of a service providers resources to a customer, resource allocation, resource requirement, resource adaptation – capability of the system to adjust the resources dynamically to fulfill the identification list of authenticated resources available for job submission, resource brokering – agent ensure that resources are available to resource modeling. I need to provision then allocate the resources in resource requirement mapping, then map the resources in different parts of the different time.

Runtime management and allocation of IaaS resources considering several criteria in heterogeneous distribution of resources, cloud users exchange, incomplete information for dynamic successive allocation in Nash equilibrium approach. So the resource provisioning approaches to perform the different techniques; network queuing model, prototype provisioning, VM provisioning and SLA oriented methods. So that all the approaches are used for resource management techniques in cloud computing environment, this computation to perform the resources to elaborate computation and manage the energy by server consumption, to use for conserve energy methodology. These techniques to perform by schedule VMs to conserve energy, both underlying infrastructure & VMs, minimize operating inefficiency and optimize data design.

Open Stack – it's used for IAS type of cloud infrastructure as a service, very popular open source cloud; you can download and install in a particular hardware configuration,

see the performance of IAS type of cloud. The resource of storage and networking systems to be managed entirely for all systems through dashboard its gives administrators control while empowering their users to provisioning resources through a wave interface. So administrator to control these resources and the user can access the VM. It access a cloud in IAS systems to be specified in open source, you can download and install give it provision of the things. It has a capability of all services through primarily use more as the infrastructure as a service, compute the network for service provision in infrastructure at the pass level on top of IAS cloud foundry and over as SaaS level.

Service Level Agreement (SLA) - A formal contract between a service provider and a service consumer, sometimes how the providers wants to have this consumer, define a formal basis for performance and availability of service provider guarantees to deliver. It contains service level objectives then objectively measurable conditions for the service and basis of selection of cloud provider.

4. SECURITY COMPONENTS AND RISKS IN CLOUD

Different types of services are performed in the cloud computing environments (IaaS, SaaS, PaaS or anything as a service), we are relying on third party service provider, the application data processes running on some third party, so its run on security with third party systems, its specified with issues on cloud components and place the data is stored, whether its seen or intercepted by some other parties. The basic components of security are confidentiality (keeping the data and resources are hidden), integrity (data integrity maintains like or origin or the source integrity, suppose we send the data from A to B, A having authentication of the source) and availability (enabling access to the data and resources), we say CIA components. Most of the attacks are denial of service systems, the resources are not having the dos attacks or ddos type of attacks. Different components looks at different way of things, I need to bring with different goals then meet its constraints on security systems, the security systems can be specified in the form of some goals, the goals are prevention, detection and recovery, one of the major security goal is prevention, prevent attackers from violating security policy, so attacker have the security policies restricts the violating security then attackers, attackers violation of security policy and recovery attack if compromised down to some extent fully or partially, then its appliance the reestablishment of assessing, repair damage continue to function correctly even if the attack succeeds, have critical systems as redundancy systems logging improvements of systems and goals comes with a cost. In security stack specify three different prominent service model IaaS, PaaS and SaaS, the IaaS infrastructure is the provider from facilities to hardware, whenever use for IaaS, PaaS and SaaS the provider has the more responsibility or to increase consumer responsibility

Security Issues; Customer use cloud services to serve their clients, running the applications on those cloud services need to establish trust relationships to the customer and service provider. Fig.6. represents that Security Responsibilities in IaaS, SaaS and PaaS provider.

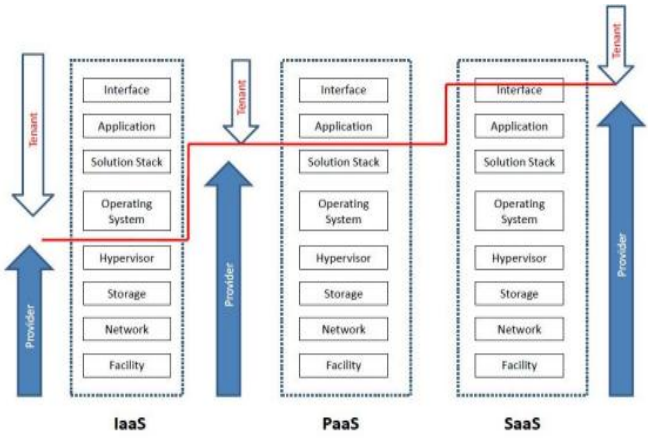

Fig.5. Security Responsibilities in Service Provider

The Infrastructure provides the facility, network, storage and hypervisor components, these components are interact with the cloud in IaaS provider, other than operating system, solution stack, application and interface are interact with ternant, its accessible on the network. The IaaS responsibility up to the hypervisor ends that it having the operating system. So the providers' responsibility up to hypervisor, PaaS responsibility is up to that platform or that were the solution stack. A SaaS responsibility goes up to the interface of consumer specification up to that application level; the services of this security are handled by the provider. In service providers provides the IaaS, PaaS and SaaS responsibilities of security systems.

5. CONCLUSION

In this paper overviewed the cloud computing environments for data storage, resource management and security issues. Then do clearly specify that trends and services in computing for applying different resources, the different resources used in resource management techniques and its different provisioning approaches with provider. Virtualization, SLA and cloud services are vulnerable in cloud computing environments.

concluded the paper with clear representation different storage techniques are available in cloud with different trending technology of name node with data node, then the resource management techniques perform that energy consumption with IaaS provider, and security methods perform with SaaS cloud, will motivate that new development of activities need to be addressed in cloud computing environments.

An Overview of Data Management in Cloud Computing

K.Yogitha Lakshmi, S.Dhanalakshmi, B.G.Obula Reddy

Abstract: ***As we all familiar with cloud computing, it's not a latest technology, rather we can mention it as an emerging technology where most of the industry is trying to store not only its crucial data for redundancy but also looking for the service management. In that scenario first thing comes in mind is management of data in most efficient way possible. So here we tried to showcase two technologies of cloud data management namely Cloud BigTable and Cloud DataStore which they have their own way of working environments. It makes so much importance to choose the right technology for the right nature of work.***

Keywords: Cloud Storage, Data Management, Virtualization, Google File Systems, Data Store

1. INTRODUCTION

Cloud computing referred as delivery of computing services such as networking, servers, databases, storage, virtualization, storage, software, business analytics and so on over the Internet as a utility just like using telephone/mobile services. It offers product innovations and flexible resources for the business like Pay per Use services from The Cloud. The advantages of cloud computing are: Flexible resources - On-demand services gives user a quick scale up or down of the resources. Metered service gives the liability to pay for what you use. Self service you can access all the IT resources without any assistance.

A. Deployment Models of Cloud Computing

Deployment models of cloud computing represents that public cloud, private cloud, hybrid cloud, community cloud and different services. The Fig.1. Shows the representation of cloud architecture in various models and its services.

Public Cloud: This infrastructure will be used by public cloud user in which some of the services will be unavailable. These resources will be provided and organized by a cloud service provider, academics or other organizations. The cloud server exists on the premises of the cloud provider. Eg: Google App Engine, Windows Azure etc.,

Private Cloud: This infrastructure is for exclusive use of a single organization with various services, it can be managed by the organization, a third party or sometimes both. It exists on or off the premises. Eg: VMWare, RedHat etc.,

Community Cloud: It can be managed, operated and owned by one or more organizations in the community, or a third party or combination of both. It may exists on/off premises. Eg: Salesforce community cloud etc.,

Hybrid Cloud: It is the combination of two or more types of infrastructure services that works under proprietary rules and standards. Eg: VMWare vCloud etc.,

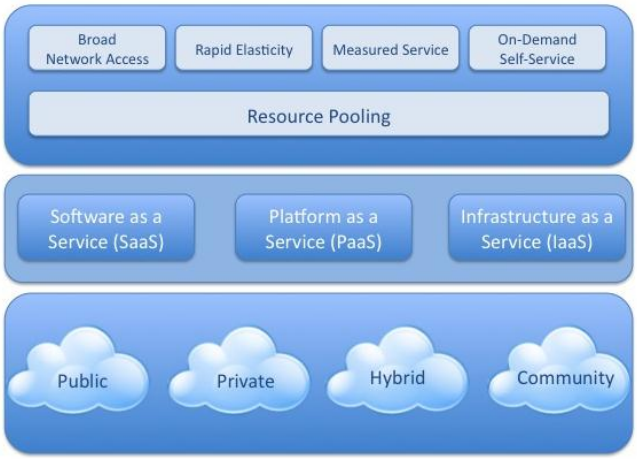

Fig.1. Cloud Architecture

2. THE ROLE OF VIRTUALIZATION IN CLOUD ENVIRONMENT

Virtualization is a multi-tenancy user infrastructure which is located at remote site and can perform function of multiple systems in one physical system by means of high speed internet. In cloud environment it comes under IaaS (Infrastructure as a Service), where the cloud consumer gets the service to use cloud based ready to access virtual storage and also some built in services. The pricing of these services depends on data storage no. of GB used per hour, network infrastructure used per hour etc., Fig.2. Represents the components stack of virtualization in hypervisor and hardware parts.

Virtualization Component Stack consists of Hardware, Operating Systems, Middleware and application layer. Operating Systems layer split into two parts:

a) Hypervisor is also called as virtual machine manager which allow user to have multiple OS in single hardware

b) Guest OS is a running Operating system within the Virtual machine.

Revised Manuscript Received on February 22, 2019.

K.Yogitha Lakshmi, Assistant Professor, Department of IT, Malla Reddy Engineering College(A),Telangana,India

S.Dhanalakshmi, Professor, Department of CSE, Malla Reddy Engineering College(A),Telangana,India

B.G.Obula Reddy, Professor, Department of CSE, Malla Reddy Engineering College(A),Telangana,India

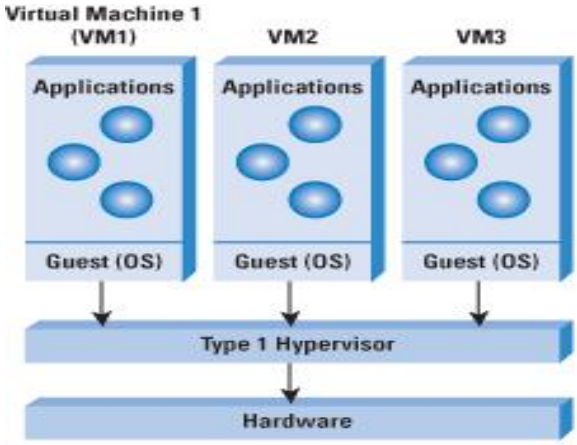

Fig.2. Virtualization Component Stack

The three goals of virtual machine are;

Equivalence: To poses unbiased hardware performance among all the VM's(Virtual Machine)

Resource Control: The VM's should be in complete control of any virtualized resources

Efficiency: The VM's instructions should be executed from its CPU rather than involving hypervisor.

3. TYPES OF VIRTUALIZATION

There are mainly three types of virtualizations namely Server virtualization, Client Virtualization and Storage Virtualization. The Fig.3. Shows the different categories of virtualizations.

Server Virtualization: It is the most common type of virtualization in cloud computing, where it gives optimum usage of server by running multiple applications on multiple operation systems at the same time on single server with the use of hypervisor by controlling CPU, Memory and other components without need of source code.

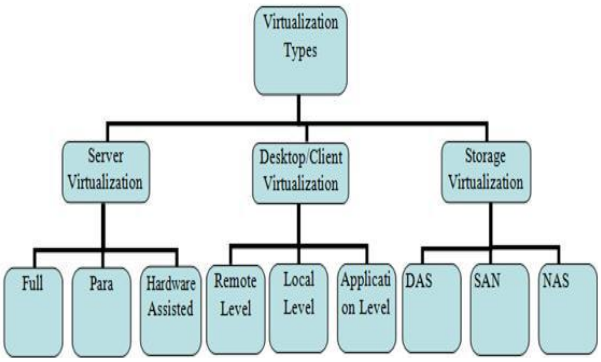

Fig.3. Types of Virtualization

Client Virtualization: In client virtualization, the administrator can manage and control the operations of client machine like personal devices. Here we need to have glance at three types of client virtualizations. First is remote level, where consumers can able to access cloud server which is located remotely anywhere and anytime across a network. Second, local level which runs on local server for the purpose of security. Third, application level virtualization which allows applications to run on isolated or private environment which is accessible by providing authentication.

Storage Virtualization: In Storage virtualization, a single storage device manages multiple network storage resources. It provides efficient storage management in large IT sector and reduces downtime. Three types of storage virtualizations are DAS(Direct Attached Storage), SAN(Storage Area Network), NAS(Network Attached Storage). DAS is a primary way of data storage, where the storage drivers are directly connected to the server. NAS follows a method of storage called sharded method which connects through the networks and it is used for file sharing, device sharing and scheduled/ Ad-hoc backup of the server. SAN is a technique of storing data in a device that is shared among different servers over a high speed network.

4. DATA MANAGEMENT IN CLOUD COMPUTING

In cloud computing data management itself is a big challenge in processing large quantity of data for the purpose of data storage, parallel processing of data execution, analytical processing and online query execution all by ensuring consistency and durability under peak loads.

Some of the cloud based analytical data management systems are: BigTable, HBase, HyperTable, Hive and HadoopDB. PNUTS and Cassandra are the web based data management systems. Here, in this paper the working nature of BigTable and Dynamo will be discussed

A.GFS (Google File System)

It is designed to manage large files in distributed networks of servers which is connected by a high speed internet. It provides atomicity during read/ writes operations of individual files. Supports read/ write and update operations simultaneously by multiple client programs.

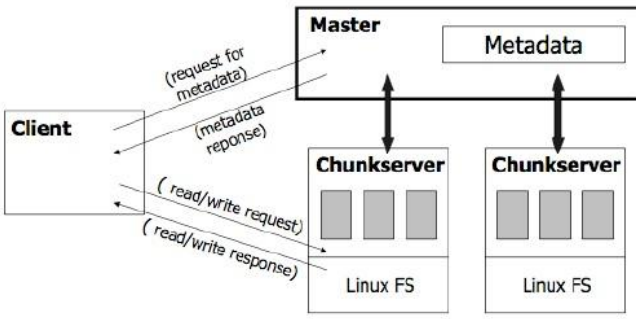

Fig.4. GFS Architecture

A single Master controls the namespace. A large file will be cut down to chunks or blocks with the size of 64MB. These Chunks (GFS) or Name nodes(HDFS) are stored on a servers called Chunk Server. The main functionality of this server is to replicate these chunks three times on different physical racks and network segments.

Read Operations in GFS: a) Client program request for metadata by sending its full path and offset of a file to MASTER or NAMENODE. b) MASTER replies back with metadata from one of its replica chunk where the data is found.

Write/Append Operations in GFS: For initiating write/append operation the process is same as read operation along with some extra steps. a) Client sends its data to be

Published By:
Blue Eyes Intelligence Engineering
& Sciences Publication

appended to all its chunk servers b) Chunk server acknowledge the receipt of this data. c) Among all its chunk server replicas, MASTER chooses a PRIMARY Chunk server which is responsible to append the client data to its secondary chunk servers.

Fault Tolerance in GFS: MASTER bind its synchronization with its replicas by sending regular Heart-Beat messages. In case of failure, chunk server meta-data will be sent to MASTER and it will choose a new Primary Chunk server.

5. MANAGING DATA IN CLOUD ENVIRONMENT

Managing data in cloud environments can be provided different storage techniques in google platforms. Its specify features of Google Cloud BigTable and Google Cloud Datastore.

A.Google Cloud BigTable

BigTable is a distributed storage system that store large amount of data such as petabytes in NoSQL cloumn-oriented way of data store developed by Google Inc. to manage its internet search and web service functions. It works on powerful database servers which gives the benefits of scalability, easy administration and maintain elasticity of cluster without any down time.

BigTable is used to store and query the following types of data:

Time Series Data
Marketing Data
Financial Data
Internet of things Data
Graph Data

The Fig.5. Represents the BigTable Storage Model of rows and columns specifications. Each column store arbitrary value as name-value pair in form of column family. At the time of table creation initial value of no.of column families will be fixed. Labels of column families can be created at any point of time. Each BigTable cell can contain multiple versions of data in decreasing order of timestamp.

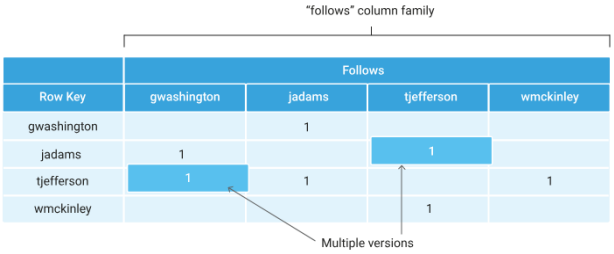

Fig.5. BigTable storage Model

Each table in BigTable will be divided into different row ranges called tablets. These Tablets will be maintained by a server called tablet server. It stores each column family in an allocated row range inside a distributed file called SSTable. BigTable maintains its meta-data table in a single meta-data server which is used to locate the user tablets in response to their read/write operations. The meta-data table itself will be divided into no.of tablets to support its large amount of data in most effective way . Root Table will help point out other meta-data tablets. It supports large parallel reads and inserts operations simultaneously on the same table.

B.Google Cloud DataStore

Google cloud Datastore is a NoSQL document database developed for incredible scalability, high performance and to support application development. The most appreciated feature in cloud datastore is to provide high performance to its subscriber even in the high incoming data traffic situation. It Maintain ACID properties and also it give high availability.

Cloud DataStore is used for applications like:

Product Catalog where it provides real-time inventory

User Profiles where the retailer can view the preferences of the user based on past interests.

Bank Transactions where ACID property will guarantee the transaction of transferred funds.

All the data in Datastore stores in one bigtable called as Entity Table. It stores data horizontally across its disks in which it is called as shared and key values are sorted lexicographically.

It can handle multiple queries at a time by various users with the help of multiple index tables. For every data set they have entity sets from where user gets the results back. for example a query will have a defined set of results say 100 entities, because of this scenarios some queries would not get support in cloud datastore. Like in traditional RDBMS cloud datastore doesn't support schema and it is a schemaless database. Cloud Datastore do not support join operations, it won't filter data from a table with multiple keyed properties or by the result of a subquery. Cloud Datastore doesn't do justice for analysis of data but it can provide assurance for a transactional data.

6. CONCLUSION

In cloud computing environment, without the virtualization technique it would not be possible to use single hardware device among the users. It is the basic service of any development in cloud computing. Data management in cloud computing shows the rapid growth of deployment in remote servers for the purpose of storage and cloud services. Cloud BigTable is mainly used for the non-transactional data where it does not give any redundancy for the data. It can be used for data analytics where you can get the results by querying historical data. Cloud DataStore is built on BigTable but they are completely different from each other, where it supports ACID properties of the transaction and it is used on transactional data. It features are similar to SQL but it cannot perform some operations.

Abstract- *Healthcare big data refers to the vast quantities of data that is now available to healthcare providers. As a response to the digitization of healthcare information and the rise of value-based care, the industry has taken advantage of big data and analytics to make strategic business decisions. Faced with the challenges of healthcare data volume, velocity, variety, and veracity, health systems need to adopt technology capable of collecting, storing, and analyzing this information to produce actionable insight. A stochastic prediction model is designed to foresee the future health condition of the most correlated patients based on their current health status. In healthcare communities, a large volume of multi structured patient data is generated from the clinical reports, doctor's notes and wearable body sensors. The analysis of healthcare parameters and the prediction of the subsequent future health conditions are still in the informative stage.*

Keywords:- *Machine Learning, Disease Prediction, Linear Regression, Logistic Regression..*

I INTRODUCTION

Healthcare big data refers to the vast quantities of data that is now available to healthcare providers. As a response to the digitization of healthcare information and the rise of value-based care, the industry has taken advantage of big data and analytics to make strategic business decisions. Faced with the challenges of healthcare data volume, velocity, variety, and veracity, health systems need to adopt technology capable of collecting, storing, and analyzing this information to produce actionable insight.

Benefits of Healthcare Big Data:

- Create holistic, 360-degree views of consumers, patients, and physicians.
- Improve care personalization and efficiency with comprehensive patient profiles.
- Inform physician relationship management efforts by tracking physician preferences, referrals, and clinical appointment data.
- Boost healthcare marketing efforts with information about consumer, patient, and physician needs and preferences.
- Analyze trends within a single hospital or greater a healthcare network to benefit research and care procedures for enhanced population health outcomes.
- Identify patterns in health outcomes, patient satisfaction, and hospital organization.
- Predict health outcomes and create preventive care strategies with data analysis.
- Optimize growth by improving care efficiency, effectiveness, and personalization.

What is driving the Adoption of Big Data in Healthcare?

The adoption of big data is in response to three major shifts in the healthcare industry:

The huge and vast amount of dataset available, government regulations, and a focus on personalized care.

Volume of Healthcare Data: When health records went digital, the amount of virtual data health systems had to handle rose steeply. In addition to EHRs, vast amounts of data come from other sources, such as wearable technology, mobile applications, digital marketing efforts, social media, and more. Data of all of this makes and adds up to an incredible amount of information, spurring health systems to adopt big data techniques and technologies to effectively bare to collect, analyze, and in order to take advantage of this information.

Government Regulations: The past 20 years have seen rapid growth in healthcare costs. Today, healthcare expenses account for around 18 percent of GDP, totaling about $600 billion. Such high costs were straining patients and led to government acts aimed at lessening this burden, most notably the Affordable Care Act (ACA). As a result, more health systems are collecting and analyzing big data in the hopes of improving performance and efficiency.

Desire for Personalized Care: Consumers in all industries expect exceptional, personalized service, also known as "The Amazon Experience". Healthcare is no different – customers want valuable, personalized care, making it the new standard to which health systems must rise. This type of care focuses on quality, engagement, and retention. Health systems are turning to healthcare big data set to provide and hold the insight necessary for providing this type of care.

What Challenges Arise with Healthcare Big Data?

A major challenge with healthcare big data is the sorting and prioritizing of information. Data capacities are so vast that oftentimes it can be difficult to determine which data points and insights are useful and which are not.

Another major challenge is setting ensuring this and that the right access to big data insights and analysis is given to the right people, so they can do their jobs smarter. Even though healthcare data is pulled from many different systems, organizations need to make sure critical personnel across the industry have easy access to the information.

There are few and also very huge number of challenges to effective data analysis resulting from heterogeneous or missing claims data. Each healthcare institution files claims, with the data coming from their other Hospital Information Systems (HIS) or input by hospital personnel at the time of the encounter or shortly thereafter. The data becomes super and even with more and great complex when we have a you factor in all the ambulatory places of service types. As a result, there are five challenges to overcome in order to obtain accurate claims data:

Billing systems are fragmented and dated: Data is often very "noisy"…practices, groups, and even practicing specialties can be inconsistent. The key is to consider directional data in combination with your local market knowledge; in other words, data should augment interactions and focused outreach to physicians, not replace it. Patients do not have unique patient identifiers: If every patient had a unique identifier, data matching would not be required. Until, and if, that happens, data matching mechanisms are required to claims together.

Diagnosis and procedure codes can be unclear: Even industry-standard grouper tools can obscure, or just plain mis-map, physician activity. Perfect data and perfect insights are very hard to achieve, so you have to advocate for, and learn to work with, directional data.

Claims data is highly inconsistent: With claims data, any field data that is not required for payment has a low probability of being filled in or completed accurately. In fact, among the few required fields for payment, along with patient, diagnosis, and procedure information, is the "rendering physician" via the NPI1 for that provider.

It's difficult to identify the referring physician: The "referring physician" field on available third-party claims is often

inconsistent, incorrect, or, most often, not filled. In fact, some clearinghouses

What is the Future of Healthcare Big Data?

In the future, healthcare organizations will adopt big data in greater numbers as it becomes more crucial for success. Healthcare big data will also continue to help make marketing touchpoints smarter and more integrated. Data available will grow as wearable technology and the Internet of Things (IoT) gains popularity. Constant patient monitoring via wearable technology and the IoT will become standard and will add enormous amounts of information to big data stores.

II RELATED WORK

Linear-Regression

Linear-regression analysis sets which is used to forecast and predict the values of different variable based on the value of another variable. The variable you want to predict variable. The variable you are using to predict the other variable's value is called the independent variable.

This form of analysis estimates the coefficients of the linear equation, involving one or more independent variables that best dependent variable. Linear-regression fits a best straight line or surface that minimizes the discrepancies between predicted and actual output values. There are simple linear regression calculators that use a “least squares” method to discover the best-fit line for a set of paired data. You then estimate the value of X (dependent variable) from Y (independent variable).

Linear-regression models are relatively simple and provide an easy-to-interpret mathematical formula that can generate predictions. Linear regression can be applied to various areas in business and academic study.

You’ll find that linear regression is used in everything from biological, behavioral, environmental and social sciences to business. Linear-regression models have become a proven way to scientifically and reliably predict the future. Because linear regression is a long-established statistical procedure, the properties of linear-regression models are well understood and can be trained very quickly.

Assumptions to be considered for success with linear-regression analysis:

For each variable: Consider the number of valid cases, mean and standard deviation.

For each model: Consider regression coefficients, correlation matrix, part and partial correlations, multiple R, R2, adjusted R2, change in R2, standard error of the estimate, analysis-of-variance table, predicted values and residuals. Also, consider 95-percent-confidence intervals for each regression coefficient, variance-covariance matrix, variance inflation factor, tolerance, Durbin-Watson test, distance measures (Mahalanobis, Cook and leverage values), DfBeta, DfFit, prediction intervals and case-wise diagnostic information.

Plots: Consider scatterplots, partial plots, histograms and normal probability plots.

Data: Dependent and independent variables should be quantitative. Categorical variables, such residence, need to be recoded to binary (dummy) variables or other types of contrast variables.

Title: Disease Prediction by Machine Learning Over Big Data From Healthcare Communities:

Authors : MIN CHEN1, (Senior Member, IEEE), YIXUE HAO1, KAI HWANG2, (Life Fellow, IEEE), LU WANG1, AND LIN WANG3,4

Publishing Year: 2017

Method: Streamline machine learning algorithms for effective prediction of chronic disease outbreak in disease-frequent communities

New convolutional neural network(CNN)-based multimodal disease risk prediction algorithm using structured and unstructured data from hospital.

Dis advanatage:

Analysis accuracy is reduced when the quality of medical.

Different regions exhibit unique characteristics of certain regional diseases, which may weaken the prediction of disease outbreaks

Advantage:

Modified prediction models over real-life hospital data.

Work efficiency is better in results

Title: The'Big Data 'Revolution in Healthcare: Accelerating Value and Innovation.USA: Center for US-Health System Reform Business Technology Office:

Authors : P. Groves, B. Kayyali, D. Knott, and S. van Kuiken

Publishing Year: 2016

Method: Technical advances have made it easier to collect and analyze information from multiple sources—a major benefit in health care, since data for a single patient may come from various payors, hospitals, laboratories, and physician offices.

Dis advanatage:

Satistical analysis have been applied been not successfully applied

Advantage:

Clear statistic are applied in classification of the data and visualization the data

Title: Mining electronic health records: Towards better research applications and clinical care :

Authors :P. B. Jensen, L. J. Jensen, and S. Brunak

Publishing Year: 2014

Method: Clinical data describing the phenotypes and treatment of patients represents an underused data source that has much greater research potential than is currently realized. Mining of electronic health records (EHRs) has the potential for establishing new patient-stratification principles and for revealing unknown disease correlations.

Dis advanatage:

A broad range of ethical, legal and technical reasons-currently-hinder-the-systematic deposition-of these-data in EHRs and their mining.

Advantage:

Integrating EHR data with genetic data will also give a finer understanding of genotype-phenotype relationships.

Title: Informational and energetic masking effects in the perception of two simultaneous talkers:

Authors :M. Chen, Y. Ma, J. Song, C. Lai, and B. Hu.

Publishing Year: 2016

Method: Traditional wearable devices have various shortcomings, such as uncomfortableness for long-term wearing, and insufficient accuracy, etc. Thus, health monitoring through traditional wearable devices is hard to be sustainable.Smart Clothing used for data aquasisation..

Dis advanatage:

Loss of data when digitally not connected to servers.

No prediction on loss of data

Advantage:

provide pervasive intelligence for smart clothing system, mobile healthcare cloud platform is constructed by the use of mobile internet, cloud computing and big data analytics.

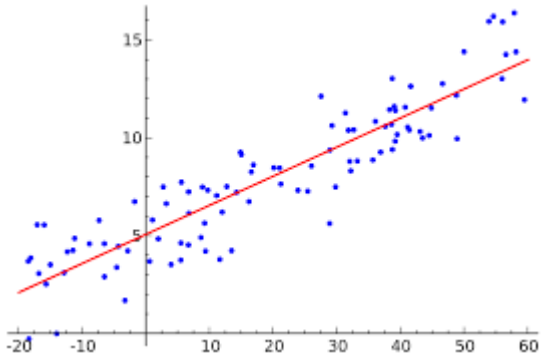
HEART ATTACK PREDICTION USING DATAMINING TECHNIQUE:

Genetic algorithms are computing methodologies constructed in analogy with the process of evolution [4] .It closely resembles the natural process of

regeneration, reproduction, inheritance evolution. Genetic algorithms are typically used for problems that cannot be solved efficiently with traditional techniques. Genetic algorithms seem to be useful for searching very general spaces and optimization problems. Each solution generated in Genetic chromosome (individual).Each chromosome is made up of genes, which are the individual elements (alleles) that represents the problem. The chromosomes is known as its genotype. This can be hexadecimal codes. The external manifestation of the genotype or the real world representation of the genotype is known as the phenotype [5].Basically there are three genetic operators are used for generating new strings. The functions of genetic operators are as follows:

1) Selection: selection Various types of crossover operators are a) single point.

2) Crossover: selecting a random gene along the length of the chromosomes and swapping all the genes after that point. Various types of crossover operators are a) single point b) two point c) uniform f) shuffle crossover g) segmented crossover [6].



3) Mutation: mutation alters the new solutions so as to add stochasticity in the search for better solution. The most common method way of implementing mutations is to select a bit at random and flip (change) its value.

There are network programming 1) mutating the judgment node

2) mutating the value of the judgment node. In associative classification attributes and values as processing nodes.

Fitness function: Ideally the discoved rules should have a) high predictive accuracy b) be comprehensible c) be interesting.

The accomplishment of a genetic algorithm is directly linked to the accuracy of the fitness function.

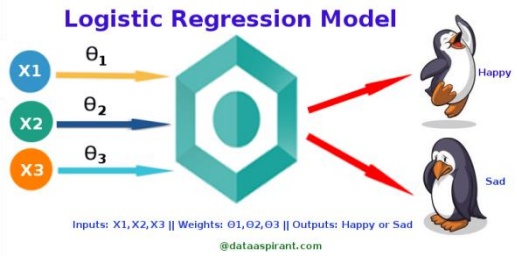
Linear Regression Model

These models comprise a linear combination of input features.

The variable is related to the linear combination of input features via a link function.

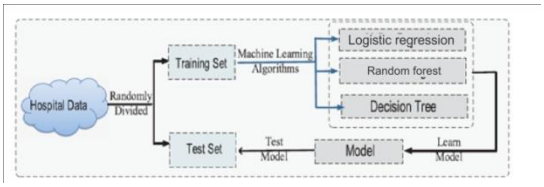
The response variable is of exponential distributions such as binomial distribution, Poisson distribution, or Gaussian distribution. Practically, when the response variable is binary. When the response variable represents count. And, Gaussian distribution is used when the response variable is continuous.

The response variable must follow a binomial distribution.



Logistic Regression assumes a linear relationship between the independent variables and the link function (logit).

The dependent variable should have mutually exclusive and exhaustive categories.



In R, we use glm() function to apply Logistic Regression. In Python, we use sklearn.linear_model function to import and use Logistic Regression.

Note: We don't use Linear Regression for binary classification because its linear function results in probabilities outside [0,1] interval, thereby making them invalid predictions.

III Proposed Work:

Logistic Regression Model

Analytical Console: Data is loaded to the console and organized, cleaning of the data is simplifiedif necessary.

Heart disease prediction: Machine learning algorithms to predict heart disease (Angiographic disease status)

The platform required for us to work is Rconsole where in all the required libraries are loaded to the console. The libraries used are

"e1071" - Used for the linear regression model for assuming the required values from the dataset.

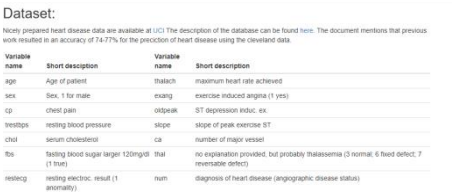
"pROC" - Assuming the statistical behaviour of the data in terms of compering the gender and age wise distribution of the data

"caret" - Holds the methods for the usage of the algorithms such as Linear Regression, logistic Regression

"randomForest" - Method of random forest are applied with this library, implementation on the data.

Dataset:

Data preparation



Load heart disease data and give columns names from the table above

```
heart.data <- read.csv("https://archive.ics.uci.edu/ml/machine-learning-databases/heart-disease/processed.cleveland.data",he
ader=FALSE,sep=",",na.strings = "?")
names(heart.data) <- c( "age", "sex", "cp", "trestbps", "chol","fbs", "restecg",
                        "thalach","exang", "oldpeak","slope", "ca", "thal", "num")
```

The diagram explains the procedural of analysis the data, by classifying the dataset to testing data and training data. First we extract the data, then we apply linear regression model on the data to acquire the important and find the combination of the columns of the data. Later on the logistic regression model is applied on the data so that the is again applied with help of us with comparison model and accuracy model for the prediction.

IV IMPLEMENTATION

Data Description:

Dataset:

Nicely prepared heart disease data are available at UCI The description of the database can be found here. The document mentions that previous work resulted in an accuracy of 74-77% for the prediction of heart disease using the cleveland data.

Variable name	Short description	Variable name	Short description
age	Age of patient	thalach	maximum heart rate achieved
sex	Sex, 1 for male	exang	exercise induced angina (1 yes)
cp	chest pain	oldpeak	ST depression induc. ex.
trestbps	resting blood pressure	slope	slope of peak exercise ST
chol	serum cholesterol	ca	number of major vessel
fbs	fasting blood sugar larger 120mg/dl (1 true)	thal	no explanation provided, but probably thalassemia (3 normal; 6 fixed defect; 7 reversable defect)
restecg	resting electroc. result (1 anomality)	num	diagnosis of heart disease (angiographic disease status)

Statistical Observation: Based on the data sets, a statistical approach is framed from the data. (Linear Regression).

Training Dataset: From all the results, we apply the random forest algorithm in finding all the possible decision trees and predict the results.

Reports: Form the above results generate the reports in terms of behavior of the data.

ALGORITHM STEPS:

Linear Regression:

1) Load the data to console

2) Check for any missing values

If any missing values:

Replace them with #999

then step 1

else:

continue

3) Sort the combination columns

4) Correlation over the columns

5) Test the data

Logistic Regression:

6) Train the data on minimum dataset

7) Check the results

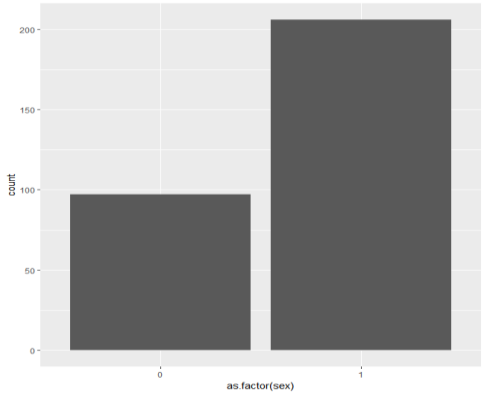
8) Apply on the complete dataset

9) Generate the results from the model.

Algorithms for Logistic regression and random forest:

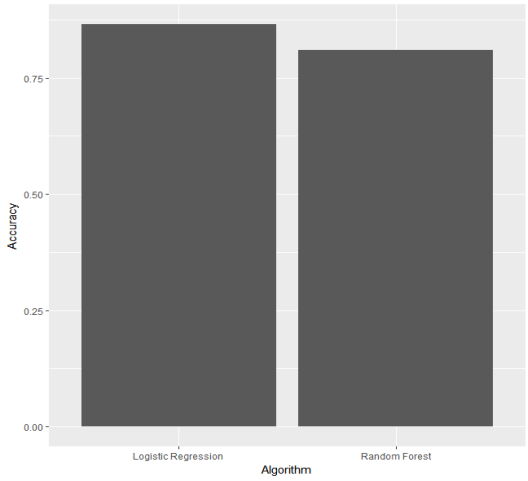
Step 1: Train the data on minimum dataset.

Step 2: Check the results.



Step 3: Apply on the complete dataset.

Step 4: Generate the results from the model.



Form the above results generate the reports in terms of behavior of the data. Missing values problem can be resolved using machine learning algorithms.

V EXPERIMENT AND RESULTS

The implementation is executed with the sample data available from a local website . The data is first categorized and then the core parameters are been identified from the dataset. The the statistical analysis of the data is executed. Once the parameters are identifiable later we have implemented with logistic regression model for the prediction of the heart diseases and compared our model with the Random forest model for the accuracy calculation. In this process the data is been categorized into testing data and training data and found out the results to be accurate and found that the logistic model provided better results compared with random forest.

The barplot describes most effected gender for the given dataset. As shown in the above barplot mostly male is effecting the disease.

Representing the accuracy barplot for training and testing dataset As shown in the above figure ,it describes about the prediction accuracy for training and testing datasets

	Logistic Regression	Random Forest
Accuracy 70	0.86516	0.80898
Accuracy 60	0.86440	0.84747
Accuracy 50	0.72729	0.80405

It represents the prediction accuracy for the dataset with different algorithms which are performed at various intervals of the dataset with training and testing data.

VI CONCLUSION

A random forest model based multimodal disease risk prediction algorithm using

structured data from hospital. To the best of our knowledge, none of the existing work focused on both data types in the area of medical big data analytics. Analysing the disease factors based on the health care data. Missing values problem can be resolved using machine learning algorithms. Disease prediction can be done based on type of the disease and type of disease, region and risk level of the patient's disease by the availability of the data.

ABSTACT:

Cloud computing is quickly becoming as an option in contrast to ordinary computing. Be that as it may, it depends on models like bunch computing, disseminated computing, utility computing and grid computing when all is said in done. Grid computing vows to turn into the future computing worldview for big business application in the wake of having demonstrated to be a very successful computing worldview for asset escalated logical applications. Enormous scale grids are intricate frameworks, made out of countless segments having a place with disjoint spaces. Existing High Performance Computing (HPC) frameworks don't give appropriate nature of service (QoS) controls and unwavering quality highlights on account of two confinements: first, standard middleware libraries, for example, Message Passing Interface (MPI) and Parallel Virtual Machine (PVM) don't give intends to applications to indicate service quality for calculation and correspondence. Second, present day fast interconnects, for example, Infiniband, Myrinet and Quadrics are enhanced for execution as opposed to adaptation to non-critical failure and QoS control. The Data-Centric Publish-Subscribe (DCPS) model — the center of Data Distribution Service (DDS) frameworks — characterizes principles that empower applications running on heterogeneous stages to control different QoS approaches in a netcentric framework. In this paper, we present our novel model of joining DDS QoS and unwavering quality controls into HPC frameworks. Our outcomes show that DDS combination into HPC includes extensive caught as far as execution and system use, when the application is for the most part correspondence.

KEYWORDS:

HPC, QoS, Middleware, Mpi, Grid Computing, Data-Centric Publish-Subscribe, Data Distribution Service.

I. INTRODUCTION

Grid computing isn't just a standard computing worldview for asset serious logical applications yet it likewise vows to turn into the future computing worldview for big business applications. An ongoing review by Forrester Research demonstrates that 37% of the organizations overviewed are in some phase of guiding or execution of grid; 41% use it for money related examination and displaying, 41% use it for run of the mill business applications, and 26% use it for logical or building counts [32].

The grid empowers asset sharing and dynamic distribution of computational conditions made out of segments from various spaces, consequently expanding access to data, advancing operational adaptability and coordinated effort, and permitting service suppliers to long ago scale to fulfill variable needs. Every one of these components add to build the expert ductivity and the use of an endeavor's foundation. Enormous scale grids are mind boggling frameworks, made out of huge quantities of segments having a place with disjoint spaces. Arranging the ability to ensure nature of service (QoS) in these conditions is a test on the grounds that worldwide Service Level Agreements (SLA) relies upon neighborhood SLAs, i.e., SLAs built up with parts that make up the grid. These segments are commonly independent and join the grid as a component of a free organization. Just if all these halfway SLAs are fulfilled, will the worldwide SLA be fulfilled. To under-stand how this can be accomplished and how the worldwide and halfway SLAs can be indicated and afterward met, it is fundamental to comprehend the design of the grid, the effect of grid asset distribution on SLAs, the conditions

among grid QoS measurements, the connections between the QoS and SLAs components, and the primary system to accomplish great QoS.

The drive behind the enthusiasm for appropriated computing when all is said in done, and elite computing (HPC) specifically, is the way that they offer a few focal points over the customary, firmly coupled supercomputers and Symmetric Multiprocessing (SMP) machines. In the first place, High Performance Clusters are proposed to be a less expensive trade for the more unpredictable/costly supercomputers to run normal logical applications, for example, recreations, biotechnology, money related market displaying, data mining and stream handling [5]. Second, group computing can scale to exceptionally enormous frameworks; hundreds or even a great many machines can be organized to suit the application needs. Actually, the whole Internet can be seen as one enormous bunch [3]. The third bit of leeway is accessibility, as in supplanting a "flawed hub" inside a group is inconsequential contrasted with fixing a broken SMP part, bringing about a lower mean-time-to-fix (MTTR) for painstakingly planned bunch setups [4].

In spite of the upsides of these disseminated computing frameworks, they present new difficulties not found in commonplace homogeneous conditions. One key test is the consistently expanding number of equipment parts in the present HPC frameworks. This expansion in the equipment parts is radically influencing the likelihood of equipment disappointments in such frameworks — and along these lines the efficiency of the end clients — since any single disappointment on such HPC groups would make the entire running activity prematurely end, bringing about several hours of calculations to be squandered.

In spite of the fact that this test is known, existing circulated memory HPC bunches can't give broad QoS-based correspondence and dependability controls due to two confinements: first, standard correspondence libraries, for example, Message Passing Interface (MPI) and Parallel Virtual Machine (PVM), don't give options in contrast to applications to control the nature of service for calculation and correspondence. Second, current fast interconnects, for example, Infiniband, Myrinet and Quadrics give high-throughput and low-idleness correspondence. Low-level informing interconnects is advanced for execution as opposed to adaptation to non-critical failure and QoS control. One of the endeavors to address the absence of broad QoS-based and solid correspondence in nonexclusive disseminated frameworks is the establishment of the Data Distribution Service (DDS) [6], which is the primary open universal middleware standard legitimately tending to heterogeneous correspondence for constant frameworks, using the publish/subscribe correspondence worldview. While the publish/subscribe model can be the answer for the conventional heterogeneous computing, one research intrigue is to help DDS particulars and its predefined QoS unwavering quality controls in the more-specific HPC conditions and fuse its most significant QoS polices, which is one of the fundamental points of this work.

II. RELATED WORK

The tr The pattern of the present High Performance Clusters and other inexactly coupled disseminated frameworks is that they are expanding regarding hubs and equipment parts. To show, taking a gander at the top500 overall supercomputers [7], we see that what used to be the #1 HPC group (i.e., The Jaguar Cluster) in June 2010 had 224,162 centers, while in November 2013, the #1 Tianhe-2 bunch had 3,120,000 centers. Strikingly, this expansion in the quantity of centers would definitely expand the likelihood of equipment disappointments in such frameworks.

A few investigations were led to investigate the connection between's adaptability in HPCs and disappointment rates [8, 9, and 10]. B. Schroeder and G. Gibson [8] supported that the accomplishment of Petascale computing will rely upon the capacity to give unwavering quality and accessibility at scale. In their exploration, the creators gathered and investigated various enormous data sets of disappointments from genuine huge scale HPC frameworks for a time of ten years. In particular, they gathered data about: (a) total hub blackouts in HPC bunches, and (b) plate stockpiling disappointments in HPC frameworks. Regarding total hub blackouts, the creators recognized that equipment is the single biggest part liable for these blackouts, with over half of disappointments appointed to this class, while programming is the second biggest classification with 20%. The rest of the rate is identified with human, condition and system blackouts. Further, the hub disappointment rate for enormous scale frameworks can be as high as 1,100 disappointments for every year. Given this extraordinary rate, an application running on such frameworks will be hindered and constrained into recuperation multiple times each day [8].

As far as capacity and hard drive disappointments, the creators found that the normal yearly disappointment and substitution rate (ARR) for hard drives in HPC frameworks is somewhere in the range of 3% and 5%. This implies in a bunch of 512 hubs, the normal disappointment rate for hard drives is around 1-2 drives at regular intervals, which coordinates our discoveries in [11]. The creators closed their examination by expressing that "the disappointment pace of a framework develops relative to the quantity of processor contributes the framework." Furthermore, as the quantity of attachments in future frameworks increment to accomplish higher Petascale and even Exascale frameworks, it is normal that the framework wide disappointment rate will increment [12].

On the other hand, these days there is little consideration on QoS-put together correspondence and unwavering quality control with respect to HPC. The explanation is that clients have seen a sensational increment in execution in the course of the most recent 10 years with respect to the HPC frameworks. What used to take one month of calculation time in 2000, is taking just a couple of hours to run today. Along these lines the most straightforward solution for this disappointment rate is to resubmit the client work subsequent to offlining (i.e., fencing) the tricky hub/center, rendering the squandered hours of the smashed activity to be disregarded. In this way, the requirement for broad QoS controls and dependable HPC situations is unavoidable when HPC employments would keep going for a few days or even a long time to run. The objective of this examination is to concentrate on the HPC QoS and unwavering quality controls — and in various HPC layers — to profit these long clients' occupations that require huge scale groups to run.

Grid computing: -

Grid Computing depends on the way of thinking of data and power sharing, enabling us to access to another sort of heterogeneous and geologically isolated assets Grid gives the sharing of computational assets, stockpiling components, explicit applications, hardware. Grid depends on web conventions and thoughts of parallel and dispersed computing. [3]

Fig 1: Grid Computing

Today grid computing offers numerous arrangements that as of now address and resolve the above issues. Grid computing arrangements are led utilizing a verity of advancements and open measures. Grid computing is turn; give exceptionally versatile, profoundly secure, and amazingly superior instruments for finding and arranging access to remote computing assets in consistent way. [4]

The Enterprise Grid Alliance (EGA) is an open, autonomous, and merchant nonpartisan network tending to approach term prerequisites for conveying business applications in a grid domain. By concentrating solely on the necessities of big business clients, EGA will empower organizations to understand the numerous advantages of grid computing, for example, quicker reaction to changing business needs, better use and service level execution, and lower IT working expenses.

QoS Metrics in a Grid Environment

In this area we address gives that include the under-remaining of QoS measurements with regards to grid conditions. We utilize the IC situation to delineate the ideas talked about here.

We think about three kinds of measurements:

- **Latency:** this sort of metric is identified with the time it takes to execute an undertaking and is estimated in time units. Inertness measurements can be characterized at various granularities. For instance, in the IC case, one might be keen on the normal time it takes to finish prompt statement demands or in the 95-th percentile of an opportunity to react to non-quick demands. These two models are illustrative of QoS measurements at the application layer. Another case of dormancy metric is the slipped by time to restore a postponed statement to the client. Refined RAMs are regularly perplexing parallel occupations that are deteriorated into undertakings apportioned to various computing assets in the grid. A case of a QoS metric at the aggregate layer is the assert age time to perform co-reservation and co-assignment of computing assets so as to run a RAM. At the asset layer, one might be keen on estimating the time it takes to get to a particular computing asset through the GRAM convention. A case of inertness metric at the availability layer is the time it takes to play out a verification in the interest of a client to a monetary association utilizing the GSI. At the texture layer, one might be keen on estimating the time taken by a database server at a medical coverage association to answer to an inquiry.

- **Throughput**: is estimated in units of work achieved per unit time. There are numerous conceivable through-put measurements relying upon the meaning of unit of work. At the application layer one might be keen on the quantity of postponed quote demands handled every second. At the aggregate layer one might be keen on the quantity of inquiries every subsequent that can be taken care of by registry services used to find assets crosswise over various VOs. Instances of throughput measurements at the asset layer incorporate I) the compelling exchange rate in Kbytes/sec under the Grid-FTP convention used to move documents from various registers hubs associated with running RAMs and ii) the quantity of questions/sec that can be prepared by the database server of a law requirement organization required by the RAM application. At the network layer, one might be keen on estimating the throughput, in Kbytes/sec, of a protected association between an occurrence of a RAM model and a database Service that gives budgetary data about a client. At last, a case of a throughput metric at the texture layer could be the quantity of CPU cycles every second got from a machine engaged with handling an undertaking that is a piece of a parallel RAM assessment work.

- **Availability:** is characterized as the division of time that an asset/application is accessible for use. In a multi-layer setting, for example, the one portrayed for the grid engineering, the thought of accessibility varies for each layer. At the application layer, one may characterize profit capacity as per the sort of solicitation. For instance, the accessibility of the quick statement demand application is the portion of time that this application is profit capable. At the aggregate layer, one may characterize accessibility as far as the services, for example, indexes and facilitating services, expected to find computing assets to run a RAM occasion. Accessibility at the asset layer might be estimated for instance as the division of time that a particular computing hub is accessible for portion to a RAM case. At the network layer, one may characterize accessibility as the level of time that an intermediary validation demand prevails with regards to verifying a client demand with a law authorization organization. At last, a case of accessibility metric at the texture layer would be the division of time that a computing hub is accessible during the execution of a RAM occurrence.

It ought to be noticed that QoS measurements at higher layers can regularly be communicated regarding QoS measurements of a similar kind at lower layers of the grid engineering. For example, the passed time to process a deferred statement demand relies upon a wide range of dormancy measurements including (I) the time expected to hold register cycles for the term of the assessment of a RAM, (ii) the opportunity to co-assign these assets, (iii) an opportunity to verify with database servers outside the insurance agency, (iv) an opportunity to acquire contributions from outer databases, (v) an opportunity to move data records to various hubs of a parallel activity that will run the RAM, and (vi) an opportunity to execute the RAM.

It is likewise imperative to consider the way that various sorts of QoS measurements communicate with each other [40]. For ex-adequate, as the heap expands, it might be more difficult to designate assets to assess a RAM and a few solicitations may must be dismissed, accordingly diminishing the accessibility of the application.

Difficulties of grid computing:- A ton of heterogeneous equipment is utilized so as to make the Grid and, what's more, these gadgets are not overseen by just a single individual however by various framework heads in each of the companies.[7] Grid pursues the moves that should be set out to tackle the full intensity of grid:-

- **No clear standard:-** Grid computing utilizes different models, yet all grids are not utilize same benchmarks. Model all grid working framework, for example, Linux, Apache and My SQL are utilizing WSRF, UDDI, WWW, SOAP and XML principles. Prophet 10g venture actualize without WSRF. IBM builds up the

Grid middleware dependent on J2EE. We can't utilize distinctive OS at a similar machine in a similar time in grid computing.

 Distributed computing Vs Grid computing: - Grid computing includes dynamic virtual association, asset sharing and distributed computing. The Grid expects to make access to computing power, logical data storehouses and test offices as simple as the Web makes access to data. Same all offices give the grid computing. So it is a test for grid computing.

 Lack of grid empowered programming: - The product, which are empowered the grid computing are less, It has restricted programming on Grid. Much programming has not copyright issues and source code of permit. It is requirement for more organization creating grid-empowered adaptation, need more engineers on grid improvement and need to create open source programming.

 Sharing Resources between Various Types of Services: - Grid utilized for sharing asset from different locales and grid has. It handles a huge measure of data as a grid stage. A great deal of locales and various servers accumulated there it is so unpredictable foundation. It gives trouble to equipment asset sharing inside virtual association.

 difficult to create: - Grid programming utilized java, XML, use web services WSDD, WSDL, UDDI, WSRF, and GT3developing rules. It is an issue who building up the grid Applications. Fundamentally that is accessible for senior software engineering designers and endeavor designers.

 Limited Area and Applications:- Grid computing is utilized to take care of for huge and complex issues. Its zone is restricted, for example, researchers, designer, investigation and specialists. Grid computing is utilized in Hollywood gleams, modern research, and biometric research and designing exploration. Grid can't use for regular issues by normal people.

 Management and Administration: - Many foundations and associations utilized grid computing. It conveys the assets on enormous topographically appropriated situations and gets to the heterogeneous gadgets and machines. So it is a significant test to deal with the organization of the grid computing.

In this paper, we present our work of embracing DDS principles into HPC, to bypass the MPI deficiencies and give QoS and unwavering quality controls in the middleware layer. It is likewise some portion of this exploration to look at the impact of embracing DDS QoS on HPC, as far as versatility, execution and adaptation to internal failure, by testing three diverse computational models. The entirety of our tests were led utilizing condition of-craftsmanship HPC advances, for example, the Quad Data Rate Infiniband interconnect and multi-center processors.

III. PROPOSAL WORK

THE HPC-DDS INTEGRATION MODEL

DDS QoS executions utilization has been restricted to the nonexclusive heterogeneous computing conditions. As far as we could possibly know, none of these endeavors were done explicitly to join DDS QoS arrangements into HPC clump occupations, and supplant the true standard MPI middleware. Therefore, one of the principle points of this examination is to inquire about the achievability of joining DDS QoS arrangements into HPC situations and exploit the settled dependability and adaptation to internal failure includes in DDS.

When looking at the properties of the two DDS and HPC, various DDS guidelines and prerequisites are like those for HPC structures, as appeared in Figure 2. Specifically, the two DDS and HPC manage intercommunication models, middleware layers, equipment foundation, and timing-related and QoS issues.

Additionally, figure hubs are spoken to as Subscribers/Data Readers and they go about as the specialist hubs. The relationship of a Data Writer with Data Reader articles (or Master to register hubs in HPC terms) is finished by methods for Topics, which go about as the informing interface "or channels" between every one of the substances, like the message passing interface (MPI) in customary HPC frameworks. Tests in the Topics are moved by using the correspondence medium, which is spoken to by the fast interconnect in the HPC frameworks.

To control the QoS strategies and include the Persistence Service in our DDS-HPC model, we devote an extra hub to have the Persistence Service libraries. In our mix, we use the standard HPC the executive's hub for this undertaking

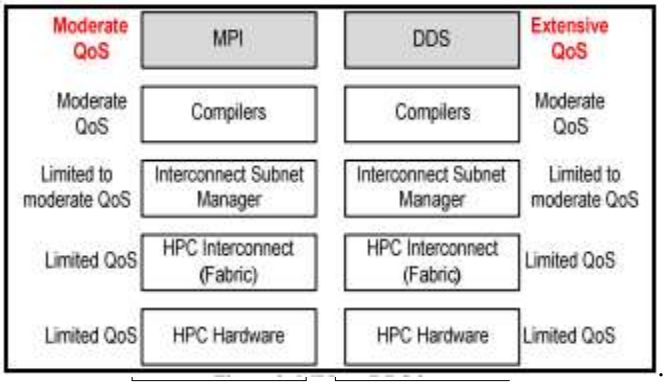

Fig 2: MPI vs. DDS layers

In DDS fundamental model, recompense between members is accomplished by having six basic substances, these are [15]: Domain Participant, Data Writer, Data Reader, Publisher, Subscriber, and Topic. Taking a shot at these substances, our mapping of the DDS standard into HPC is shown in Figure 3 and can be depicted as pursues: the HPC ace hub is spoken to by the DDS Publisher/Data Writer element, since its principal obligation in traditional HPC frameworks is perusing data from input sources, sending the halfway data to process hubs (Subscribers/Data Readers in DDS), and afterward gathering the outcomes back. Ordinarily, HPC conditions utilize one ace.

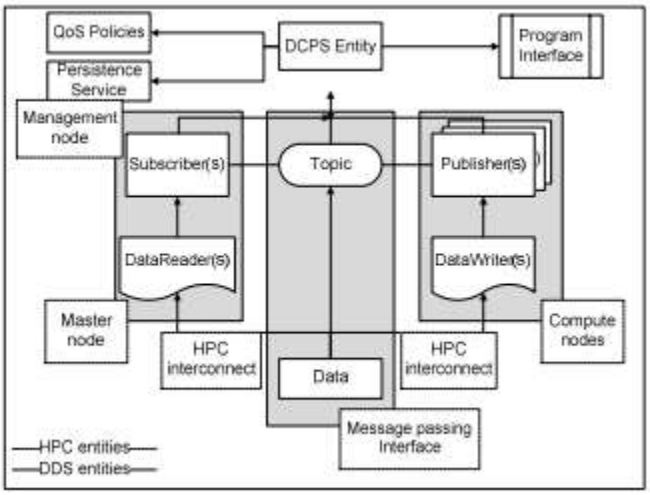

Fig 3: HPC-DDS integration model

Most hub collaborations in the essential DDS usage are single direction correspondence, that is, from the publishers to subscribers. These publishers and subscribers need to turn around their jobs to set up a two-way correspondence. To mirror the two - route association between the ace and register hubs, and have it like the ordinary MPI-based frameworks, we generate two strings in the Publisher/Data Writer (i.e., ace hub), where string 0 goes about as the publisher for sending data, while string 1 goes about as a Subscriber/Data Reader for accepting the last data from the processes. Moreover, all figure hubs have a similar structure for their two-way correspondence.

A. Executed Quality of Service Policies

As depicted before, having power over Quality of Service (QoS) is one of the most significant highlights of the DDS standard. Each gathering of senders and beneficiaries in the framework can characterize free QoS arrangements, though the middleware guarantees if the QoS understanding can be fulfilled, along these lines building up the correspondence or showing an incongruence mistake. Some data about some significant QoS strategies are featured underneath, and more arrangements can be found in the Object Management Group Specification Document [6]. To empower the DDS dependability QoS on our DDS-HPC plan, we received three fundamental QoS arrangements in our usage; these are strength, unwavering quality, and history.

During the execution of our DDS - HPC usage, the autonomous "perseverance service" is run on a different physical server (i.e., the administration hub) to help the "solidness" QoS approach. This tirelessness service spares the published data tests with the goal that they can be conveyed to buying in beneficiaries that join the framework some time in the not too distant future, regardless of whether the publishing application has just ended.The ingenuity service can utilize a record framework or a social database to spare the status of the framework. In the event of a disappointment in the tirelessness service, the framework executive may instate another case of the service (or reboot the down service if conceivable) to continue the usefulness of the framework without losing the present status. The recently instated tirelessness service would peruse the composed checkpointed status as characterized in the strategy document.

The second QoS approach, which is unwavering quality, shows the degree of dependability mentioned by a Data Reader or offered by a Data Writer. Data senders may set various settings of dependability, shown by the number of past issues they can keep in their stockpiling (or memory) to retry transmissions. Subscribers may then request varying degrees of dependable conveyance, going from a quick however problematic "best exertion" to an exceptionally solid all together conveyance. This gives per-data stream unwavering quality control. On the off chance that the unwavering quality sort is set to "Solid," the compose activity on the Data Writer may be blocked if there is a likelihood that the data can be lost, or if as far as possible, determined in the RESOURCE_LIMITS QoS, will be expended. In these cases, the RELIABILITY choice "max_blocking_time" designs the greatest span the compose activity may square.

Further, if the unwavering quality sort is set to "Dependable," data-tests produced from a solitary Data Writer can't be made accessible to the getting hubs if there are more established data-tests that have not been conveyed at this point because of a correspondence issue. I.e., the DDS middleware will endeavor to discover different ways and retransmit data - tests to remake a right depiction of the Data Writer history before it is available by the beneficiaries.On the off chance that the dependability type is set to "BEST_EFFORT," the service won't resend the missing data-tests, however, will guarantee that the dataset will be put away in the Data Reader(s) history, in a similar request they were made by the Data Writer. Thusly, the beneficiary hub may lose a few data-tests however it will never observe the estimation of a data-object change from a more up to date an incentive to a more established worth.

The third strategy, history, controls the response of the middleware when the estimation of an occasion changes before it is at long last imparted to a portion of its current Data Reader substances. In the event that the sort is set to "KEEP_LAST," at that point, the middleware will just endeavor to keep track of the most recent estimations of the data and dispose of the more seasoned ones. For this situation, the worth controls the greatest number of qualities the middleware will keep up and convey. The default (and most as often as possible utilized setting) for this QoS is "1," demonstrating that solitary the latest worth ought to be conveyed.

In the event that the history type is set to "KEEP_ ALL," at that point the middleware will endeavor to keep and convey every one of the estimations of the sent data to existing beneficiaries. Like the RELIABILITY QoS, the assets that the middleware can use to hold the various qualities are constrained by the settings of the RESOURCE_LIMITS QoS. On the off chance that the point of confinement is come to, at that point the response of the middleware will rely upon the RELIABILITY QoS. That is, on the off chance that the unwavering quality is set to "BEST_EFFORT," at that point, the old qualities will be dropped, while in the event that dependability is set to "Solid," at that point the middleware will hinder the sender until it can send the progressing old qualities first to all beneficiaries.

IV. RESULT ANALYSIS

Performance Evaluation and Results

This segment exhibits our trial results for testing the Node-to-Node gushing application. In the trials, we tried the two DDS and MPI executions by spilling 5GB and 10GB of data, while every single detailed estimation is the normal readings of three runs.

Figure 4 shows our benchmark to assess the versatility and runtime of MPI and DDS, utilizing 10GB and 50GB of gushed data. Unmistakably, the MPI supplanted the DDS execution with the utilization of the low-level MPI _Send and MPI_Recv capacities, where it was fit for accomplishing the greatest one - path throughput of 1,519MB/s with the 50GB test, contrasted with a most extreme throughput of 1,323MB/s for the DDS usage.

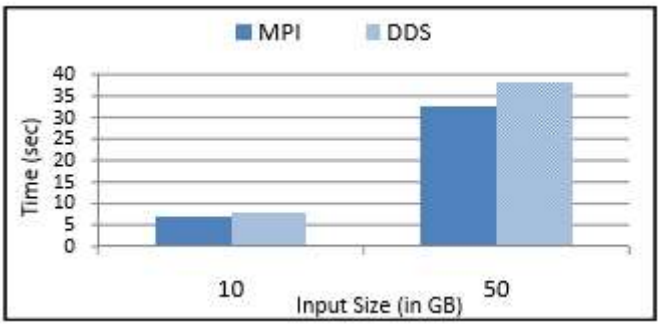

Fig 4: Node-to-Node Throughput

The QoS approach DDS_SYNCHRONOUS_PUBLISH_MODEhad to be set to empower sending huge data and train the middleware to utilize its very own string to send data, rather than the client string. The synchronous correspondence includes extra overhead as shown in the test.

Figure 5 shows the slipped by time for connecting with another hub in the DDS area, supplanting a smashed hub, and resending the data once more. By setting the DURABILITY QoS to TRANSIENT, the Data Writer stores all the sent examples in memory and resends them to the new hub once it joins the area. This setting was just relevant to the 10GB info size since the 50GB information must be put away in the Data Writer's perpetual stockpiling (by setting the DURABILITY QoS to PERSISTENT). Utilizing the PERSISTENT setting brought about ridiculous readings because of the exorbitant stockpiling access overhead. This test is additionally not appropriate to the MPI execution.

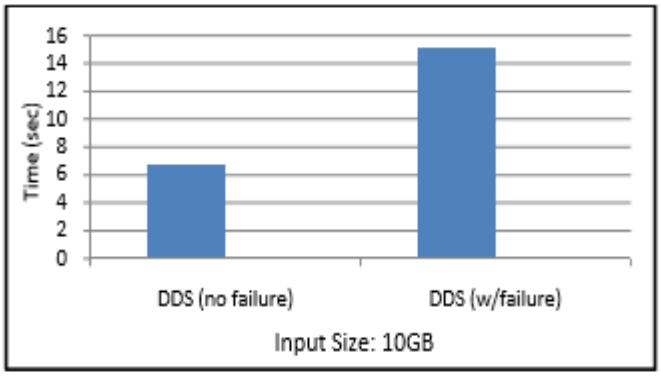

Fig 5: Failing the receiver in DDS while running the Node-to-Node application

Conclusion:

In this paper Grid models give a fascinating service-situated stage for logical and business applications. These stages give dynamic asset sharing utilizing open guidelines giving a nature of service that couldn't be accomplished generally. This paper researched a portion of the important issues that must be considered in planning grid applications that convey suitable QoS for business applications: the meaning of measurements, connections between asset assignment and SLAs, and QoS-related instruments. This component is significant for some pragmatic cloud stages since top asset requests frequently drive cloud suppliers outfitted their IT-framework with an ever-increasing number of servers, which thus expands the structure and operational expenses of cloud foundations. We distinguish difficulties and openings in grid computing. However, the fundamental goal of our paper is that to discover the issues and difficulties of grid condition, if these difficulties are expelled by specialists the grid computing can turn out to be progressively full of feeling and incredible. We exhibited our work of receiving the DDS standard into HPC to evade the MPI inadequacies and give QoS to HPC applications. As exhibited in our tests, DDS incorporation into HPC includes extensive caught as far as execution and system used when the application is for the most part correspondence bound, while the presentation is practically identical to those MPI - based applications when the program is calculation bound. In the two cases, the arrangement is a reasonable choice for those applications in which QoS is viewed as a need,

or for those HPC clump occupations that would run on product equipment, where the probability of disappointment isn't unimportant.

ABSTRACT- Biometric systems will be systems that empower people to be recognized in the electronic condition utilizing some physical and social attributes. Iris recognition framework is one of the viable biometric recognition systems. The primary objective of this investigation is one that Machine Learning recognition of the human from the iris images according to the nearby surface structures. The advanced iris images were gotten from the CASIA database. The surface highlights were removed from the four neighborhood iris locales of the portioned image by utilizing Gray Level Co-Occurrence Matrix. The element extraction of the iris was finished by biometrics GSCM (Gray Scale Co-occurrence Matrix), Gray Level Run Length Matrix, and Hausdorff Dimension. The Biometric Graph Matching calculation is utilized, which is utilized to coordinate the graph between the preparation image and the test image of the iris biometric. The BGM calculation utilizes graph topology to characterize distinctive element estimations of the iris layouts. A SVM -Support Vector Machine classifier is utilized to recognize certifiable and deception. The outcomes give preferred execution and validation over the current technique. These outcomes gave an improved execution against present strategies.

I. INTRODUCTION

The significance of security in numerous zones has empowered the advancement of various systems identified with this subject. There are a few kinds of systems that people can use to advance themselves. The most commonly utilized techniques are ID cards, uncommon passwords, and so on. Be that as it may, there are a few drawbacks to these strategies on the off chance that ID cards can't be found or the passwords are overlooked. That is the reason; expanding security question has uncovered different security systems as of late. One of these systems is biometrics systems that can distinguish character in an electronic domain [1]. Biometrics is the study of checking character by examining organic information. It is utilized for mechanized systems that are created to identify the personality by recognizing the person's quantifiable physical and social attributes. In rundown, biometrics communicates quantifiable natural hints of the individual and it very well may be physical, for example, fingerprints, retinal vessels, face, eyes, and hands, or conduct, for example, mark and composing mood.

Among all these physiological properties, iris designs have a structure of great and complex tissues. The iris surface is all around saved all things considered and the copying, recording, and copying of the iris tissue is troublesome. These surface properties differ from individual to individual. Every iris has its own one of a kind structure and it gives a complex framework that is steady and doesn't change over its lifetime [3].

These days, the compositional structure of iris recognition systems is commonly comparable. Acquiring the surface highlights from preprocessed images and the assessment of the outcomes by utilizing diverse classification strategies are a common way in thinks about. The utilization of different element extraction and classification strategies makes the uses of iris recognition systems extraordinary.

II. RELATED WORK

Considering iris recognition systems; broad research has been conducted in this field and different methodologies have been displayed.

The greater part of these examinations depend on the most recent fifteen years [4-5]. The principal fruitful iris recognition framework was proposed by J.Daughman in 1993 [4]. In spite of the fact that this work was distributed numerous years back, despite everything it keeps up its logical incentive as it gives answers for all aspects of the iris recognition framework.During the time spent removing highlight vectors from iris images, distinctive element extraction techniques, for example, Laws Texture Energy Measurements (TEM) [5], Gabor Wavelet Transform (GWT) [6], Wavelet Packet Transformation (WPT) [7], Discrete Wavelet Transform (DWT) [8], Principal Component Analysis (PCA) [6], Independent Component Analysis (ICA) and Gray Level Co-Occurrence Matrices (GLCM) [9] were utilized. Moreover, classifiers, for example, k-Nearest Neighbor (k-NN) technique [5], Artificial Neural Networks (ANN) [8] and Support Vector Machines SVM [2] were utilized for the classification of iris images.

There are various methodologies for include extraction dependent on GLCM and GLRM are displayed by an alternate creator. In this segment, some examination papers have been investigated. S. B. Kulkarni et al. [1], proposed an iris recognition framework in which highlights are separated by utilizing GLCM and GLRLM systems. The extricated highlight vectors are ordered by utilizing a SVM classifier. This framework gives 75% exactness for GLCM, 57.14% for GLRLM and 88.89% for a combination of GLCM [9] and GLRLM procedures. Asim Ali Khan et al. [2], proposed iris recognition for individual verification utilizing SVM and NN procedures. The framework utilizes the CASIA V.1 database for assessment. Hough change used to portion out the iris from the eye image. Gabor channel separates the highlights from the fragmented image. ANN and SVM classifier is utilized to order the component of iris. From the outcome, it is discovered that the SVM classifier gives higher precision than the ANN. ANN gives 83.65% and SVM gives 90.25% precision.

Amol M. Patil et al. [3] present a surface component extraction system dependent on GLCM and Hausdorff Dimension procedure. The matching of the iris is finished by the BGM calculation. It utilizes graph topology to characterize the element vector of the iris. The separated element vectors are then characterized by the SVM classifier.

Upasana Tiwari et al. [4] utilize the CASIA and MMU database for an individual recognizable proof framework utilizing iris. In this framework, the highlights are extricated utilizing a Gabor channel and diminished its dimensionality by the PCA calculation. SVM classifier groups the iris into approved and unapproved classifications.

S B Kulkarni et al. [5] proposed a mixture include extraction procedure by the combination of GLCM and GLRLM method. This framework doesn't variation to the iris turn. The SVM classifier gives 75% precision for GLCM, 57.14% for GLRLM and 88.89% for a combination of GLCM and GLRLM strategy for a standardized image while it gives 82.35% exactness for GLCM, 57.14% for GLRLM and 94.73% for a combination of GLCM and GLRLM for standardized iris information.

III. PROPOSED WORK

In this paper, we present a decent approach for individual recognition utilizing iris crisscross example. This framework incorporates image obtaining, preprocessing to dispense with clamor, iris confinement, and iris standardization, image honing, include extraction, and classification. The Block graph of the proposed framework is appeared in fig.1.

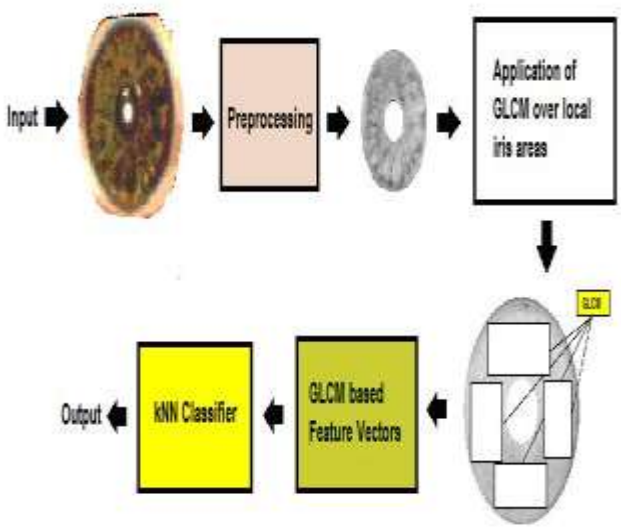

Fig 1. Block diagram of the proposed system

a) Pre-Processing

Before the component extraction process, all images were-handled in this stage. The size of the images utilized in the application is 576x768 pixels. Since the images utilized in this investigation are in 3D PNG organization, they were converted to 2-D grayscale position by utilizing the MATLAB 2011a program. The student and sclera zone of each image were then forgotten about by the division procedure with the goal that lone iris tissue stayed in all images.

b) Segmentation

Since the inner and external limit of an iris can be almost displayed as a circle, the inside coordinates (xc, yc) with inner span ri and external range ro of the circle can be determined for every iris image. Accept all the iris images have roughly a

similar institutionalization and confinement, at that point the region among inner and external limits (ri<area<ro) can be sectioned by utilizing MATLAB 2011a. A portion of the divided iris images utilized in the examination are appeared in Fig. 2.

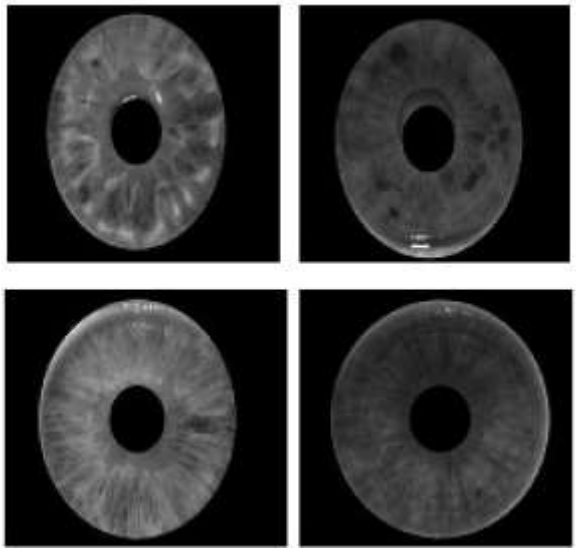

Fig 2. Sample segmented images

c) Feature Extraction

GLCM was applied to the distinctive neighborhood iris areas of the divided image as appeared in Fig. 3. The surface highlights acquired from the four diverse nearby iris zones were watched most reasonable parameters by checking intra correlation among the neighborhood iris locales. Accordingly, the parameters were included consecutively and an element vector with a length of 4x22= 88 highlights (22 highlights for every nearby iris zone) was constructed for each image. Computation subtleties were clarified in a thirty segment.

3.1 Gray Level Co-Occurence Matrix (GLCM)

GLCM is a component extraction strategy proposed by M. Haralick and it characterizes the connection between two neighboring pixels in a grayscale image [1]. The first of these pixels is known as the reference pixel and the second as the neighboring pixel. The conveyance in the matrix is balanced according to the separation between the pixels and the edge. This matrix is a square matrix of N size what's more, it predicts a capacity that speaks to the joint likelihood dispersion of gray level matches in an image [2].

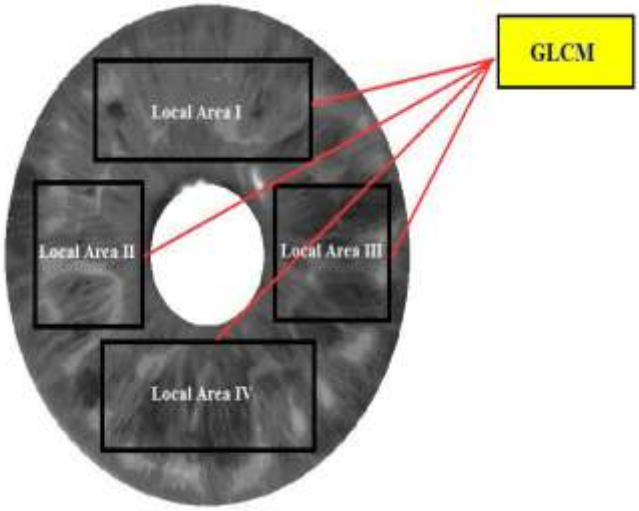

Fig 3. Extraction of the texture features from iris local areas.

Notwithstanding the separation between pixels, it is additionally important to know the bearings of the pixel sets. The most common known bearings are 135, 90, 45, 0 and the even likenesses of these edges [2]. A case of a co-occurrence matrix is given in Fig. 4. Here, the quantity of gray levels, the separation (d) between the pixels and the bearing point (theta) were picked 8, 1 and 0, separately. Since the (1,1) pixel pair at the coordinates I (1,1) and I (1,2) in the image matrix (I) is rehashed once, the estimation of the pixel pair in the co-occurrence matrix (f) becomes f (1,1) = 1. So also, since the (6,2) pixel pair is rehashed multiple times in the matrix I, the estimation of the pixel pair (6,2) in the matrix f can't avoid being f (6,2) = 3. These means are rehashed for the other pixel matches in the image matrix and the co-occurrence matrix of the whole image is determined along these lines [3].

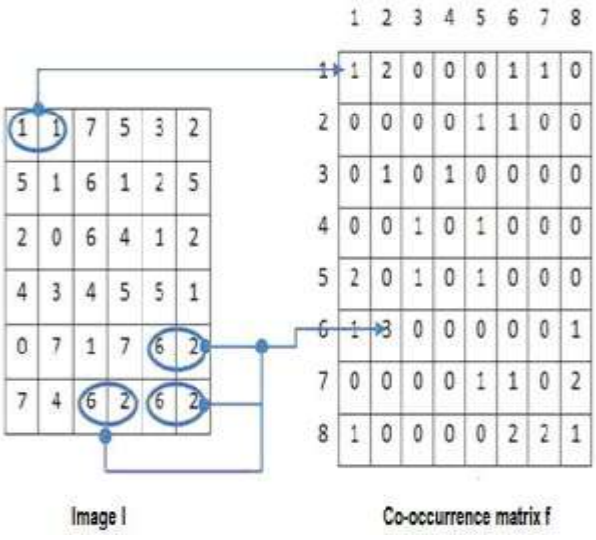

Fig 4: GLCM MATRIX

3.2 Grey-Level Run Length Matrix Algorithm

The gray-level run-length matrix (GLRLM) gives the size of homogeneous runs for each gray level. This matrix is computed for the 13 distinct headings in 3D (4 in 2D) and for every one of the 11 surface lists got from this matrix, the 3D esteem is the normal over the 13 bearings in 3D (4 in 2D). The component (i,j) of GLRLM corresponds to the quantity of homogeneous runs of j voxels with force I in an image and is called GLRLM(i,j) from that point. We should feature that comparisons of results with other programming supporting surface investigation ought to be performed with extraordinary consideration. The figuring of the surface lists coming about because of the matrix GLRLM can vary between programming. For example, in pyRadiomics (v1.1.1), after the estimation of the matrix GLRLM and before the extraction of the textural records, the matrix is edited (gray-level hub of GLRLMs trimmed among least and most extreme watched gray-levels and a run-length hub of GLRLMs trimmed to a greatest watched run-length). This moves lists (i,j) of the matrix and consequently the estimations of the subsequent textural lists.

GLRLM_SRE,GLRLM_LRE, Short-Run Emphasis or Long-Run Emphasis is the distribution of the short or the long homogeneous runs in an image.

GLRLM_SRE=Average over 13 *directions*(1*H*∑*i*∑*jG LRLM*(*i*,*j*)*j*2)

GLRLM_LRE=Average over 13 *directions*(1*H*∑*i*∑*jG LRLM*(*i*,*j*)·*j*2)

Where *H* corresponds to the number of homogeneous runs in the Volume of Interest.

GLRLM_LGRE, GLRLM_HGRE, Low Gray-level Run Emphasis or High Gray-level Run Emphasis is the distribution of the low or high grey-level runs.

GLRLM_LGRE=Average over 13 *directions*(1/*H*∑*i*∑ *jGLRLM*(*i*,*j*)*i*2)

GLRLM_HGRE=Average over 13 *directions*(1/*H*∑*i*∑ *jGLRLM*(*i*,*j*)·*i*2)

GLRLM_SRLGE, GLRLM_SRHGE, Short-Run Low Gray-level Emphasis or Short-Run High Gray-level Emphasis is the distribution of the short homogeneous runs with low or high grey-levels.

GLRLM_SRLGE=Average over 13 *directions*(1/*H*∑*i* ∑*jGLRLM*(*i*,*j*)*i*2·*j*2)

GLRLM_SRHGE=Average over 13 *directions*(1/*H*∑*i* ∑*jGLRLM*(*i*,*j*)·*i*2*j*2)

GLRLM_LRLGE, GLRLM_LRHGE, Long-Run Low Gray-level Emphasis or Long-Run High Gray-level Emphasis is the distribution of the long homogeneous runs with low or high grey-levels.

GLRLM_LRLGE=Average over 13 *directions*(1/*H*∑*i* ∑*jGLRLM*(*i*,*j*)·*j*2*j*2)

GLRLM_LRHGE=Average over 13 *directions*(1/*H*∑*i* ∑*jGLRLM*(*i*,*j*)·*i*2·*j*2)

GLRLM_GLNUr, GLRLM_RLNU, Gray-Level Non-Uniformity for a run or Run Length Non-Uniformity is the non-uniformity of the grey-levels or the length of the homogeneous runs.

GLRLM_GLNUr=Average over 13 *directions*(1/*H*∑*i*(∑*jGLRLM*(*i*,*j*))2)

GLRLM_RLNU=Average over 13 *directions*(1/*H*∑*j*(∑*iGLRLM*(*i*,*j*))2)

GLRLM_RP, Run Percentage, measures the homogeneity of the homogeneous runs.

GLRLM_RP=Average over 13 *directions*(*H*∑*i*∑*j*(*j*·*G LRLM*(*i*,*j*))).

3.3 Hausdorff Dimension by Box Counting Method Algorithm

A quantitative investigation of edge unpleasantness is completed to represent the level of harshness of information images. Commonly known as the Hausdorff Dimension (H.D.), the calculation appeared in figure 3 gives the total border unpleasantness as a fractal measurement. The fractal measurement depicts the complexity of an article; on account of gadgets introduced here, this calculation gives edge harshness which infers parasitic emanation locales for incredibly unpleasant borders [1]. On Hausdorff Dimension scale, an element of 1 likens to a smooth line, while 2 infers fractal complexity like that of a Julia set, and in light of the fact that the gadgets displayed here are considered truncated fractals, the fractal measurement determined is bound by as far as possible, for example 1 < H.D. < 2. The calculation to accomplish this beginnings with an information electron micrograph image transferred inside Matlab (figure 3), at that point the Canny calculation [2] is utilized to discover the edge inside the image and superimposes a lattice of N squares over the edge while counting the involved squares that the edge goes through (upper right, N(s)). This is continued for an expanding number of squares and the fractal measurement (H.D) is given by the inclination of the logarithm of the quantity of squares log N, over the quantity of squares involved by the edge log N(s), as showed by figure 3 (base) and condition (1)

$$H.D = \frac{\log N}{\log N(s)} \ldots\ldots$$

3.4 Classification

In the classification step, it is meant to coordinate the examples to the closest classes according to their element spaces with insignificant blunder. The exhibition of the classifier relies upon well-characterized properties.

Classifiers can be analyzed in two gatherings, conventional and smart. Conventional classifiers are based on Bayesian choice hypothesis which is a measurable technique. K closest neighbors (kNN), Fisher's straight classifiers, greatest likelihood, paired tree strategy, and multivariate Gaussian models are for instance of conventional classifiers. In this investigation, the kNN strategy was utilized for the iris recognition framework.

3.4.1 K- Nearest Neighbor (k-NN) Algorithm

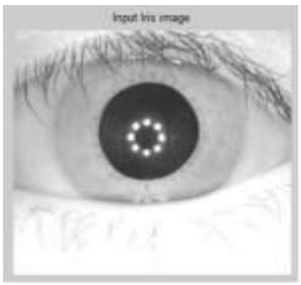
KNN is a nonparametric calculation and it very well may be utilized for both classification and relapse in the example recognition applications. Non-parametric implies that no presumption has been made about the fundamental information or its circulation. K-NN is perhaps the least complex calculation in machine learning. It is less complex and takes less time when compared to different classifiers (ANN, SVM, and so on.) [6].

In this technique, information classification is made according to a dominant part vote of its neighbors and the information is selected to the most common class among its k closest neighbors. For instance, on the off chance that k equivalent to 1, at that point the information will be allocated to the class of that 1-closest neighbor. Interestingly, before characterizing, the properties of each class are unmistakably determined ahead of time. What's more, the presentation of the framework is influenced by variables, for example, the similitude measure, the quantity of adequate practices in the example set, and the edge esteem. In any case, the most significant control parameter is the quantity of closest neighbors (k). The given example is grouped by looking at the separations to the closest neighbor k [7].

The capacity learned in the k-NN calculation can be discrete and genuine esteemed. In discrete-esteemed capacities, xr is the example point to be characterized and xs is the learning point. Loads equivalent to 1 at a common Euclidean separation (ci=1, i=1, 2, … , p) [8].

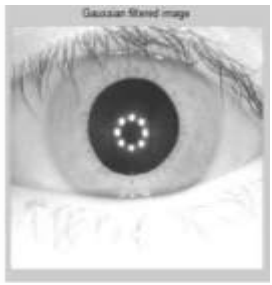
3.4.2 Support Vector Machine (SVM)

SVM is applied for the classification of information individuals. Information individuals or in information focuses there are two things that might be certifiable or faker. The careful strategy is to arrange the two information focuses is hyperplanes. The edge indicates the greatest width in the hyperplanes. The support vector is the informational index used to characterize the vectors [11]. To separate among objects of different class enrollments are known as hyperplanes classifiers. Support Vector Machines are explicitly to play out this kind of activity. In the event that the informational collections are not took into account isolating the hyperplanes, all things considered, utilize a delicate edge. It implies hyperplanes that different a considerable lot of the information focuses yet not all information focuses. To construct ideal hyperplanes, SVM applies an iterative preparing calculation that is utilized to decrease issue acknowledgment. SVM supports classification, relapse and furthermore it can deal with unmitigated factors and different continuous. For all out factors, different sham factors are made with 0 and 1.



4 RESULTS AND DISCUSSIONS

The proposed framework is actualized in MATLAB 2013(b). To play out the examination, the images from the CASIA and UPOL database have been used. The subjective and quantitative examination of the framework is appeared in the underneath subsections.



4.1 Qualitative analysis

The qualitative analysis of the proposed iris recognition system is as shown below

CASIA database:

(a)

(b)

(d)

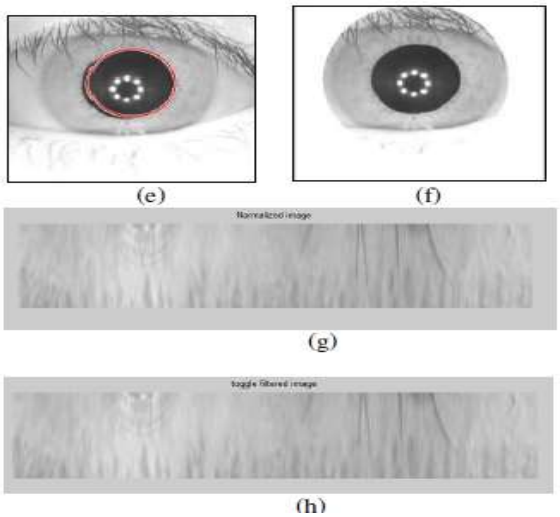

Fig 5 Qualitative analysis CASIA database:(a) Input Image from CASIA database (b) Gaussian filter output (c) Gradient image (d) Canny Edge detection output (e) Pupil detection (f) Iris detection (g) Normalized image of **Daugman's** rubber sheet Model output (h) Toggle filter output

4.2 Quantitative analysis

The statistical analysis of the proposed system is evaluated by the accuracy parameter.

Table1. *Quantitative analysis* Combined GLCM and GLRLM approach Indicates 50 person data feature

Feature extraction technique / Classifier	GLCM+GLRLM (UPOL database)	GLCM+GLRLM (CASIA database)
SVM	92.00%	68.00%*
KNN	75.8%	93.33%

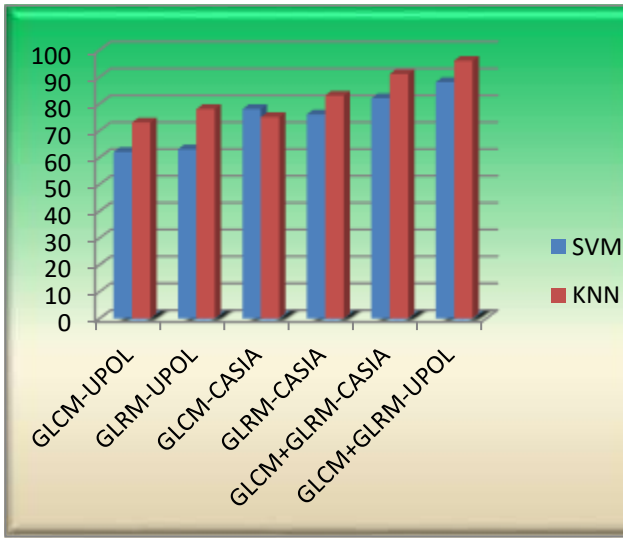

Fig 6 Comparative analysis of different Classifier

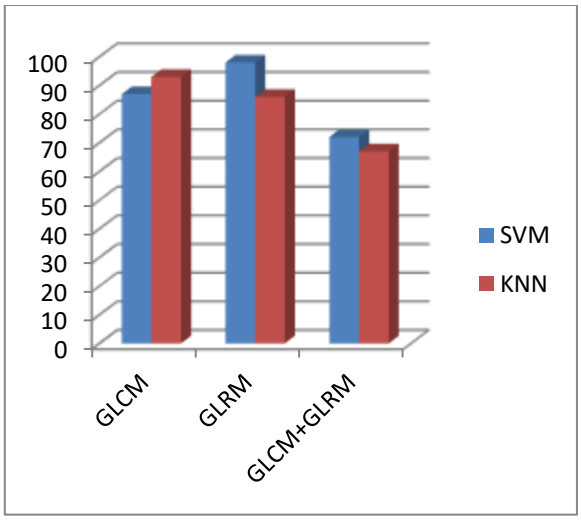

Fig 7 Execution time analyses

5 CONCLUSION

The proposed strategy includes the biometrics subtleties is separated by utilizing two systems, for example, GLCM (Gray Scale Co-occurrence Matrix) and Hausdorff Dimension (HD). From GLCM surface highlights like vitality, contrast, entropy, Correlation Coefficient, homogeneity is removed. Shape highlights like standard deviation, mean and shape highlights like region, border minor pivot length, significant hub length, robustness, whimsy are determined from Hausdorff Dimension (HD). Precision for CASIA database with combined GLCM+GLRLM approach which is most noteworthy among all other proposed approaches. The computation time required for GLRLM highlights is comparatively less. It is discovered that when various names for the SVM classifier get builds, at that point memory required playing out the classifier get an expansion. Later on, the exactness of the framework will increment by utilizing distinctive component extraction systems and classification methods. From the aftereffects of the proposed framework, it is concluded that KNN classifier gives 93.33%.

An Examination Of Big Data And Blockchain Technology

S. Dhanalakshmi, G.Charles Babu

Abstract-: ***Blockchain technology is the process of development of bitcoin, the blockchain technology as a distributed ledger of cryptocurrency transactions for digitized, decentralized, trusted and secured manner. The mainstream of blockchain technology is bitcoin, bitcoin concept made with ledger of every single transaction, transactions allows for hashing mechanism to verify the large amounts of data. Big data task requires that large amount of computational space, to generate the terabytes of data for ensuring the successful data processing techniques. The major impact on big data analytics requires more number of data and generated data can be depending upon different sectors from different organizations. This paper presents a state of definition, characteristics, transaction process, and applications, along with discussion of big data analytics are introduced. In blockchain technology covers the flaws of big data in fruitful relationship, with the factors of security, transparency, decentralization and flexibility, so that data to be analyze in different and efficient way for organizations all sizes in data analytics form.***

Keywords: Big Data, Blockchain, Bitcoin, Cryptocurrency, Classification, Components, Use Cases

I. INTRODUCTION

Big data is used for large data volumes, these data volumes are generated from heterogeneous sources. Its generally refers to massive volumes of complex, high velocity, variable data, diverse types of data, to enable the different technique, and analyze the data, then the data to be managed in effective manner. The scales of big datas; memory capacity of the human brain about 2.5 peta bytes, within two minutes 13 peta bytes amount of data that could be downloaded from the internet. Some examples of big data are social networks, web logs, video and audio archives, military surveillance, astronomy, atmospheric science, genomics, commercial, sensor networks, RFID, biogeochemical and etc. Blockchain technology is a ledger of transaction, the ledger of transactions are shared in trusted environment, then the transactions and records are maintained and growing continuously in distributed manner, the transaction can be inspect with everyone but no single user control. The data are stored in blocks, and blocks are chained together, then block is sealed by hash function, these types of systems are centralized systems. Blockchain work like public ledger, a ledger has different entries of transactions, new entries of transactions are added to the end of the block, if you make change in any blocks the hash of all subsequent blocks also change. If the transactions are done in the same order in their ledgers, any reflection is their, also done with all nodes. The ledgers are distributed and synchronized, need for consensus mechanisms, this consensus mechanisms a protocol which makes all the nodes agree on the transactions and their order. Another kind of blockchain is distributed ledger, distributed ledger and blockchain are often used interchangeably. Hyperledger Fabric and R3 Corda is an example of distributed ledger technology.

II. BLOCKCHAIN

Blockchain technology is sequence of blocks, essentially a trustless, peer-to-peer and continuously growing database of records. All the blocks are ordered and recorded in public ledger, no parent in first block of blockchain; this block is named as genesis block, and the next block points to the hash of the previous block with one parent block. Each block of transactions points to Merkle root. The components of blockchain are block header and transactions; block header is called metadata about a block; the metadata consists of a) previous block hash, b) mining statistics used to construct the block and c) merkle tree root. All the blocks are connected in linked list format, each block having some header, the header connects to the transactions in block, if any transaction to be changed the header of block also changed. Figure 1 shows that sequence of blockchain diagram, and the list of records to be connected in sequence.

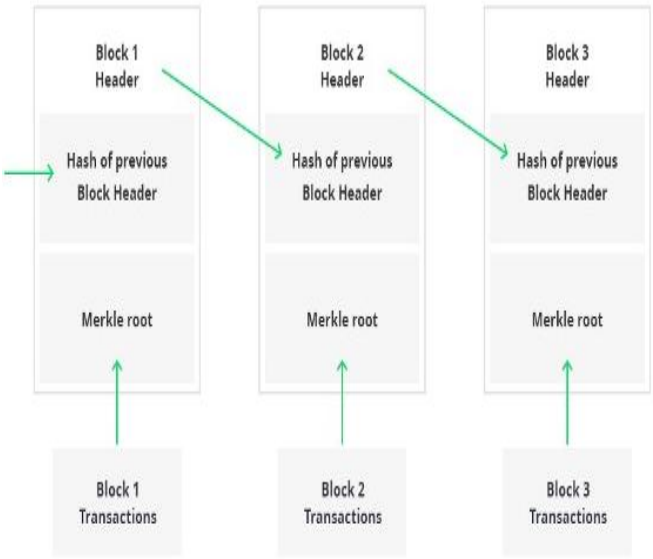

Figure.1. Blockchain Sequence

G.Charles Babu, Professor, Department of Computer Science and Engineering, Malla Reddy Engineering College (Autonomous), Telangana, India

A. Bitcoin

The first application of blockchain is bitcoin systems, the system form that peer to peer network (software that runs on machines of all stakeholders to form the system), permissionless (no identity - no need to sign up anywhere to use; no access control – anyone can participate in any role) and completely decentralized systems (no central party for ordering or recording anything). Bitcoin system releases the token is called BTC, bitcoin is the first cryptocurrency created in 2009, the bitcoin system implements the combination of public transactions & PoW Consensus functions. It's a decentralized system with no central authority for transaction, no one can involved in to the system for direct transactions. Bitcoin systems, its performs two broad operations; transaction management (transfer of bitcoins from one user to another) and Money Issuance (regulate the monetary base). Types of nodes in bitcoin are; Users with wallets - wallets carry user's key pairs, track ownership and authenticate transactions, Miners - compete with each other to add new block of transactions on the blockchain by solving puzzles in PoW system, and Exchanges - portals where users can buy or sell Bitcoin tokens (BTC) in exchange for fiat or other cryptocurrencies.

Table 1. Cryptocurrency Applications on Blockchain

Currency Name	Features	Consensus
Bitcoin(BTC)	First decentralized ledger currency – 2009	PoW
Bytecoin (BCN)	Focused on user privacy through impassive and anonymous transactions - 2012	PoS
Litecoin (LTC)	Uses scrypt as a hashing algorithm in cryptocurrency concept - 2011	PoW (Scrypt)
Peercoin (PPC)	Uses PoW and PoS functions - 2012	PoS with Hybrid
Emercoin (EMC)	Trusted storage for any small data (DNS, PKI, SSL infrastructure etc.) – 2013	PoW
Ripple (XRP)	Designed for P2P debt transfer - 2013	PoS
Waves	An open blockchain platform to develop applications for high volume transactions - 2016	PoS
Omni (MSC)	Both a digital coin and a communication platform built on top of bitcoin blockchain - 2013	PoS
Gridcoin (GRC)	The first cryptocurrency linked to citizen science through Berkley Open Infrastructure for Network Computing - 2013	PoS
Namecoin (NMC)	Used for creating a censor-resistant - 2011	PoW (SHA-256)
Dogecoin (DOGE)	First "Joke Currency" based on internet meme - 2013	PoW (Scrypt)
Myriad	Multiple mining algorithms - 2014	Multi-algorithm PoW
Blackcoin	A type of mining pool - 2014	PoS
Vericoin	Autoexchange to bitcoin for payment - 2014	PoS
Fericoin	Implements a monetary policy - 2012	PoS (SHA2256)

B. Cryptocurrency

Cryptocurrency is the application on blockchain; it's the decentralized currency replacement that acts as to traditional fiat currency (government and central financial institutions). It can have two roles; the currency to represent values of goods and services, other as an investment instrument to the market stock. Cryptocurrency can be classified into two types; altcoins and tokens. Altcoins run their own blockchains, can be divided into, based on bitcoin blockchain (such as Litecoin and Dogecoin) and not based on bitcoin blockchain (ripple or ethereum), and other types are Tokens; its usually represent any asset that is tradable, resides on top of another blockchain; such as non-fungible (used to create verifiable digital scarcity), the examples are cryptokitties, decentralized and fungible tokens (true digital cash), in fungible most tokens are act as a currency, ex., Bitcoin, ether, Zcash. The various cryptocurrency domains are healthcare, mining, eCommerce, Identity, Storage, Gambling, Privacy, Entertainment, Computing, stable, virtual reality, financial, Crowd Funding and etc., The crypto assets can be classified into infrastructure (other systems can be built upon very easily), currency (stores the value in user currency replacement) and services.

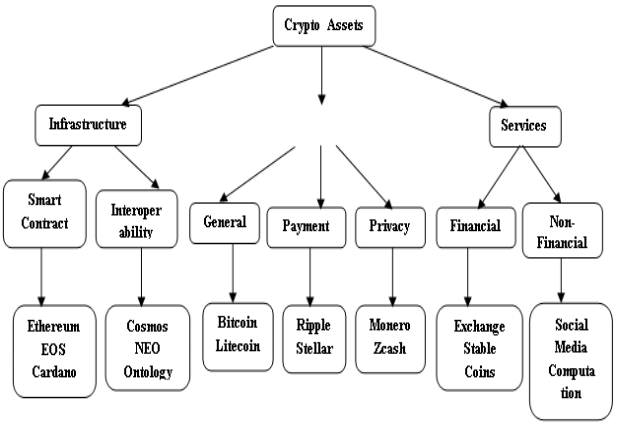

Figure.2. Crypto Assets Classification

C. Building Blocks of Crytpocurrency

Cryptocurrency system is a encryption technique, to generate and verify the units of currency & transfer of funds. It has three main features of cryptocurrency, a secure blockchain, wallets, and mining. Cryptocurrency having three main building blocks; the building blocks are distributed ledger, consensus algorithms, and currency.

a) In distributed ledger – it's a fundamentally asset databases, it has two types unpermissioned (its for public blockchain, everyone has a copy. Ex. Bitcoin, IOTA) and permissioned (private and only accessible to certain parties. Eg. Hyperledger fabric, Quorum)

b) Consensus Algorithms – it's defining that; nodes reflect the same state of ledger, certain set of rules, and remove third party. The variants are Proof-of-Work, Proof-of-Stake, DPoS, PoA, PoT, PoC, PoB, PoR, BFT , PoI, Delayed PoW and etc.,

c) Currency – Currency is define that; representation for values of goods and services. The properties of currency; unforgeable, limited supply, computationally infeasible to duplicate and not be double spent

D. Blockchain Components

The blockchain components can be categorized in to several parts; the components are cryptographic hash function, transactions, asymmetric-key cryptography, addresses, ledgers, blocks, consensus models, forks and smart contracts.

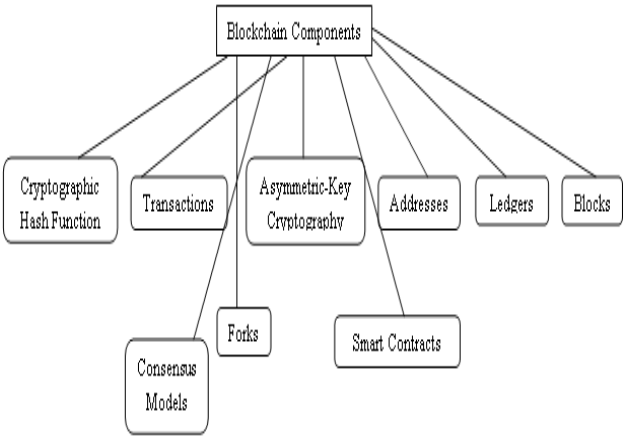

Figure.3. Blockchain Components

The cryptographic hash functions - data can be any size, text, image and file, most common hash function secure hash algorithm (SHA256), the output of SHA256 is 32 bytes (256bits), if every hash computation takes 1 Millisecond.

- Transactions - it represents interaction between parties that is transfer the currency between two users. Each block in a blockchain can contain zero or more transactions; it consists of inputs and outputs, the inputs – assets that are to be 'transferred', and outputs – where the assets 'go'.

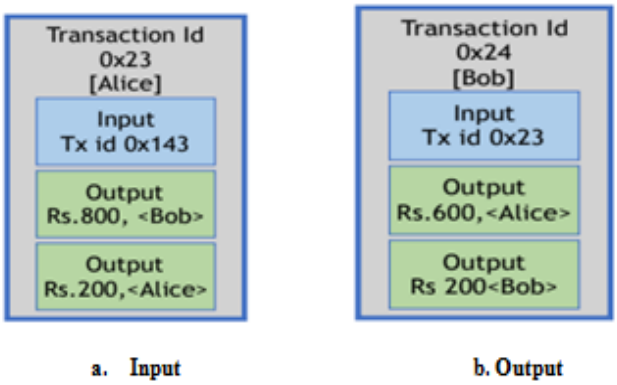

Figure.4. Transactions of Input and Output

Asymmetric-key - Asymmetric key consists of public key and private key of two pairs of key systems. In Blockchain network used for asymmetric-key cryptography in secured systems, the systems serves as bitcoin addresses, and used to digitally sign the transactions systems. The encryption key is public and decryption key is private key (anyone can encrypt the data, but decryption only done for intended receiver).

Addresses – In blockchain network, the addresses are used only once, using cryptographic hash function.

Ledgers – It's a collection of transactions, every user maintains their own copy of the ledger

Blocks – A block contains block header (metadata) and block data (list of validated and authentic transactions)

Consensus Models – Determining the next block in the systems, verify and construct a valid block and add to chain, by computing a cryptographic block hash then generating new currency.

Forks – software changes periodically

Smart Contracts – code and data deployed in the blockchain network

E. Types of Blockchain

The blockchain are categorized into public blockchain, private blockchain and consortium blockchain.

1. Public Blockchain – this type of network systems everyone can read and see, & open to all in the platform, and can validate the transactions. Other name of public blockchain is permissionless blockchain; it's a entirely decentralized and peer-to-peer network, very slow compared to private blockchain. Example: Bitcoin
2. Private Blockchain – access permission is limited, and writes access for the private blockchain is controlled by one organization; private blockchain network is shared by encrypted database. Its otherwise called permissioned blockchain, private blockchain also dencentralized and peer-to-peer network. Network members are known, but transactions process are secret for Verifying and validation process, then the transaction systems provide higher level efficiency. Example: Hyperledger Fabric
3. Consortium Blockchain – This system is combination of both public and private blockchain, its partly decentralized network, consortium blockchain network allow for registered participant or everyone to access, and controlled by preset of nodes, then its provides the efficiency and transactional privacy.

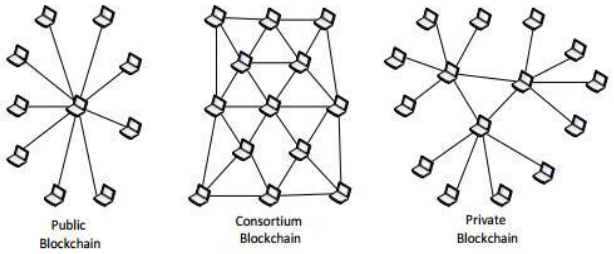

Figure.5. Public vs Consortium vs Private Blockchain

III. BIG DATA TECHNIQUES

Big data techniques, can be classified or identified by 3 parameters (3v's); volume, velocity and variety. The first parameter volume denotes data size, amount of data. The amount of data generated from facebook, the typical data centre like Google, Amazon, the data are generated in the form of trillion of bytes. The second perspective type of parameter in big data technology is velocity, like the speed of change of data in social networking website, and the third important aspect of analytics in big data; it's a kind of geospatial applications, also variety of data applying blockchain for big data applications.

Big Data Enabling Technologies

It's a collection of data and process using different open source tools. The open source tools are; Apache Hadoop, Hadoop Hdfs, Hadoop Yarn, Hadoop Map Reduce, Hive, Cassandra, Apache Zookeeper, Apache Hbase, Apache Spark, No SQL, Kafka, Spark Streaming Ecosystem, Spark MLib, Spark GraphX.

a) Apache Hadoop – Apache hadoop systems are open source framework in big data. It has different basic parts:

• Hadoop Distributed File System (HDFS) – this type of systems in hadoop are, performing storage process, and split into different data & distribute the nodes in cluster; Scaling out of H/W resources and Fault Tolerant

• MapReduce - Programming model that simplifies parallel programming. (Map-> apply (), Reduce-> summarize () and Google used MapReduce for Indexing websites, and other parts of Hadoop systems are;

• YARN – A Programming model for processing big data. Flexible scheduling & resource management over HDFS. Yahoo uses YARN to schedule jobs over 40,000 servers

b) MapReduce function, In MapReduce function, hadoop distributed file system move to the map function with the input of (key,value) pairs, the pairs are shuffle & sort ; its produce the intermediate values, the values merged into reduce function, after reduce function final key and value can be produced.

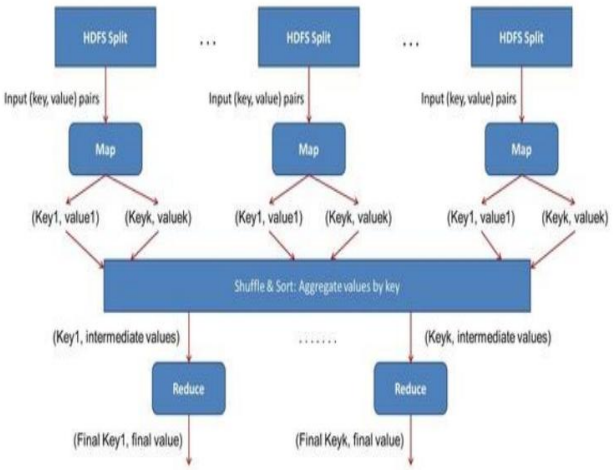

Figure.6. MapReduce Function

c) YARN – YARN is a Yet Another Resource Manager. The resources can be allocated and executed on different cluster nodes.

d) Hive – To access big data, Hive systems support for HSQL.

e) Apache Spark – its otherwise big data analytics framework, academic & industry gained lot off attraction in apache spark, its designed for fast computation

f) ZooKeeper - ZooKeeper is a highly reliable distributed coordination kernel, which can be used for distributed locking, configuration management, leadership election, work queues,...

Zookeeper is a replicated service that holds the metadata of distributed applications. Key attributed of such data; small size, performance sensitive, dynamic and critical.

g) NoSQL - NoSQL technology is new and with wide variety of databases that can stored unstructured data.

h) Cassandra – Data is placed on different machines with more than one replication factor that provides high availability and no single point of failure.

IV. BLOCKCHAIN USECASES IN BIG DATA & RESULTS

Big data analytics process provided in the form of both industry and academia. It operating and managing with own data in Blockchain technology. The blockchain systems ensure that privacy and integrity of data, it predicts large amount of data in big data techniques but focus on validating data, the data to be brought together in decentralized manner and the origin of the data linked in chained manner. The use cases of blockchain technology in big data can be specified that, a) Ensuring trust (data integrity) – verification process ensures its quality, the blockchain record verify authenticity of the documents, b) preventing malicious activities – consensus algorithms to verify transactions and generate the computational power, c) Making Predictions (Predictive Analysis) – predict large sets of data to predict future outcomes and gathered structured data from individual devices, d) real-time data analysis – analysis the data in large scale of organizations to achieve blockchain enabled system, after analyzing observe changes in the data, make possible to change quickly in real time manner, and e) manage data sharing – data can be stored in blockchain network and monertize it, outcome of the network . Stored on the blockchain platform.

V. CONCLUSION

The paper summarizes the overview of blockchain technology and big data systems. In blockchain systems provide the immutable, distributed, decentralized data & also highlight the cryptocurrency and bitcoin systems. Big data systems highlight the importance different enabling techniques revolutionize the way to process and analyze data. Further research to incorporate the different applications and use cases of blockchain technology and Big Data techniques

An Efficient and Secured Framework for Mobile Cloud Computing

A.Sai Hanuman, P.S.V.Srinivasa Rao, J.Sasi Kiran, G.Charles Babu, B.Sankara Babu

Abstract*: By and by days the market of PDA is creating at a quick. Everyone has a versatile, tablet, fablet (tablet with calling office). Flexible customer will accomplish 6.5 billion preceding the completion of 2012,6.9 billion preceding the completion of 2013.Together with a perilous improvement of the convenient applications and ascending of appropriated figuring thought, compact disseminated registering (MCC) has been familiar with be a potential development for adaptable organizations. MCC consolidates the disseminated figuring into the flexible condition and beats obstacles related to the execution (e.g., battery life, amassing, and information transmission), condition (e.g., heterogeneity, flexibility, and openness), and security (e.g., steadfastness and insurance) discussed in compact enlisting. This paper gives an information about adaptable disseminated figuring application security, issues . The issues, existing plans and procedures are discussed.

***Index Terms*: About four key words or phrases in alphabetical order, separated by commas.**

I. SCOPE OF THE WORK

Compact disseminated registering is one of flexible advancement floats later on since it solidifies the upsides of both convenient figuring and circulated processing, thusly giving perfect organizations to versatile customers. The essential of movability in appropriated registering delivered Mobile disseminated figuring. MCC gives increasingly potential results to get to organizations in accommodating manner. It is typical that after specific years different adaptable customers will going to use dispersed processing on their mobile phones. As shown by a progressing report by ABI Research, a New York-based firm, more than 240 million businesses will utilize cloud benefits through mobile phones by 2015.That traction will drive pay of flexible disseminated processing to $5.2 billion. With this prominence, this manuscript has given a framework of adaptable appropriated processing in which its definitions, security, problems and inclinations are displayed. Prevalently it deliberated dataset security away in cloud and hugeness of data security. This manuscript has researched different parts for giving data security so Mobile Cloud Computing might be comprehensively recognized by different customers in future. It moreover suggested an instrument to give arrangement, get the opportunity to control similarly as uprightness to versatile customers. The handling capacity of convenient structures is improved by Cloud enlisting. Mobile phones can rely upon conveyed processing to perform computationally genuine exercises, for instance, looking data mining, etc. The use of flexible circulated registering vanquishes execution related tangles for instance exchange speed, amassing point of confinement and battery life, similarly as condition related issues for instance openness, flexibility and heterogeneity. Dispersed registering is changing the Internet handling establishment. Since by far many organizations are access from cloud over Internet, MCC has been introduced. The security hazard has pushed toward getting to be obstruction in the brisk improvement and generous usage of flexible conveyed processing perspective. The security perils have advanced toward getting to be catches in the quick flexibility of the versatile appropriated figuring perspective. Basic undertakings have been submitted in research affiliations and the insightful network to build secure versatile appropriated processing circumstances and systems. This paper reviews the possibility of adaptable conveyed figuring similarly as problems of security normal inside the setting of convenient application & disseminated registering. The standard vulnerabilities in structures with possible game plans are discussion about here.

Mobile phone contraptions are commonly used in our step by step lives. Regardless, these devices show obstructions, for instance, short battery lifetime, confined computation control, little memory gauge and unordinary framework arrange. As such, different courses of action have been proposed to alleviate these obstructions and widen the battery lifetime with the usage of the offloading system. In this manuscript, a new framework is suggested to offload genuine count endeavors from the mobile phone to the cloud. This framework uses a headway model to choose the offloading decision logically subject to four essential parameters, to be explicit, essentialness use, CPU use, execution time, and memory use. Additionally, another security layer is given to guarantee the moved data in the cloud from any attack. The preliminary outcomes showed that the structure can pick a sensible offloading decision for different sorts of adaptable application assignments while achieving colossal execution improvement. Also, not exactly equivalent to past methodologies, the structure can shield application data from any peril.

Objectives of the work

Revised Manuscript Received on September 03, 2019

Dr.A.Sai Hanuman, Professor, Dept of CSE, Gokaraju Rangaraju Institute of Engineering and Technology, Bachupally, Hyderabad, Telangana.

Dr.P.S.V.Srinivasa Rao, Professor, Dept of CSE, Vignan's Institute of Management & Technology for Women, Ghatkesar, Medchal Dist, Telangana.

Dr. J.Sasi Kiran , Principal &Professor, Dept of CSE, Farah Institute of Technology, Chevella, Rangareddy, Telangana.

Dr.G.Charles Babu, Professor, Dept. of CSE, Malla Reddy Engineering College(Autonomous), Maisammaguda, Secunderabad, Telangana.

Dr.B.Sankara Babu, Professor, Dept of CSE, Gokaraju Rangaraju Institute of Engineering and Technology, Bachupally, Hyderabad, Telangana.

• To plan Mobile Cloud Computing: Issues, Security, Advantages, and Trends
• To ponder Privacy and Security of Mobile Cloud Computing (MCC)
• To structure Mobile Cloud Computing Issues and Solution Framework
• To look at An Efficient and Secured Framework for Mobile Cloud Computing
• To ponder secure data planning framework for versatile appropriated processing

II. LITERATURE REVIEW

C. Erway, A. Kupcu, C. Papamanthou, and R. Tamassia (2009) In versatile conveyed processing, phones can rely upon appropriated figuring and information storing resource for perform computationally thought exercises, for instance, looking, data mining, and media dealing with. Despite giving ordinary estimation organizations, compact cloud moreover improves the assignment of standard uniquely delegated framework by seeing mobile phones as organization center points, e.g., identifying organizations. The identified information, for instance, territory encourages, prosperity related information, should be arranged and set away in a sheltered style to guarantee customer's security in the cloud. To this end, we present another adaptable cloud data taking care of framework through trust the board and private data separation. Finally, a use pilot for improving youngsters' driving prosperity, which is called FocusDrive, is acquainted with demonstrate the game plan.

A. Fiat and M. Naor (1994) Cloud preparing is another and promising advancement that is changing the perspective of ordinary Internet enrolling and no doubts the whole IT industry. Dispersed figuring is foreseen to stretch out in the versatile condition using on the fast advances in remote access developments. These adaptable applications are worked around compact circulated registering frameworks and models. In the Mobile Cloud condition, customers might remotely store their data similarly as acknowledge high gauge on-demand cloud applications without the hindrances of getting and keep up their own one of a kind neighborhood hardware and programming. In any case, data security is up 'til now a vital concern and is the standard block shielding circulated figuring from being even for the most part grasped. This stress begins from the manner in which that sensitive data set away in the open fogs is administered by business expert centers that most likely won't be totally dependable. In that limit, there are a couple of security and assurance issues that ought to be tended to. This segment gives an outline on the appropriated processing thought sought after by a portrayal on convenient dispersed registering and the various security issues important to the flexible circulated figuring condition.

L. Cheung, J. Cooley, R. Khazan, and C. Newport (2007) Mobile gadgets (e.g., tablet, wireless, pcs, etc) are dynamically transforming into a fundamental bit of human life. These Mobile devices still need in resources diverged from a standard information taking care of contraption, for instance, PCs and workstations. The response for thrashing of these challenges is Mobile Cloud Computing. We propose another adaptable framework that enables direct use of cloud resources for increment the capacity of advantage obliged PDAs. The basic features of this model join the package of a singular application into different fragments. Compact applications can be executed in the PDA or offloaded to the cloud clone for execution. The results exhibits that the execution of execute application on adaptable or cloud the extent that memory exhausted using unmistakable detachment and number of centers are shut. Most of benefits ate up on convenient mobile phone will decrease around to the half of memory used for running application on the adaptable so to speak. On the contrary side, Although Cloud Computing is an unprecedented headway in the domain of preparing, there moreover exist disadvantages of dispersed registering, for instance, security of data. As such, there is a remarkable need of encryption procedure with a lot of security and with immaterial key size. There for, the principal center for ensuring security is to developed new cross breed cryptography show. Along these lines, new cross breed cryptography show is created for achieving security in Mobile Cloud Computing. The results exhibit the power of new computation. The rule duty of our investigation is to develop a safe flexible cloud establishment that will enable wireless applications that are passed on both with respect to data and figuring.

D. Boneh, X. Boyen, and E.J. Goh (2005) Smartphone devices are commonly used in our step by step lives. Regardless, these contraptions show confinements, for instance, short battery lifetime, compelled estimation control, little memory measure and surprising framework organize. Thusly, different courses of action have been proposed to direct these confinements and expand the battery lifetime with the usage of the offloading technique. In this paper, a novel structure is proposed to offload genuine figuring endeavors from the phone to the cloud. This framework uses a streamlining model to choose the offloading decision logically subject to four central parameters, to be explicit, imperativeness use, CPU use, execution time, and memory use. In addition, another security layer is given to guarantee the moved data in the cloud from any strike. The test outcomes showed that the framework can pick a fitting offloading decision for different sorts of adaptable application assignments while achieving basic execution improvement. Additionally, not exactly equivalent to past strategies, the structure can shield application data from any risk.

J. Bethencourt, A. Sahai, and B. Waters (2007) In this manuscript, we introduce a far reaching security system to check the data accumulating in open fogs with outstanding concentration on lightweight remote gadget store & recuperate information without revealing data substance to the cloud expert associations. I order to reach this aim, our answer revolves around the going with 2 research course: Initially, we introduce a novel Privacy Preserving Cipher Policy Attribute-Based Encryption (PP-CP-ABE) to guarantee the data of customer. Using PP-CP-ABE, light-weight contraptions might securely redistribute overpowering encryption & unscrambling exercises to cloud authority communities, without revealing data &utilized security keys. Secondly,

we suggest an Attribute Based Data Storage (ABDS) structure as a cryptographic access control system. The ABDS reaches the data theoretical optimality to the extent restricting estimation, accumulating & correspondence overheads. Especially, ABDS bounds cloud organization charges by reducing correspondence overhead for data organizations. Our implementation assessments display the quality of security & efficiency of the showed course of action similar to computation, correspondence, and limit.

G. Ateniese, R. Expends, R. Curtmola, J. Herring, L. Kissner, Z. Peterson, and D. Tune (2007) Cloud enlisting is a promising development that is changing regular Internet figuring perspective and industry of IT. With progression of remote access developments, appropriated processing is depended upon to develop to flexible circumstances, where PDAs and sensors are utilized as data gathering center points for cloud. In any case, customers' stresses over data security are the essential preventions that hinder appropriated processing from being comprehensively gotten. These stresses are begun from the manner in which that sensitive data lives in open fogs, which are worked by business pro associations that are not trusted by owner of data. Therefore, new secure organization structures are relied upon to address security stresses of customers for utilizing disseminated registering methods.

III. METHODOLOGY

The MCC will be essentially the interconnection of appropriated registering, flexible handling and remote frameworks to influence mind blowing computational resources for versatile customers, to orchestrate directors, similarly as conveyed processing providers. This openness enables adaptable customers to utilize cloud structure to vanquish the confines of compact development. A complete aim of MCC is to empower execution of rich convenient applications on phase of PDAs, with a rich customer experience. The MCC gives business chances to versatile framework managers similarly as the providers of cloud. Even more thoroughly, MCC might be described as a rich adaptable figuring development that keep up uprightness among resources of contrasted fogs and framework propels toward that give, indefinable limit, and transportability to get countless telephones wherever. The central designing is produced using the sections: adaptable customers, compact managers, organize get to providers (lSP), and cloud expert communities, independently. The building is showed up in Figure. Flexible customers, convenient customers are the end customers that send diverse organizations through accommodating cell phones, tablets that are in developments.

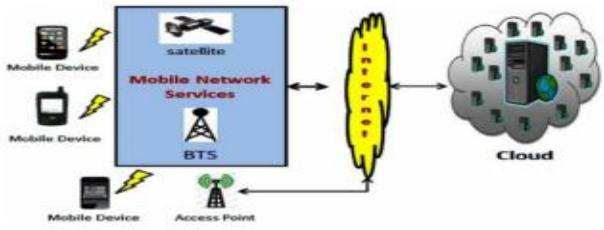

Figure: Mobile Cloud Computing Architecture

MOBILE OPERATOR

The adaptable director are remote authority association that has the rights to offer access to customer to organizations like radio range, billings, remote system, retail ,customer care & giving spine organizations. A basic typical for a convenient framework head is that it should guarantee or control access to a radio range license from an authoritative or government component. A second most portraying typical for a MNO is control the parts of the framework establishment imperative to offer organizations to endorsers over the approved range.

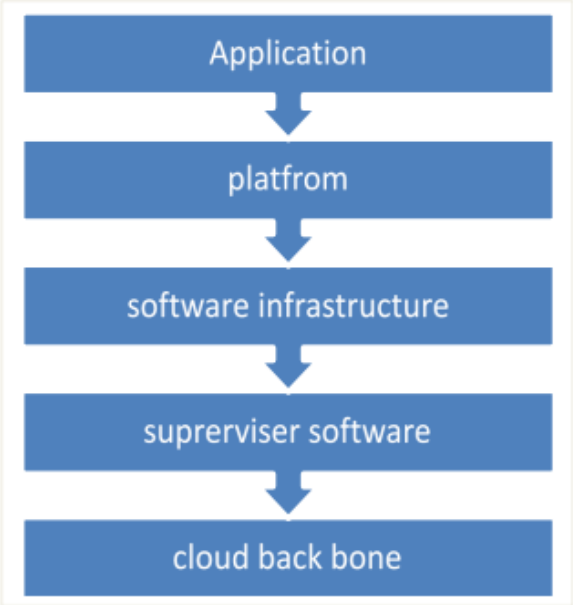

Figure 1:Layered architecture of MCC

The layer configuration is showed up in Figure 1. The spine layer builds up security perception on the physical structures of cloud. These helpers in checking the machines &servers in cloud establishment. The structure layer screens VMs in cloud. Distinctive activities, for instance, Storage check, VM isolation, VM development, audits Cloud Service Monitoring&Risk Evaluation are done in this layer to confirm cloud have organizations. Application layer executes works out, for instance, customer the officials, key organization, approval, endorsement, encryption and data blend. To pull in clients, the cloud authority center (CSP) wants to concentrate on all the security problems to provide an exceedingly secure condition.

Security risks

1. Protection as cloud condition incorporates immense no. of customer to give organization, constructs far reaching no. of ways of adaptable customers and applications. Each customer's data should be secure and covertly directed. Simply affirmed customer has rights to get to endorsed data.
2. Security Privacy is need of a person to control customer's near and dear information. In cloud various potential results like insider customer threats, outside attacker risks, data spillage, etc can hurt security of cloud customer.
3 .Multi-inhabitance in multi-residency of cloud, social affair of customer shared organization given by single programming or application.
In such a circumstance,

each convenient customer's data is separated and remains imperceptible to other flexible customer.

4. Thing reusability-A model prepared for making cloud based applications with reusability by recouping the parts from the cloud section vault by using configuration organizing counts and distinctive recuperation procedures.

5. Data remanence-It is the remaining depiction of data that have been some way or another or another apparently annihilated or ousted. Data protection could be broken inadvertently, in light of data remanence.

6. Programming Confidentiality-It is suggests trusting that particular application or strategies will keep up and handle the customer's near and dear data in secure manner.

7. Genuineness Integrity in cloud insinuates protected from unapproved abrogation, change, theft. The data genuineness in direct terms is upkeep of soundness of any data in the midst of trades like trade, recuperation or storage. The deletion, alteration might be accidentally or intentionally.

8. Endorsement: It is the segment by which a system makes sense of what measurement of access a certain affirmed customer must need to confirm resources compelled by structure.

IV. RESULTS

Performance Evaluation

Computation Performance of PP-CP-ABE:

To estimate the execution of showed PP-CP-ABE plan, we survey the count overhead of master associations &customers subject to both speculative examination and preliminary outcomes. Directly off the bat, we examination the amount of expensive cryptographic exercises over G0 and G1, i.e., coordinating, exponentiation, duplication, performed by master centers and customers' contraptions. In our examination we acknowledge that the passage course of action TESP has a1 characteristics related by an AND reasonable entryway and TDO simply has 1 property. Additionally, the root center point is an AND gateway.

In the going with table, we considered the amount of exponentiations, increments and hash to G0 exercises realized on customer side& ESP side in encryption re-appropriating, where a1 is the amount of properties in TESP :

	Exp G0/G1	Mul G1	Hash to G0
ESP	2a1/0	0	a1
User	3/1	1	1

We additionally give an examination of the quantity of exponentiations, duplications, reversal, and matching activities caused by decoding redistributing on client side &DSP side as appeared in the accompanying table, where a1 is the quantity of characteristics in TESP.

	Exp G1	Mul G1	Inv G1	Pairing
ESP	a1	2a1	a1	2a1+1
User	1	2	1	0

From above examination, we might observe that count overhead is immediate for pro associations (DSP& ESP) and consistent for the customer. Among all exercises, mixing will be more computationally focused.

Beside the speculative examination, we in like manner performed exploratory estimations. In perspective on CP-ABE open source adventure, we completed &surveyed the PP-CP-ABE on PC with 1.6GHz Intel Atom processor running Linux2.6.32. The calculation time is evaluated with the use of clock ticks returned by clock_t clock(void) work in standard C library. To depict that a substantial part of estimation overhead will be re-appropriated to authority associations, we run server &customer on a comparative stage and recorded the amount of clock ticks.

In Figure 2, we took a gander at count overhead achieved on authority associations and customers in encryption and unscrambling re-appropriating. The computation overhead is resolved similar to 10 based logarithms, i.e., log10, of thousands (K) timekeepers ticks. As ought to be clear from figure, over 90% of encryption &over 99% of unscrambling estimation are executed by expert associations.

Storage Performance of ABDS:

We examine limit execution of ABDS and differentiation it and a couple of related cryptographic access control game plans: impart encryption plans (Subset-Diff), BGW broadcasting encryption, get the chance to control polynomial (ACP) plot. The execution is assessed the extent that figure content accumulating overhead, key amassing overhead (structure parameters and open/private keys set away on the customers & TA). We mean full scale number of customers in framework with N and a customer needs to share a record to some irregular plan of beneficiaries in the structure. The close outcomes are shown in Table 2. The Ciphertext Storage Overhead in Subset-Diff scheme, the degree of ciphertext is O(t 2 • log2 t • log N), with t as most prominent no. of interesting customers to deal the cipher text. For BGW plot, the cipher text gauge is O(1) or O(N 1 2) as uncovered. In ACP plot, degree of message relies upon the dimension of access control polynomial, those reciprocals to the amount of present recipients. Consequently, the message measure is O(N). To control a great deal of recipients S utilizing ABDS, the range of cipher text relies upon the amount of thing terms in f min S. In the makers construed lower bound& upper bound on typical no. of thing terms in a constrained SOPE. Likely, the typical no. of message required is ≈ log(N).

V. CONCLUSION

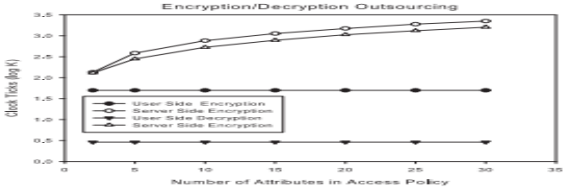

Figure 2: Graph Performance evaluation of the encryption and decryption outsourcing

Considering, we proposed an exhaustive security system for the cloud data

storing organizations to check data board in open fogs. Particularly, our answer engages lightweight remote gadgets to securely store and recuperate their data in open cloud with unimportant cost. To this end, we suggested a novel Privacy Preserving Cipher Policy Attribute-Based Encryption (PP-CP-ABE) to verifyencoded data customer. Using PP-CP-ABE, light-weight gadgets might be securely redistribute heightened encryption &unraveling exercises to cloud authority communities, without revealing data & utilized keys. Furthermore, we suggested an Attribute Based Data Storage (ABDS) structure as a cryptographic access control framework. ABDS achieve information theoretically perfect the extent that constraining figuring, storing and correspondence overheads. Especially, ABDS limit the costs o cloud charged by cloud pro communities similarly as correspondence overhead for data organizations. Our execution assessments determine the security quality &profitability of our answer in regards to figuring, correspondence and limit.

Dr.B Sankara Babu, Professor in Computer Science and Engineering, completed his Ph.D from Acharya Nagarjuna University, Guntur and has over fourteen years of academic and research experience in Gokaraju Rangaraju Institute of Engineering and Technology. His research interests are Data Mining, Big Data Analytics, Machine Learning and Internet of Things in which he has more than 30 publications in various reputed journals and conferences

A Systematic Approach Toward Description And Classification Of Cyber Crime Incidents

G.Charles Babu, A.Sai Hanuman, J.Sasi Kiran, B.Sankara Babu

Abstract: ***The headways in PC frameworks and systems have made another condition for criminal acts, generally known as cybercrime. The cybercrime episodes are events of specific criminal offenses that represent a genuine danger to the worldwide economy, security, and society's prosperity. This paper presents a far reaching comprehension of cybercrime occurrences and their relating offenses consolidating a progression of methodologies announced in applicable writing. At first, this paper audits and recognizes the highlights of cybercrime episodes, their separate components and suggests a combinatorial occurrence portrayal diagram. The diagram gives the chance to efficiently join different components or cybercrime attributes. Furthermore, a complete rundown of cybercrime-related offenses is advanced. The offenses are requested in a two-level order framework dependent on explicit criteria to aid better characterization and connection of their separate episodes. This empowers an intensive comprehension of the rehashing and fundamental criminal exercises. The proposed framework can fill in as a typical reference surpassing deterrents getting from confusions for cybercrimes with cross-fringe exercises. The proposed diagram can be stretched out with a rundown of suggest edactions, relating measures and successful approaches that coordinate with the offense type and in this way with a specific occurrence. This coordinating will empower better observing, dealing with and moderate cybercrime episode events. A definitive goal is to fuse the blueprint based portrayal of cybercrime components to a total occurrence the executives framework with standard working methods and conventions.***

Index Terms**: *PC frameworks, cybercrime, portrayal diagram, worldwide economy.***

I. SCOPE OF THE WORKT

The headways in PC frameworks and systems have made another condition for criminal acts, broadly represented as cybercrime. The cybercrime episodes are events of specific criminal offenses that represent a genuine risk to the worldwide economy, security, and prosperity of society. This paper presents a thorough comprehension of cybercrime occurrences and their relating offenses joining a progression of methodologies revealed in applicable writing. At first, paper surveys and recognizes the highlights of cybercrime occurrences, their separate components and proposes the combinatorial episode portrayal outline. The mapping gives the chance to deliberately consolidate different components - or cybercrime attributes. Moreover, an exhaustive rundown of cybercrime-related offenses is advanced.

The offenses are requested in a two-level characterization framework dependent on explicit criteria to aid better arrangement and connection of their separate episodes. This empowers an intensive comprehension of the rehashing and fundamental criminal exercises. The proposed framework fills typical reference overwhelming hindrances getting from misunderstanding with cross-fringe exercises for cybercrimes. The proposed diagram can be reached out with a rundown of prescribed activities, relating measures and powerful strategies that coordinate with the offense type and in this manner with a specific episode. This coordinating will empower better observing, taking care of and moderate cybercrime episode events. A definitive goal is to consolidate the pattern based depiction of cybercrime components to a total episode the board framework with standard working strategies and conventions.

Late advancements in the correspondences and Information Technology (IT) unlocked the entryway on recent applications that empower transmitting data precisely and rapidly. The advancements have obviously negative angles, for example, empower the digital predators to direct their online assaults against the people in question. Besides, this paper relies upon the correlation between the KSA and UK enactments to battle the digital provocations. Where, the KSA and UK enactments were ordered by explicit cybercrime types. Besides, the target of this examination is to enhance KSA enactments as far as fighting the new kinds of cybercrimes seemed dependent on the UK battling activities.

II. OBJECTIVE OF THE STUDY

- To plan A Systematic Approach towards Classification and Description of Cyber Crime Incidents
- To examine Legal Aspects of Cyber security
- To ponder Cybercrimes-based Legislations Classifications, a Comparative Research between KSA and UK
- To think about Cyber-wrongdoing: An audit of the proof
- To consider Cyber Crime in the Society: Problems and Preventions

III. LITERATURE REVIEW

Wow Essay (2009) The offices of PC innovation have not turned out without downsides. Despite of the fact that the life is so rapid and quick, yet flung under the shroud of danger from the deadliest kind of culpability named as 'Digital wrongdoing' without PCs, government and organizations activities would nearly stop to

Revised Manuscript Received on March 25, 2019.

Dr.G.Charles Babu, Professor, Dept. of CSE, Malla Reddy Engineering College(Autonomous), Secunderabad – 500100, Telangana, India.

work. The multiplication of incredible, shoddy, easy to understand PCs has empowered an ever expanding the number of individuals to apply them and more vitally, depend as a feature of their ordinary lifestyle. As the government offices, organizations and people keep on depending on developing extent, so the crooks restriction of digital wrongdoings is dependent on appropriate investigation of their comprehension and conduct on different dimensions of society. Thusly, at present original copy an efficient awareness of digital violations and its effects on zones like Soci-eco-political, adolescent and customer trust, with the upcoming patterns are clarified.

Shantosh Rout (2008) Eventual fate of Internet is available for anyone among typical clients. Fears of a digital world still proliferate, while the potential harm degree can be brought by scale misrepresentation is almost absolute. These nerves are essential to be reasonably moderate with learning the issues are being tended to, although not quick enough. The Internet's value has substantiated in various ways that are sufficient to guarantee it does not curving into a no man's area of criminal movement and a support for the malevolent. The administration has an imperative task to carry out; nevertheless a large portion of counteractive action should be refined by business elements bear programming and with the capacity to halt the extortion. Depending on the customer instruction the projects influences a level of conceivable accepted people. The other users should be secured through the measures that do not pressure and requires the impressive interest. The security issues should be simple and successful in the working environment. Regardless of either cybercrime is as yet an suitable issue, however, due to the elevate of development over Internet, is its essential to illuminate with the goal that cybercrime substance will relate to certifiable violations, if worse.

Prasun Sonwalkar (2009) The authentic copy not only discusses digital violation's comprehension yet furthermore clarifies the effects over unique dimensions of the public. This helps the network to verify the online data fundamental associations that are not protected due to digital wrongdoings. The awareness of conduct of digital offenders and digital violation's effects on society will identify the suitable way to breakdown the circumstances. The finest method to beat the wrongdoings are comprehensively grouped into three classes, namely, (1) Cyber Laws (alluded as Cyber laws), (2) Policy making and (3) Education. These approaches deal with digital wrongdoings either exceptionally inferior critical work or having nothing in considerable lot of the nations. This work requires either embellishing the current work or setting updated standards for regulating the digital assaults.

D. L. Shinder and M. Cross (2008) Over the most recent two decades, organizations, customers, and governments around the world have moved into the internet and cloud condition so as to direct their organizations. Numerous individuals spend a critical piece of their every day life in the internet, making and getting a charge out of new sorts of social connections which were impractical or fiscally reasonable 20 years prior. In any case, offenders have recognized prizes from online fakes in this manner, the dangers and dangers have expanded too. Securing the internet will be an empowering agent and will result in better utilization of the computerized condition. Along these lines, verifying it requires a joint exertion by all partners which incorporates the law authorization offices, governments, the innovation ventures, and the people in the general public.

PricewaterhouseCoopers. (2014) Cyber wrongdoings are another class of violations to India quickly growing because of broad utilization of Internet. Unscrupulous and avaricious individuals exploit simple and free access to Internet and play out any demonstrations to fulfill their necessities. The need could be physiological or mental in nature.2 Online shopping and wide utilization of "internet based life" are main driver of digital wrongdoings. Much mindfulness made for digital violations and clients were taught. Yet at the same time individuals don't grumble it to specialists. Indeed, even someone do it at that point additionally police or wrongdoing branch powerless to clear such gripes in sensible timeframe. Deferral in equity will prompt NO enlistment of whine. This isn't sound circumstance in free just INDIA.

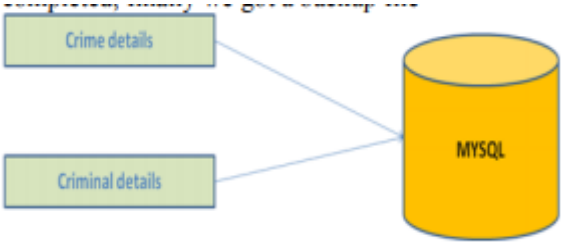
IV. METHODOLOGY

Data Prepossessing Module

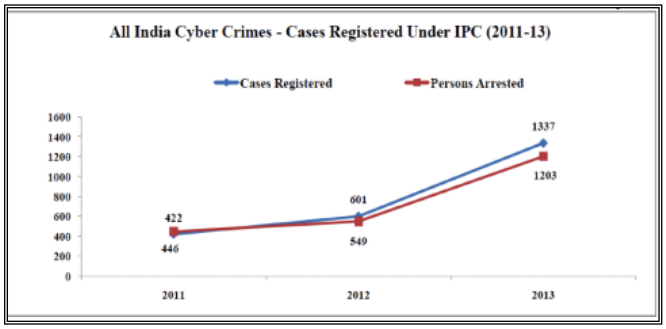
Data Ingestion Module along with Sqoop

Data Analytic Module along with Hive

Data Analytic Module along with Pig



Data Analytic Module along with Map Reduce



Data Analytic Module with R

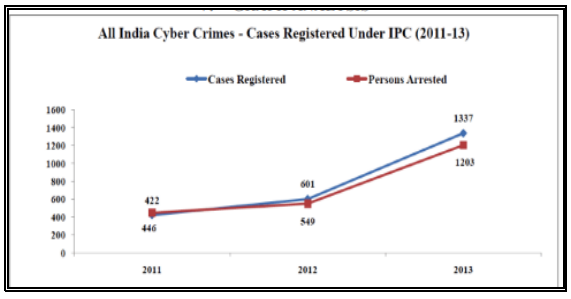
Data Analytic Module With java age

Gather necessity dataset and Backup the document on mysql

We need to make another table by right tapping on the database and choosing make new table, first section will be the Id which will be a whole number, at that point all procedure will be finished, at long last we got a reinforcement document.

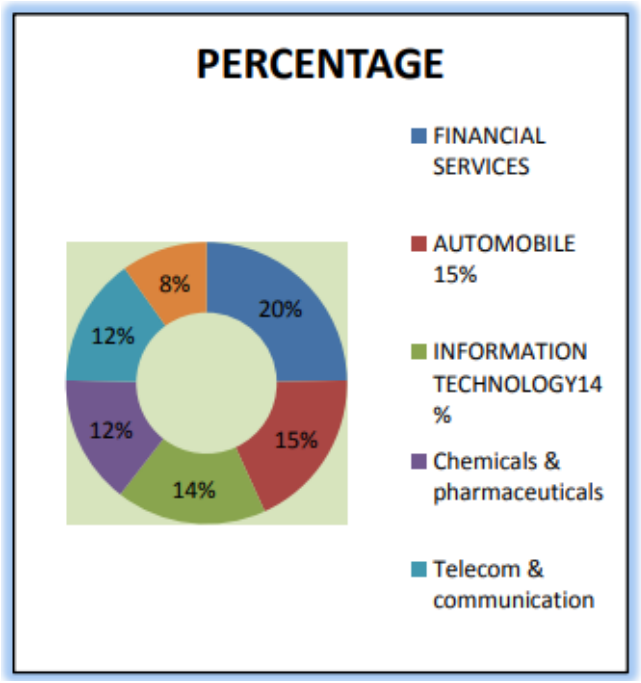
Data ingestion using Sqoop

Information ingestion Module with Sqoop: The motive of this module is to deed the dataset into Hadoop (HDFS). Sqoop is an interface application responsible for exchanging the information between Hadoop



and social databases. In this module, the dataset is pushed into Hadoop (HDFS) through the Sqoop tool. Utilizing the Sqoop features, perform the parcel capacity, to some extent that, the event needs to accompany the distinguishing segment or in the event needs to accompany the dataset with explicit scenarios supported by Sqoop and data is placed in Hadoop (HDFS).

Data processing Module with Hive



Hive is an framework house for Hadoop. It runs SQL queries through Hive inquiry language (HQL). Hive, is an initiative by Facebook. The Hive underpins Data Manipulation Language (DML), Data definition Language (DDL), and client characterized capacities. This module deals with dataset investigation by HIVE through Hadoop (HDFS). For examination, dataset HIVE utilizes the HQL Language. The utilization process in Hive was performed using tables' manifestations, bucketing idea, partition, and join operations. Later, the Hive deals with the examination of main Structure Language.

V. RESULTS

VI. CONCLUSION

This paper showed the wrongdoing information examination utilizing Hadoop. The capacity of huge information will change the way the present cybercrime to get criminal record. In the adjacent future we will see execution of enormous information examination in wrongdoing information investigation. Huge information gives security and protection. This paper proposes a structure which is pointing that it will enhance the execution of Map Reduce remaining tasks at hand and in the meantime will keep up the decency. The cybercrime frames test to the Islamic enactments, on the grounds that there is no unmistakable proof just as the cybercrime occurs in virtual condition. Subsequently, the enactment in KSA relies upon Islamic Law, in this manner the principle issue is non-consciousness of laws, and the Saudi youth have almost no learning about cybercrimes and their threat on the general public.

Likewise, nonappearance of the proof structures another test to the KSA courts to give equity goals in regards to the cybercrime, where an absence of specialized foundation to comprehend the idea of the wrongdoing in fact is viewed as a primary test for Department of contending wrongdoing in (CPVPV) - KSA. Other than the way of life of Saudi individuals keep the vast majority of unfortunate casualties from revealing their cases particularly when they presentation to sexual dangers. Besides, grouping cybercrimes in UK as indicated by enactments utilized in the courts can be abused to build up new enactments in KSA against cybercrimes, with taking into contemplations the social and religion contrasts. Applying new enactments in KSA against cybercrimes ought to enhance battling the new kinds of cybercrimes as needs be.

Secure and Verifiable Policy Update Method on Big Data Access in Cloud Storage

G.Charles Babu, A.Sai Hanuman, J.Sasi Kiran, B.Sankara Babu

Abstract*: Disseminated figuring would be one of advancements which will expect a fundamental occupation in the best in class time of PC structuring field. As a result of the high volume and speed of immense data, it is a fruitful decision to store huge data in the cloud, as the cloud has capacities of securing tremendous data and dealing with high volume of customer get to requests. Trademark Based Encryption (ABE) is a promising system to ensure the end to-end security of huge data in the cloud. In this paper, we propose a novel arrangement that enabling gainful access control with dynamic methodology invigorating for gigantic data in the cloud. We fixate on working up a re-appropriated approach reviving method for ABE structures. Our system can avoid the transmission of mixed data and cutoff the figuring work of data proprietors, by making usage of the as of now encoded data with old access approaches. Also, we in like manner propose approach invigorating computations for different sorts of access courses of action. Finally, we propose a beneficial and secure methodology that empowers data proprietor to check whether the cloud server has revived the figure messages precisely. The examination shows that our course of action invigorating redistributing plan is correct, whole, secure and profitable.

***Index Terms*: Big Data, Cloud, Attribute Based Encryption (ABE), Policy Updating.**

I. INTRODUCTION

Disseminated figuring would be one of advancements which will expect a fundamental occupation in the best in class time of PC structuring field. As a result of the high volume and speed of immense data, it is a fruitful decision to store huge data in the cloud, as the cloud has capacities of securing tremendous data and dealing with high volume of customer get to requests. Trademark Based Encryption (ABE) is a promising system to ensure the end to-end security of huge data in the cloud. In this paper, we propose a novel arrangement that enabling gainful access control with dynamic methodology invigorating for gigantic data in the cloud. We fixate on working up a re-appropriated approach reviving method for ABE structures. Our system can avoid the transmission of mixed data and cutoff the figuring work of data proprietors, by making usage of the as of now encoded data with old access approaches. Also, we in like manner propose approach invigorating computations for different sorts of access courses of action. Finally, we propose a beneficial and secure methodology that empowers data proprietor to check whether the cloud server has revived the figure messages precisely. The examination shows that our course of action invigorating redistributing plan is correct, whole, secure and profitable.

II. LITERATURE REVIEW

Prayla, S et al (2018) Our course of action engages the cloud server to feasibly stimulate the figure content when another entry approach is controlled by the information proprietor, who is besides arranged to help the resuscitate to counter against cheating practices of the cloud. It in addition draws in (I) the information proprietor and qualified clients to adequately confirm the validness of a client for getting to the information, and (ii) a client to help the data gave by different clients to rethink plaintext recuperation

Taniya Jain (2017) As the term shows the Big data it suggests we are work for the something huge or can state something broad in the Amount, Data the high volume is known as the gigantic data. Directly a Day for securing the data archive in the Computer Science Engineering we are used the Hard circle, a part of the limit put, these limit contraptions may store the data in a Giga byte capacity and Terabyte capacity or some more, now every day we are used the some new development call the cloud condition. So in this work I am ponder the gigantic data securing process in the Cloud condition, colossal data bringing from the cloud securerly.

Vishnu R. Lembhe et al (2016) in enlisting condition, the limit of tremendous data is main problem. So to vanquish this store the gigantic data in cloud since it has capacities of securing enormous proportion of data and taking care of a high volume of customer get to requests. Appropriated figuring use the Attribute Based Encryption (ABE) for giving the end to end security for enormous data in a cloud. Using this ABE technique, reviving has been a trying issue in the past executions, immediately data proprietors need to recuperate the data and after that re-encode the new access approach and send back to the cloud .Due to this, high correspondence and computational weight was on the data proprietors. So to vanquish this issue of existing structure here proposed another system that intensely revives a technique for gigantic data in the cloud. Data proprietors need to just check whether figure content has been invigorated precisely or not.

Kalpana, V et al (2014) the course of action invigorating has reliably been a trying issue when ABE is used to construct get the chance to control contrives and develop another procedure to redistribute the technique reviving to the server. Attribute Based Access Control technique is used to avoid the transmission of encoded data and breaking point the computation work of data proprietors, by making use of the in advance mixed data with old access courses of action. A methodology invigorating count called LSSS is used for gainful and secure procedure empowers data proprietor to check whether the cloud server has revived the figure messages precisely.

III. PROPOSED SYSTEM & OBJECTIVES

The proposed structure revolves around adopting care of the strategy invigorating issue in ABE structures, and proposes an ensured and certain procedure revive redistributing method. As opposed to recuperating and re-encoding the data, data proprietors simply send game plan reviving request to cloud server, and let cloud server invigorate the methodologies of mixed data particularly, which infers that cloud server does not need to unscramble the data beforehand/in the midst of the methodology invigorating. This arrangement can satisfy all the above necessities, and keep up a vital separation from the trading of mixed data forward and in reverse and farthest point the computation work of data proprietors by making full use of the in advance encoded data under old access courses of action in the cloud.

Objectives:

1. To examination the course of action invigorating issue in ABE systems and develop another procedure to redistribute the methodology reviving to the server
2. To find the expressive and profitable data get the opportunity to control plot for enormous data, which engages compelling intense plan reviving
3. To examination the successful and secure methodology for checking, paying little heed to whether the figure works are invigorated precisely by the cloud server

The methodology invigorating is a troublesome thing in trademark based access since when data proprietor stores data into the cloud, it doesn't have a copy of it in neighborhood structures. If a particular data proprietor needs to change the data he needs to trade data back to his neighborhood site from the cloud, encode it again and move back to the server. Consequently, it achieves a high correspondence overhead and generous count inconvenience on data proprietors. This motivates us to develop another procedure to re-fitting the task of methodology reviving to cloud server.

The remarkable trial of re-appropriating approach reviving to the cloud is to guarantee the going with requirements:

1) Correctness: Users who have sufficient qualities ought to at present have the ability to unscramble the data mixed under new access game plan by running the main deciphering estimation.

2) Completeness: The course of action reviving procedure should have the ability to invigorate any sort of access approach.

3) Security: The system invigorating should not break the security of the passageway control structure or present any new security issues

Features of Attribute-based Access Control: In colossal data time, the volume of data is high and it is extending in a fast. The proposed trademark based access control (ABAC) method is exceptionally sensible for controlling tremendous data than ordinary access control systems due to the going with features:

1) Policy Checking Entity Free: In ABAC, get to approaches are portrayed by data proprietors yet don't require any substance (e.g., the server) to check these procedures. Or maybe, get to game plans in ABAC are maintained certainly by the cryptography. On account of this key component, ABAC is by and large associated with control immense data in cloud conditions, where cloud servers are not trusted to execute get to courses of action.

2) Storage Efficiency: In standard Public Key Cryptography, for each datum, diverse copies of figure works are conveyed whose number is with respect to the amount of customers. Contemplating the high volume of tremendous data, it achieves a massive storing overhead despite when simply increasing the volume of gigantic data. Fortunately, in ABAC, only a solitary copy of figure content is delivered for each datum, which can diminish the limit overhead in a general sense.

3) Dynamic Policies yet Same Keys: Data proprietors can use a comparative open key to encode data under different access methodologies, and customers don't need to change their riddle keys either. Likewise, data proprietors can change get to plans of existing figure messages by simply sending an interest to the cloud server, and let the server do the methodology change without spilling out any unstable information of the data and also the keys.

System Model

We consider a safe conveyed stockpiling structure for different masters, as showed up in Fig.1. The system appears in this paper incorporates five particular components: the overall declaration specialists (CAs), the property experts (AAs), the cloud (server), the information (proprietors) and the information buyers (clients).

CA:

Every CA is an overall trusted in support master in the structure. They recognize the enrollment of the significant number of customers and AAs in this system. What's more, the CAs is accountable for the scattering of overall secret key and overall open key for each genuine customer in the structure. Regardless, they are not locked in with any quality organization and the creation of secret keys that are connected with properties.

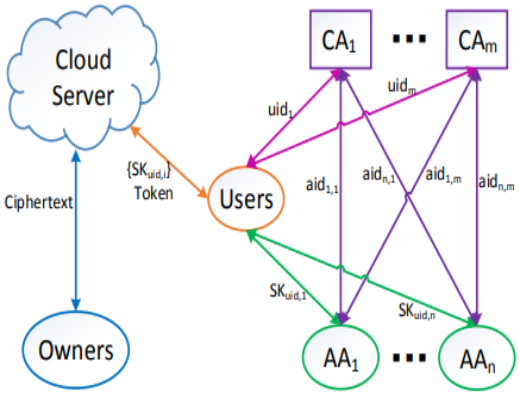

Figure 1: System Model of our Scheme

AA:

Every AA is a self-ruling property expert. Every AA is accountable for issuing, revoking and invigorating customer's credits as shown by their own one of a kind employment or identity in its space. Every attribute is connected with one single AA. In any case, each AA can manage an abstract number of characteristics. It is responsible for making an open quality key for every trademark it directs and a secret key for each customer accomplices with their properties. Every AA has positive direction over the structure and semantics of its properties.

Cloud server:

The cloud server stores the proprietors' data and gives data get to organization to customers. In this paper, the cloud server creates the unscrambling token of a figure content for the customer by using the customer secret keys issued by the AAs. Furthermore, the server also does the invigorate undertaking of the figure content when a property refusal happens.

Information Owner:

The Data Owner in this system portrays the passageway game plans of data. Under the methodologies, the data proprietors encode the data previously re-appropriating them in the cloud. Without relying upon the server to get the data get the chance to control, all the legitimate customers in the system can get to the figure content. In any case, the passageway control happens inside the cryptography. Exactly when the customer's attributes satisfy the passage game plan described in the figure content, can the customer decipher the figure content?

Customer:

A cloud customer could be an undertaking or one single customer. Each customer in the system is doled out with a couple of offers of an identity from the CAs, which can be collected and registered as its remarkable overall customer character. To unscramble a figure message that can be gotten to uninhibitedly from the cloud server, each customer may display their riddle keys issued by a couple of AAs together with its overall open key to the server. By then the system asks for that it make an unscrambling token for some figure works. Subsequent to tolerating the unscrambling token, the customer can translate the figure content using its overall puzzle key. The server can deliver the correct deciphering token, exactly when the customer's characteristics satisfy the passage technique portrayed in the figure content. To store the riddle keys and the overall customer's open key on the server, thusly, if no secret keys are invigorated for the further unraveling token age, the customer require not present any puzzle keys.

Key Generation:

Here Keys are delivering for every last one of a kind reports. At the period of customer recouping any archive key is essential for access the record. In a straight arrangement, the riddle is viewed as a part of a restricted field, and the offers are procured by applying an immediate mapping to the puzzle and a couple of self-governing unpredictable segments.

Course of action invigorates Authority:

The master delivers the key with the objective that proprietor can scramble the data and customer can unscramble the data. It checks the data is shielded moreover offer affirmation to the data. Each customer data is consigned with an overall customer personality and can uninhibitedly get the figure works from the Authority.

IV.METHODOLOGY

Characteristic BASED ENCRYPTION (ABE):

Property Based Encryption (ABE) has ascended as a promising methodology to ensure the end to-end data security in disseminated stockpiling structure. It empowers data proprietors to portray get to techniques and scramble the data under the methodologies, with the ultimate objective that just customers whose qualities satisfying these passage courses of action can unscramble the data. At whatever point more affiliation and tries re-proper their data into the cloud, the methodology reviving transforms into a significant issue as data get to techniques may be changed effectively and as regularly as conceivable by data proprietors. Nevertheless, this procedure invigorating issue has not been considered in existing quality based access control designs. The procedure invigorating is a troublesome issue in quality based access control systems, in light of the way that once the data proprietor re-appropriated data into the cloud, it would not keep a copy in close-by structures. Unscrambling is simply possible when the amount of organizing is something close to an edge regard d. Plan impediment is indispensable security feature of Attribute-Based Encryption .An adversary that holds distinctive keys should simply have the ability to get to data if no short of what one individual key stipends get to. The issue with property based encryption (ABE) plan is that data proprietor needs to use each affirmed customer's open key to scramble data. The utilization of this arrangement is bound in the bona fide condition since it uses the passageway of monotonic credits to control customer's passage in the system.

a) Key Policy Attribute Based Encryption (KP-ABE):

It is the balanced sort of built up model of ABE. Customers are named with a passageway tree structure over the data properties. Point of confinement entryways are the centers of the passageway tree. The properties are connected by leaf center points. To reflect the passageway tree Structure the secret key of the customer is described.

Figure compositions are named with sets of characteristics and private keys are connected with monotonic access structures that control which figure messages a customer can unscramble.

Key Policy Attribute Based Encryption (KP-ABE) plot is intended for one-to-numerous correspondences. KP-ABE conspire comprises of the accompanying four calculations:

Setup: Algorithm takes input K as a security parameter and returns PK as open key and a structure expert riddle key MK.PK is used by message senders for encryption. MK is used to create customer secret keys and is known just to the pro.

Encryption:

Algorithm takes a message M, individuals all in all key PK, and a course of action of characteristics as data. It yields the figure content E.

Translating:

It takes as data the customer's riddle key SK for access structure T and the figure content E, which was encoded under the property set. This figuring yields the message M if and just if the property set satisfies the customer's passage structure T. The KP-ABE plan can achieve fine-grained get the opportunity to control and more versatility to control customers than ABE contrive. The issue with KP-ABE contrive is the encryptor can't pick who can decipher the mixed data. It can simply pick clear attributes for the data; it is inadmissible in some application because a data proprietor needs to trust in the key underwriter.

Quality Based Access Control with Efficient Revocation in Data Outsourcing Systems:

This proposes a passageway control part reliant on figure content methodology attribute based encryption to approve get the chance to control courses of action with compelling characteristic and customer denial technique. The fine-grained get the opportunity to control can be refined by twofold encryption plot. This twofold encryption framework abuses the characteristic based encryption and specific social affair enter scattering in every property gathering. The advantage of this arrangement is securely managing the redistributed data. This arrangement achieves powerful and secure in the data redistributing structures.

Property Based Encryption with Verifiable Outsourced Decryption:

This plan changes the main model of ABE with re-appropriated translating to think about irrefutable status of the progressions in existing system. This new model forms a strong ABE scheme with clear redistributed unscrambling also does not rely upon unpredictable prophets.

Security Issue:

Multi-master CP-ABE tradition empowers the central pro to unscramble all the figure compositions, since it contains the expert key of the system; Revocation Issue: Protocol does not support quality disavowal.

Access Control:

Access control gives the endorsement to the customers which gives the passageway benefits on data and distinctive resources. Access control can be engaged in most of the enlisting condition, for instance, Peer to Peer, Grid and Cloud. Dispersed capacity organizations are gotten to through a circulated stockpiling entry. Access control is generally said to be system or procedure that grants, denies or limits access to a structure. It in like manner perceives when the unapproved customers endeavoring to get to the system. The generally used access control procedures are character based access control models. Access control in cloud depends upon the circulated stockpiling and its data security and the passageway decision ends up being especially essential decision in cloud. Access control is basic part in the server homestead of government and business Access techniques are for each situation irregular state decision that chooses how gets to are controlled and get to decisions are made. The inspiration driving access control in cloud is to keep the passageway on challenge in cloud by unapproved customers of that particular cloud which will redesign security in the cloud condition.

V.TRIAL RESULTS

Around there we have taken a gander at two symmetric figurings to be particular AES and Serpent. The parameters which are considered for examination are time taken for archive encryption and number of records as information. We have exhibited the relative examination of the two computations through graph that shows that Serpent encryption count gives ideal execution over AES encryption estimation.

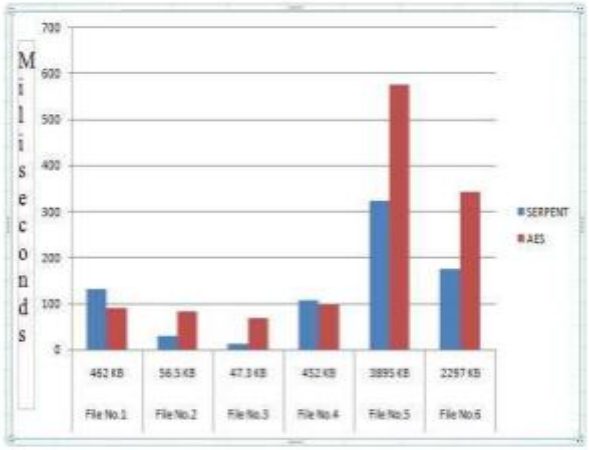

Figure 2: combined graph of AES and Serpent

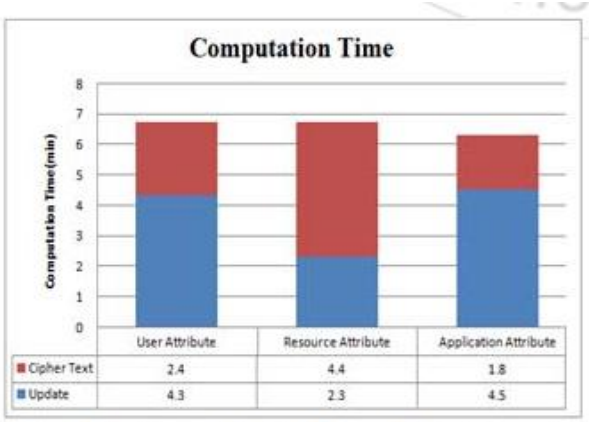

Figure 3: Computation time between Update keys and new cipher text components

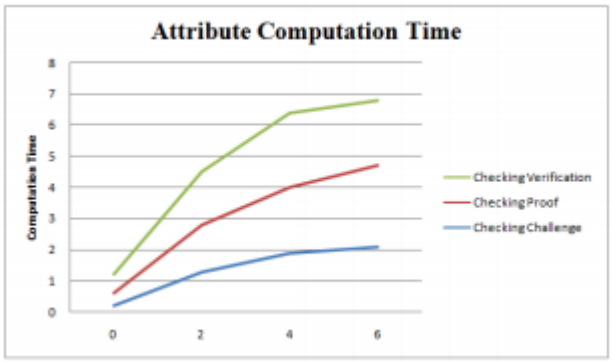

Figure 4: Computation evaluation of policy checking

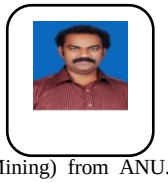

To change the entrance arrangements of encoded information in the cloud, a minor technique is to give information proprietors a chance to recover the information and re scramble it under the new access strategy, and after that send it back to the cloud server. Be that as it may, this technique will bring about a high correspondence overhead and overwhelming calculation load on information proprietors.

VI. CONCLUSION

The proposed arrangement guarantees that the genuine data proprietor could pass the cloud server's affirmation and legally invigorate the figure content identifying with the proprietor's data, check and execution. A dynamic technique get the opportunity to control plot is secure in the customary bilinear social affair show. We have in like manner proposed an expressive property based access control plot for huge data in the cloud, and organized plan invigorating figurings for different sorts of access approaches. In addition, we proposed a procedure which engages data proprietors to check the rightness of the figure content invigorating. We moreover separated our arrangement to the extent rightness, climax, security and execution. The passageway control plot is based on prime demand get-togethers, in light of the way that the social event exercises on prime demand bundles are altogether faster than the ones on Composite ask for get-togethers. A dynamic game plan get the opportunity to control plot is secure in the regular bilinear social occasion show. Open key encryption moreover called as amiss encryption incorporates a few keys, open key and private key accomplices with a substance. Certification the data security in the cloud.

A Study and Enhancement on Storage and Energy Efficient Using Cloud Computing

G.Charles Babu, Y.Rokesh Kumar, Balasani Venkata Ramudu

ABSTRACT:--- Cloud computing is the most recent "evolving paradigm" that has transformed the way by which the Information Technology based services and facilities can be offered explicitly. It has renovated the model or technique of storing and managing data for scalable, real time, internet based applications, programs soft wares and resources satisfying end users' needs appropriately. Owing to the requirement of energy savings, several approaches to location sensing based energy-efficient solutions have been explored. The power consumption quantity of these infrastructures have gradually reached 1.5% from 1.1% of the total electricity consumed across the entire globe, and is expected to rise even more than this. Firstly, we state a systematic methodology for exploring the energy efficiency of most significant data center domains, including the utility server and network hardware equipment, as well as cloud management systems and the corresponding appliances consisting of a software package that can be predominantly utilized by end users. Secondly, we utilize the above mentioned approach for analyzing the already available scientific implementation and industrial literature investigations on state-of-the-art practices in the data centers and their equipment. Finally, we extract the existing practical challenges faced during implementation and highlight futuristic advancement directions.

Keywords: Cloud computing, energy efficiency,

I. INTRODUCTION:

Cloud computing is an emerging innovative service mode. It enables the end users and its clients to get roughly unconstrained computing skillset and ample variety of information tasks from the internet resources. This sort of new pattern configuration refers to the permutation and expansion to the IT infrastructure, through the network based technology to the required resources which include hardware platform, and software structures, virtual combination into a trustworthy and high performance and intact computing platform. In cloud computing, all users' facts and specific information are stored in the cloud resources Nodes. Several creative and ingenious trends are opening up the era of Cloud Computing, which is completely an Internet-based expansion and requires the use of computer technology. The ever most economical and added powerful processors, coupled mutually with the (SaaS) software as a service computing architecture, are transforming the available data centers into pools of computing service on a vast scale of the technology. The accumulating tremendous network bandwidth and reliable yet flexible network connections make it even more probable that the users can now subscribe for a very lofty quality services from data to software that is solely inherent on the remotely available data centers located globally. Moving the existing facts and elements into the cloud offers extremely liable convenience to the end users as they need not care about the complications of direct hardware management. The major challenge faced in this sector is utilization of energy efficiently and precisely thereby developing an eco-friendly cloud computing technology which is easily accessible.

II. LITERATURE REVIEW:

Beloglazov et al (2012) proposed the vitality mindful asset distribution calculations using the dynamic solidification of virtual machines. The structural standards for vitality proficient administration of mists, asset assignment strategies and booking calculations were advanced remembering the coveted nature of-benefit parameters and power utilization highlights of changing gadgets. The outcomes uncovered that in contrast with static asset designation systems, the proposed procedure productively lessened vitality utilization in cloud server farms.

Dong et al (2015) acquainted voracious assignment scheduler with examine vitality productive undertaking booking for cloud server farms. The errand task was figured as whole number programming issue to diminish the vitality utilization by cloud information servers by proposing the most-effective server-first undertaking planning plan. Reproduction results demonstrated that the vitality utilization utilizing proposed planning plan was 70 times lesser than the one dependent on arbitrary based assignment booking plan.

Neeraj Kumar Sharma et al (2016) Due to the developing interest of cloud administrations, distribution of vitality proficient assets (CPU, memory, stockpiling, and so forth.) and assets usage are the major testing issues of an extensive cloud server farm. In this paper, we propose an Euclidean separation based multi-target assets assignment as virtual machines (VMs) and outlined the VM movement arrangement at the server farm. Assist the assignment of VMs to Physical Machines (PMs) is done by our proposed half breed approach of Genetic Algorithm (GA) and Particle Swarm Optimization (PSO) alluded to as HGAPSO. The proposed HGAPSO based assets assignment and VM movement not just spares the vitality utilization and limits

the wastage of assets yet in addition maintains a strategic distance from SLA infringement at the cloud server farm.

Tejaswini K et al (2015) Cloud registering is a rising innovation which gives metering based administrations to customers. Distributed computing technique deals with ITC based administrations and also give the procedure for processing assets through virtualization techniques over web. Server farm is soul of distributed computing as it contains accumulation of various servers on which the entire Business data is put away and applications run solitarily. The fundamental objective of every one of these methodologies is to improve the vitality use in cloud. This paper gives review of writing overview on ways to deal with have vitality productive cloud.

Mueen Uddin et al (2009) have proposed a specific system for huge and complex server manors to have vitality effectiveness with low CO2 discharge to the earth. The system comprises of five stages with the end goal to actualize green server farms for cloud. This paper has segregated the datacenter assets into various pools and implements green measurements like PUE, server farm effectiveness on those assets to quantify the execution of every asset independently and furthermore utilizes virtualization innovation for appropriate usage of green IT server farm.

III. OBJECTIVES:

1. To investigate open research challenges in vitality effective asset administration for virtualized Cloud server farms.
2. To create calculations for vitality productivity
3. To play out a relative investigation of various vitality productivity approaches in distributed computing
4. To examination the Energy Efficiency Techniques In Cloud Computing.

Virtualization: Virtualization is an innovation that permits at least two diverse working frameworks running next to each other on only one PC or installed controller. It is being embraced in the designing scene at a high rate. It helps in better usage and working of more productive frameworks. As multi-center processors are supplanting single-center processors, numerous processor centers are probably going to be underutilized in a run of the mill framework. Most applications will have just a limited measure of parallel asks that can be executed at a given time, leaving numerous processors inactive.

Storage as a Service: By the use of capacity as an administration, consumers can re-appropriate their facts squirrel away requirements to the cloud. Every handling phase is performed on the client's PC which is considered to have a very strong state drive (e.g., streak based strong and state stockpiling), and the client's essential information and facts stockpiling is stored in the cloud. Information records or data management may incorporate archive folder, photos/images, or audio and video recordings. Documents stored astray in the cloud can be acquired to from any PC with the aid of an Internet association whenever and wherever required across the globe. Be that as it may, to make any change or modification to a record, it should initially be downloaded, and then altered utilizing the client's PC and after that the adjusted document with the appropriate modification is transferred back to the cloud. The exclusive cloud specialist co-op guarantees that there is adequate free space presents in the cloud and furthermore is responsible with the reinforcement of information that is modified. At last after a client transfers a document or information or data to the cloud, the client can allow read and change benefits to different clients. One of the best case of capacity as an administration is the Amazon Simple Storage benefit which known worldwide.

Results & Discussions:

Erection of a vitality productive cloud show not only demonstrates just vitality effective host machines. Other existing segments of a total cloud framework ought to likewise be considered for vitality mindful applications. A few research works have been done to construct vitality productive cloud parts exclusively. In this segment we will examine the territories of an ordinary cloud setup that are in charge of significant measure of intensity dissemination and we will combine the conceivable ways to deal with fix the issues considering vitality utilization as a piece of the cost capacities to be connected.

Energy Efficient in Cloud Computing: The Energy – Efficient manages playing out indistinguishable errands from previously while devouring less vitality, bringing about lower costs: It decreases the carbon outflows, to accomplish a greener domain. Vitality productivity isn't vitality protection. Vitality protection is decreasing or abandoning a support of spare vitality. Vitality utilization at various levels like equipment, servers other system gadgets, diverse wired and remote systems. He additionally studied that most extreme vitality is expended for cooling of gadgets as opposed to genuine usage.

Vitality productivity has turned into an inexorably imperative worry in server farms in light of issues related with vitality utilization, for example, investment costs, implementation costs, and natural effect. Although vitality misfortune due to problematic utilization of offices and tending to vitality wastage in IT gear still requires the appropriate plan and timely execution of vitality mindful asset administration frameworks. This proposal centers around the advancement of asset distribution strategies to enhance vitality effectiveness in server farms. It utilizes three ways to deal with enhance productivity for streamlined power and execution: scaling virtual machine (VM) and server handling abilities to decrease vitality utilization; enhancing asset use through remaining burden union; and misusing asset heterogeneity.

Energy efficiency: Vitality effectiveness: Energy productivity can be characterized as a decrease of vitality utilized for a given administration or level of action. In any case, because of scale and multifaceted nature of server farm gear it is to a great degree hard to characterize special administration or action that could be inspected for its vitality proficiency. Thusly, we distinguish four situations inside a framework where vitality isn't utilized in effective route, yet rather it is lost or squandered, as appeared in Figure 1.

Published By:
Blue Eyes Intelligence Engineering
& Sciences Publication

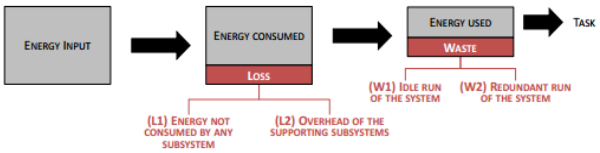

Figure 1: Circumstances where energy is lost within a system.

The two terms characterize wasteful vitality utilization from a rationalist perspective, where vitality misfortune alludes to a vitality conveyed to the framework, however (L1) not devoured by the corresponding subsystems, e.g., vitality lost because of transport or change. This likewise incorporates (L2) vigor overhead of the auxiliary subsystems, for example, cooling or lighting inside a server farm, where Cloud administration segments are provisioned and is considered as its fundamental reason. Vitality squander alludes to a vitality utilized for its principle reason, anyway for the (W2) inactive keep running of the framework, e.g., processor being turned on however running inert. Moreover, (W2) excess keep running of the framework is additionally considered as vitality squander, e.g., keeping a cooling framework at greatest amidst the nights when the temperatures are fluctuating and lower than the normal.

Energy Efficiency Metrics: There is nobody single vitality effectiveness metric that is fitting for all cases and for all datacenters in light of the fact that no two datacenters have a similar scale, capacities, expenses, and outstanding tasks at hand. In addition, a metric may try to evaluate office productivity or IT gear proficiency. Along these lines, activities, for example, Green Grid, vitality star, and SPEC have proposed various diverse measurements. Understanding the measurements may give a superior perspective of how vitality can be advanced. The measurements can be classified as office, IT gear, or a mix of the two.

At the office level, Data Center framework Efficiency (DCiE) is the rate reverence contingent by isolating IT hardware. PUE, the reverse of DCiE, is the proportion of aggregate datacenter vitality use to IT gear vitality utilization. PUE is well known datacenter effectiveness metric since it was among the primary measurements and is straightforward. What's more, not all PUE estimations incorporate similar overheads, same time length, and true estimations. The Corporate Average Datacenter Efficiency (CADE) metric consolidates estimations of vitality effectiveness and usage of office and IT gear. The server PUE (SPUE) metric evaluates the vitality proficiency of the IT hardware itself, and is the proportion of aggregate server input capacity to control devoured by the segments specifically associated with calculation, for example, CPUs, DRAM, and so forth.

Energy Efficiency Techniques in Cloud Computing:

Vitality effectiveness has risen as a standout amongst the most imperative outline prerequisites for current processing frameworks. Distributed computing has brought about the foundation of substantial scale server farms far and wide. Server farms keep on expending tremendous measures of electrical power, adding to high operational expenses and carbon impressions to nature. Different vitality proficiency strategies have been gone for in the server farms under exploratory conditions. The reasonable use of these strategies is still under investigation. These methods are:

Dynamic Voltage and Frequency Scaling (DVFS): Change the voltage dynamically and recurrence of the CPU as a host as per the outstanding task at hand and afterward adjusts the CPU control utilization in like manner, which would modify the execution level also [13]. DVFS empowers processor unit to keep running at various mix of recurrence with voltage to lessen the utilization of power of the processor unit. This procedure watches the vitality use E of an errand running with a specific recurrence f that can be communicated with the accompanying condition E = k .v^2.f.t where k is a gadget subordinate consistent, v is the voltage and t is the execution time.

Dynamic Component De-Activation (DCD): is actuation and deactivation of the segments based on characterized principles prompting better execution. The inert disjoins or segments could be turned off or moved to less power expending state like rest mode and tentatively confirmed that a perfect server expends around 70% of the power used by a completely used server.

Resource Throttling: It is an answer for controlling the clients are permitted to devour the cloud assets. Asset throttling should be possible in different routes at the equipment or at the product level with the end goal to meet the execution prerequisites and limit the vitality utilization. In a cloud domain, there are a few parameters throttled the Network data transfer capacity, stockpiling, CPU use and I/O tasks.

VM Consolidation: In a distributed computing condition, each physical machine has various virtual machines whereupon the applications are run. Outstanding task at hand combination implies better source use and effective vitality putting something aside for cloud information utilizing movement of virtual machinery setup (VM) and re-distribution of remaining burden. VM can be exchanged over the hosts as indicated by the shifting needs and accessible assets. The VM movement technique centers on moving VMs so that the power increment is minimum. The most power proficient hubs are chosen and the VMs are exchanged crosswise over to them. It evacuates the idea of territory in the appropriate virtualized situations.

Datacenters:

A datacenter is an office in which various servers, stockpiling units, and systems administration gear, together with all non-processing equipment, for example, cooling plant and continuous power supplies, are gathered in light of normal natural prerequisites, physical security needs and also for simplicity of support. Datacenters extend in size from server rooms that help little to medium-sized associations to server cultivates that run substantial scale cloud administrations.

The development of vast scale datacenters is likewise determined by the expanded abilities of cloud administrations, quick development of distributed

computing as the accepted worldview by which online administrations are given, and the uncommon measure of information being produced by present day applications. These datacenters generally have a huge number of servers that devour enormous measures of intensity. Hence vitality utilization has turned into an imperative concern on account of its effect on capital costs, working costs, and ecological supportability.

Administration of such heterogeneous framework requires adaptable and far reaching CMS with cutting edge checking capacities. Coordinating direct administration of supporting frameworks, for example, cooling and power supply includes extra layers of multifaceted nature. Nonetheless, even with ICT gear administration alone, CMS requires observing data on advancement, execution, state, information measure, and additionally equipment measurements with the end goal to help savvy booking and equipment coordinating. Encourage enhancements include organization of Clouds through streamlining activities more than a few geologically appropriated server farms. Such methodologies require not just communication among programming and equipment inside a solitary server farm, yet a trade of data, client load and information over the globe also.

Usage of Cloud in Energy Efficient Manner:

Alongside enhancing the vitality proficiency of server farms, the server farms in the Cloud Computing idea can give use to enhancing the vitality productivity on a bigger scale. Rather than utilizing separate processing frameworks, clients can solidify their registering necessities and move to the Cloud Computing condition, or, in other words than the littler figuring frameworks because of its greater scale. Vitality proficiency models, for example, Clear display created by the Lawrence Berkeley National Laboratory give a way to deal with examine vitality investment funds when moving to Cloud. It gauges capability of up to 95% of decrease in vitality utilize contrasted with existent business programming use, incorporating client relationship administration (CRM), efficiency and email programming. Computerized ones can likewise have huge vitality sparing effect. This incorporates video industry that by using Cloud Computing idea can stream video over the web, which decreases vitality utilization by 15% contrasted with delivery it on CDs and DVDs.

But utilizing Cloud Computing idea for its fundamental reason, the Cloud Computing framework and its adaptable nature can likewise be used in a roundabout way for vitality improvement. Methods, for example, DVFS and controlling on/off machines can be utilized for recurrence direction of a power arrange. Utilizing this methodology, server farm's dynamic load can be utilized for managing power request and hence generation, or, in other words keeping ideal recurrence of the power matrix. In addition, power suppliers pay for such an administration of dynamic load, empowering the server farm to procure a half of million dollars every year. Also, rather than just devouring vitality, current server farms are getting to be vitality makers with on location control generators. Not just that this methodology lessens costs for the server farm, it additionally diminishes control misfortunes because of a vitality exchange and the heap on a vitality network.

IV. CONCLUSION:

The most pertinent significance of Cloud Computing is incessantly increasing the reputation of Energy efficiency in Cloud Computing in parallel. This publication confers the various practices and procedures of energy efficiency in Cloud Computing which is considered as the cutting edge of worldwide research in today's scenario. It is also established that Energy Efficiency along with Cloud Security in a cloud computation environment is quite complicated. However, if the major discrepant parameters like CO2 emission security for decrease at data central level can give a solution for both the challenges to some extent.

A Schematic Approach on Web Data Mining In Online Spread Detection of Terrorism

A.Sai Hanuman, G.Charles Babu , P.Vara Prasad Rao, P.S.V.Srinivasa Rao ,B.Sankara Babu

Abstract: ***Dread based oppressor advancement has extended in explicit bits of the world. Dread based oppressor packs use Facebook, WhatsApp, messages to spread their information on the casual network. It is key to recognize mental fighting and keep its spreading before a particular time. The basic idea of this undertaking is to reduce or stop spreading of mental mistreatment and to clear all of these records. A dread based oppressor is spreading their mental fighting activities using the web by talk, content, accounts. Dread based oppressor clusters are utilizing the web as a medium to convince irreproachable people to share in mental oppressor practices by goading the all inclusive community through webpage pages that move upset individuals to take an interest in the dread monger affiliation. This needs a lot of human effort to execute this endeavor will assemble the information and find the dread monger social affairs. To diminish the human effort, we execute the structure which perceives dread monger groups in online life. Mental persecution has built up its hidden establishments exceptionally some place down in explicit bits of the world. With extending dread based oppressor works out, it has ended up being basic to check mental persecution and stop its spread before a particular time. So as perceived web is an imperative wellspring of spreading dread mongering through talks and accounts. Dread monger affiliations use web to rationally condition individuals and advance mental aggressor practices through provocative site pages that persuade defenseless people to join mental oppressor affiliations. So here we propose a compelling web data mining structure to recognize such web properties and standard them thusly for human review.***

Index Terms: ***web data mining, terrorism, web structure mining, dread monger affiliations.***

I. SCOPE OF WORK

Dread based oppressor affiliations are using the web to spread their exposure and radicalize youth on the web and urge them to submit mental oppressor works out. To decrease the online impression of such dangerous destinations we need to make a

System which perceives unequivocal watchwords in that particular website and if those catchphrases are found, by then that webpage should be boycotted. Data Mining (DM) similarly as Web Mining (WM) is used together from time to time for compelling system progression. WM moreover contains content mining methodologies that empower us to yield and think significant substance from unstructured data. Content mining empowers us to recognize models, catchphrases and imperative information in unstructured compositions. The planning mode in the mental oppressor following system is used to choose the inclinations and interests of an ordinary dread monger gathering. It is performed by site page planning utilized by the dread monger in the correct technique for time. The strategy for disclosure in the dread monger following system is used to perform steady examining the traffic on the web. It is gotten by the social occasion watching the substance that is available on the web. This, along these lines, raises the alert if the information utilized is related to the dread monger lead and it isn't care for the direct and excitement of the typical customer. The adjustment of the mental aggressor following structure tests is executed on the earth of the adjacent framework and it is surveyed. This fast learning based framework is used for following the mental oppressor by analyzing the web traffic data as indicated by the information was given by the survey. This assignment works by learning the fundamental lead and energy of the dread based oppressors by using the web data mining count to remove the printed substance of mental oppressor destinations. The regular lead of the mental activist is gained by the profitable examinations which are utilized to play out the ceaseless recognizable proof of dread based oppressor from the social occasion of commonplace customers. Mental abuse is portrayed as: "An unlawful one-sided use of physical or extrasensory severity (or danger of it) for further political goals went for customary people or non-warriors, etc., to change current game plans their methodologies and structure". WM is the use of information extraction systems and data mining used to discover patterns and gain from the World Wide Web (WWW). By and large, WM has three classes, namely:

• Web Content Mining - exposure of important facts from substance, picture, sound or video content in the WWW.

• Web Structure Mining - examination of the center and affiliation (chart) fundamental single destinations, similarly as greater aggregations of interrelated regions

• Web Usage Mining - normally referred as Web examination incorporates isolating profitable fact from server

logs and distinctive sources organizing use plans.

Various experts and specialists examined the issue to handle such issue. National security load up in like manner realized best frameworks to think about the fear activities and media in light of the way that those are generally visited by social orders a great part of the time and society are needy for those. Dread mongers suspected that it was definitely not hard to scourge people; they can without quite a bit of a stretch spread the fear among a living thing, Society and some particular country. Security is major point behind this to shield our country from such dangers. Computerized security is one of the streams concentrating on security over net and recognizing the bad behavior scenes. Here we are going to express our proposed technique for distinguishing fear related activities on net. How such activities are to be perceived and told with the objective that one come to consider future threats. Data mining oversees it since huge part to more strengthen the security essentials.

The Internet is a capable correspondence structure that is continuously used by dread monger relationship to safely talk with their accomplices, organize movement plans, spread deliberate exposure messages, raise holds, and bring new supporters into their frameworks. Governments and understanding associations are calling to put noteworthy undertakings being created of new procedures and progressions for recognizing dread monger practices on the web in order to turn away future shows of fear. TDS presents a manual for such an effort.

By strategies for substance checking and examination of pages gotten to by a social affair of web customers, it is possible to prompt their normal regions of premium. It is in like manner possible to perceive customers that get to express, possibly absurd information on the web. Using this strategy, continuous web traffic watching may be per-formed to recognize dread mongers as they get to ordinary fear related substance on the between net. Fear Detection System (TDS) depicted in realized this approach.

II. OBJECTIVES OF THE STUDY

To consider an audit paper on estimate of online spread of mental fighting on twitter

- To Detect Online Spread of Terrorism Using Data Mining
- To structure Unauthorized Terror Attack Tracking Using Web Usage Mining
- To design an approach to identify terror activities
- X Graphics CLUS: Hyperlinks related to Web Mining activities and Terrorism Content destinations for Security issues related to Homeland.
- To structure a collective DM application for Analysis of universal terrorist attacks.
- To consider Multilanguage Semantic Behavioral Algorithms to discover dread based oppressor related online substance.

III. LITERATURE REVIEW

Ghada M. Tolan and Omar S. Soliman (2015) Terrorist bunches utilize the Web as their framework for different purposes. One model is the enclosing of new neighborhood cells that may later finish up exceptional and perform shows of fear. The Terror Tracking utilizing Web Usage Mining (TTUM) is away for finding on the web access to odd substance, which may join fear based oppressor made objectives, by examining the substance of data gotten to by the Web clients. TTUM works in two modes: the arranging mode and the conspicuous confirmation mode. In the arranging mode, TTUM picks the typical interests of a pre indicated get-together of clients by dealing with the Web pages gotten to by these clients after some time. In the affirmation mode, TTUM performs steady checking of the Web traffic made by the watched collecting, dismantles the substance of the got the chance to Web pages, and issues a caution if the got to data isn't inside the standard interests of that get-together and like the fear based oppressor interests. A starter modification of TTUM was finished and assessed in a near to structure condition. An imaginative learning based system for mental oppressor following by exploiting Web traffic substances as the overview data is exhibited. The proposed technique learns the common lead ('profile') of fear mongers by exercising an information mining tally to the printed dread related Web objectives. The subsequent profile is promoted by the framework to execute nonstop divulgence of clients related with fear based oppressor works out. The Receiver-Operator Characteristic (ROC) performance depicts that this framework can beat a heading-based interruption recognizing evidence structure.

F. Bolz (2001) In this paper we are dialog about the Data pre-arranging is an essential undertaking of TTUM application. All things considered web mining framework can be utilized for seeing and staying away from dread dangers accomplished by mental oppressors wherever all through the world. Information Mining (IM) and Web Information Mining (WIM) improvements will in a general sense impact counter-mental mistreatment. As we are seeing, one of the basic worries of our country today is to perceive and anticipate fear monger assaults. This is also changing into the objective of different countries on the planet. We have to look at the various IM and WM headways and perceive how adjusts for counter-fear based oppression.

Kumar., V., Zinovyev., R., Verma., Tiwari., P (2018) Multilanguage Semantic social calculations mapped to AI techniques so as to gather and assess mammoth extent of heterogeneous and complex Multimedia and Multilanguage fear based oppressor related substance from both the Surface and the Deep Web, so as to find (by "landing at an obvious goals"), see, break down, and screen potential mental lobbyist related exercises and individuals. At the social occasion a live demo of to-date got results and some examination starting from EU DANTE experience (a H2020 EU maintained ask about undertaking) will be appeared.

B. Thuraisingham (2003) Data mining has wound up being one of the key highlights of different country security works out.

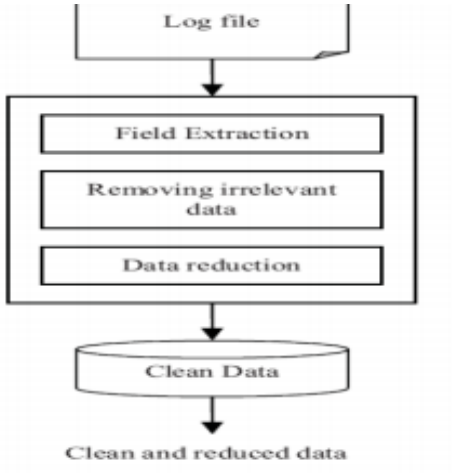
Reliably utilized as methodologies for seeing extortion, looking into hazard, and thing retailing, information mining fuses the utilization of information examination gadgets to find adequately dim, extensive points of reference and relationship in enormous instructive records. As for country security, IM can be a strategy to see fear-based oppressor works out; for instance, cash correspondences and exchanges, and to perceive and seek after specific mental aggressors themselves, for example, through improvement and development records. While information mining tends to a noteworthy improvement in the sort of illustrative contraptions beginning at now open, there are impediments to its capacity. One basic is that paying little heed to the manner in which that IM can support uncover points of reference and affiliations, it doesn't inform the client regarding the respect or embodiment of these models. These sorts of choices are made by client. A subsequent imprisonment is while IM can see relationship among processes or possibly factors; it doesn't for the most part perceive a innovative accord. Gainful IM demands talented, explicit and enlightening masters for examining the structure and decipher the yield.

A. Sachan and D. Roy (2012) Terrorism has wound up being a boss among the most tedious issues to regulate and a noticeable danger to humanity. To upgrade counter-mental battling, two or three research works are making able and cautious frameworks; information mining is unquestionably not a one of a kind case. Tremendous information is skimming in our lives, in any case the extraordinary accessibility of honest to goodness fear monger strike information in the open space makes it disappointed to battle mental battling. This remarkable copy bases on information mining blueprint structures and reviews the action of United Nations in counter-fear mongering. It isolates the execution of classifiers, for example, Multilayer Perceptron, Lazy Tree, Naïve Bayes classifiers and Multiclass for viewing the precedents for fear based oppressor ambushes the world over. The database for fundamental arrangement is delivered utilizing distinctive open and open access hotspots for a noteworthy long time 1970-2015 including 156,772 pronounced strikes causing gigantic debacles of property and lives. This work counts the mishaps happened, slants in assault rehash and places dynamically inclined by considering the strike commitments as evaluation class.

A. Malathi and Dr. S. SanthoshBaboo (2011) As the examination is client need based system, a few additional models may found. For prospective research work, there are two or three skylines to work upon with this examination. As an issue of first centrality is accomplishing a precision of classifiers up to 99%. This ought to be possible by acquired estimations and noteworthy neural systems near to the classifiers utilized in proposed research work or a mix of the varying classifier. During the examination process, work extended to the tertiary solicitation of a fragment of traits and all things considered till right hand for the improvement of quality. It has focal points and downsides also. Obliging the solicitation of at-12 tributes lessens the figuring multifaceted structure yet for divisions having a scarcely low event that induces biasing nature. One of the destinations is to in like way expand the sub-depiction layers and recognizes both so as to discover persistently pleasing models. So likewise comparatively similarly as with tremendous educational rundown needs Big Data to dispose of propensity and change in want. Moreover, utilizing fear monger information it is conceivable to foresee the affiliations associated with the proclaimed strikes. In any case, further examination should be conceivable to recognize a fear monger bunch utilizing chronicled information. In IM, frameworks may be passed from finding the guides to counter fear based oppression by making Terrorist Association Prediction Model (TAPM). The structure parameters are online substance, works out, easygoing affiliation information, telephone calls, messages, and so on by utilizing the diagram and model mining.

IV. METHODOLOGY

Web burrowing estimations are used for mining the abstract information that is open in the site pages in the wake of social event the printed information the words appropriate to the dread based mistreatment is recognized. Locales that have been made using various stages, particular count and differing programming tongues are pursued. The proposed system can check whether the locales and the substance on the web are progressing and spreading the activities related to mental fighting and the dread based mistreatment related exposure is checked and a short time later recognized. The proposed system is used to recognize and separate the locales and besides orchestrate them as necessities be as the dread based abuse related and the run of the mill genuine customers and sort them as the common customer or the mental aggressor. Data mining and web data mining are the two features that are to be used together for this recognizable proof strategy.



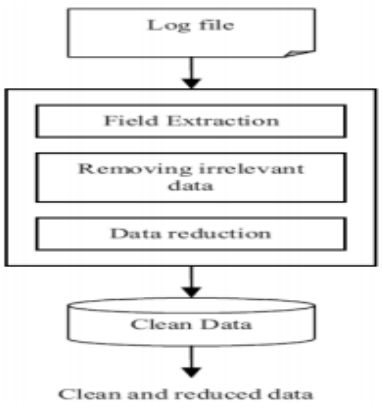
Data mining methodology is utilized to choose and describe the precedent from the available social affair of the destinations and the data from the locales mined are the colossal volume of data sources, the results gained are commonly used. WM is similar to DM since it incorporates the substance mining procedures that are used to look at the data and besides removing the profitable precedent from unstructured data. The proposed structure is extensively used by the governing body for antagonistic to fear mongering affiliations. The proposed system intends to help such relationship for following the dread based oppressor. Destinations must have characteristics that are referenced:

Weight Balancing: This is required by the destinations since the chairman can get to the system by the available logs of the manager subject to the stack that is given to the server is to be confined and set specialist over it. This is practiced for the passage of the executive.

Accessibility: For the straightforward receptiveness of the records and store the other available information for basic access independently.

The structure must be anything but difficult to utilize: The Website that is given to the open must be straightforward for basic use. The system must be powerful and moreover reliable. Straightforward help of destinations is essential for web data mining. These credits are said to be trailed by destinations for compelling mining of the locales.

Working System stream



Information Storage: The deferred outcomes of preprocessing from the logs of web server are verified in a social database to enable clear recovery and examination.

Information Preprocessing (IP): The preprocessing changes over the foul information into the information discussions urgent for example revelation. The motivation driving IP is to enhance the information quality and expansion mining exactness. IP contains extraction of field, information cleaning. This stage is likely the frustrating and intolerant advancement of the general procedure. This structure basically portray it immediately and express that its central endeavor is to "clean" the harsh web log records and supplement the managed information into a social database, to apply the IM frameworks in the subsequent time of technique. Hence, the standard undertakings are:

1) Web log extraction that aggregate information in web server.

2) Web logs cleaning process and expel the bounty data.

3) Parse the information and spot a social database or an information stockroom and information is reduced to utilize in rehash examination to make plot reports.

Field Extraction

The log segment encompasses assorted ranges for discrete preparation. The way toward isolating range from the current line of log document is referred as the field extraction. The server encompasses the arranged characters as the dividers. The effectively utilized separator is the 'space' character.

Information Cleaning (IC)

Information cleaning disposes of irrelevant or insignificant things in the examined information. A site can be gotten to by an extensive number of clients. The fizzled HTTP status codes are consolidated into log information. IC is generally site unequivocal, and joins superfluous notes to installed articles is not a fundamental for reason behind examination, including notes to style records, portrayals or sound reports. All things considered passages are purposeless for examination stage is cleared from log documents. Through DC, blunders and oddities will be perceived and expelled to enhance the possibility of information. Estimation had cleaned uproarious information similarly as diminished isolated, conflicting and immaterial deals as indicated by sort out 4 and 5. Blunder demands are counterproductive for the way toward mining. The mentioning are cleared by investigating offer status. For instance, the status 404 shows the referenced asset isn't closeness. By at that point, this log region in log reports is exhausted. Furthermore, pointless log information is in addition executed URL name postfix, for example, gif, jpg, etc in stage 6 and 7. At long last, regard and suffering records stay in SLT of database after information cleaning.

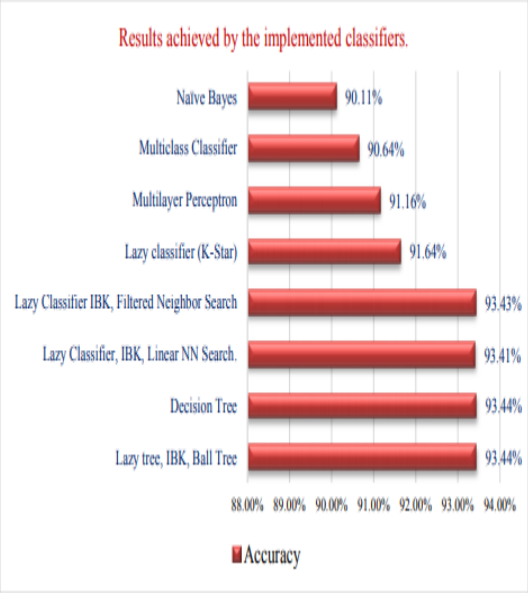
Central focuses

•It gives showing data.

•Web logs give an animating better procedure for get-together data on guests.

•To make changed web look devices, which can comprehend an individual's advantage demand in an individual route by investigating and profiling the client's solicitation direct?

•The information mining systems used to effectively perceive noxious executable before they run.



•Integrate information sources Clean/change information sources enhances the profiles of Terrorists and Examine results of Activities / Reports regarding the Prune results, last outcomes with data regarding the fear mongers and mental oppressor rehearses mine the information.

V. RESULTS

The classifiers utilized are: The Lazy-classifier IBK Filtered Neighbor Search and direct-NN, Multiclass Classifier, Decision Tree Random Forest, Lazy classifier K-star, Multilayer Perception, Ball Tree and Naïve Bayes. The accomplished outcomes with top of the line exactness' going from 90 to 95 %. Figure 5 depicts the execution outcome of utilized classifiers. The outcome tables demonstrate the yields accomplished by Multilayer Perception, Lazy Classifier K-star and IBK, Multiclass Classifier, Choice Tree

Random Forest and Naïve Bayes. The examination attempted to coordinate worldwide mental oppressor assaults by using different substance mining classifiers, for example, Decision Tree capricious woods, Lazy classifier IBK, NN, K-star and Filtered Neighbor Search. The reasonable exactnesses regarding classifiers execution is accomplished. This examination can be utilized to draw structures for disconnecting data about the dread strikes. A touch of the results of the work are as per the going with:

• Out of complete announced assaults from 1970 to 2015 which are 156772, 14664 are confirmed, 75966 are Not-Claimed and 66142 are bewildering.
• The degree of asserting the strikes by fear based oppressor affiliations fluctuates from 10-15 percent. This examination accomplished a rate of 11%. (Notwithstanding how maintained that assaults more occurred from 2016 and few more commitments taken to ambushes for the reason the degree is variable).
• The certified stake is Asia in continuing with ambushes which are in every way that really matters 45% of the immovable assaults.
• Law Enforcement and Government bodies are the practical objectives making up to 40% looked for after by Citizens is 22%.
• The loss occurred because of fear based oppressor strikes is most critical for Moderate afflictions which are detached from each other individual 64%.
• The sorts of strike, for example, assaulting and furnished catch are extensively seen is 48.45 and 24.50 percentages freely.
• Explosives, Firearms and Bombs are the noticeable weapon sent in the ambushes with 50.47 and 33 percentages independently.

Classifiers Graphical Result

The Clustering module gets to the assembled vectors and performs unsupervised gathering achieving n packs addressing the normal subjects seen by dread monger customers. For each gathering, the Terrorist-Represent or module enrolls the centroid vector (demonstrated by Cvi) which addresses a subject ordinarily gotten to by dread mongers. Along these lines, great deals of centroid vectors address a ton of dread mongers interests suggested as the 'Ordinary Terrorist-Behavior. Content examination is used to discover dark, genuine models and associations in considerable enlightening records. In reality, even substance examination has a remarkable potential to perceiving dark substance files, there is an obstruction that human created language is so far tangled for machine to understand semantic ramifications of it. Consistently, various examinations have been made by using quantifiable methods to address reports into noteworthy game plans, for instance, TF-iDF. This is the most principal system for making sense of which words are basic in the given substance educational gathering. Nevertheless, execution state subject to TF-iDF isn't sufficient if the proportion of data is pretty much nothing. What's more, this philosophy depends upon the sack of words to register TF-iDF regard

$$TF\ (t) = \left(\frac{n}{N}\right)$$

$$IDF\ (t) = \log_e\left(\frac{T}{t}\right)$$

n = Number of times term t appear in a document
N = Total number of terms in document
T = Total number of document
t = Number of documents with term t in it

VI. SOME COMMON MISTAKES

The Typical-Terrorist-Behavior relies upon a ton of Web pages that were downloaded from mental oppressor related goals and is the guideline commitment of the ID estimation. In order to make the revelation computation progressively definite, the route toward making the Typical-Terrorist-Behavior must be reiterated irregularly due to changes in the substance of mental aggressor related site. Common Terrorist-Behavior depends upon the amount of packs. Right when the amount of gatherings is higher, the Typical-Terrorist-Behavior joins more topics of excitement by mental activists where each subject relies upon less pages. It is hard to estimate what the perfect number of packs is. For the circumstance mull over showed in the accompanying region distinguishing proof execution for two settings of the amount of bundles are shown. The marker issues an alert when the likeness between the passageway vector and the nearest centroid is higher than the predefined edge implied by tr:

$$Max\left(\frac{\sum_{i=1}^{m}(tCv_{i1}, tAv_i)}{\sqrt{\sum_{i=1}^{m} tCv_{i1}^2 . \sum_{i=1}^{m} tA_i^2}}, \ldots, \frac{\sum_{i=1}^{m}(tCv_{in}, tAv_i)}{\sqrt{\sum_{i=1}^{m} tCv_{in}^2 . \sum_{i=1}^{m} tA_i^2}}\right) > tr$$

VII. CONCLUSION

As the examination is client need based methodology, several additional points of reference can be found. This ought to be possible by hereditary estimations and huge neural systems near to the classifiers utilized in the proposed research work or mixer of diverse classifiers. The examination proceeded up to tertiary game-plan of a touch of properties and everything considered up to partner for individual trademark, which incurs inclinations and disadvantages too. Restricting the solicitation of at tributes lessens the estimation multifaceted nature for vaguely depressed event, it prompts biasing. The objective is to correspondingly develop the sub-gathering attributes and layers to discover powerfully strong precedents. Additionally with huge edifying rundown needs Big Data to dispose of tendency and change in want. In like manner, utilizing mental attacker information it is conceivable to anticipate the affiliations attracted with the detailed strikes. Regardless, further examination can be done to perceive a psychological oppressor bunch utilizing clear information. In the lieu of proposed work, IM, approaches are sent from determining the guides to counter fear mongering by making TAPM. The structure parameters are online substance, works out, easygoing system information, telephone calls, messages, and so forth by utilizing the layout and point of reference mining.

Improved Data Security for Storing and Authenticating in Cloud using ERSA Algorithm

Rokesh Kumar Yarava, J Kavitha

Abstract*: Present days, huge amount of data stored with cloud service providers. The Third- party auditors (TPAs), with support of cryptography, are frequently utilized to prove this data. Auditing will be capability for cloud clients to prove the existence &functioning of their supplier's security measures. Authentication is done by using username and password. The important point in authentication is to protect data from the access of unauthorized people. The proposed scheme is Enhanced RSA (ERSA) Algorithm. This paper presents solution to enhance the security and privacy to stored data in cloud. Result demonstrates that this scheme can progress the security of data that stored in cloud.

Index Terms — cloud computing (CC); information security; confidentiality; integrity, Enhanced RSA (ERSA) algorithm

I. INTRODUCTION

The cloud computing will be an administration delivering method on internet. It could offer clients with versatile benefits as needed through the web &generally distinguished & applied. To use the resources of computing are very securely and effectively, people start to pay attention to unseen safety issues in cloud. The access control will be very significant dimensions to ensure the cloud computing safety.

The environment of CC will be usual disseminated environment; consequently the anonymity, dynamism, &distribution of data services &assets have notable characteristics of CC environment [1].

The main technique utilized in cryptography may be encryption. This technique conserves integrity & confidentiality of information. The confidentiality characteristic will be information constantly produced available to approved gatherings. The integrity is not permitting unapproved gathering to change the information that will be saved by client. The access control is the main significant dimension to ensure the safety of CC, numerous clients are using this access control to their data is confidential [2].

Cloud is also permits the similar strategy towards the concern of security. As stated by cloud environment, encrypting the information of clients might be finished by 2 parts, they are CSP or TPA. The 2 elementary purposes for development in storage of data in clouds are cloud based storage framework recoveries clients the overhead connected with assets that might make fundamental for an accepted in-house information storage result, & in its place, offloads these overheads to cloud, and ability proliferation compelled personal versatile registering devices [3].

Therefore, in present days the clients become under the encrypting methodology their sensitive information before sending it to cloud for storage. The ERSA technology utilizes 2 extra prime numbers in standard RSA method. This thought is raised from security RSA & high speed method that utilized 2 random numbers to generation procedure of key. Using this proposed algorithms proposed method insures the confidentiality, integrity, availability and durability property of service which will improve the cloud services reliability [5].

This idea is raised from Security RSA &High Speed method that utilized 2 random numbers for key generation procedure. Using this proposed algorithms proposed method insures the confidentiality, integrity, availability and durability property of service which will improve the cloud services reliability.

II. BACKGROUND

The public framework of auditing the data safely stored in CC & gives a PPA protocol. It empowers an outside auditor to audit cloud information of clients without know the information. A productive remote information auditing technique to storage the safety information in CC. Furthermore to dynamic operation, 3rd party verification, &other functions [1].

The TCM is presented under control method. The common trust among cloud service nodes & clients have guaranteed by trust device. The trust clients are access to cloud; concurrently clients might choose reliable service nodes of cloud. The method had a best malicious detection capability & adaptability. In environment of CC, whereas the reliability & safety of both connection parties have ensured, after the safety of information might be efficiently connections among cloud & clients [2].

The storage frameworks with various information sources are very applicable in numerous real world situations. The CSSP preserves a cloud storage giving the essential structure to make, store &upgrade outsourced databases, &makes this information accessible to subscribing customers. The customers are provided for read-only access to data base& commissioned approved customers have permitted to make variances under database [3].

In DCS supplier has infinite access to stored information, & this perspective turns into particularly critical whereas hybrid or public clouds have utilized.

Revised Manuscript Received on October 22, 2019.
Rokesh Kumar yarava, Assistant Professor, Dept. of CSE, Malla Reddy Engineering college (Autonomous), Hyderabad, India.
J Kavitha, Assistant Professor, Dept. of CSE, Malla Reddy Engineering college (Autonomous), Hyderabad, India.

The data stored in CC will be secured from hardware faults. Whereas utilizing the CC & DCS in specific, there arises few problems associated to integrity & confidentiality of data in procedure of transmission & storage [4].

In RSA, an asymmetric key technology utilizing 2 diverse keys to decryption & encryption procedures. The size of key might be differed to create the procedure of encryption is strong. Consequently, it will be critical to the attackers to interrupt the information. Expanding key size correspondingly increments the time taken for procedure of decryption & encryption [5].

This paper introduces an enhanced data auditing and authentication scheme which helps to improve privacy of data owners this proposed theory.

III. PREVIOUS WORK DONE

The work [1] recommended a grid-based charging & joint routing technology for industrial remote rechargeable sensor networks. The authors Tie Qiuet. All recommended a greedy method with little world to enhancing the robustness for heterogeneous IoT. The suggested schema utilizes a best load dissemination approach that significantly lessens the computational overhead of customer. The recommended plan incorporates a lapse reaction scheme, & outcomes indicate that result has better error-handling capacity & provides lesser overhead payments for communication & computation than other methodologies.

The work [2] suggested trust based access control strategy in multi-domain of CC. The suggested strategy joining with TM, MTBAC method. The MTBAC method take credibility of cloud service nodes & behavior trust of clients under deliberation. The relationships of trust among service nodes of cloud & clients have recognized towards mutual trust component. The access control safety issues have resolved by executing MTBAC method under CC environment. The results represents that MTBAC method might ensure the collaboration among cloud service nodes & clients.

The work [3] suggested Auditing for information reliability & integrity in cloud storage. The suggested model introduces a scheme of query authentication for cloud-based storage framework whereas information will be retrieved towards customers & populated towards numerous sources. The framework permits customers to confirm the integrity & authenticity of retrieved information in proficient & scalable way, without need of implicit trust on storage service supplier. The suggested method will be rely on lately suggested “multi-trapdoor hash functions”, utilizing its assets to accomplish neighbor consistent computation &correspondence overhead to validating inquiry responses, in any case of the information size, or the amount of sources.

The work [5] recommended system for upgrading the information safety in cloud toward executing hybrid (Rsa&Aes) encryption method. The encryption may be completed by utilizing 1 popular asymmetric or symmetric key method like DES, AES, Blowfish, DES, RSA, & triple DES and so on; RSA method is a asymmetric key method utilizing 2 diverse keys for decryption & encryption procedures. The size of key might be varied to make encryption procedure will be strong. Therefore, it will be critical for attackers to interrupt the information. Expanding the size of key consistently enhances the time for decryption & encryption procedure. The suggested method lessens the time for decryption &encryption procedures by separating the document under pieces & increases the quality of method by expanding the size of key. This quality paves the path to store the information in cloud towards the clients without any trouble.

IV. EXISTINGMETHODOLOGIES

4.1 An Efficient Protocol with Bidirectional Verification

The suggested auditing protocol helps dynamic information operations that will be proficient& analyzed to safe in random oracle method. The suggested auditing protocol gives the help for statistical examination & bidirectional confirmation. The public framework of auditing the safety of information stored in CC & offer PPA protocol.

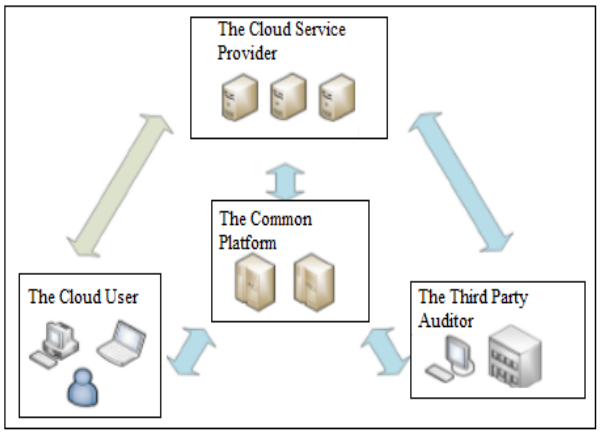

Fig. 1, System model

The recommended plan empowers an outside auditor to audit clients cloud information without learning the information. To make preparing much efficient, the calculations of customer account for little portion of total computation. Whereas the document will be changed, the owner of information might check to find if significant portions have in better situation. Further, the information manager might define the area of error, thus securing the information, which not been transformed.

V. 4.2 A MUTUAL TRUST BASED ACCESS CONTROL MODEL

The recommended system is presented trust computation method under access control method. The mutual trust among cloud service nodes & clients have ensured by trust mechanism. The MTBAC method not recognizes attitude of client trust & ensure the access of clients request postures no malevolent risk to cloud server, & takes cloud administration node's validity under account.

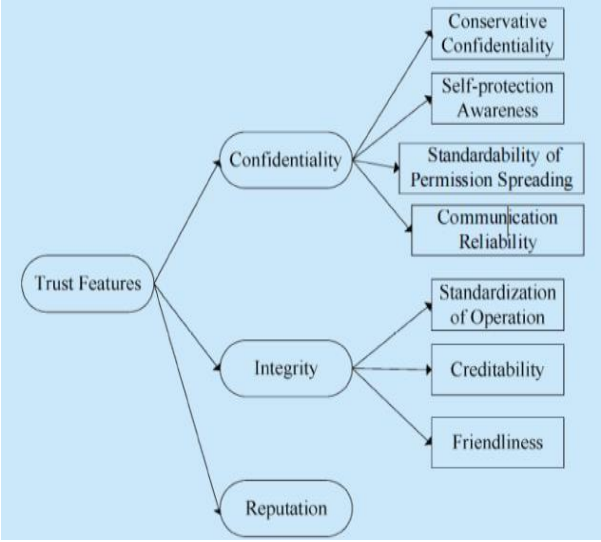

Fig. 2, the Division of Trust Attribute

The mutual trust method of cloud service nodes & clients has 2 part construction. One portion will be trust evaluation method of client's attitude & another portion will be trust computation method by cloud service nodes. The network level, made dependent upon of 3 attributes, reputation, confidentiality, & integrity.

VI. 4.3 Efficient and Scalable Query Authentication with Multiple Data Sources

The recommended system introduces a new component for query verification in cloud-based storage framework with help for several sources, which accomplishes persistent computation & correspondence overheads in any case of size of information, or amount of sources. The suggested plan accomplishes this towards producing confirmation tags of individual information components & aggregating tags of different information components utilizing a new system dependent on late suggested standard named as multitrapdoor hashing plan.

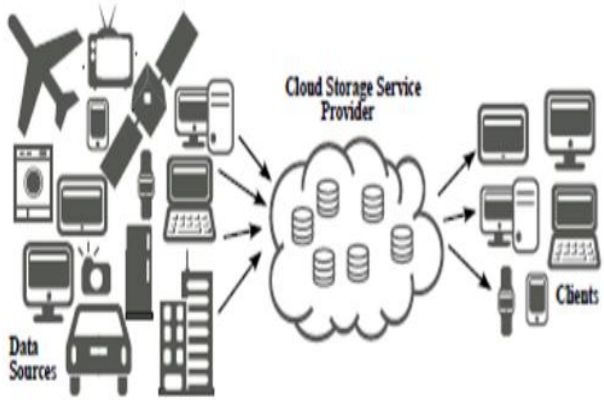

Figure.3. Cloud based storage system

The query authentication method for multi-source cloud based storage frameworks to give high safety & light weight operation. In terms of cost of operation, goal will be to decrease the communication, computation, & storage overhead at every entity utilizing cryptographic method, which scales with numerous sources, databases size & response of query.

VII. 4.4 The Method of Ensuring Confidentiality and Integrity Data

A method that describes the use of separate services outside the cloud for authentication, data management and metadata storage to eliminate the possibility of obtaining unauthorized access to data, and the use of metadata to perform integrity control. The owner of the database limits the access to data that is stored in an encrypted form and does not allow provider to interact with database.

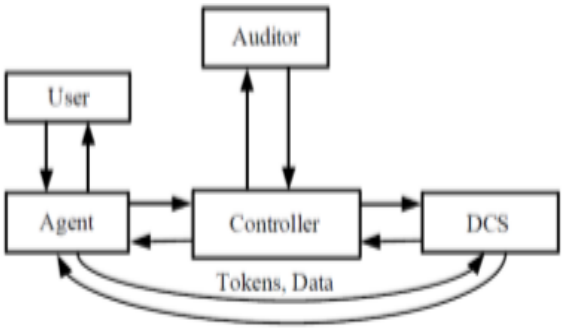

Fig. 4, Methods of encrypted data handling

Proposed a system of storage and generation of metadata based on checksums of information and time is introduced. Proposed method derived the set of methods of encrypted data handling in DCS that develop consists of procedures of saving, receiving and deleting data from DCS. All operations with encrypted data carried out in cloud computing should be performed without decryption. It is essential to store encryption keys beyond cloud computing.

VIII. 4.5 Enhanced RSA Algorithm with Varying Key Sizes for Data Security

The main technique utilized in cryptography will be encryption. This technique conserves integrity & confidentiality of information. The confidentiality characteristic will be information constantly produced available to approved gatherings. The integrity is not permitting unapproved gathering to change the information that will be saved by client. Numerous clients are using this access control to their data is confidential.

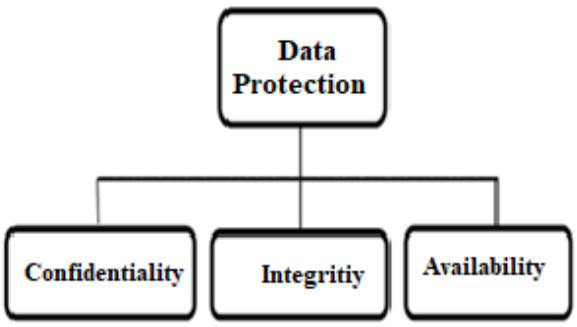

Fig. 5, Data protection method

The encryption may be completed by utilizing 1 popular asymmetric or symmetric key method like DES, AES, Blowfish, DES, RSA, & triple DES and so on; RSA method is a asymmetric key method utilizing 2 diverse keys for decryption & encryption procedures.

The size of key might be varied to make encryption procedure will be strong. Therefore, it will be critical for attackers to interrupt the information. Expanding the size of key consistently enhances the time for decryption & encryption procedure. The suggested method lessens the time for decryption & encryption procedures by separating the document under pieces & increases the quality of method by expanding the size of key. This quality paves the path to store the information in cloud towards the clients without any trouble.

IX. Analysis and Discussion

The auditing protocol support dynamic data operations, which is efficient and has been analyzed to be secure in the random oracle model. Proposed auditing protocol provides the support for bidirectional authentication and statistical analysis [1].

The access control is the main significant dimension to ensure CC safety. The mutual trust among cloud service nodes & clients have ensured by trust method. The trust clients are access to cloud, and concurrently clients might choose the most credible service nodes of cloud [2].

A new method for query authentication outcomes in cloud based storage framework with help for numerous sources, which attains constant computation & communication overheads irrespective size of data, or the several sources [3]. Whereas utilizing CC, DCS in specific, there arises an extent of topical problems associated to integrity & confidentiality of data in procedure of transmission & storage. Few services outside the cloud for data management, authentication, & storage of metadata to remove the probability of acquiring unauthorized access of information, & utilization of metadata to execute integrity control [4].

X. Proposed Methodology

First, Proposed Methodology proposes schemes which will helps to enhance security and authentication in cloud services. Proposed method introduce encryption and description scheme which eventually improves authentication process. First user login if user exists otherwise first user registration by using registration form. After the successful completion of login process then user can himself get the authority for storing the data into the cloud. Authorized user can select the two random picture or image from the gallery then form the one new image from these two images and this one new image is called as image fusion because this new image is a combination of these two images. Image fusion uses the numbers of XOR keys then user can select the random XOR key number. From these keys one strong password is generated and using this password, the user can select required data those are placed into the cloud. So that user can select maximum data for storing into the cloud and also achieve the security for stored data.

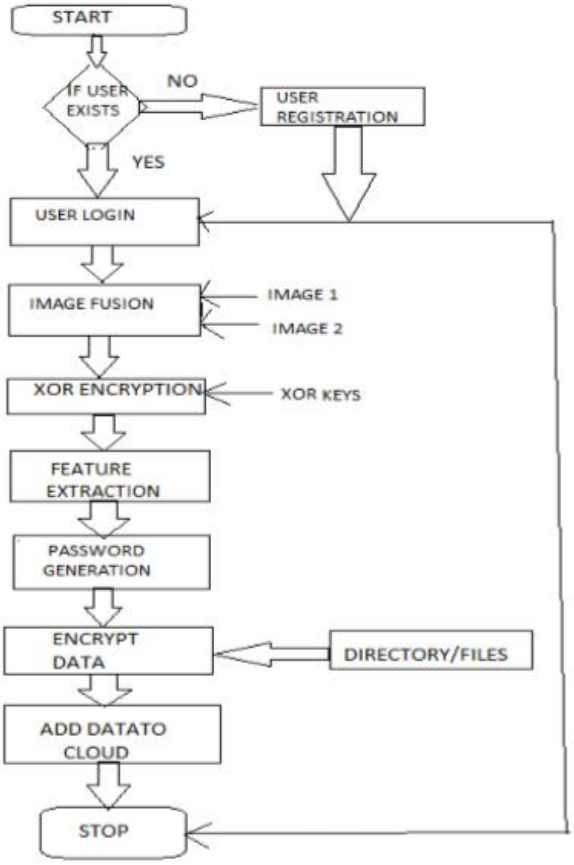

Figure.6. Data Encryption

XI. Outcome and Possible Result

This paper proposes a development concerning decryption &encryption time. The decryption & encryption time for secure RSA, high speed method &the suggested algorithm ERSA are taken into consideration for better performance. It is extremely scalable in terms of communication &computation overheads irrespective of data size, or numerous sources. Thus, overall, the proposed scheme achieves superior scalability and efficiency.

XII. Conclusion

This manuscript concentrated on speed is still improved in suggested method ERSA by separating the document into numerous blocks. Apart from incrementing the speed, the execution of ERSA method makes the increments the security strength. The outcome represents the decrease in decryption & encryption time as stated by ERSA than secure RSA & high speed.

Future scope

In this paper suggested method ensures the integrity &authenticity of choosing the query outcomes. In future plan is to prolong this mechanism to offer complete assurances that permit the customer to prove the cloud, returns each document, which satisfies the situation of query, help the diverse kinds of queries.

Energy Efficiency Analysis between Green computing and Cloud Computing

J Kavitha, Rokesh Kumar Yarava

Abstract*: Usually cloud computing is based under effective data computing but green cloud computing focus on energy efficiency of device and computing mainly based on computing architecture. Here cloud computing is also known as green computing due its better effective energy. The purpose of green computing is to decrease the usage of harmful resources, maximizing energy efficiency throughout the living span of the good and also to promote the recyclability or bio degradability of useless goods plus misuse materials of the factory. In order to simulate the hardware by utilizing software, green computing plays a major role for various technologies like virtualization, green data center, cloud and grid computing and power optimization. Here computer resources are effectively utilized by replacing the data center standalone server system by artificial server so as to run the software by less number for large computers called as virtualized. Finally this paper is fulfilled by the advancement of recognized energy efficient computing.

Keywords: Cloud Computing, Green data center, Power optimization, Energy efficiency.

I. INTRODUCTION

Green computing and green technology are referred as ecofriendly by the usage of computer technology as well as technology related to other resources. The execution of energy effective central processing unit plus its peripherals and servers are included in green computing.

The main purpose of green technology is to reduce consumption of resources and also to improve the electronic waste (e-waste) disposal.

Green computing is huge in rising area that is intended for reduction energy that becomes the top priority in all segments of IT market and it is also needed for energy effectiveness that became a serious issue in designing of effective presented computing.

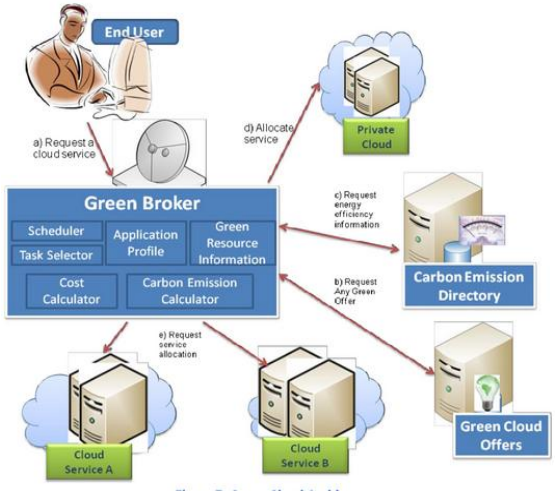

Fig 1 cloud computing for green computing

Those growing accessibility about high speed internet plus corporate IP associations may be empowering the delivery novel network-based services. Same time Internet-based mail administrations have been operating to a significant number years, management contributions bring stretched with fit in network-based ability plus network-based registering. These new administrations would be advertised both will corporate also distinct limit clients. Administrations about this sort need been generically known as cloud registering services. Those cloud registering administration model includes those provision, by a administration provider, for vast pools for high-octane registering assets and high-capacity capacity units that would imparted around wind clients as needed. There are a lot of people cloud administration models, in any case generally, conclusion clients subscribing of the administration need their information facilitated Toward the service, Also need registering assets allocated on interest from those pool. That administrative provider's advertising might additionally stretch out to the product requisitions obliged toward the end client [2]. With make successful, those cloud administration model likewise obliges a high-sounding system on give acceptable connection among those last client plus the administration provider infrastructure.

Cloud registering possibly offers a general budgetary benefit, in that end clients stake a large, centrally figured out how pool of stockpiling furthermore registering resources, as opposed owning and overseeing their systems. Frequently utilizing existing information centers likewise a basis, cloud administration suppliers put

Revised Manuscript Received on October 25, 2019.

Rokesh Kumar yarava, Assistant Professor, Dept. of CSE, Malla Reddy Engineering college (Autonomous), Hyderabad, India.

resources into those important foundation and management.

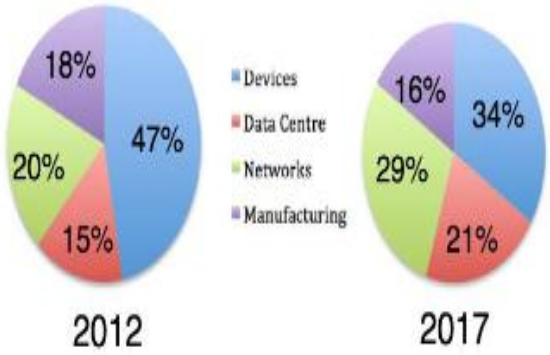

Figure.2. Electricity consumption by main components in ICT Sector

Figure 2, graphically depicts those examination about subside Corcoran and Anders Andrae for "Emerging patterns done power utilization for customer ICT" [15]. Assessing data, field records, Furthermore former researches, the writers have guessed that by the quite a while 2017, those power necessities of the cloud information Centers will bring arrived at an amazing 21%. This will be a disturbing conclusion, which might help gigantic sums for carbon dioxide emanation over our officially hampered surroundings. Various requisitions would run by information centers that fill in under cloud registering. Portion information will be transformed inside seconds, whereas, expansive information nourishing looking into imparted fittings stage takes more occasion when methodology will. Those cloud registering on-demand office countenances tests at different information will be with make processed, one by one alternately simultaneously. Asset Furthermore chance allotment is must with keep away from delay Also generation about wrong comes about [9].

Information centers are unavoidable; they are necessary for information storing, accessing, preparing and other administrations. The rate from claiming Vitality utilization may be alarmingly high, and the significant downside on this utilization is that, just a little portion for this vitality will be really used to generate a yield. The information centers need aid heavy spender on keep up, the extra foundation such as coolers, will administer those temperature about vast number from claiming servers inside an information Centre, includes of the expense and in addition the carbon foot shaped impression. Green cloud registering aides with those convoluted procedure for accomplishing decrease to Vitality utilization amidst proficient utilization of base.

II. GREEN COMPUTING TECHNIQUE MEANT FOR ENERGY EFFICIENCY.

Comprehension the routes done which control utilization effects those "greenness" of At whatever technology, Furthermore particularly registering technology, may be a vital venture to decreasing this use and instruct others. This area depicts those dissimilar particular systems that could be used to reduce energy operation**.**

2.1 Turn off equipment when not being used.

Powering down gear may be those simplest, more successful and a large portion clear approach to decrease registering control utilization. This adjustment be unreasonable because the fundamental gesture about powering rotten a processing device will fundamentally decrease its force consumption, in spite of the fact that it will be vital to note that huge numbers units might at present devour an little sum about control alternately "phantom load".

2.2 Machine control reserve funds Modes:

organization of force utilization be a normal, thus far frequently ignored, characteristic for A large portion Pcs and working system lying on the advertise nowadays. The boundary with wider selection may be that a lot of people Figure force reserve funds modes with make badly arranged by there might a chance to be a little delay into exiting a control cautious mode once again with typical utilize. Safety is understandable, in spite of the fact that with observant system association and gradual acclimation with an exchange technique for operational, this reluctance could make beat.

2.3 Monitor sleep mode

Permit those display will dip rotten behind sitting still to some time period will be an additional undoubtedly utilized technique for moving forward energy efficiency. While a screen fall sleeping alternately enters a "stand by" approach, it enters a small control utilization condition. The display will be plain, for no light emit as of it. To pattern, dell 20 widescreen LCD utilization give or take 55 watts about energy when it is looking into. Done rest mode, those force use drops on approximately 3 watts, bring regarding noteworthy energy preserve rites.

2.4 Hard disk sleep mode

A workstation could put its tough plate drive over a small control rest approach the point as they would unmoving pulley. solid plate drive ahead desktop machines camwood use 10 watts or additional The point when over utilize same time journal workstation drives use less Anyhow vitality reserve funds need those profit from the battery charge an aggregation. Working system settings once more deal with this mode naturally when arranged. This setting gives little funds and may be minimally intrusive, for All the more noteworthy funds time permits utilizing system standby mode [3].

2.5 system standby Mode

System standby will be a standout amongst those the vast majority compelling control sparing Characteristics. Later than specific moving phase, a workstation will close the vast majority from claiming its parts essentially decreasing force use. Unstable memory remains dynamic in this way that whatever that client might have been attempting for will at present make there at those workstation wakes up starting with standby approach. An desktop machine so as to employs further 100 watts without moving might utilize Similarly as little Concerning illustration 5 watts The point when over standby mode, utilizing you quit offering on that one twentieth of the power it utilized when sitting still.

2.5 Hibernal mode.

Those hibernal mode dives one venture further over

standby mode toward totally powering off the PC. Invoke the hibernal approach reasons the recollection state on a chance on the way to spare on the solid plate in front of powering down. When hailing crazy from claiming hibernal mode, those machine restore the recollection state, chronic the machine to it's pre-hibernate condition. A desktop machine determination devours pretty nearly 3 watts for hibernal mode vs. 5 watts for standby.

III. CLOUD COMPUTING ENERGY EFFICIENCY TECHNIQUE

A.

B.

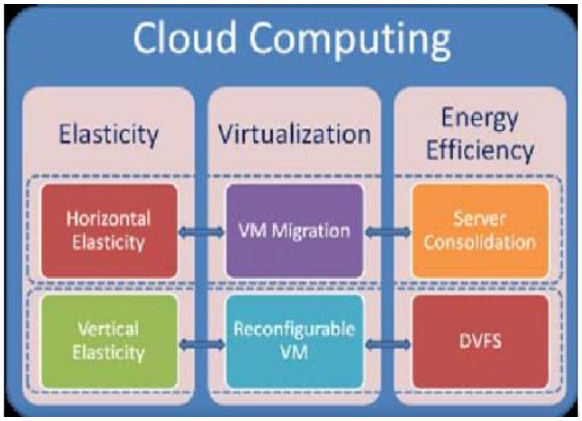

Fig 3 energy efficiency techniques

3.1 Applications

SaaS model need altered those route provisions and product would disseminate and utilized. Ever increasing amounts organizations need aid exchanging on SaaS Clouds with minimize the cost. Thus, it need get to be exceptionally imperative to tackle the energy efficiency during requisition level itself. though, this layer need accepted next to no fascination since a significant number provisions would as of now around utilize and the vast majority of the new requisitions are basically upgraded versify about or created utilizing A while ago executed instruments. Should accomplish energy efficiency during provision level, SaaS suppliers ought to pay consideration clinched alongside deploying product looking into straight sort of system which could execute those programming A large portion effectively [4]. This necessitates those Look into and Investigation of exchange-off the middle of execution and Vitality utilization because of execution of programming with respect to numerous platforms and equipment. To addition, the Vitality utilization during those compiler level Also code level ought further bolstering make recognized by programming developers in the plan about their future requisition usage utilizing Different Vitality productive techniques suggested in the expositive expression.

3.2 Cloud Software Stack: Virtualization and Provisioning

In the cloud stack, a large portion meets expectations in the written works tackle the tests by IaaS supplier stage the place Look into centering may be once planning Also asset administration to decrease the measure about animated assets executing those workload about client provisions. The combination for VMs, VM migration, scheduling, interest projection, high temperature oversaw economy Also temperature-aware allocation, Also load adjusting would utilized similarly as fundamental techniques to minimizing energy utilization. Likewise examined for past section, virtualization assumes a paramount part in these techniques because of its a few features for example, such that consolidation, carry on with migration, and execution confinement [4]. Merging serves done overseeing the exchange-off the middle of performance, asset utilization, Furthermore Vitality utilization. Similarly, VM relocation permits adaptable also changing asset administration same time encouraging shortcoming management and bring down upkeep cosset. Because of numerous levels about abstractions, it is generally difficult should look after sending information of every virtual machine inside a cloud datacenter. Accordingly, Different backhanded shipment estimation systems be utilized for combination about VMs.

3.3 Datacenter level: Cooling, Hardware, Network, and Storage

To begin with stage is those advanced mobile development of the datacenter and picking of its area. There need aid two real variables in that one may be vitality supply also different may be energy efficiency from claiming gears. Hence, those datacenters are being constructed done such an approach that power could a chance to be produced utilizing renewable wellsprings for example, sun Also wind. Presently that datacenter area will be chosen dependent upon their geological appearance; environment, fiber-optic connectivity and entry to an abundant provides about competitive vitality. because principle worry from claiming cloud suppliers will be business, vitality hotspot may be Additionally seen basically As far as cosset not carbon outflows. In turn territory of worry inside a datacenter may be its cooling system that contributes should practically 1/3 for downright Vitality utilization. Two sorts of methodologies would use: air and water built cooling systems. On both approaches, it will be vital that they specifically cool that hot gear as opposed whole room region. Subsequently newer vitality productive cooling systems would recommend dependent upon fluid cooling, Nano fluid-cooling systems, Furthermore in- server, in-rack, also in-row cooling by organizations for example alternatively the outside temperature/climate can need immediate sway on the vitality prerequisite for cooling system. Percentage systems need be construct the place outer cool air is utilized to uproot warmth starting with those datacenter.

3.4 Monitoring/Metering

First level is those advanced mobile development of those data center and picking of its area. There would two real elements in that person will be vitality supply and different will be energy efficiency from claiming gears. Hence, those data centers are constantly constructed previously, such an approach that power could a chance to be created utilizing renewable sources for example, sun and wind. At present the data center area will be concluded In view of their geological features; climate,

fiber-optic connectivity Also get to a plentiful should measure those bound together effectiveness of a data center and move forward its' execution per-watt, those Green Grid need recommended two particular measurements identified as the power utilization Efficiency (PUE) and Data center infrastructure effectiveness (DciE).

PUE = Total Facility Power/IT equipment efficiency. DciE = 1/PUE = IT equipment Power/Total facility power x 100%. The downright office energy is characterized by that energy measured during that utility meter that is committed exclusively of the data center power [5]. Those it gear energy is characterized Likewise those energy devoured in the management, processing, and capacity alternately directing of information inside the data center.

3.5 Network Infrastructure

At system level, the energy efficiency will be attained possibly toward that network level (i. E. Organize boundary card) or in that base level (i. E. Switches and routers). Those energy efficiency issue over systems administration is as a rule alluded on as "green networking", which identifies with embedding energy-awareness in the plan, in the units Furthermore in the conventions of network. Present would 4 categories about results advertised on literature, in particular asset consolidation, virtualization, specific connectedness, and proportional registering. Asset combination serves done regrouping those under-utilized units to decrease that worldwide utilization. Comparable to consolidation, specific connectedness of units comprises for dispersed instruments which permit the single bits from claiming gear on try unmoving pulley for a few time, Similarly as transparently as time permits from whatever remains of the networked gadgets. The Contrast between asset merging and specific connectedness will be that the combination applies should assets that would impart inside the system foundation same time particular connectedness permits turning off unused assets during those edge of the organization. Virtualization Concerning illustration examined in the recent past permits more than one administration with work on the same bit of hardware, accordingly moving forward the fittings usage. Proportional registering could a chance to be connected should an arrangement as a whole, on organizes protocols, and also should distinct units and segments. Progressive Voltage scaling and versatile join rate need aid commonplace illustrations for proportional registering. Dynamic Voltage scaling lessens that vitality state of the CPU Similarly as A capacity of a framework load, same time versatile join rate applies a comparative idea will organize interfaces, lessening their ability, and consequently their consumption, by a capacity of the connection pack.

IV. ENERGY CONSUMPTION ANALYSIS

To compute the measure for energy inspired by data centers, two measurements be built by Green –cloud grid, and global consortium [6]. Those measurements are control use adequacy (PUE) and information focal point foundation effectiveness (DCiE) Similarly as characterized belowPUI=Total office power/IT supplies control DCiE=1/PUE= (IT gear Power/Total office force) *100%. Those it supplies energy will be those load conveyed will at registering fittings resources, same time the aggregate office control incorporates other vitality facilities, specifically, those vitality expended Toward All that that helps it supplies load.

On cloud infrastructure, a network alludes all the will all multicore server alongside its parallel preparing units, organize topology, force supply unit and capacity ability. Those generally Vitality utilization of a cloud earth might be ordered as takes after:. E cloud = ENode + ESwitch + EStorage + EOhters utilization of vitality Previously, An cloud surroundings Hosting n number for networks and m amount of exchanging components might make communicated as:. ECloud = n (ECPU + EMemory + EDisk + EMainbosrd + Emainboard + ENic) + m(EChassis + ELinecards + EPorts) + (ENASServer + EStrorage controller + EDiskArray) + EOthers.

V. CONCLUSION

Here we investigate the energy effectiveness methods previously, cloud and green registering. It need be demonstrated so as to couple real parts for cloud building design which are answerable for high amount of force dispersal in cloud. Reasonably be expected approaches on help each division for outlining anenergy efficiency model about green & cloud registering need been examined. This review talked about techniques for enhancing that energy efficiency of registering. To registering resources, the results fill in toward distinctive levels, starting with distinctive networkss to whole infrastructures the place they take advantage for late propelled functionalities for example, such that virtualization. A standout among the primary leverages to decrease those electric bill and the carbon foot shaped impression of it base is should build the vitality familiarity with clients and suppliers.

An Insight on Machine Learning Algorithms and its Applications

R. P. Ram Kumar, Sanjeeva Polepaka, Lazarus S F, Dasari Vamsi Krishna

Abstract— Machine Learning (ML) furnishes the ability of insights on automatic recognizing patterns and determining the prediction models for the structured and unstructured data even in the absence of explicit programming instructions. Today, the impact of Artificial Intelligence (AI) has grown up to several heights, ranging from Life sciences to the Management techniques. The integration of ML led to reduce or eliminate the errors in the prediction, classification and simulation models. The objective of the paper is to represent the ML objectives, explore the various ML techniques and algorithms with its applications in the various fields.

Keywords: Machine learning, Supervised learning, Unsupervised learning, Semi-supervised learning, Reinforcement learning,

I. INTRODUCTION

The ML is a process of making the system to learn automatically based on the earlier experimental data. The objective of ML is to determine the predictions based on the existing data. The following shows the procedure for ML adopted by Gartner [16].

Step 1: Gather the input data (may be structured or unstructured)

Step 2: Apply the ML algorithms (such as Supervised, Unsupervised, Semi-supervised, and Reinforcement Learning methods)

Step 3: Determine the Output (such as predictive, exploratory, classification)

After the data collection process, knowledge extraction or pattern determination process is imitated from the observations. ML has the following subdivisions based on the observations summarized from [17]. They are;

- Supervised learning,
- Unsupervised learning,
- Semi-supervised learning and
- Reinforcement learning.

The ML process is viewed as two phases, namely, (a) learning phase and (b) prediction phase. The training data is fed to the learning phase for predictions. In the prediction phase, the predicted results are obtained for the new data regarding the concerned trained model.

II. MACHINE LEARNING APPROACHES

The following section deals with the machine learning approaches.

Supervised Machine Learning (SML): SML approach's aim is to learn the mapping function 'f' from the input variable (X) to the output variable (Y) as represented in the equation (1) summarized from [18].

$$Y = f(X) \quad (1)$$

The mapping function tries to estimate during the arrival of novel input data (X) and forecast the corresponding output variable (Y). This algorithm learns from the training set and stops learning when the acceptable performance level is reached. The subdivisions of SML are classification (output variable needs categorization) and regression (output is real value). Some of the examples of SML algorithms are linear regression, random forest and Support Vector Machine (SVM).

UnSupervised Machine Learning (USML): The objective of the USML is learning, understanding and exploring the unlabeled input data (X) without historical data [19] and [17]. The USML is subdivided into association (discover rules to describe the data) and clustering (discover inherent group in data). Examples of USML include apriori and k-means methods for association and clustering problems, respectively.

Semi-Supervised Machine Learning (SSML): The SSML is considered as a mixture of SML and USML, and arises when huge unlabeled input data (X) with few labelled data (Y) [18]. That is, the mixture of very few labelled data and huge unlabeled data. The SML and USML algorithms can be applied to get knowledge and discover the data.

Reinforcement Learning (RL): The objective of RL is to map the actions according to situations to yield the maximum reward. During the mapping process, the algorithm should take in to account the immediate next and future rewards too. Some of the examples include Temporal Difference, Markov decision, Q-learning and Monte-Carlo methods [20].

The understanding of data types also referred as measurement scales in ML becomes mandatory for exploring the data analysis. Understanding the data type helps in dealing the right visualization (ML) method. The data types are broadly classified into (1) Categorical and (2) Numerical values. The former type represents the characteristics and the later represents the countable data. Categorical data is sub-divided into (a) Nominal type, to label the discrete variables without order, and (b) Ordinal type, to label the discrete variables with ordering. Numerical

Revised Manuscript Received on August 05, 2019.

R.P. Ram Kumar, Professor, Department of CSE, Malla Reddy Engineering College (A), Secunderabad, Telangana, India.

Sanjeeva Polepaka, Associate Professor, Department of CSE, Malla Reddy Engineering College (A), Secunderabad, Telangana, India.

Lazarus S F, B. Tech., Department of CSE, Malla Reddy Engineering College (A), Secunderabad, Telangana, India.

Dasari Vamsi Krishna, B. Tech., Department of CSE, Malla Reddy Engineering College (A), Secunderabad, Telangana, India.

data is further sub-divided into (a) Discrete data, i.e., the countable data and (b) Continuous Data (represents the measurable data) is subdivided into interval and ratio data [21] and [22]. Table 1 shows the summary of applications of ML algorithms on the corresponding data types summarized from [23].

Table 1 Categorization of ML Algorithms

ML algorithm types / Data types	SML Algorithm	USML Algorithm
Discrete values	Classification or Categorization	Clustering
Continuous values	Regression	Dimensionality Reduction

III. MACHINE LEARNING TECHNIQUES

The following section deals with the introduction to ML techniques summarized from [1], [2], [4], [5] and [6]. They are;

A. Supervised Learning:

It is the common method adopted in industry use cases. Here both inputs, as well as desired outputs, are provided to a system with the aim to classify the future data. It is a routine process when an algorithm learns from a new training dataset. Self-driving cars, Chabot's, face recognition methods adopts Supervised Learning approaches.

B. Unsupervised Learning:

It is a complicated process and prone to use in smaller applications. "Teaching themselves" one of Machine Learning's property implies Unsupervised Learning. There are no explicit target outputs available in this method. In this approach, the classification is carried without the prior knowledge, that is, there is no prior knowledge about the data being classified. For example, clustering and association related problems fall into this learning approaches.

C. Semi-Supervised Learning

It is the study of how computers learn in the presence of labeled and unlabeled dataset. This technique put forths the protocol that generation of labelled data is costlier than the unlabelled data. Examples of this learning approaches are speech analysis and web content classification.

IV. MACHINE LEARNING ALGORITHMS

The following section deals with the description regarding the traditional ML algorithms summarized from [5], [7] and [8]. They are;

1. Naïve Bayes Classifier (NBC) Algorithm

NBC algorithm helps to classify a webpage, a document, a lengthy text note or an email, it is not easy to do it manually. Its popular application is spam filtering. The classifier function assigns a population's element value as one of the accessible categories. Sentiment Analysis is also its popular application. It performs well when we have categorical input variables.

2. K-Means Clustering Algorithm

When a user searches for a keyword "jaguar" in the World Wide Web (WWW), results will be the aggregation of Jaguar animal, Jaguar car and Jaguar Mac Operating System. The similar characteristic featured contents (may be text, images, videos, etc) are grouped and displayed to the user. The grouping (also referred as clustering) of similar features is done by K-means clustering Algorithm. Further, this algorithm is adopted by many search engines (namely, Google and Yahoo) to group the web pages based on the similarity and identifies 'relevance rate' of concerned search results.

3. Support Vector Machine (SVM) Algorithm

SVM, a supervised algorithm, is used for classification problems. SVM learns about classes of input dataset which are differentiated by a line in the dataset to classify the new data. It is categorized as Linear and Non-linear SVM. Linear SVM can classify using just a hyperplane but it's not possible for non-linear SVM. This technique does not make any substantial assumptions on the data. It is used to forecast stock market values.

4. Apriori Algorithm

Apriori algorithm, an unsupervised algorithm, depicts association rules from the input data set.

Association rule entails that on occurrence of item 'X', item 'Y' happens definitely, similar to "if-then" rule. For instance, ***IF*** a person purchases bike, ***THEN*** certainly they will purchase helmet. Critical observations on such purchases are examined to ensure the optimum decisions. Detecting unfavourable drug reactions and auto-complete applications are its applications.

5. Linear Regression (LR) Algorithm

LR algorithm depicts the association between the two variables and how they influence each other. It shows the impact on the dependent variable (termed as factor of interest) when the independent variable (termed as explanatory variables) is changed. It is a wide spread ML technique with rapid speed. Estimating sales and risk assessment is its applications.

6. Decision Tree Algorithm

It uses the branching method to represent the possible consequences for a decision with respect to specific scenario. The decisions in a tree are inversely proportional to the expected precision. Two sub-categories of decision tress are Classification and Regression trees. The classification and regression trees are used during the classification of nature and continuous/numerical variables, respectively. The decision tree classification is mainly used in finance and banking sectors to classify the loan applicants based on the probability of payments in a specific periodic intervals.

7.Random Forest Algorithm

Random Forest algorithm works by creating a cluster of decision tree with a subset of randomly chosen data. The prediction performance is improved by repeated training of a model with random samples. The final prediction is made from the integration of decision trees output followed by the polling procedure.

8. Logistic Regression Algorithm

Mainly this type of classification is applied to classify the discrete classes. For instance, to detect the mail as spam or not, online transaction made as a genuine or fraud, tumor classification as benign and malignant, etc. This type of regression transforms the desired output using sigmoidal function to determine the probability value. If the resultant classification is with two outputs (for instance, benign or malignant), then it is referred as Binary Logistic Regression. On the other hand, if the resultant output is of categorical values (for instance, dogs, cats, horses, etc), then it is referred as Multi-Linear Logistic Regression method.

V. MACHINE LEARNING APPLICATIONS

The following section deals with the insight on ML applications summarized from [9] and [10].

Spam Detection: Received emails are identified whether they are spam if yes then they are not shown to the user with regular emails in their inboxes. All these spam emails are maintained in a separate folder. This is done by learning how to recognize a spam mail by identifying the characteristics from newly received ones.

Face Detection: Identifying faces from a given number of photos and tagging them automatically if next time the same face is detected for a new photo. Currently, Facebook is popularly known for using this technique where when we upload a picture some suggestions of friends are automatically detected and shown to the user whose friends are in the picture. For example, Google photos separate all the pictures according to people in it.

Credit Card Fraud Detection: According to customers past transactions, if there are any inappropriate purchases made then the customer is warned immediately about the condition.

Digit Recognition: Machine's camera detects postal codes that are handwritten and arranges all the letters according to the geographical locations they have to reach. The machine is trained to learn handwritten numbers and transforms into digital signs.

Speech Understanding: Deals with listening to a speech by the user, understand user intentions process what machine has understood. Machine is expected to follow instructions from the users accurately. "Cortana" by Windows, "Siri" by Apple and "Okay Google" by Google are popular and successfully implemented applications of this technique.

Product Recommendation: With all the data of a customer's past purchases or interests online, the machine will recommend some products which would attract customers to view them and maybe even purchased. Flipkart, Amazon and many other e-commerce sites have been implanting this technique where we receive only recommended products as advertisements.

Medical Diagnosis: For detecting diseases more accurately, hospitals these days are using machines that could decide whether a person is affected with any diseases for symptoms he/her has, with the help of complete data about all diseases and symptoms. IBM designed a system with 95% precision in predicting the cancerous images in contrast to 75%-84% precision by doctors.

Stock Trading: Given the current and past price fluctuations of a stock, the machine decides to hold or sell the stock for better service of the customer(s).

Customer Segmentation: With the help of past behavior patterns, the ML algorithms tries to predict the number of users who will choose the paid versions from the trial versions. Amazon Prime has implemented this technique.

Chat smarter with Allo: Allo is a messenger application by Google which will learn from its users, how they are responding to what kind of messages and recommend the user with a response that he /she has thought of typing.

Financial Service: Companies can identify the company insights of financial sector data and can overcome the occurrence of financial fraud. It is used to identify the opportunities for investment and trade. We can also prevent the financial risks prone institutions by using cyber surveillance and take necessary actions to prevent fraud.

Transportation: By the travel history and pattern of travelling in various routes, machine learning helps in Transportation Company to predict the problem in routers and advice their customers to choose a different route. Transportation firmly uses machine language to carry out data analysis and data modelling.

Few other applications of ML are as follows:

Computational Intelligence: For many years computational intelligence is being developed actively. Constant improvements and improvements are being carried out on classical methods like machine learning algorithms. These days computational intelligence has been for many applications directly or indirectly.

Natural language processing: It is a field that which involves both computer understanding and manipulation of human language and its good in gathering new possibilities. It is mostly seen in a large pool of legislation or other document sets, trying to discover new patterns or to root out corruption. It is a better way to analyze, understand and find the meaning of human language easily and smartly. By using NLP developer can perform tasks such as speech recognition, entity recognition, automatic translation, and summarization.

Discrete Event Simulation is a technique where patients are modeled as an independent event associating each with some attribute information like age, weight and problematic scenarios, etc. Natural Language Processing is a technique used for system to read the physician's notes and convert it to digital data. Proprietary Predictive model is used to make predictions such as admissions can be predicted by hospitals to spread expertise which is in short supply. Disease prediction and diagnosis is achieved by helping radiologists to make intellectual decisions with radiology data (for

example, CT, Radiographs and MRI).

Sentiment Classification: It is difficult to classify documents based on sentiment rather on topic, like separation of comments into positive and the negative categories. Hence, the following ML techniques are adopted to classify the sentiments and subjected to further analysis.

- Naïve Bayes method is a trendy algorithm for text classification process; it is given some texts and its results to learn on how to decide about new text.
- Maximum Entropy classification it is an alternative technique to work on natural language processing although it fails to perform sometimes.
- Support Vendor Machine is highly effective and can perform better than the other two techniques but they are large margin classifiers rather than probabilistic classifiers. It is useful very much because classifying texts according to sentiments is not easy for human to carry out, whereas machine learning has made it simple.

Mobile Devices: ML techniques when applied on portable devices like Sensors, Smartcards, Smartphones, computing handheld and automotive systems had proved efficient. As mobile terminals are improving a lot these days mobile technology has encouraged technological advancements. The techniques like Naïve Bayesian, Decision trees and C4.5 are supportive for mobile devices. These techniques major categorised as supervised, unsupervised and reinforcement these are used to represent learning methods.

Here, machine learning approach is provided with some training examples for given function. Support Vector Machines (SVM), K-Nearest Neighbour (KNN), Random Forests and Decision trees are some of supervised algorithms. There is no supervisor available and learning in the Unsupervised ML category. Training samples and testing samples uses these techniques. Each ML technique has few strengths and weakness. It gives brief about techniques for application in mobile devices. It presents performance measures for machine learning algorithms.

Data Mining: There are two styles of data mining algorithms summarized from [13], [14] and [15]. They are (1) Predictive, and (2) Descriptive

Predicting the value of special attribute using the other attribute is called predictive whereas deriving the patterns that summarize the relationship among data points is called descriptive.

Supervised Data Mining: It is a pre specified target variable. Its goal is to specify the relationship between predictors and target. Model is provided with many training data where the target is known. It is applied to the data where the target is unknown

Unsupervised Data Mining: It is mostly used to determine whether the classes or clusters exist in data and also for exploratory analysis. All variables are treated in same way.

Pattern Recognition: Pattern recognition is the other main problem in machine learning. Pattern recognising algorithm generally aims to provide a reasonable answer for all possible inputs and to perform closest to matching of input. It uses two learning methods, namely (1) Supervised leaning and (2) Unsupervised learning method.

VI. CONCLUSION

The paper presented an overview and insight on the Machine Learning approaches and techniques applied to various applications. Apart from the applications, the paper also put forth an idea of applying the algorithms and its performances to various scenarios. For instance, whenever there exists a sample, the supervised machine learning algorithm comes in to the picture, whereas on the other hand, analyzing the data without existing data, the clustering technique from unsupervised machine learning algorithm is very useful in providing the solutions. As a future enhancement, authors would like to work on intelligent decision support systems integrated with machine learning techniques for predicting the cardiac diseases.

Automatic Telugu Handwritten Character Recognition with the Help of Legendre-Sobolev Divergent Machine Learning Model

P. V. Ramana Murthy, CH. G. V. N. Prasad

Abstract: ***Online handwriting recognition or character recognition is the process in which a handwritten message is recognized by processing the handwritten data. It is the way toward changing over manually written characters to machine design. In penmanship, the strokes are made out of two arrange follows in the middle of pen down and pen up marks. Wide scope of highlights is extricated to play out thse acknowledgment. A complete internet hand-written recognition system for Indian language such as Telugu that addresses the ambiguities in separation just as recognition of buttons the recognition relies on conceptual model of penmanship structure joined with either a prejudicial model for stroke command. Such a methodology be able to flawlessly incorporate language and content data in the reproductive model then manage comparative and non-comparable strokes utilizing the single discriminative stroke grouping model. In this examination, we are utilizing disparate Legendre Sobolev conditions with the assistance of AI model, to such an extent that accomplishes 99.65% precision and improved the condition of craftsmanship esteem.***

Index Terms: ***Automatic telugu handwritten, machine learning, Legendre sobolev divergent equation.***

I. INTRODUCTION

The acknowledgement is performed in a simple base up design, beginning through the strokes, also the ambiguities at every phase are protected as well as moved to the following phase aimed at getting the greatest plausible outcomes at every phase. We additionally existing the aftereffects of different pre-handling, highlight determination also arrangement thinks about on a huge informational index gathered from local language journalists in 2 diverse Indian dialects: Malayalam as well as Telugu. The framework accomplishes a stroke level precision of 95.78% as well as 95.12% on Malayalam and Telugu information, separately [1]. The Akshara level exactness of the framework is about 78% on a corpus of 60, 492 words commencing 367 authors. The field of acknowledgement of manually written content is as yet a fascinating zone of research. Numerous writers have accomplished amazing outcomes in the field of manually written numbers for English digits however just a couple of them consume investigated the territory of numbers written in Indian provincial contents like Telugu. Penmanship acknowledgement is a difficult assignment that has been seriously examined for a long time in the field of PC vision and example acknowledgement. Because of difficulties similarly the assortment of composing styles, strokes also shapes the exactness is as yet restricted. Much study has been performed in the sector of English numerals,

Revised Manuscript Received on July 9, 2019

P.V. Ramana Murthy, Research Scholar, Rayalaseema University, Kurnool, AP, India (Associate Professor, Dept. of CSE, Malla Reddy Engineering College (Autonomous), JNTU-H Hyderabad, India)

Dr. CH. G.V.N. Prasad, Professor, Dept. of CSE, SICET(A), JNTU-H Hyderabad, India

but there is a long way underneath exploring local numerals. India is a multilingual nation, which has 22 noteworthy dialects transcribed in 13 distinct contents. Right around 460 million individuals in India utilize local contents for composed correspondence like topping off the bank structure or transfer messages, the numbers are composed on those are in local contents which are here and there hard to distinguish. Along these lines, a legitimate acknowledgement framework is expected to recognize those digits and words. Highlight extraction assumes a significant job in the accomplishment of any acknowledgement framework. It necessitates that highlights ought to hold invariant attributes inside a similar class though consuming discernible qualities amongst different classes. Szarvas et al. [2] assessed the consequently improved highlights educated through the Convolution choice trees on passer-by location also clarified the AI mix gave the most noteworthy precision. Since both CDT and ML have just accomplished wonderful exhibitions in number acknowledgment, our concentration in this examination is to use their benefits through joining those composed [3]. The effort existed in the paper [3] centers around the digits written in 4 local dialects: Bangla, Devanagari, Oriya also Telugu. Segment 2 provides a short depiction of the condition of-workmanship methods (Literature Review). Segment 3 depicts the hypothetical parts of the procedure basic for getting it. Segment 4 depicts the anticipated work in full detail. In Section 5, analyses also results are quickly clarified. Area 6 has a talk in regards to the outcomes acquired. At long last, the work is finished up in area 7 with a touch of clarification in regards to future research.

II. LITERATURE REVIEW

In the sector of transcribed English numerals, some notable research has also been performed, but the range of numbers published in any of the regional dialects was not so studied. In[3], Surinta et al. 2013 used personality form recorded by 8-directional coordinates in conjunction with the nonlinear SVM classifier to acknowledge Bangla Numerals and achieved 96.8 times accuracy. Xu et al. [5] built up a various leveled Bayesian system which proceeds the database pictures legitimately as the system input in addition to arranges them utilizing a base up methodology. 87.5% acknowledgement precision has remained accomplished through an informational collection comprising of 2000 written by hand test pictures.

In (Khan et al., 2014) [6], Sparse portrayal classifier on behalf of Bangla number acknowledgement is presented where the acknowledgement rate of 94% was accomplished. In [7],

a quad-tree founded list of capabilities be utilized; the precision rate of this model was 93.38%. HBDR [Handwritten Bangla Digit Recognition] utilizing MLP stood exhibited in (Basu et al., 2005) [9] where the normal acknowledgement rate utilizing 65 concealed neurons achieves 96.67%. Das et al. [4], suggested a hereditary calculation created district testing methodology also accomplished 97% precision. All around as of late, Convolutional Neural Network (CNN) is utilized "Manually written Bangla Character Recognition" (Rahman et al., 2015) [10] with no element removal in earlier. The exploratory outcomes demonstrate that CNN achieves superior to elective techniques. For acknowledgement of Devanagari Numerals, Authors in [12][Arya et al. 2015] consume utilized Gabor channel constructed component descriptor through 3 distinctive channel sizes viz. 7x7, 19x19 also 31x31. The last characterization is implemented utilizing the Nearest Neighbor also SVM classifiers. The 98.06 percent acknowledgement accuracy is achieved. In[13] Showmik et al., grid-based Hausdorff segregation is suggested to provide a identifier speaking at the object room to the hand-written numbers. For setup, the Arbitrary Forest classifier is used and 93.03 percent accuracy has been achieved. In[14], Johnson et al. suggested an edge-dependent OCR structure produced by a dim pixel with either a zonal mass concentrate. Model Irregular Forest was used as a classifier. The 92.57 percent acknowledgement accuracy was achieved. Contractive self encoders were used in[15], which teaches the features by capturing data types. SVMs have been used to characterize and 96 percent accuracy was achieved. In[16] Prabhanjan also Dinesh et al. 2016, the near and global hints were deleted and SVM was used to arrange. A 98.77 percent accuracy was achieved. In[17], Mishra et al. used linear cosine shift (DCT) and linear wavelet shift (DWT) to acknowledge Oriya Numerals and achieved 92% and 87.50% accuracy. For the recognition of Odia numerals, the identification of form features based on the bi-quadratic interjection approach is demonstrated in[18]. In[19] Pujari et al. performed the character recognition of Odia numerals using SVM. They used perspective and hint of ebb and stream to obtain a recognition level of 95 times. In 2014, in addition to the Nave Bayes classifier, Sarangi et al.[20] calculated the suitability of LU factorization as well as asked for 85.30 percent accuracy. The author suggested a method to interpret Handwritten Telugu scripts using Zoning Features for the acknowledgement of Telugu numerals, In[21]. The acknowledgment precision is observed to be 78%. In [22] Saikumar, K explains deep learning based spinal card injury regarding image processing relations to machine learning mechanisms.

III. EXISTED WORKS

The existed methodology depends on the idea of crossover classifier. Our perception is that the half and half classifier repays the points of confinement of the separate classifier through joining the benefits of together. Fig.2, clarifies the projected strategy. Right off the bat, the digits pictures on behalf of preparing are pre-processed hooked on a structure that can be effectively feed addicted to the classifier, at that point highlights are extricated from the pictures utilizing CNN. At long last, grouping is performed utilizing SVM. In this paper, we have considered four noteworthy dialects to be specific Bangla, Devanagari, Oriya also Telugu. ISI Kolkata dataset was used for Devanagari, Bangla and Oriya Numerals, which includes 22556 instances consisting for Devanagari by 1049 individuals. There are 23392 instances for Bangla consisting of 1106 individuals and 5970 samples from 356 individuals for Oriya. This dataset was compiled from 368 parts of correspondence, 274 request forms of occupation and an unusually organized data collecting system. Telugu numerals used the CMATERdb dataset. It includes three thousand instances, three hundred per digit. The images of the instance are provided in Fig.

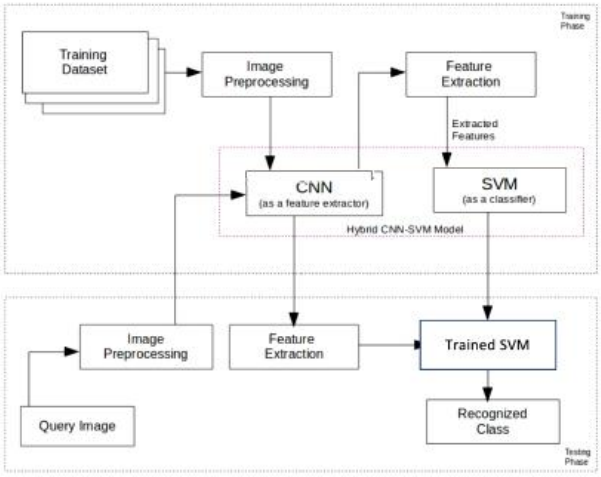

Figure: 1 Existed Work

Table :1 sample of digits

English Numerals	Sample Handwritten Numeral Images			
	Bangla	Devanagari	Oriya	Telugu
0	০	०	୦	౦
1	১	९	୧	౧
2	২	२	୨	౨
3	৩	३	୩	౩
4	৪	४	୪	౪
5	৫	५	୫	౫
6	৬	६	୬	౬
7	৭	७	୭	౭
8	৮	८	୮	౮
9	৯	९	୯	౯

The motivation behind pre-preparing is to improve the picture information and upgrading the picture by evacuating undesirable mutilations for additional handling. In this stage, we pre-process the dataset. Every picture in the dataset is changed over addicted to grayscale then after that resized to 28 X 28. In this stage, we utilize a Convolution Neural Network to concentrate highlights commencing the pictures. CNN consequently concentrate highlights from the crude pictures while giving a specific level of invariance to interpretation and scaling. The photo images pre-handled are reinforced into the CNN data section and the last pixel results are handled as hints.The development of the model suggested is shown in Fig. 1.

At this level, in the SVM classifier, the highlights divided from the CNN model are encouraged. Bolster Vector Machine has been used to rate the numbers in one of the 10 categories with two unique part capabilities: Linear and RBF Radial Base Function). Table: 1.Explains the depiction of images in a CNN sheet midway. First, we're giving the model an image, pre-forming it and producing an item vector using CNN. Then these examples are urged to recognize the number in the SVM classifier.

Figure: 2 Existed Works Based On Non-Trainable And Trainable Parameters

This methodology demonstrated to be very delicate to the nearness of numerous ascenders or descenders, bringing about mistakes of the center stature gauge. Additionally, short words can be risky. An optical assessment of one hundred words, haphazardly picked tests from misrecognized test information, appeared around 33% of the acknowledgment blunders being because of conflicting slant or center stature estimation. By this get 98.3 % exactness for capitalized and 86.7 % precision for bend molded penmanship.

IV. PROPOSED SYSTEM

The proposed work is an endeavor to build up an acknowledgement framework for perceiving the transcribed digits written in one of the local dialects like Telugu. The proposed framework initially standardizes the info picture having single digit from that point ML functions as an element extractor while Legendre Sobolev unique condition as a classifier. Assessments were targeted to ISI Kolkata's benchmark database (with Bangla, Devanagari, and Oriya dialect numerals) also CMaterdb (with Telugu language numerals). The results show that our system works highest for Devanagari English with an accuracy of 99.41% and for Bangla, Telugu, and Oriya, the accuracy is 99.14%, 99.16%, and 94.54% individually. In this way, the presentation of the proposed methodology is superior to anything condition of-workmanship approaches.

$$(f,g)=\frac{1}{2}\int_{-1}^{1} f(x)g(x)dx + M[f'(1)g'(1)+f'(-1)g'(-1)], \quad \text{-- eq(1)}$$

For each capacity f with the end goal that (f, Bˆ n) exists for n = 0, 1 ... present the Nth incomplete whole of the related Fourier-Sobolev arrangement for bend molding forecast appeared in eq(1)

$$S_N(f)=\sum_{n=0}^{N} c_n(f)\hat{B}_n(x) \quad \text{------ eq(2)}$$

Eq(2) traces the continues curve tracking such that if any single pen down and pen up strokes are identified easily. This is main advantage compared to existed work[1][2][3]

$$\begin{gathered} cn(f) = (f, B\hat{}\ n). \\ ||SN\ f||Lp([-1,1]) \le C||f||Lp([-1,1]) \quad \text{----- eq(3)} \\ \forall N \ge 0, \forall f \in L\ p\ ([-1, 1]). \end{gathered}$$

This eq(3) supporting to main strokes resembles at eq(1).

$$(f,g)=\frac{1}{2}\int_{-1}^{1} f(x)g(x)dx + M[f'(1)g'(1)+f'(-1)g'(-1)]$$

----- Eq(4)

Eq(4) explains that integral functions with 1st order multiplications and shiftings, these paramters link with

$$(f,g)=\int_{-1}^{1} f(x)g(x)dx + \sum_{k=1}^{K}\sum_{i=0}^{N_k} N_{k,i} f^{(i)}(a_k)g^{(i)}(a_k), \quad N_{k,i}>0$$

--- Eq(5)

Eq(5) has been examined in and for I = 0 in [4]. Likewise, we allude to [12], where some intriguing outcomes about Fourier developments as for Sobolev symmetrical polynomials are acquired.

$$P_n^{(\alpha)}(cos\theta)=\frac{1}{\sqrt{\pi n}}\left(sin\frac{\theta}{2}cos\frac{\theta}{2}\right)^{-\alpha-1/2} cos(k_\alpha\theta+\gamma_\alpha)+O(n^{-3/2}).$$

------- Eq(6)

Eq(6) explains angle modifications depending upon the theta value p_n is the probability of error strock and pen down and pen up uproach.Telugu character recognition (TCR) is based on an optical frame that allows a gadget to differentiate the personalities obviously. There are a few uses of ML, few of which are as follows, such as programmed mail arrangements, bank controls, library mechanization, vision handicapped assist perusing, language processing and safeguarding apps that give researchers a lot of excitement. The reputation accuracy is greater in OCR frameworks for printed texts as opposed to Telugu structures published by text pattern recognition (THCR)[1, 2, 3 and 4]. In essence, there are two types of HCR: online and offline. The information is captured in Online HCR throughout the

calligraphy process with the assistance of a distinctive brush on an electronic substrate, although accounts are verified in Offline HCR images of pre-written message[5]. Precision is littler for Offline HCR as comprehensive in text[1, 2 and 3], it is real in view of differential point problems, decipherability, overwriting, and verification of document and disturbance problems[2]. Similarly, there are no available norm or benchmark information, and dissecting Indian content on HCR could be a notable deterrent. Some conventional libraries such as MNIST, NIST, CEDAR and CENPARMI are accessible to Latin numerals[6], as there is no institutionalized Indian content database as it may be. Little records that are collected in the study facility[6] support the previous exams. Clients ' descriptive quality is one of all comprised teaching characteristics. It's a boring errand to distinguish after they separate from the formed personalities.

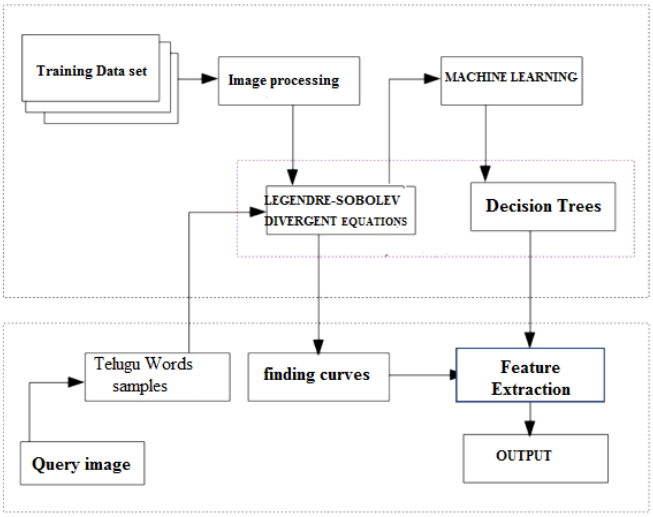

Figure: 3 block diagram of proposed work

Training data set is collected from MIT data blog which is available in web site, collected samples and applying machine learning and Legendre-Sobolev equations. Machine learning is applied with the help of Decision tress concepts. Here number of trees depending upon no of available samples. Shown in figure:3

$$\int_0^1 |\hat{B}_n(x)|^q dx \sim \begin{cases} c & if\ q < 4 \\ log\ n & if\ q = 4 \\ n^{q/2-2} & if\ q > 4 \end{cases} \text{-------- Eq(7)}$$

Equation 7 explains that the curve fitting and feature extraction methods based on proposed block diagram

$$\int_0^1 |\hat{B}_n(x)|^q dx \sim \int_0^{\pi/2} \theta\ |\hat{B}_n(cos\theta)|^q d\theta \text{ -------- Eq(8)}$$

Equation 8 is a supproting equation this decides that hand curve and angle method

$$= O(1) \int_0^{n^{-1}} \theta\ n^{q/2} d\theta + O(1) \int_{n^{-1}}^{\pi/2} \theta\ \theta^{-q/2} d\theta \text{ ---- Eq(9)}$$

Equation 9 is single curve hand down and hand up approach.

$$= O(n^{q/2-2}) + O(1) \text{-----Eq(10)}$$

This euation 10 is final orientation of proposed method.

V. RESULTS

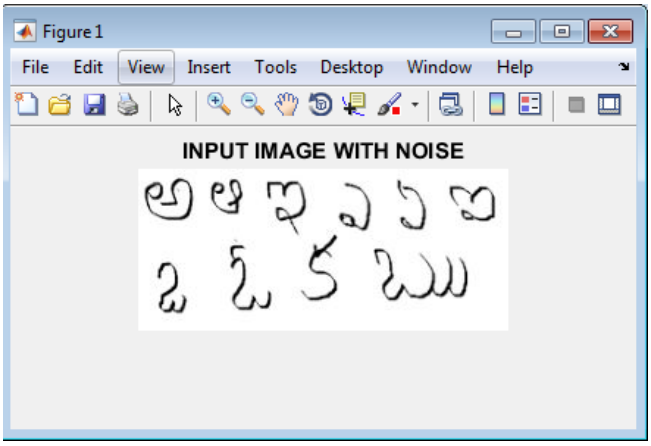

Figure : 4 input image

Figure : 5 output image

Figure 4 and 5 explains that proposed method results which are obtain from machine learning tool box and calculated errors strokes like single stroke and hand down & hand up approches. Output contains no errors and calculating efficiency. Using proposed equations with machine learning decission trees.

VI. CONCLUSION

Manually written character acknowledgment for Telugu characters is investigated throughout this work. A total assortment of 1500, 750 examples utilized for preparing also 750 examples for the testing territory is created and furthermore standardized to 300x300 pixels. These methods give better exactness by utilization of various classifier. This survey gives data about various classifier utilized in character acknowledgment methods. This far reaching dialog will give knowledge into the ideas included, and maybe incite further advances in the territory. The guarantee for what's to come is an altogether higher presentation for pretty much every character acknowledgment innovation territory. The popularity accuracy obtained by exploitation of Legendre-Sobolev divergent machine learning is 98.25%. (with all strokes).

Abstract

As per the global digital report, 52.9% of the world population is using the internet, and 42% of the world population is actively using e-commerce, banking, and other online applications. Web services are software components accessed using networked communications and provide services to end users. Software developers provide a high quality of web service. To meet the demands of user requirements, it is necessary for a developer to ensure quality architecture and quality of services. To meet the demands of user measure service quality by the ranking of web services, in this paper, we analyzed QWS dataset and found important parameters are best practices, successability, availability, response time, reliability and throughput, and compliance. We have used various data mining techniques and conducted experiments to classify QWS data set into four categorical values as class1, 2, 3, and 4. The results are compared with various techniques random forest, artificial neural network, J48 decision tree, extreme gradient boosting, K-nearest neighbor, and support vector machine. Multiple classifiers analyzed, and it was observed that the classifier technique eXtreme gradient boosting got the maximum accuracy of 98.44%, and random forest got the accuracy of 98.13%. In future, we can extend the quality of web service for mixed attributes.

1. Introduction

The WWW was invented by Tim Berners Lee and a group of members in 1994, European Particle Laboratory in Geneva, Switzerland, the idea of hypertext information to keep personal information. W3 means a client program in one system which starts to display one object by clicking an option and retrieve another object from another system which is at remote server using network communication [1].

The web services are self-contained, loosely coupled to describe modular applications can be designed for interoperable business applications. The internet is mostly used B2C, B2B, e-commerce, and others, the growth of IT across companies worldwide to perform business activities. Web service uses technologies like XML, WSDL, UDDI (service discoveries), and SOAP protocols. Web service (WS) provided by internet, based system. The web page can be accessed by locating the service registry. The elements are used to build the web application one of the important web components is UDDI; the protocols are used for searching and publishing services. Web services use SOA architecture, which has three are roles, provider, requester, and registry. A service provider is the one who can publish, searching, and finding services. To discover applications by UDDI is a registry of services, the requestor is the end users who want to access the web services which are published by the service provider. Web service (WS) discovery is to identify the service with descriptions (WSDL), and APIs of business services. WS links the use of each WS interface.

In 2018, Global Digital Suit reported, 4 billion people (approximately) were using the internet across the globe among the total population of 7.593 billion, internet users are 52.95%, i.e., 4.021 billion, an active social media user 42.09%, i.e., 3.196 billion. The unique mobile users are 67.62%, i.e., 5.135 billion active mobile users in that 38.95%, i.e., 2.958 billion and applications like facebook, twitter, and other web-based applications. The applications are

Received October 20, 2018; Revised February 12, 2019; Accepted March 12, 2019

increasing very rapidly the designer and developer to ensure the quality design and development of applications which meet the client demands of user satisfaction of services [2]. Web service uses a dynamic business environment and user interactions, service quality, and satisfaction. For example, e-commerce, web service using SOA architecture, interactions of type and applictions used in large, medium, and small service users, features with service components have properties, functions, and operations [3]. Day to day business activities by web services made with quality of services, web service selection is the most important for the consumer to access applications. The rest of the paper deals with section 2 as related works, section 3 is the proposed approach, section 4 provide the results and discussions and finally section 5 ends with a conclusion and future scope

2. Related Work

M A Almulla et al. [4] proposed a model to classify into specific domains operated on text, similar service by the Fuzzy expert system; the results are compared with other methods. The WS quality dataset UDDI registries have 205 services which are classified into 11 classes or domains such as business, communication, and communication and others. Makhlughian et al. [5] use of CBA tool the services on demand, quality constraints, execution time, and accuracy of selections. Limitations do not know the importance of specific quality parameters. Mohanty et al. [6] used QWS dataset contains web services which can be classified into four categorical values using Markov Blanket, Naive Bayes, and Tabu search, the WSRF from data, naive Bayes is 85.62% using QWS data, and others methods used. The limitations are a quality model available, but prediction accuracy is low. Chen Li. et al. [7] use of models Naive Bayes, supporting vector machine 391 web services into service classifications using rough set theory classification of web pages into nine different classes like education, food, economy and weapons, limitations do not provide the best quality of web service.

The Guosheng Kang et al. [8] use of collaborative model filtering (CF) is a method to predict the interest of users, choice, preference, likes, and dislikes. In CF approach there are three concepts first, functional relations (keywords, input, and output), second is the score of the cosine similarity metricsof the users, and third is the utility operations the QoS into high and low values. Mohan Patro, et al. [9] used classifiers to classify the WS on QWS data set that are Fuzzy related techniques with feature selection, Gain ratio and Information gain with three methods which are compared. Hussein Al-Helal et al. [10] proposed an algorithm reparability as a metric to determine the web services plans equal or more tolerant plans. To discover and re-use web services in the organization to select the services which are business and quality of service (QoS) needs. The QWS dataset is used for experiments.

RK Mohanty et al. [11] proposed WS classification using PNN, BPNN, Treenet, GMDH, SVM, J48, CART to predict quality, identify and measure the quality and user satisfaction. DA Adeniyi et al. [12] used methods of KNN, CART, neural network (NN) model in the study. The RSS readers' data class labels, website, data categorical values world, business, politics, sports, etc. WS classification J. Liu et al. [13] are using naive Bayes semantic web to describe an attribute of Web service using method data preparation, classifying of OWLSTC dataset, semantic web into seven different areas. The heuristic approach proposed by M Makhlughian [14] by pre-processing, classification according to QoS levels of candidate service and ranking and selecting the best service. Class association rules using QWS dataset with non-functional and security parameters are not addressed.

Quality need for non-functional web service, in the real-world dataset, 21358 web services, over 30 million real-world web services by various counties, failure due to some of the causes like HTTP bad request, server error, bad gateway, service not available, network un-reachable, connection refused, time out and the Response time of users [15]. Soumadip Ghosh et al. [16] method neuro fuzzy classifier input vector, fuzzification into artificial neural network (ANN) and classifier into defuzzification. Experimental results by the use of UCI repository dataset KDD, breast cancer, iris, and other datasets find the classification accuracies.

Web service design, consumers, re-use functionality. Ali Ouni etc. [17] proposed a hybrid approach which uses heuristic-based approach to the design quality of web interfaces. The experimental results conducted 26 real-worlds Amazon and Yahoo. Web service classified by selection, discovery, and composition. The Yilong Yang et al. [18] proposed a deep neural

network service classification approach. The 10000 real-worlds web services into 50 categories of values. Evelum Setoani et al. [19] use re-usable text classification in Bahasa Indonesia.

Web services demand, provide good solutions with the interoperable property. Multifaceted match making framework, web service quality, and user seeks best quality services. Sambasivam et al. [20] identified 21 quality parameters, and experiments conducted 1000 web services, service discovery and search. Xiong et al. [21] proposed a novel deep learning hybrid approach for web application recommendation and improving performance. Web-based applications increase rapidly very fast. The designer and developer ensure to provide high quality services for customer satisfaction.

Problem definition: The software developer aim is to design and develop the best application which will meet the user specifications (including functional and non-functional parameters) according to the service level agreement (SLA). Web service quality is measured by the ranking of the web application. The ranking of web services using classification and predictions. We have used QWS dataset for conducting the experiments to find web service quality using various data mining methods (i.e., classification and predictions). The classification of web service helps the software designer to improve quality and performance. The proposed model is shown in Figure 1. This is applied for this problem to solve and web service classifications using input dataset.

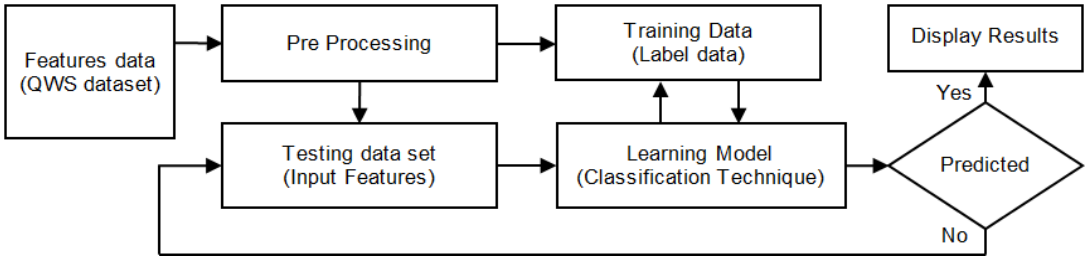

Figure 1. Quality of web service classification learning model

3. Proposed Approach

The internet-based applications quality is considered by non-functional parameters for satisfying the user requirements with functional parameters. The proposed model is shown in above Figure 1. The data mining algorithms are used to classify the quality of web services, i.e. QWS dataset. Initial stage use pre-processing, selection of training data with a testing dataset with use of various classification methods used to find a ranking of web services. Let the dataset consist of A_1, A_2,.., A_n each which belongs to class C_i, where C_i in {C_1, C_2,.., C_n} where C_i>= 2. Quality is most important, which compared with attributes like load distribution, service direction, throughput, cost, response time, and other elements. For example, e-commerce web applications provide functionality as per the SLA with satisfying quality parameters. The QWS dataset [22] was relevant objects in the domain. In this case, data contains various quality parameters such as response time, throughput, availability, accessibility, reliability, best practices, compliance, latency, and documentation. The classification of web services are Class-1 (high quality), Class-2m (quality), Class-3 (average quality), and Class-4 (poor quality services). This is applied for this problem to solve and web service classifications using Input dataset, learning methods (classification techniques such as random forest, artificial neural network, J48 decision tree, eXtreme gradient boosting, K-nearest neighbor and support vector machine) are used, and feature selections like response time, accessibility, reliability, throughput, availability, compliance, and best practices and training data to classify the data into categorical values (Rank 1, Rank 2, Rank3 and Rank4).The quality of web service QWS dataset consists of 2507 samples using classification approaches to find the accuracy of classification methods. Find the density of feature attributes response time is skewed left, availability is right side skewed, throughput is increasing and gradually decreasing, successability right side skewed, the reliability of curves, compliance curves, best practices at the range and class labeled ranked as 1, 2, 3 and 4, are shown in Figure 2. The QWS data read input, in initial stage pre-processing, training (labelled data) with testing (input data) using learning models such as

random forest (RF), Artificial Neural Network, J48 Decision Tree, eXtreme gradient boosting, KNN classifier, and SVM methods are used to classify and predict testing dataset into class labels(Class-1, 2, 3 and 4) for the experimental results conducted using R programming. The details of the algorithms are discussed below.

3.1. Random Forest

The random forest is a decision tree which has a collection of decision trees known as forest, the new object attribute classification of the class label, 1, 2, 3, and 4. The forest is chosen classification has the most votes overall tree in the forest. Algorithm1 explains random forest.

Algorithm 1. Random Forest

```
Input: QWS dataset
Output: Classification label class-1,2,3 and 4
Begin
   Step 1: The training set is N and sample training set in a growing tree
   Step 2: If input variables m< M each node, m is variable, M is a best to
           split node.
   Step3:  Find the Class label in the best split criterion leaf node.
   Step 4: Each tree grew at the maximum possible extent; then there will be no
           pruning.
End
```

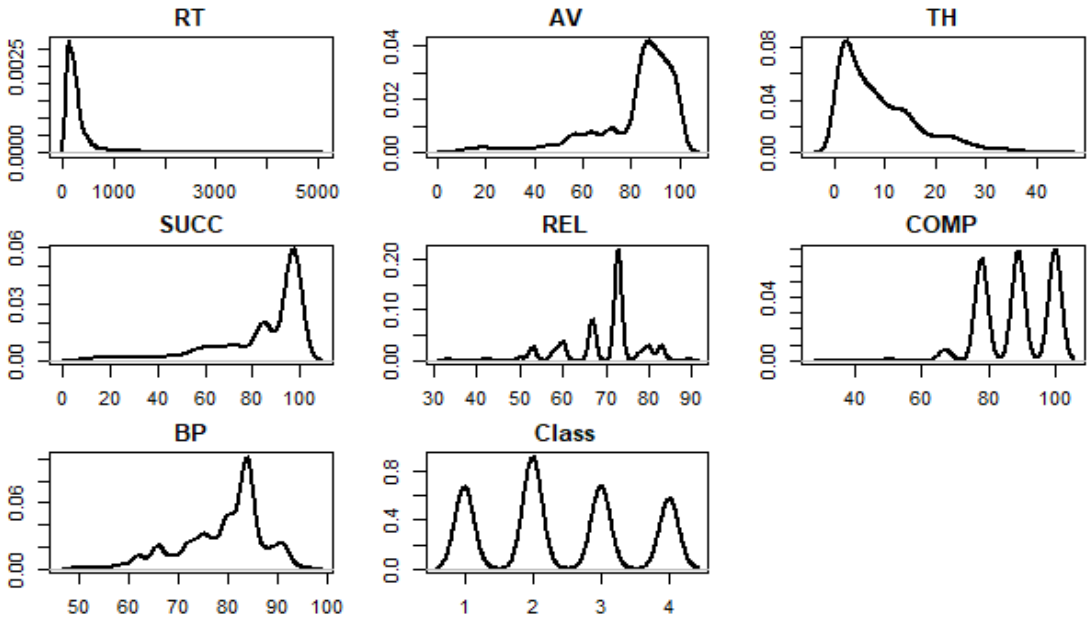

Figure 2. QWS data density values

RF classification, here we have used in experiments 500 trees, split each variable by 2, out of bag error (OOB estimate error)value is 1.79% using R programming. The results of random forest confusion matrix are shown in the Tables 1 and 2. It gives the comparative study of predicted class variables with observations.

Table 1. Random Forest-confusion Matrix

Prediction	Rank1	Rank2	Rank3	Rank4	Class Error
Class-1	583	2	2	6	0.016863406
Class-2	3	803	0	0	0.003722084
Class-3	1	1	587	10	0.020033389
Class-4	2	5	13	489	0.039292731

Table 2. Comparative Results with Actual Values asnd Predicted Classes Using Random Forest Algorithm Using Ten-fold Cross-Validation

Prediction	Observation	Rank1	Rank2	Rank3	Rank4	rowIndex	Mtry	Resample
Class1	Rank1	0.900	0.002	0.032	0.066	15	1	Fold01
Class4	Rank4	0. 062	0. 130	0.086	0.722	16	1	Fold01
Class3	Rank3	0.032	0.000	0.890	0.078	17	1	Fold01
Class4	Rank4	0.004	0.000	0.014	0.982	28	1	Fold01
Class1	Rank1	0.986	0.000	0.006	0.008	30	1	Fold01

Kappa and accuracy: Siegal and Castellan (1998), Carletta (1999), kappa control agreement P(A) for agreement change P(e). Kappa is an inter-rate qualitative agreement for categorical items and robust measure calculation, where Pr(e) is calculation, kappa is corrected measure classification for true classes, poor <= 0.2, Fair is equal to 0.2 to 0.4, moderate is in-between 0.40 to 0.60, good accuracy is 0.60 to 0.80, excellent measure is 0.80 to 1.0. Kappa statics is a mean for evaluating the prediction classifier performance across all instances. Classification measure for N items into mutually exclusive kappa measurement is described in (1):

$$\mathrm{K} = (\Pr\,(\mathrm{e}) - \Pr\,(\mathrm{e}))/((1 - \mathrm{pr}(\mathrm{e})) \quad (1)$$

Pr(a) probability of classification success, accuracy, Pr(e) probability to chance of success, Pr(e) replaced to Pr(b) agreement measure classification a and b, Summary of sample sizes of 2257, 2256, 2256, 2255, 2256, 2255 etc, by re-sampling results across tuning parameters with random forest classifier Cross-Validated(10 fold) and Kappa measurement are shown in Table 3.

Table 3. Random Forest Classifier Accuracy and Kappa Measurements of QWS Data Fine Tuning

S No	Random Forest Accuracy	Kappa Measure
1	0.9780699	0.9704352
2	0.9832524	0.9774364
3	0.9820508	0.9758201

3.2. Artificial Neural Network (ANN)

NN consists of an input layer which accepts input data here QWS dataset seven attribute values, the hidden layer used for weighing factors to calculate predictions and forward to the output layer, which predicts the class labels. A neuron is called processing elements (Artificial neuron is biological neurons). In Figure 3 shows ANN, let there be 'n' inputs {X_{i1}, X_{i2}, …, X_{ij}}, here we have taken seven input attributes of QWS data, Each X_{ij} is associated with weights Wij, Bias(c) is a network,used to calculate the net-input by adding input X_{ij}., Threshold (Θ_i), it is the reached to exceed the value of input neurons. Output (O) is after executing operations is a nonlinear functional (F_i) value [23, 24]. We have conducted experiments using neural network of QWS dataset 2507 samples, seven predictors and four classes 'Class1', 'Class2', 'Class3', and 'class4'. The generated Algorithm 2 is discussed below.

Algorithm 2. ANN: Neural network-classification and prediction of class labels of QWS data

```
INPUT:  D is an input dataset of training tuples which are associated with
        target values Rank1,2,3, and 4.
        L: learning rate of the network, Feedforward network use multilayers
        for accuracy
OUTPUT: A Trained NN with testing data to classify and predict class labels
        1,2,3 and 4

BEGIN
   Step1:  Initialize weights, bias and in networks and biases in the network
           Repeat until the condition is not satisfied
   BEGIN
      Step2:  Each training data records Xi, in D
```

```
    BEGIN
        Step3:  // Propagate input data forward to layer
        Step4:  For input of each layer with j
            BEGIN
            Compute Result (Fi) = Input (Xi);// result of i/p is actual i/p
            data.
        //if More than one hidden layer improves the performance accuracy
        Step5: each hidden layer or result at output layer unit J
            NetInput (Xj)=∑WijFij+Θj // calculate net input j which
            corresponds to the previous layer i, and compute Function output
            Fi  as Output (Oj)= (1/1+e-lj), calculate result output(sigmoid)
            for input each j value.
            each input j
            END// Step 4 end
        Step6: propagation errors if any
            each unit for  j  in the results of the output layer
            Errj=Fj(1-Fj)(Tj-Fj);// compute the error  if any
            For each input j in hidden layers; from considering last to the
            first hidden layer
            Compute Errj=Fj(1-Fj) ∑k ErrkWjk;// calculate error respect to
            next higher layer k
            weight for  Wij in the network associated with each layer and
            value
        BEGIN
            ΔWij=1+Err j Fj// increment of weight
            Wij= Wij+ ΔWij;//  update the weight value
        END
    Step7:  For   bias Θ  in each network  update value
           Δ Θj=(l) + Err j // Bias increment
    END
  END
END
```

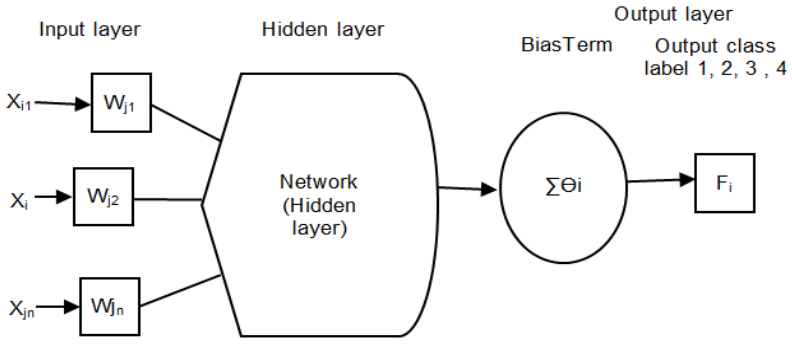

Figure 3. Artificial Neural Network Model

The experimental results conducted using R programming with QWS data and ANN confusion matrix is described in Table 4. ANN predicted values with observation comparison described in Table 5. Re-sampling of ANN with Kappa measures and the results are described in Table 6.

Table 4. Artificial Neural Network Confusion Matrix

Prediction	Rank1	Rank2	Rank3	Rank4
Class-1	587	1	2	1
Class-2	2	803	2	3
Class-3	2	1	587	4
Class-4	2	1	8	501
Accuracy (average): 98.11%				

The Accuracy (average): 98.11% fine-tuning accuracy is 98.20 Accuracy=9, and decay is 9 and 0.06

3.3. J48 Decision Tree

Is an approach which acts as a classification predictor from the list of values, the target is dependable value, and it is used to predict target value. The J48 Decision Tree is described in Algorithm 3.

Algorithm 3. J48-Classification of QWS data using Decision Trees

```
DTreeQoS(DatapartitionDp, data attributes)
Input: QWS data Attributelist(RT,AV,TH,SUCC,REL,COMP,BP)
RT Response time, AV: Availability, TH: Throughput, SUCC, Successability, REL:
Reliability, COM: Compliance, BP: Best practices.-

QWSselectionMethod: Procedure for splitting into individual classes.
Output: Decision Tree with class labels class-1,2,3 and 4.

Step1.   Create a new node N
Step2.   If data records partition Dp of the same class of type(1,2,3, and 4),
         then return the leaf
         Node N label with relevant class type as 1,2,3 and 4.
Step3.   If (data attribute list)is EMPTY  thenReturn N, leaf node, the
         majority of classes in data partition Dp / //    majority of classes
         of class type
Step4.   apply QWSselectionMethod(Dp, data attribute list) to find the best
         splitting criterion.
Step5.   Splitting criterion  label N
Step6.   If splitting data values and Multisplit permitted then//
Step7.   Adddataattributelist←data attribute list- splitting attribute; //
         removing splitting attribute
Step8.   For the result of the splitting criterion of each // To find classify
         label
Step9.   Let Dresult be set of data records in Da satisfy result; //
         apartition result
Step10.  If Dresult is EMPTY then   add to leaf label of majority class label
         in Da to node N; else add a node returned by DTreeQoS (Dresult,
         dataattributelist) to node N;
Step12.  end for
Step13.  Return N
```

Applying Algorithm3 (J48 Decision tree) on QWS data, which consists of 2507 record samples, results into four classes namely: 'Class1', 'Class2', 'Class3', and 'Class4' using seven predictors. Re-sampling: Cross-Validated (10 fold), using R language the summary of sample sizes of 2256, 2256, 2257, 2256, 2257, 2256, etc. the results shown in Table 7, and accuracy is 97.56637% and Kappa value is 96.72248%. Tuning with parameter 'C' was a constant value of 0.25. Tuning parameter at constant value M is held at 3.

Table 7. The Comparative Study of J45 Classification Predictions with Observations

S No	Prediction	Observation	Rank1	Rank2	Rank3	Rank4	RowIndex	Size
1	Class2	Rank2	0.0000	1.0000	0.0000	0.0000	2	0.25
2	Class1	Rank1	0.9979	0. 0020	0.0000	0.0000	5	0.25
3	Class1	Rank1	0.9979	0.0020	0.0000	0.0000	10	0.25
4	Class1	Rank1	0.9979	0.0020	0.0000	0.0000	12	0.25
5	Class4	Rank4	0.0000	0.0000	0.0000	1.0000	16	0.25

3.4. eXtreme Gradient Boosting (XGboost Technique)

This is a machine learning algorithm, supervised learning to find the tasks regression, ranking, and classification. Prediction (Y_i) for given a value (X_i,) using a linear model is used to prediction $Y'_i = \sum \Theta_i X_i$, where weight input, the prediction, can have different interpretations, the task depends on regression or classification, Θ_i co-efficient denote parameter the model is used for ranking the outputs. XGboost technique (eXtreme gradient boosting) uses seven predictors, four classes as Class-1,2,3 and 4, experiments at Cross-Validated (10 fold) of sample sizes: 2258, 2255, 2256, 2256, 2257, 2257, etc. The experimentations with XGBoosting method results are shown in Table 8, and Table 9 XGboost confusion matrix across tuning parameters.

Table 8. eXtreme Gradient Boosting Classification of QWS Comparisons Accuracy with Kappa Measures

S No	Theta	Alpha	Nrounds	Accuracy
1	0e+00	0e+00	50	0.9828397
2	0e+00	0e+00	100	0.9828397
3	0e+00	0e+00	150	0.9828397
4	0e+00	1e-04	50	0.9832381
5	1e-01	1e-04	100	0.9836046

Table 9. eXtreme Gradient Boosting Confusion Matrix

Prediction	Rank1	Rank2	Rank3	Rank4
Class-1	583	1	0	1
Class-2	3	800	0	3
Class-3	0	2	590	10
Class-4	7	3	9	495
Accuracy (average) : 98.44%				

The Accuracy (average) : 98.44% fine tuning accuracy is 98.45% constant value is 0.3 optimum model largest value, 50 rounds lamda=0.1, accuracy=9, and decay is 9 and 0.06

3.5. K-Nearest Neighbors Classification (KNN)

KNN classification algorithm [25] input have ‘k’ closet training tuples in the feature selection, the object being assigned to the most common is ‘k’ nearest neighbors. Find the most similar object from training data; the testing data will look into the training dataset to be the most similar object based on feature selection and distance functions. KNN algorithm is described in Algorithm 4.

Algorithm 4. KNN Approach

```
Input:  Given records and attributes S, from Matrix a=[Aij]
Output: classification label (class-1,2,3 and 4)

Each record classified into Rank the web service (WsRF: Web service Relevancy
Function)
begin

Step1. Given a set of records and attributes, form matrix A= [aij]
Step2. For each record P in the Test data do
       For each record in A, in the training data A do
       Calculate the similarity of input testing data which is most similar to
       trained
       dataset EUDistance(P,A)
       Store DIS_Array(Pi,Ai) and find the class label.
       end for
       end for
end
```

QWS dataset 2507 samples, for seven predictors and into four classes: 'Rank1', 'Rank2', 'Rank3', 'Rank4', use of cross-validation, 10 fold the sample sizes of 2255, 2256, 2256,

2257, 2258, 2257 etc, and Re-sampling results across tuning parameters and result conducted shown in Table 10. KNN with k value 5 is maximum accuracy of 89.34%.

3.6. SVM with Radial Basis Function Kernel Approach

This is a method used to classify the data. SVM classification use maximize margin for accurate values. It is a linear classifier, where Ai is input, W is variable of a straight line with constant B. IN (2)-(5) depicts the processing:

$$\mathrm{bF(Ai, W, B)} = \mathrm{sign(AiW + B)} \quad (2)$$

where Ai, is input data which is a variable and B is constant of a straight line:

$$\mathrm{WAi + b} \geq 1 \quad (3)$$

if Fi =+1 where W is a variable of line, tshe linear line WA_i+b is maximized margin M=2/|W|, minimize 1/2W_tw with the subject to Minimize (w) =1/2 Wt W and subject to output(wA_i+b) ≥1

$$\mathrm{WAi + b} \leq 1 \quad (4)$$

if Fi =-1 where W is a variable and

$$Fi(WAi + b) \geq 1 \quad (5)$$

for all remaining values.

QWS dataset 2507 samples experiments conducted using R programming with seven predictors and four classes: 'Rank1', 'Rank2', 'Rank3', 'Rank4', re-sampling, sampling the use of cross-validation ten-fold, the results using SVM with RBFK method are shown in Table 11. Summary of sample sizes: 2257, 2256, 2256, 2258, 2256, 2257, etc. re-sampling results across tuning parameters.

Table 10. The KNN Classification of QWS Data and Comparisons with Accuracy with Kappa Measurement

S No	K value	Accuracy	Kappa
1	5	0.8934794	0.8556596
2	7	0.8855096	0.8446677
3	9	0.8739349	0.8287782

Accuracy is at k=5, optimal model, the largest value

Table 11. SVM with Radial Basis Function Kernel with classify QWS Data Accuracy and Kappa Measurements

S No	C	Sigma	Accuracy	Kappa
1	1	0.1	0.9397494	0.9184620
2	1	0.2	0.9489032	0.930877
3	1	0.3	0.9548937	0.9390387
4	1	0.4	0.9548985	0.9390593
5	1	0.5	0.9573018	0.9423314

Accuracy at largest optimal value when sigma = 0.6 and C = 1

4. Results and Discussions

WS objects need the quality of services; this is associated with each object, in business process coordinating to deal with services and managing service qualities. To provide quality services according to user requirements, WS real-time applications use of video, text, image, and other elements by users, QoS of web service, satisfies the end-user requests. For example, the response time of Website quality is associated with various parameters like network, application services. The designer aim is to monitor the quality contents and ensure quality services. The customers require quality services, high availability, security, cost optimization, and others [26]. WS layer, quality monitored, and adjusted parameters, for example bandwidth, communication layer by web service, which handles message contents in a real-time layer which communicates with services between client and server. The web services quality parameters of access control the information of data audio, video, a text document and other documents with various parameters influence to measure the quality of software. Here we have taken QWS dataset, and the results are executed using R- Language and identified most important influence parameters are best practices, successability, availability, response time, reliability, throughput, and compliance shown in Figure 4 in web application development. The existing web service classification methods and its accuracy values are shown in Table12.

Table 12. Web Service Classifications of Existing Methods and Accuracy Values

S No	Classification Method	Accuracy
1	Naïve bays	83.62%
2	Group Method of Data Handling(GMDH)	98.32%
3	Back propagation and Neural Networks(BPNN)	97.22%

The accuracy values of classification methods implemented using R Language, and results are shown in Figure 5, computed classification accuracy, and kappa measurements graph are also shown. Figure 6 shows the results WS classifications using (ANN) method. The Figure 7 shows the accuracy of randomly selected predictors. Figure 8 shows the accuracy, number of iterations web service classifications by extreme Gradient boosting method. Randomly selected predictors for is shown in Figure 7, in which the prediction at a minimum accuracy by KNN is 89.39% and maximum accuracy by XGboost techniques are 98.44%.

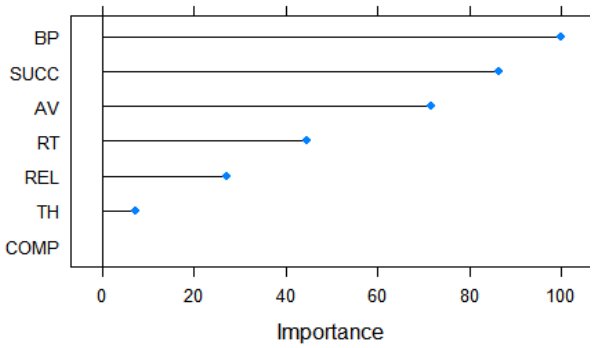

Figure 4. Importance of Web Services

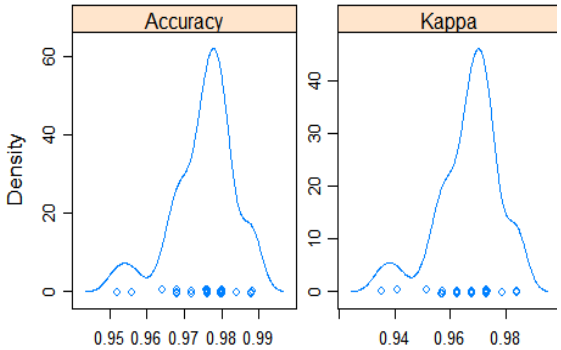

Figure 5. Web Service Classification accuracy with kappa measurements

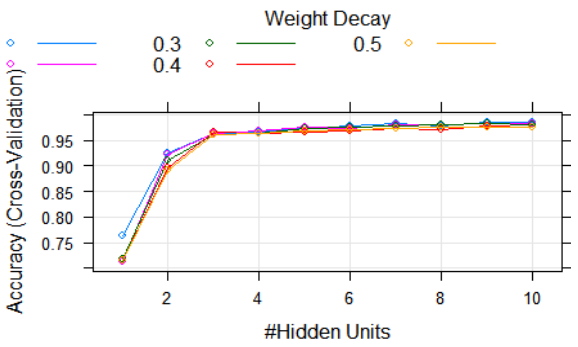

Figure 6. Web service classification using Artificial Neural Networks

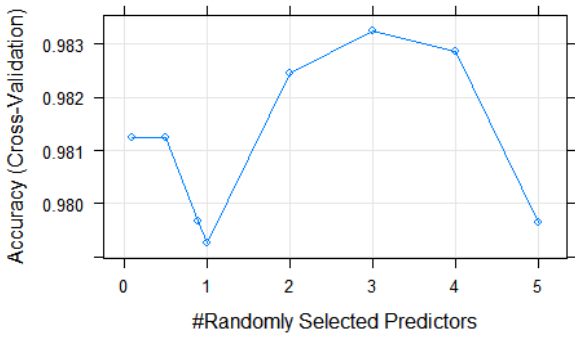

Figure 7. Randomly selected predictors

The eXtreme gradient boosting method results are described in Figure 8 that shows the accuracy by using alpha at iterations with the minimum which is 98.44% and the maximum value is 98.45% by iterations with alpha values. eXtreme gradient boosting method got the highest accuracy compared with various data mining methods accuracies are shown in Table 13. The experimental results conducted with QWS dataset using R language and various classification methods and comparative study of accuracy with fine tuning values are shown in Table 13.

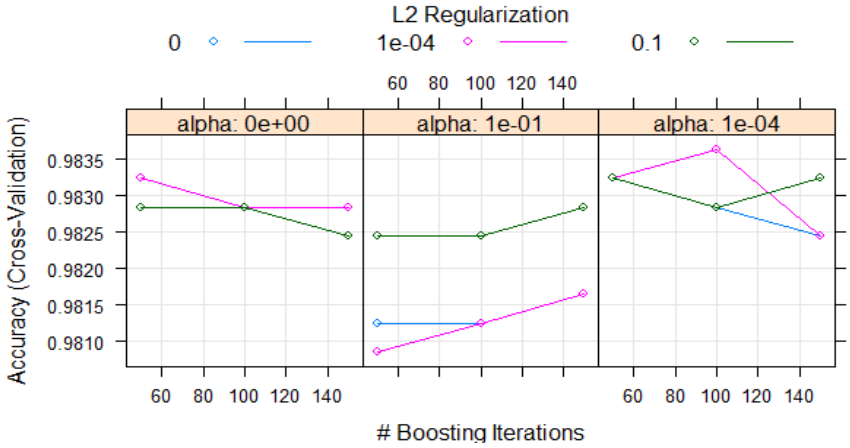

Figure 8. eXtreme gradient boosting method, alpha, first, second and third iterations with alpha values the comparison graph

Table 13. Web Service Classifications Using QWS Dataset, Various Methods, and Accuracy Values

S No	Classification Method	Accuracy	fine tuning Accuracy
1	Random Forest	98.13%	98.32%
2	Artificial Neural Network	98.11%	98.20%
3	J48 Decision tree	97.56%	97.57%
4	eXtreme Gradient Boosting	98.44%	98.45%
5	K Nearest Neighbor	89.34%	89.35%
6	Support Vector Machine	95.73%	95.74%

5. Conclusion and Future Scope

Web service is most important for business service; the user demands high-quality web services. The designer must provide high-quality web services based on demand. To meet the industry demands and policies, we recommended the best practices [27, 28] used for preventive measures, quality standards which will improve the performance of web applications, Successability depend on the availability of web applications by backup and fault tolerant systems, response time plays a significant role in interactive web user to the web server, reliability, throughput, and compliance. The existing methods depicted in Table12. We have taken QWS dataset using various data mining methods random forest, artificial neural network, J48, eXtremetgradient boosting, and Supporting Machine methods are described in Table 13, in which the accuracy is improved by using method eXtreme gradient boosting is 98.44%, improved fine-tuning performance has 98.45% and random forest has 98.13% and fine-tuning performance is 98.32%. In future use of mixed parameters will be suggested to improve the overall performance of web application by classifications, predictions, the recommendations to improve the quality software.

Acknowledgment

Thanks to Dr. Eyhab Al-Masri, Asst. Professor, the University of Washington for providing QWS dataset.

ABSTRACT

Bitcoin has been improving in its market share and competing with actual currencies in the real world. In this context, there is increase in the applications developed for crypto currencies and general applications that can be used in distributed environment. The block chain used for cryptocurrencies like Bitcoin became famous for other applications as well. Ethereum like platform has its support for developing applications of that kind. In this paper, Bitcoin is focused as crypto currency and regression analysis is performed on the financial data. An algorithm is proposed to have regression analysis. The paper also provides the dynamics of Bitcoin in the perspective of its usage as crypto currency. It also throws light into the concept of application development using Ethereum. Ethereum is the platform to build distributed applications where millions of computers and users can involve for secure communications. The results revealed that Ethereum platform is useful and regression analysis showed the performance dynamics found in the financial data.

Keywords – Crypto currency, Bitcoin, regression analysis, Ethereum platform

1. INTRODUCTION

The term currency has acquired two broad meanings. They are physical currency that is in the form of coins or notes measured in, for example, Euros and electronic currency that is not tangible in nature. Alternative currencies are various forms of electronic currencies other than physical currency. Bitcoin has emerged as one of the electronic currencies or electronic cash. It is decentralized digital currency that does not need a central governing bank or a governing entity. In other words, Bitcoin is a new kind of money with innovative payment network. There are many factors that influence the exchange rate of physical currencies like Euro. The factors include inflation, political stability, economic conditions, recession, and interest rates. The aim of this thesis is to investigate the hypothesis that "the factors affecting traditional macro-finances do not drive Bitcoin price". Towards this end, a methodology is formulated with a conceptual framework required to complete the research. From the analysis of the research findings, it is understood that the Bitcoin prices are not predictable as done in the case of traditional currencies. Its presence of digital form is one of the fundamental reasons why the Bitcoin currency is not affected by factors that influence standard currency. Another important observation in the study is that there are some other factors like media, word of mouth and advertising affect price of Bitcoin. The remainder of the paper provides more details on Bitcoin and crypto currency and provides regression analysis besides the concept of developing distributed applications with Ethereum platform.

2. RELATED WORK

This section provides review of relevant literature on cryptocurrency and its related works.

2.1 The concept of alternative currency

According to Levy &Glimcher [8], complementary or alternative currency is a term predominately applied to denote any currency that is used as a determined alternative to the multinational or dominant national currency system. Patel et al. [10] argued that alternative currencies are often created by the corporation, individual or an organization. Moreover, such form of currency can be created by either local or state governments [11]. Luther and White [9] opined that an alternative system of currency might develop naturally once people consider using a particular commodity as currency. The current literature provides several argumentative explanations regarding the concept of alternative currency. Levy

&Glimcher [8] opined that an alternative or complementary currency could act as a certain medium of exchange (exchanging alternative currency for traditional currency and vice versa) which definitely is not a country's recognized currency. However, it is thought of or considered as a currency system that supports, in fact, supplements the national currencies.

However, according to Levy &Glimcher [8], complementary currency is seldom considered as legal tender. Legal tender is the payment medium that is recognized by a legal system and valid across a country in general. For instance, Euro coins or bank notes are considered legal tender in the European Union. The application of complementary currency adheres to agreement between two distinct parities which may consider exchanging currency. Luther and White [9]argued on the concept as he stated that complementary currencies were created to stimulate, protect or orientate a nation's economy. Alternative currency is considered as a tool that is applied to advance any specific environmental, social and political goal (Burnside, Eichenbaum&Rebelo, 2016).

Experts such as Patel *et al.* [10] highlighted several interchangeable terms, which are used for denoting alternative currency. One such example would be the term "community or local currency". Various experts often consider several private currencies to be alternative currencies, which are majorly issued by various private enterprises. Kim &Dilts [8]opined that alternative currency is majorly injected in an economy for a plethora of purposes. Moreover,Luther and White [9]exemplified several such purposes in his research procedure. The expert claimed the necessity of issuing alternative currency when a nation intends to augment its definite financial health and stability [8]. Xiao *et al.* [11] advocated the usage of alternative currency during situations when a nation or a particular community has no sound access to designated financial capital. Details of crypto currency such as Bitcoin are reviews more in [12]- [20]. The bottom line is that Bitcoin became famous as crypto currency.

2.2 Factors That Impact the Value of Currency

CiaianandRajcaniova (2016) stated that foreign exchange rate is one of the most significant means by which value of economic health of the country is determined. The value of currencies is dependent on some factors such as interest rate, political stability, gross domestic product, inflation, import ratio, export ratio and price of Gold [8]. Change in market inflation can cause changes in currency exchange rates. In addition, changes in interest rate affect value of currency as well as euro exchange rate. The Government Debt is dependent on political stability by which value of currencies are changed [8]. A country with Government Debt is less acquires foreign capital that leads to inflation and impact on the value of currency. The above mentioned factors determine the value of currencies and help the country to avoid potential falls in the rates of currency exchanges by analysing the factors. The factors also ensure that currencies are exchanged at proper rate (Burnside, Eichenbaum&Rebelo, 2016).

According to Dembiermont *et al.* [6], the primary factor that contributes towards the overall strength or weakness of a particular currency is the interest rate of the country. As stated by, Xiao *et al.* [11] interest rates are the determined amounts that a country needs to pay in order to borrow a certain sum of money. The rate of interest rate level moves definitely lower or higher by a nation's central bank to stimulate or either slow the economy down [11].

Inflation is another essential factor that impacts the value of currency in a country [8]. This economic factor is essentially determined by the rise in prices of the commodity and the services of the nation [10]. When a particular product witnesses rise in its price, it essentially signals the determined underlying demand for the products [10]. It is a matter of common fact that higher prices may not seem good to a consumer [10]. However, a country is seemed to be benefited from a certain moderate increase in their respective inflation in a growing or developing economy [10]. Several central banks have a certain target inflation rate for their rate of economy which is approximately 2 % per year [11]. The growth in economy and current account balance are other two factors which cause a certain increase or decrease in the value of the currency [8]. Furthermore, there are economic elements like GDP, export and import rate and their respective ratio influence currency fluctuation in an economy [11. These are explored in the below given portion of this literature review.

However, several experts have presented contradictory views on this aspect of currency valuation. Kim &Dilts [8]opined that the central bank of a particular nation creates currency and

ISSN:2005-4238E-ISSN:2207-6360
Vol-128-Issue-1-July-2019

uses such to purchase government based debts (which essentially lowers the rate of interest). A certain fall in interest rate may lead to a simultaneous increase in aggregate supply and aggregate demand. The repercussion of this policy on the overall market value of money or currency depends on major expectation, but a bigger increase in respective (along with the associated surge in people's confidence) may essentially counter or may moderate the decline in the determined value of the currency [8].

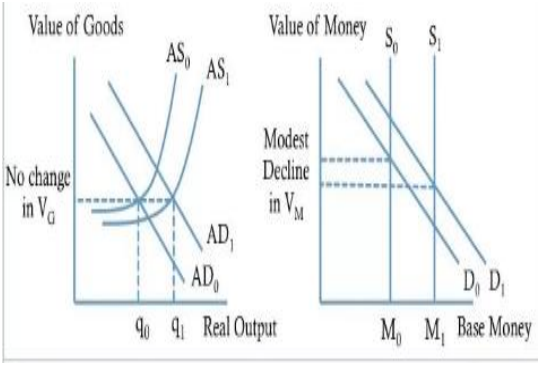

Figure 1: Graph representing lowering of interests and the exhibited illusion of prosperity

As shown in Figure 1, it reflects the lowering of interests and also illusion of the prosperity. It is to know actual value of goods and actual value of money [8].

3. TECHNOLOGY AND DYNAMICS OF BITCOIN

3.1 Understanding Bitcoin

In order to study the impact of alternate currency and its impact on financial industry, a comprehensive understanding of Alternate Currency is required. In this section, the innovation, arrival and impact of currencies such as bitcoin and other forms are explored in great detail. Bitcoin is synonymous with alternate currency and has drawn the attention of a variety of fields from cryptography to economics and computer science apart from financial aspects as well [3].

Bitcoin is one of the most successful cipher or cryptocurrencies in the world. It was first introduced to the world by the genius mind of Nakamoto [5], who used a 'systematic structural specification' for this purpose [3].

"*The root problem with conventional currency is all the trust that's required to make it work. The central bank must be trusted not to debase the currency, but the history of fiat currencies is full of breaches of that trust,"*[5].

The purpose of the bitcoin is its decentralised philosophy. It is an emerging technology which challenges conventional trading currencies. Bitcoin is one of the first forms of cryptocurrency to emerge and has slowly changed the ways of money. The currency at its time of debut in 2008 to its current format in 2018 has evolved achieving astounding values of approximately $330 per bitcoin. Hence, it is necessary to focus on a study of this transactional currency exchanged for fiat currencies [5].

There are several aspects to this unique currency. First and foremost, digital currency did have its own history. But the difference that Nakamoto[5] brought about to this currency is that, the applied the unique concept of 'public key cryptography,' in making these digital cryptocurrency[5].

The purpose of bitcoin, for Nakamoto was to free the currency systems from the control of the governments and therefore a decentralisation which is far different from the 'fiat currencies' which use central banks in the current system. The philosophy is to build 'trust' among participants of the bitcoin market during the process of the formation of the block chain technology using two key inputs – (A) Cryptography methods and (B) Hash functions. The evolution of this system has expanded theoretical studies in this science and is emerging as advanced levels of 'machine learning [5].

Though, Nakamoto's identity is shrouded in secrecy, his white paper has stood the test of time and bitcoin continues its ascendency of the cryptocurrency scenario [3].

Nakamoto defined in his seminal work, 'Bitcoin: A peer-to-peer Electronic Cash System,' that the fundamental feature of this currency is to use the ledger format for transactions which were rendered in the form of block chain. Hence, the key components of bitcoin as proposed by Nakamoto are: 1) Blockchain or the ledger for all transactions (2) Mining- the capability of the decentralised authority to authenticate transactions. This process is uniquely termed as mining records [3].

3.2 Validation by Users

The principle adopted for the purpose of validation is the concept of 'mining.' The users will begin by validating the transaction and its integrity prior to adding it to the block chain. The process of validating is very expensive as it involves

ISSN:2005-4238E-ISSN:2207-6360
Vol-128-Issue-1-July-2019

encryption and using complex alphanumeric keys. As soon as the user, who is also called the miner, performs the integrity check of all of the transactions and adds them to the block chain, then the user will perform the mining. These efforts are rewarded by BTC currency and thus the bitcoin or the currency is created or generated records [3].

3.2 Enabling Technology of Bitcoin

Bitcoin; The exchange rate is determined by fiat currencies. The bitcoin prices are in relationship are between actual markets as well as Bitcoin markets. Hence, the difference is in terms of bitcoin market and the currency markets. Since bitcoin is virtual currency and relies on block chain technologies, the factors or economic size E, Velocity V and the capacity of the Bitcoin market, B are related in a close relationship, where market variables are measurable. These are captured from the Blockchain platform. Hence, if P is the price level of the goods and services then it can be determined indirectly by considering the global macroeconomic indexes in real time [4].

Hence Price of Bitcoin (P_B) = PE (Price into the economic size)/VB or Velocity into the bitcoin market [4]

$$P_B = \frac{PE}{VB}$$

Blockchain; The decentralisation is the derivation that cryptocurrencies pursue and is in direction opposition to the fiat currencies which are valuation of the central banks.

A discussion on decentralisation identifies the following goal framework about (1) transaction ledger has to be maintained and managed (2) The right to validation transactions has to be handled at user end (3) New bitcoin is creation has to be managed. An answer to these goals was found only in the technology of block chain [4].Hence, blocks that are generated in block chain are directly involved in trading and creation of bitcoin. They are directly influenced by the supply and demand of bitcoin. Thus, block chain technologies with relation to bitcoin market are an example of working seamlessly between high-level cryptography and market economics [1].

The solution to the goals mentioned above is to include the participant as part of the Bitcoin network itself. It is the participant who will provide the necessary hardware resources through their own computer. These are called as 'distributed systems.' The relay or the issuing and transaction of money are handled by P2P networks. The block chain then records the trading history and is then shared on the network. The entire past transaction history is then verified by every network participant. The unit is also called as the 'block' and will provide every degree of latest transaction and the most important hash value. This value is derived from the 'previous block' and the attempt is to create irreversible data which works with has function and indicates the next block [4].

Thus, the basic premise of block chain technology is validation by the users themselves and thus eliminating the need for third parties or banks to centrally validate the currency generation. Instead every user in generating the coin has already performed the validation or the arrival or origin or birth of the coin.

The advantage of bitcoin is that it allows a participant on the network to perform the process of mining. Every transaction then becomes into a further node or block where further operations are performed and decentralised phase is developed. The actions or sequences are independent and are broadcast horizontally or from each participant in the network to every other participant on the network. This process is continued until all of the transactions are spread across the network. The block chain is thus cloned or copied to all of the participants in the network, and becomes a 'full node,' apart from storing each of the records [3].

3.3 Bitcoin Price Formation

According to Bouoiyour&Selmi [2]showed evidence of significant body of research investigating the facts which drive bitcoin prices and the main determinants of it. The least influential factor was macroeconomic factors, financial factors, speculative factors and technical determinants apart from the general events (like socio-economic-political-geographic) which derive the value of bitcoin. The researchers relied on 'Bayesian quantile regression' to determine the structure of the dependency relation between price and its determinants, within the framework of conditional distribution of bitcoin price movements. With the aid of the statistical tool they were able to they identified three groups of determinants. The year in consideration for the study influenced the prices.

The first group of determinants was the adoption of bitcoin in trade, associated with China's sluggish economic growth. When markets improved, two key influences were Brexit and the demonetization exercise in India. In normal mode of market functioning, there was anxiety about Trump's ascendency of United States Presidency. However, the fear of US sanctions and similar upheavals actually led to further interest of investors in the alternate currency option. Thus, during that phase, prices of bitcoin rose significantly. The last group of influencers were – bitcoin circulation speed, price of gold, demonetization of currency in Venezuela and the hash rate as fundamental influencers in bitcoin price markets heading into decline[2].

3.4 Economics of Bitcoin and Market Opportunity

Literature review will establish the current economies which are supportive to this format of currency and gain insight over the trading opportunities of digital currencies in foreign exchange. There is no legal recognition in the use of complementary currency and is usually an agreement between parties for the purpose of exchanging currencies [8]. However, despite the dominance of traditional currencies, the opportunities that the new finance format offers are unique and exciting. The intrinsic as well as volatile value is creating wider interest and participation in digital finance [3].

BTC transactions are on the rise and adoption of bitcoin. The price of BTC shows dramatic price peak prior to 2013. The change in adoption of bitcoin due to increase in number of bitcoin exchanges and finite supply of bitcoin, to become a major opportunity for speculative investments;

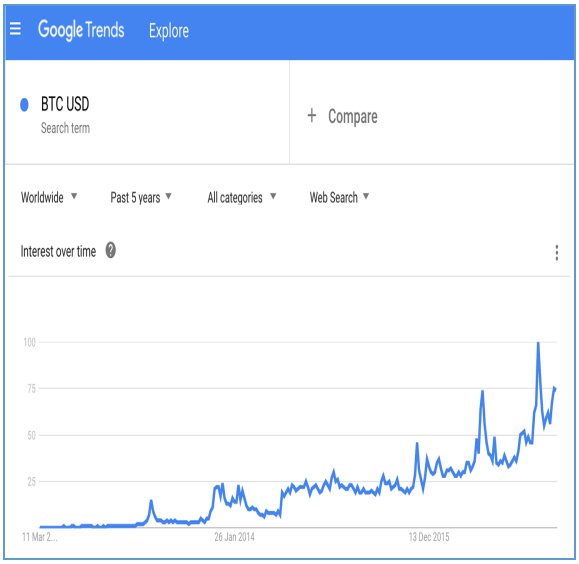

Figure 3: Bit coin market from Google Trends

The market for bitcoin has been continuous and has been providing opportunities for trading and markets are showing tendency for high volatility. The issue of volatility will provide opportunities and signify changes in terms of price and increase in returns. The flip side of this is that an increase returns will also provide opportunities for risk taking. The predictive model for high volatility in the market is related to accuracy for significantly for an exclusive random model [3].

4. LINEAR REGRESSION ALGORITHM

This algorithm takes dataset as input provides regression results. The regression analysis is made by the algorithm. It is known as linear regression algorithm.

Algorithm: Linear Regression
Input: Dataset D (described in Section 6.1)
Output: Regression results

1. For each Mass Window
2. Use peaks with highest intentions
3. Compute distance matrix
4. Perform cluster analysis
5. Prune duplicated well-behaved clusters
6. End For

ISSN:2005-4238E-ISSN:2207-6360

9.      Fit regression line
10.     Compute statistics
11.   End For
12.   Return statistics
```

Algorithm 1: Linear regression algorithm

As presented in Algorithm 1, it is understood that the dataset is taken from financial domain as described in Section 6.1 and the data is subjected to regression analysis. It includes clustering, well behaved cluster analysis, removal of duplicated well-behaved clusters and finally performing actual regression to generate results.

5. APPLICATION DEVELOPMENT WITH ETHEREUM

Ethereum is the platform to develop decentralized applications with ease. Such applications do have distributed architecture and serve specific purposes. In addition to this, those applications provide interactions among different parties. It supports the API used for Bitcoin and BitTorrent to have peer to peer network that can be used by users across the globe. Ethereum also supports blackchain technology that can be used to have secure financial and other applications in distributed environment. Ethereum Virtual Machine (EVM) is a distributed virtual machine where millions of computers can participate. It supports two kinds of accounts namely externally owned accounts (EOAs) and contracts. The contracts can serve different purposes like maintaining data store, serving as an account, manage relationship between many users and provide library functions. In a betting application, the parties involved can have secure communication with Ethereumapplication as shown in Figure 4.

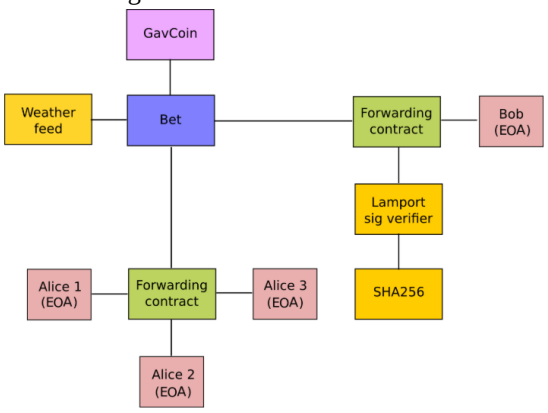

Figure 4: Distributed interactions in an Ethereum application

As seen in Figure 4, in a betting application, there are secure interactions among different parties in the world. Ethereum application can help to achieve such complex interactions with end to end security.

6. EXPERIMENTAL RESULTS

6.1 Data Used for Regression Analysis

Data has been collected from http://fundforpeace.org/fsi/ that contains the price details of Bitcoin besides Fragile States Index. The data reflects different attributes like Year, Bitcoin Price, USD/EUR/ and GoldUSD. It also provides other attributes related to fragile states index for countries like USA, Kuwait, Latvia, United Kingdom and Switzerland. An excerpt of data collected is presented in Table 1.

Year	Bitcoin	USD/EUR	goldusd	USA	Kuwait	Latvia	United Kingdom	Switzerland
2014	854.0	1.4	1292.0	35.4	59.0	48.0	34.3	23.3
2015	229.0	1.1	1150.0	35.4	57.5	48.5	33.4	22.3
2016	409.0	1.1	1339.0	34.0	58.5	47.4	32.4	21.8
2017	1197.0	1.1	1318.0	35.6	58.5	46.4	33.2	21.1
2018	9521.0	1.2	1316.0	37.7	58.5	46.4	33.2	21.1

Table 1: Shows dataset used for regression analysis

The data reflects the aforementioned attributes from the years 2014 to 2018. The data shows how the Bitcoin has improved in price from 2014 to 2018. It also shows the GoldUSD performance over the years. The ratio of USD/ERU is also reflected in the data.

6.2 Regression Analysis Made

Regression analysis has been made for the purpose of analysing bitcoin and Euro prices and the factors that drive the prices or exchange rates of the same. Data of some countries are considered for data analysis as mentioned before. Different factors that affect fiat currency such as Euro are analysed. In the same fashion, the bitcoin prices are driven by certain factors. The factors that influence Euro may not be same for Bitcoin. This is actually the part of the hypothesized model that has been tested in this chapter. Gold prices are also considered in order to have better analysis. The predictability of fiat currency and the unpredictability of Bitcoin as per the hypothesized model are evaluated. Irrational behavioural theory as discussed in the literature is used to deal with the factors that drive price of Bitcoin. The rationale behind this is that the Bitcoin, according to literature, is influenced by different factors like media, popularity, and technology usage and user base.

The statistical modelling approach known as Regression Analysis is used to predict or estimate relationship among different variables. If there is statistically significant relationship between sets variables, it can be detected using regression analysis. In other words, the relationship among given variables is modelled using regression analysis. It makes use of the concept of independent variables and dependent variables. The independent variables are known as predictors. It reveals the changes in the value of dependent variable when the independent variables are subjected to changes. The function employed on the independent variables is called regression function. Thus it helps in prediction of significant relationships or forecasting in other words.

Regression analysis needs proper data preparation which is taken care of in this thesis. The data presented in Table 1 is appropriately used in the Regression analysis. The regression analysis tool is taken from the spreadsheet application known as Microsoft Excel. The regression analysis makes use of formulae related to sum of squares, degree of freedom, mean square, F value and significance or P value. Based on the P-value, it is possible to know how two sets of variables are significantly related. Sum of squares is computed as $SSB = \Sigma n_j (\bar{X}_j - \bar{X})^2$, degree of freedom is computed as m-1, mean square is calculated as SSB/m-1, F value is computed as (SSB/m-1)/(SSE/n-m) and finally significance is computed where m is the number of columns while the n indicates number of responses considered. There is concept of between groups and within groups considered internally for the regression analysis. R square and adjusted R square are computed as in Eq. 1 and Eq. 2 respectively.

$$R^2 = \frac{F*(m-1)}{(n-m)+(F*(m-1)} \quad (1)$$

$$Adjusted\ R^2 = 1 - \frac{(n-1)(1-R^2)}{(n-m)} \quad (2)$$

In the process of regression analysis mean and standard deviation are computed as in Eq. 3 and Eq. 4.

$$\text{Mean } \mu = \frac{Sum\ of\ values}{Total\ number\ of\ elements} \quad (3)$$

$$\text{Standard Deviation } \sigma = \sqrt{\frac{(x_i-\mu)^2}{N}} \quad (4)$$

7. CONCLUSION AND FUTURE WORK

In this paper we focused on the understanding of Bitcoin and its trends and dynamics in the real world. It throws light into different aspects associated with the crypto currency. They include Bitcoin, block chain and Ethereum. Bitcoin is the virtual currency made using cryptography technologies. Its operations are protected in distributed peer to peer environments using Blockchain. Ethereum is used to build distributed applications that make use of security primitives that are used in Bitcoin and BitTorrent kind of distributed P2P applications. An algorithm is proposed and implemented to have regression analysis on the financial data related to Bitcoin. It is understood that Bitcoin as crypto currency technology has advanced right from its inception in a progressive manner. The empirical study also revealed the utility of the Ethereum platform for building P2P distributed applications that provide secure interactions among many users across the globe. In future we intent to work on building an Ethereum application with block chain technology that can be used to safeguard biomedical documents in a distributed multi-user environment.

Multiple Linear Regression On Movie Data For True Rating Prediction

Sireesha Jasti, Tummala Sita Mahalakshmi

Abstract— Amino acids are little bio-particles with different properties. Data mining, being the science of mine dealing with the databases for gathering information and knowledge, has lately developed innovative axes of functionalities and stimulated an promising discipline, called Sentiment Analysis. Now-a-days, Sentimental content is available across the social media websites in a form such as consumer comments or reviews for the products, movies, testimonials, significance in discussion forums. Well-timed sentimental discovery of the online content on these websites have significant role that supports the distribution and monetization. Consideration of the sentiments of individual on diverse elements and goods facilitates to serve better services in terms of recommendation structures, contextual advertisements, and marketplace trend analysis. The focus on this research is to facilitate the swift detection of true and positive analysis of movie reviews. This research study highly discusses the regression algorithm that aims to predict with over 89% accuracy the true rating of the movie reviews based on the users matching profiles and the given reviews which of those may be false positive or true negative.

Keywords— Sentiment Analysis, Multiple Regression, Analysis of Variance (ANOVA), Movie Review, Prediction.

I. INTRODUCTION

Mining a valuable data from a large data set can be achieved through a process called Data mining. Clustering, Classification and Regression are various analyzing tools which can be availed for the tasks like sentiment analysis [1][2]. One important aspect of data mining is a sentiment mining through which the imperative data be able to excavate depending on the affirmative or unconstructive sense of data composed so far. Opinion mining referred to be Sentiment Analysis employs analysis of text, Natural Language Processing, in addition to computational semantics to discover and dig out biased information from the source content [3]. For this reason, a statistical model is adopted namely Multiple Linear Regression Analysis algorithm.As it frequently affords superior predictive ability and also presents a basic estimate of the relative significance of every variable in the correlation. This algorithm predicts the true positive review of a particular movie accurately compared to logistic regression [23] and multivariate regression analysis.

Multiple Linear Regression Analysis is a statistical model that helps to portray data as well as explicate the liaison involving a dependent and set of independent variables. The said model constitutes three phases: 1) Scrutinizing the correlation and data directionality, 2) model estimation or line fitting and 3) estimating the weight and expediency of the model [4].

II. REVIEW STATUS

Studies demonstrated that Sentiment Analysis is still in use for a range of applications from promotions, reviews, feedback and social media these days. Sentiment Analysis in expansion got a primary significance in making decisions. Sentiment Analysis provides the intellectual information associated with communal views, as it analyzes diverse reviews, tweets. It is a demonstrated tool for predicting several noteworthy events like box office act of movies [11]. For Sentimental Analysis, many of the available techniques were used. Few of them are:

Dey, L., at al., [12] focused web crawling framework to assist the swift discovery and analysis of sentimental contents in reviews of hotels and movies. Researchers made use of statistical techniques for taking into account the essentials of subjective style and polarity of sentence. Supervised machine learning algorithms namely K-Nearest Neighbor (K-NN) and Naïve Bayes'(NB) were discussed by comparing on the whole accuracy, precisions and recall values. They proved that Naïve Bayes' in the case of reviews on movies, produced outlying results compared to K-NN but for hotel reviews the algorithms proved to be less significant with almost equal accuracies.

Liu, B. et al., [13] used large scale datasets to assess the scalability of Naive Bayes classifier (NBC). Researchers presented an effortless and absolute system to mine sentiments from large datasets using NBC and Hadoop framework. NBC is employed to attain superior grain control of the analysis process for a Hadoop implementation. They showed that NBC is able to scale up to examine the sentiment of millions of movie-reviews through escalating throughput. The dataset used is Cornell dataset on which the code was executed that resulted in 80.85% average accuracy.

The researchers [14] presented a framework that integrated Word2vec and Convolutional Neural Network (CNN). Primarily, the word2vec anticipated by Google was utilized to calculate word vectors that are the input for the CNN. Word2vec is adopted to represent words in vector form and reflect the distance between words. Subsequently, a 7-layers architecture model is applied for analyzing sentences sentiment utilizing word2vec and CNN. In order to advance

Revised Version Manuscript Received on August 19, 2019.

Sireesha Jasti, Research Scholar, GITAM University, Visakhapatnam, Associate Professor, Dept of CSE, Malla Reddy Engineering College (A), Secunderabad, Telangana, India.(Email: sireeshjasti@gmail.com)

Dr. Tummala Sita Mahalakshmi, GITAM University Visakhapatnam, A.P, India.(Email: sita.tummala@gitam.edu)

the generalizability and accuracy of the model, Parametric Rectified Linear Unit (PReLU), Normalization and Dropout technology were used. The framework is then tested on a movie review dataset with fives labels termed as positive, fairly positive, neutral, negative and fairly negative and achieved test accuracy of 45.4% which is improved compared to Recursive Neural Network (RNN) and Matrix-Vector Recursive Neural Network (MV-RNN).

The authors in [15] built a Treebank to defeat the deficit of labeled and large corpus in accessible models. Recursive Neural Deep Model (RNDM) was proposed to envisage the labels similar to positive, negative at sentence level. The model has attained high performance to Maximum Entropy (ME), Support Vector Machine (SVM), and Nave Bayes (NB). ICTCLAS, a Chinese word segmentation tool is considered to segment 2270 movie reviews. The anticipated model enhanced the prediction of sentence sentiment labels by 90.8% closing 13550 Chinese sentences and 14964 words.

R. Socher, et al., [16] used the model RNTN (Recursive Neural Tensor Network) for Semantic Compositionality purpose by using the dataset with 11,855 solitary sentences from movie review database. The RNTN accomplished 80.7% accuracy in sentiment forecast, a progress of 9.7 % above bag of features.

P. Ruangkanokmas et al. [17] used the model Deep Belief Network with Feature Selection (DBNFS) for Feature Selection on five sentiment classification datasets in which one is movie review dataset with totality 2,000 labeled reviews out of which 1000 are positive and 1000 negative. The accuracy outcomes are evaluated against earlier works and confirmed that DBNFS is better than Deep Belief Network.

Lee, S., et al., [18] selected Internet Movie Database (IMDb) data as the subject for analysis, and categorized movie reviews by six fields namely 'action', 'animation', 'comedy', 'drama', 'horror', and 'sci-fi'. Highest and lowest grade movies are considered to train the model and movie data since two years is collected to test the proposed model. Using Semantic Orientation from Point-wise Mutual Information (SO-PMI) technique, they constructed tailored sentiment dictionary per field and compared predicting accuracy on review ranking for enhancement. The performance improvement is 2.82% in on the whole due to the personalized dictionary on 'sci-fi', an utmost accuracy expansion amongst six fields. The researchers conclude that the text with verbs and adverbs plays a key role in improving performance of sentiment analysis.

Researchers [19] in their study considered five accepted classification algorithms in machine learning alike NB, SVM, ME, Classification and Regression Tree, and Random Forest to provide a relative evaluation on three different datasets namely Large Movie Reviews Dataset V1.0, Polarity Dataset V2.0 and IMDb dataset. Naïve Bayes, Tree and Random Forest could not be trained on large movie reviews dataset. Naïve Bayes classifier produces very poor results on Polarity dataset and IMDb dataset. Tree and Random Forest algorithms turn out average results on both Polarity Dataset and IMDb Dataset. SVM and Maximum Entropy outperformed well to outstanding algorithms on all the three datasets though the unprocessed data is given as input especially on Large Movie Review Dataset with 86% and 84% respectively.

Neethu M S and Rajasree R [20] used four different algorithms NB, SVM, ME and Ensemble classifiers. All the classifiers had approximately similar accuracy. NB has improved precision evaluated against remaining three classifiers, but a little poorer accuracy and recall. SVM, MEClassifier and Ensemble classifiers have analogous accuracy, precision and recall. The researchers attained an accuracy of 90% whereas NB with 89.5%.

AkshayAmolik and Dr.M.Venkatesan [21] in their paper used two machine learning classifiers NB and SVM. These two algorithms performed well and also provided higher accuracy. The results show that they got 75 % accuracy form SVM and 65% accuracy form NB classifier. They have concluded that, the accuracy of classification can be increased by increasing the training data.

Nagamma P and Pruthvi H.R [22] in their study used clustering combined with classification model to reduce the data employed for prediction and result in good accuracy. The classification with and without clustering resulted similar for smaller datasets. The authors concluded that the use of clustering with classification model could be seen principally in case of large datasets.

Teja, J.S., et al., compared three major algorithms namely NB, SVM and Logistic Regression based on accuracy precision and recall. The result analysis claims that highest accuracy was achieved by Logistic Regression(92.15), followed by SVM and NB. [23]

Any classification algorithm works well and produces better output only when the data is consistent. It can be concluded that cleaner the data, better the performance of an algorithm in forecasting the movie success rate.

III. RESEARCH METHODOLOGY & RESULTS

The idea proposed in the present work is to perform analysis on movie data using Multiple Linear Regression Analysis model considering number of parameters for the derivation of algorithmic performance and true review rating prediction. In this study, the emphasis is on Multiple Linear Regression Analysis algorithm to amplify the accuracy. The architecture of the proposed True Movie Rating Prediction System is shown in Figure1.

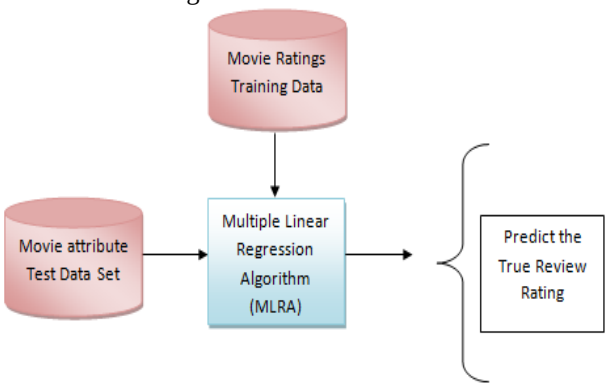

Figure 1: Structural Design of the Proposed System

The system is based on labeled dataset of reviews on movies from IMDb dataset that includes attributes like actor, actress, director, story, screenplay, climax and other relevant attributes along the movie rating labels with utmost quantity of reviews for every movie, around or less to 100 and number of movies considered is around 50. The Multiple Linear Regression Analysis model is trained with this dataset. A test dataset has been taken from IMDb reviews which are not rated with any rating labels. The test dataset is applied on the model that helps to predict the true review rating with a precision of 89%. The Multiple Linear Regression Analysis algorithm performed well in predicting the true review compared to the performance of Logistic Regression and Multivariate Regression Analysis.

Multiple Linear Regression Analysis - MLRA

The aim of this study is to calculate probability of true rating of the review by applying the statistical technique, namely Multiple Linear Regression model. At least two predictor variables are enclosed in the model [25]. Multiple linear regression model with two forecaster variables (independent) $x_1$and $x_2$is shown in (1).

$$Y= \beta_0 + \beta_1 x_1+ \beta_1 x_2 \quad (1)$$

Where Y is a dependent variable and β_1, β_2 are regression coefficients.

trainModel=lm(train$OverallRating~train$Hero+train$Heroine+train$Director+train$Story+train$Theme+train$ArtDirector+train$MusicDirector+train$SupportingArtists+train$Dance+train$Fights+train$ScreenPlay+train$IntervalBang+train$Climax,data=train)

Here the trainModel is the dependent variable and the parameters like OverallRating, Hero, Heroine and so on applied to the linear model (lm) are the independent variables.

This Multiple Linear Regression Analysis (MLRA) system is implemented in two stages. In the primary stage, the training data set is applied to Multiple Linear Regression Analysis [5] algorithm. Then for assessing model and predicting values, the test data set is utilized. In the final stage, Analysis of variance (**ANOVA**) is a statistical technique that helps to make analysis of disparities among group means and their allied procedures [6].

IV. EXPERIMENTAL RESULTS

This method is built and carried out by means of .NET framework; Visual Studio IDE; SQL Server, and a graphical GUI technology, termed as winForms. In the present work, IMDb movie dataset is used to prepare a training set that can be applied to model the relationship between attributes of dataset and the given movie rating ranging from 1 to 5. The regression line represents the estimated true rating of the movie for a certain blend of the entered features [7]. Scatter plot is given using a linear equation (2)

$$Y=\beta_0 + \beta_1 x_1+ \beta_2 x_2+.....+ \beta_i x_n \quad \text{for i = 1…n.} \quad (2)$$

Where Y is dependent variable, x_1, x_2,…x_n are independent variables and β_0, β_1.. are regression coefficients.

The divergence amid the regression line and solitary data point is the distinction that the model cannot explicate. This inexplicable distinction is called as residual. Eq (3) illustrates the technique of least squares to diminish the residual.

$$\sum (y_i - \beta_0 - \beta_1 - x_1 - \widehat{\beta_2 - x_2} - - - \beta_p - x_n)^2 \Rightarrow min = \beta_0 + \beta_1 - x_1 + \beta_2 - x_2 + \beta_3 - x_3 + - - + \beta_p - x_n \quad \text{for i = 1…n.} \quad (3)$$

The multiple linear regressions' variance σ^2 is estimated by (4)

$$\sigma^2 = \frac{\sum e_i^2}{n-p-1} \quad \text{for i = 1…n.} \quad (4)$$

Where e_i is the predicted value of i^{th} sample, n being a size of sample; p adds up to the number of autonomous variables. Following the receipt of the multiple linear regression equation, evaluate the usefulness and validity of an equation. R^2 is an important gauge to validate the probable linear line (5)

$$R^2 = SSR / SST \quad (5)$$

Where SSR is Regression sum of squares SST is the total sum of squares [26]. To discover if the multiple linear regression model fits efficiently, an adjusted R^2 can be deliberated as

$$adjusted\ R^2 = R^2 - J(1 - R^2)/N - P - 1 \quad (6)$$

Where P is the total independent variables and N is size of a sample.

The final step for the regression analysis is an analysis of significance. Multiple linear regression employs two tests. F-tests being the first tests if the value of R^2 is 0. Later on, multiple t-tests are performed to scrutinize the significance of every individual intercept as well as coefficient. Finally, The t-test has the void hypothesis [24] that the coefficient or intercept be zero [8].

ANOVA offers a statistical test to test out whether the means of several groups are identical, and consequently simplifies the *t*-test to three or more means. ANOVA is further conventional and is suitable to an extensive range of realistic problems [9]. A sample dataset with attributes such as MovieID, Actor, Actress, Director that is used as training set and test set for the model are shown in Table 1 and Table 3 respectively.

Table1: Sample Data set to use as Training Set for True Rating Prediction of a Movie

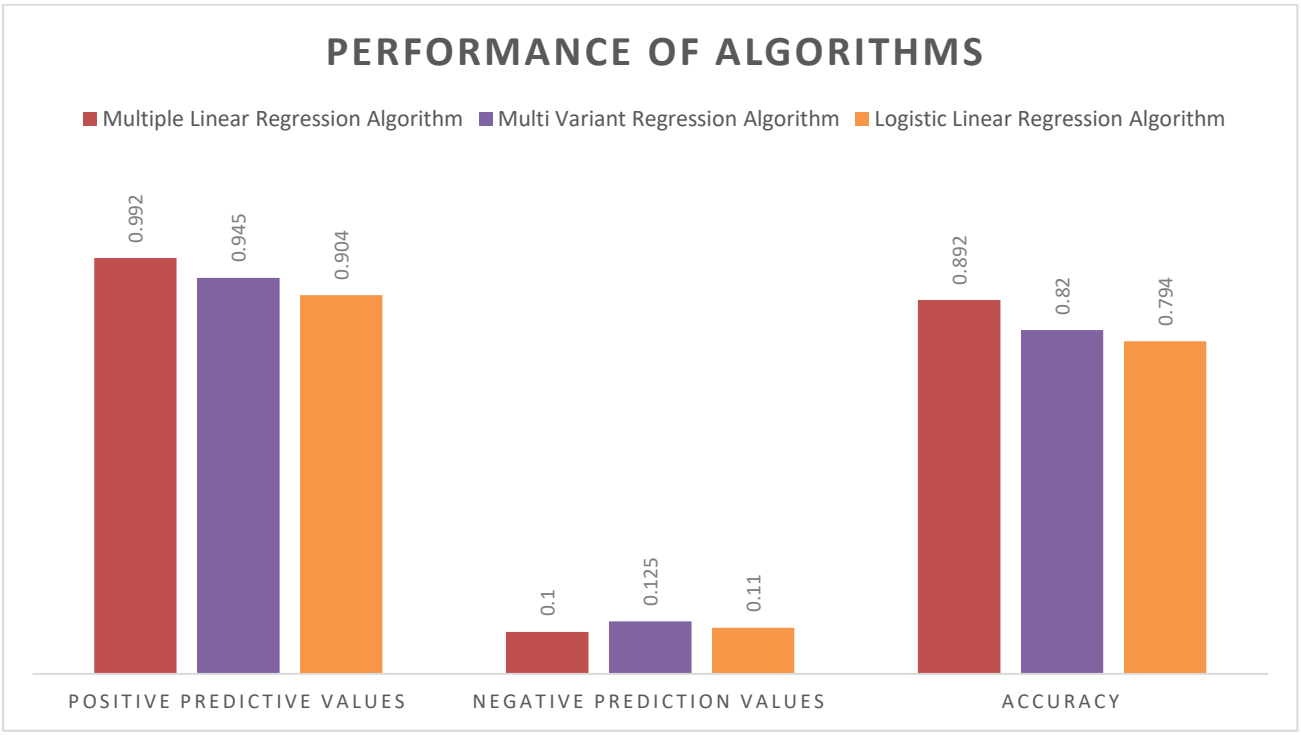

Figure 5: Performance measures of each algorithm considered for predicting the movie rating labels.

V. CONCLUSION

To predict the true positive rating of a movie has become a great concern in commercial aspects. It provides the rating of the movie that falls between the ranges from must see to unwatchable depending on the user profile settings. The scale of the study is to explore the prediction accuracy of true positive rating of the movie and to estimate the performance of data mining technique used in such an environment. For this a machine learning algorithm [10] is adopted. MLRA learns the training data set and builds a model that allows application of test data on it. Logistic regression and multivariate regression algorithms were also applied on the same data in the same way. From the trial outcome it is verified that MLRA algorithm is most suitable for envisaging accurately the true positive reviews based on the attributes with over 89% compared to multivariate regression with 82%, logistic regression with 79% predicting accuracy. To conclude, we can say that Optimum Predictions could be obtained by this MLRA Model.

Abstract

Diabetes Mellitus is one of the growing fatal diseases all over the world. It leads to complications that include heart disease, stroke, and nerve disease, kidney damage. So, Medical Professionals want a reliable prediction system to diagnose Diabetes. To predict the diabetes at earlier stage, different machine learning techniques are useful for examining the data from different sources and valuable knowledge is synopsized. So, mining the diabetes data in an efficient way is a crucial concern. In this project, a medical dataset has been accomplished to predict the diabetes. The R-Studio software was employed as a statistical computing tool for diagnosing diabetes. The PIMA Indian database was acquired from UCI repository will be used for analysis. The dataset was studied and analyzed to build an effective model that predicts and diagnoses the diabetes disease earlier.

Keywords

Diabetes, Classification, Clustering, Regression, SVM, K-NN, Neural Networks

Introduction

As we all know that the growth in technology helps the computers to produce huge amount of data. Additionally, such advancements and innovations in the medical database management systems generate large volumes of medical data. Healthcare industry contains very large and sensitive data. This data needs to be treated very careful to get benefitted from it. Diabetic Mellitus is a set of associated diseases in which the human body is unable to control the quantity of sugar in the blood. It results in high sugar levels in blood, may be as the physique cannot create sufficient insulin, or may because cells should not respond to the formed insulin. The focus is to develop the prediction models by using certain system trained methods. The system learning is one of the branches of synthetic intelligence as it helps the computer to learn on its own.[1] The two classification of ML are supervised and unsupervised. The Supervised learning calculation utilizes the past experience to influence expectations on new or inconspicuous information while unsupervised calculations to can draw derivations from datasets.

Machine learning algorithms are:

Supervised Learning Techniques:

Classification

This is a procedure of detecting the obscure information label name utilizing recently known (preparing information) class mark.[2] The familiar supervised learning methods are mentioned as follows.

i. Random forest
ii. SVM
iii. K-Nearest neighbors
iv. Decision tree
v. Naïve Bayes

Regression

It is also a prediction modeling method such as classification. It detects the association between the free (given) features with few target (new) features.

The popular algorithms are:

i. Simple Linear Regression
ii. Multiple Linear Regression
iii. Logistic Regression
iv. Polynomial Regression
v. Linear Discriminant Analysis (LDA)

Unsupervised Learning Techniques

Clustering

Cluster investigation or grouping is a process of classifying the similar instances into classes called groups.[3] Some of the grouping methods are as follows:

i. Mean based grouping for the given number of clusters ‘k’

© 2020 The Author (s); Helix E-ISSN: 2319-5592; P-ISSN: 2277-3495

ii. Level-by-level grouping based on similarity distance metrics.

R-Studio Tool

R studio 3.4.1 is used in this study. R-Studio is a United Improvement Environment for R programming language founded by JJ Allaire. It uses command line interpreter. It is used for statistical computing and graphics. Since it is having many built-in packages it can manipulate huge dataset for analysis

Proposed System

The propose a classification model with boosted accuracy to predict the diabetic patient. In this model, we have employed different machine learning techniques are using like classification, regression and clustering. The major focus is to increase the accuracy by using resample technique on a benchmark well renowned PIMA diabetes dataset that was acquired from UCI machine learning repository, having eight attributes and one class label.[4] The proposed framework is shown in Figure 1.

The description of each phase is mentioned below:

Data Selection

Data selection is a process in which the most relevant data is selected from a specific domain to derive values that are informative and facilitate learning. PIMA diabetes dataset having 8 attributes that are used to predict the diabetes at earlier stage. This dataset is obtained from UCI repository.

Data Pre-processing

It also includes machine learning technique that includes changing crude information into reasonable configuration. The various activities involved here are Cleaning the data, integrating the data and transforming the data and Discretizing the data.[5]

Feature Extraction through Principle Component Analysis

Feature Extraction on the dataset to determine the most suitable set of attributes that can help achieve better classification. The set of attributes suggested by the PCA are termed as feature vector. Feature reduction or dimensionality reduction will be benefitted us by reducing the computation and space complexity.

Resampling Filter

The supervised Resample filter is applied to the pre-processed dataset. Resampling is a sequence of techniques used to rebuild your sample data sets, combining training sets and validation sets. In this study, Boot strapping resampling technique to enhance the accuracy.[7]

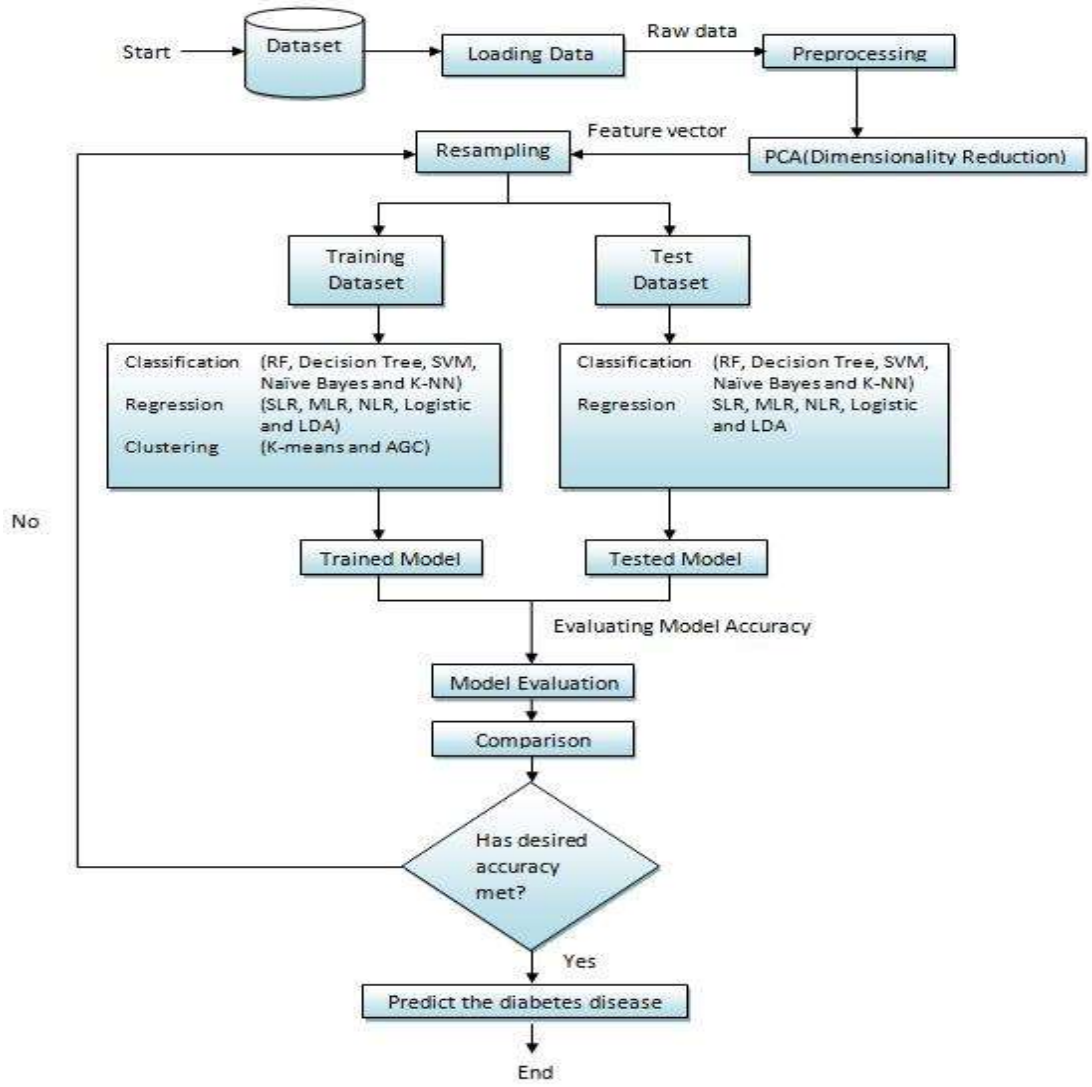

Figure 1: Proposed System for Diabetes Prediction System

Machine Learning Techniques

Classification

Random Forest Technique

Random Judgement Forest is an outfit knowledge technique used for supervised learning methods and extra jobs that operates by building a group of decision trees during learning phase and label the class that is the frequency of the class labels used in classification and mean can be used for prediction of the independent trees. Irregular choice woods right for choice trees tendency for overfitting to their given known dataset.[8]

Support Vector Machines (SVM)

It is one of the most partition of classification Algorithms family. It is utilized strategy to implement prediction, guessing a class label and outlier analysis of data. SVM will grouping the information dependent on the hyper plane. The hyper plane should totally isolate the two class labels in the better way and the most extreme edge hyper plane ought to be picked as a best divider. The various classes of SVM are as follows:

i. Linearly separable Classifier
ii. Non-Linearly separable Classifier

Decision Tree

Decision tree algorithm is mainly used to produce a classification on training data and regression model into a tree structure, which is based on previous data to classify/predict class or target variables of future/new data with the help of decision rules or decision trees.[10] It can be useful for both numerical and categorical data. In a complete decision tree, the root node in each level is a starting point or the best splitting attribute in that position which helps to test on an attribute. The yield of the test will create branches. Leaf hub will go about as a last

 © 2020 The Author (s); Helix E-ISSN: 2319-5592; P-ISSN: 2277-3495

class mark or target variable to characterize/foresee the new information. Arrangement rules are attracted from root to leaf.

Naïve Bayes Method

The naive Bayes algorithm performs classification tasks in the field of ML. It can perform classification very well on the dataset even it has huge records with multi class and binary class classification problems.[11] The main application of Naive Bayes is text analysis and Natural Language Processing. Bayes theorem works based on conditional probability.

It can be represented as: $P(X \mid Y) = [P(Y \mid X) * P(X) / P(Y)]$

Here X and Y are two events and, P (X|Y) is the conditional probability of X given Y. P(X) is the probability of X.

P(Y) is the probability of Y. P (Y|X) is the conditional probability of Y given X.

k-Nearest Neighbors

K-NN is also a supervised learning model used for classification. It is also a significant choice for the classification type of analyses. In order to detect the target class label of a supplied data, this method detects variation between nearest given data classes and new given data values with the concern of K-value. [12] It uses K feature value in between 0-1usually.

Regression

Simple Linear Prediction Model

It explains the association between individual and dependent variables to detect the outcome of the dependent feature. A Simple prediction model uses only one individual feature.[13]

The simple linear regression model is represented as

y= (b0 +b1x)

Here, x (independent variable) and y (dependent variable) are two factors involved in simple linear regression analysis. Also, b0 is the Y-intercept and b1 is the Slope.

Multiple Linear Model Regression

It explains the association between two or more independent features and a dependent feature to guess the labels of a dependent feature.[14] It will take two or more individual variables. Dependent feature has a continuous but an independent variable may be discrete or continuous values.

The multiple linear regression model is represented as

y= (p0 +p1x1+p2x2+…+pnxn)

Here x1, x2,..., xn (independent variable) and y (dependent variable) are two factors involved in multiple linear regression analysis. Also, b0 is the y-intercept and p1, p2,…, pn is the slope.

Logistic based Prediction

It is one type of binary classification method and is used when the dependent feature is nominal. It models the association between one dependent feature and one or more independent variables.[15]

The various types of Logistic Regression are:

a. Binary class labeled Regression
b. Multinomial Regression
c. Ordinal type Regression

The categorical response has only two possible outcomes. Multinomial Logistic Regression has three or more outcomes without ordering whereas Ordinal Logistic Regression has three or more outcomes with ordering.

Polynomial Regression

Polynomial Regression is a type of prediction analysis which explains the association between the individual variable and dependent feature as polynomial of degree of ‘n’. It models a non-linear association between the independent variable and restrictive average of dependent variable. It should be represented as

x = a + b * y ^ n

Here ‘x’ is Dependent Variable, ‘y’ is Independent Variable and ‘n’ is Degree.

It is used to fit the data very well when the data is below and above the regression model. It minimizes the cost function and provides optimum result on the regression.[16]

Linear Discriminant Analysis (LDA)

It is a process of using different data elements and reflecting different functions to detect class labels of objects or instances separately. [17] It is applicable in the fields of Pattern Recognition and Prediction analysis.

Clustering

Mean based Clustering for the given ‘K’ Clusters

K-means grouping is not a supervised system learning algorithm. It can be used to solve clustering problems by classifying the dataset into a number of clusters k (group of similar objects), which defines the number of clusters which is assumed before classifying the dataset.[18]

 © 2020 The Author (s); Helix E-ISSN: 2319-5592; P-ISSN: 2277-3495

Hierarchical Clustering

It is a type of clustering which is used to build a ladder of groups. The two methods of this type of grouping techniques are Agglomerative nesting and Divisive analysis. The first method is used to group objects into clusters based on their similarity. The result obtained at last is a tree representation of objects called 'Dendrogram'. Divisive Analysis is a best down methodology where all perceptions begin in one bunch, and parts are performed recursively as one moves down the pecking order. A hierarchical clustering is often represented as a dendrogram. Each cluster will be representing with centroids. Distance will be calculated by using linkage.[19]

Results and Discussions

Indian diabetes dataset named PIMA were used for analysis for this study. It consists of eight independent attributes and one independent class attribute. The study was implemented by R programming language using R Studio. Machine learning algorithms like classification (Judgement Tree, Bayesian Classification, KNN and Ensemble Learning), regression (linear, multiple, logistic, LDA) and clustering (k-means, hierarchical agglomerative) are used to predict the diabetics disease in early stages. Measure Performance model by using accuracy.

Table 1: Predictive Analysis of Machine Learning Algorithms

S. No	Algorithm	Accuracy
1	Random forest	73%
2	Decision tree	67%
3	SVM	82%
4	Naïve Bayes	76%
5	K-NN	81%
6	Simple linear regression	88%
7	Logistic regression	78%
8	LDA	78%
9	k-Means	71%
10	Hierarchical agglomerative	64%

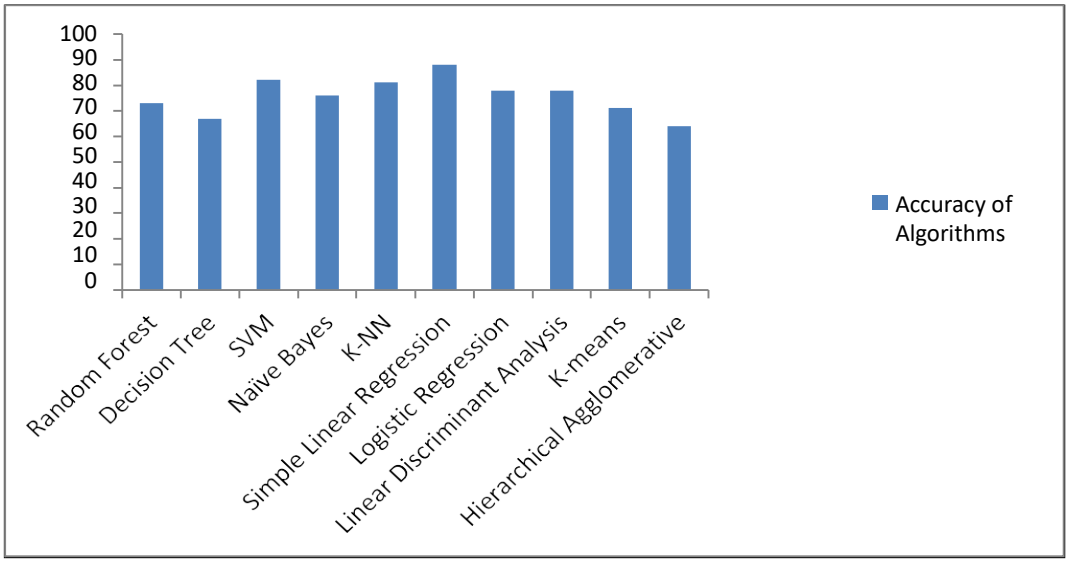

Figure 2: Comparison of Accuracy of Various Algorithms

Conclusion and Future Work

Knowledge extraction creates a significant position in various fields such as Simulated Intelligence and Device Learning, Database Systems and more. The core objective is to enhance the accuracy of predictive model. This PIMA dataset will increase the accuracy of almost all algorithms but the SVM and linear regression leads over others. In future many advanced techniques will be used to increasing the accuracy of the algorithms.

Abstract- ***The global deployment of cloud data centers is empowering enormous scale logical work processes to improve execution and convey quick reactions. This exceptional geological dissemination of the calculation is multiplied by an expansion in the size of the information taken care of by such applications, bringing new moves identified with the effective information the executives crosswise over destinations. High throughput, low latencies or cost-related exchange offs are only a couple of worries for both cloud suppliers and clients with regards to taking care of information crosswise over server farms. Existing arrangements are restricted to cloud-gave capacity, which offers low execution dependent on inflexible cost plans. Thus, work process motors need to ad lib substitutes, accomplishing execution at the expense of complex framework designs, support overheads, diminished dependability, and reusability. In this paper, we present Over Flow, a uniform information the executives framework for logical work processes running crosswise over geologically disseminated destinations, intending to receive monetary rewards from this geo-decent variety. Our answer is condition mindful, as it screens and models the worldwide cloud framework, offering high and unsurprising information taking care of execution for exchange cost and time, inside and crosswise over locales. Over Flow proposes a lot of***

pluggable administrations, assembled in an information researcher cloud unit. They furnish the applications with the possibility

to screen the hidden foundation, to endeavor shrewd information pressure, de duplication, and geo-replication, to assess information the board costs, to set an exchange off among cash and time, and streamline the exchange procedure as needs be. The framework was approved on the Microsoft Azure cloud over its 6 EU and US server farms. The tests were led on many hubs utilizing manufactured benchmarks and genuine bio-informatics applications (A-Brain, BLAST). The outcomes demonstrate that our framework can show precisely the cloud execution and to use this for proficient information scattering, having the option to diminish the fiscal expenses and move time by up to multiple times.

Keywords: Big Data, scientific workflows, cloud computing, geographically distributed, data management.

I. INTRODUCTION

Big Data is working on different storage model on multiple nodes in a single cluster. WITH their globally distributed data centers, cloud frameworks empower the quick improvement of enormous scale applications. Instances of such applications running as cloud benefits crosswise over destinations extend from office shared apparatuses (Microsoft office 365, Google Drive), web indexes (Bing, Google), worldwide financial exchange investigation instruments to excitement administrations (e.g., sport occasions broadcasting, enormously parallel diversions, news mining) and logical work processes [1]. The majority of these applications are sent on different destinations to use nearness to clients through substance conveyance systems. Other than serving the nearby customer demands, these administrations need to keep up a worldwide cognizance for mining questions, upkeep, or observing tasks, that require huge information developments. To empower this Big Data preparing, cloud suppliers have set up various

server farms at various topographical areas. In this unique situation, sharing, dispersing, and dissecting the dataset results in incessant huge scale information developments crosswise over broadly appropriated destinations. The focused on applications are figure serious, for which moving the preparing near information is fairly costly (e.g., genome mapping, material science reenactments), or just requiring huge scale start to finish information developments (e.g., associations working a few server farms and running standard reinforcement and replication between destinations, applications gathering information from remote sensors, and so on.). In all cases, the cost investment funds (predominantly calculation related) should balance the critical between site separate (organize costs). Studies demonstrate that the between server farm traffic is relied upon to significantly increase in the next years [2], [3]. the current cloud information the board benefits ordinarily need instruments for progressively organizing exchanges among various server farms to accomplish sensible QoS levels and advance the cost-execution. Having the option to successfully utilize the hidden stockpiling and system assets has in this way turned out to be basic for wide-zone information developments just as for combined cloud settings. This land conveyance of calculation turns out to be progressively significant for logical revelation. numerous Big Data logical outstanding tasks at hand empower these days the parceling of their info information. This permits to perform the majority of the preparing autonomously on the information segments crosswise over various destinations and afterward to total the outcomes in conclusive stage. In probably the biggest situations, the informational indexes are as of now apportioned for capacity over various locales, which disentangles the undertaking of

planning and propelling topographical dispersed handling. Among the famous models, we review the 40 PB/year information that is being produced by the CERN LHC. The volume bridges single site or single organization ability to store or process, requiring a framework that ranges over various locales. This was the situation for the Higgs boson disclosure, for which the preparing was stretched out to the Google cloud framework [4]. Quickening the way toward understanding information by parceling the calculation crosswise over destinations has demonstrated compelling additionally in different regions, for example, taking care of bio-informatics issues [5]. Such remaining tasks at hand regularly include a colossal number of factual tests for affirming potential critical locale of interests (e.g., connects between cerebrum districts and qualities). This handling has demonstrated to profit enormously from dispersion crosswise over destinations. Other than the requirement for extra process assets, applications need to agree to a few cloud suppliers prerequisites, which power them to be sent on topographically dispersed destinations. For example, in the Azure cloud, there is a cutoff of 300 centers apportioned to a client inside a server farm, for burden adjusting purposes; any application requiring more process power will be in the end disseminated over a few destinations. All the more for the most part, a huge class of such logical applications can be communicated as work processes, by depicting the connection between individual computational undertakings and their information and yield information in an explanatory manner. Not at all like firmly coupled applications (e.g., MPI-based) imparting straightforwardly by means of the system, work process assignments trade information through documents. As of now, the work

process information dealing with in mists is accomplished utilizing either some application explicit overlays that guide the yield of one undertaking to the contribution of another in a pipeline style or, all the more as of late, utilizing the Map Reduce programming model, which does not fit each logical application. When sending a huge scale work process over numerous server farms, the geologically dispersed calculation faces a bottleneck from the information moves, which bring about mind-boggling expenses and huge latencies. Without proper structure and the executives, these geo-different systems can raise the expense of executing logical applications. In this paper, we handle these issues by attempting to comprehend to what degree the intra and between server farm moves can affect on the all out make the range of cloud work processes. We initially look at the difficulties of single site information the board by proposing a methodology for proficient sharing and move of information/yield documents between hubs. We backer putting away information on the figure hubs and moving records between them legitimately, to abuse information territory, and to keep away from the overhead of associating with a common document framework. Under these conditions, we propose a document the executives administration that empowers high throughput through self-versatile choice among different exchange procedures (e.g., FTP-based, Bit Torrent-based, and so forth.). Next, we center around the more broad instance of huge scale information dispersal crosswise over geologically circulated destinations. The key thought is to precisely and powerfully anticipate I/O and move execution in a dynamic cloud condition to prudently choose how to perform move advancements over united server farms. The proposed checking administration refreshes progressively the presentation models to reflect changing remaining

burdens and differing system gadget conditions coming about because of multi-occupancy. This learning is additionally utilized to foresee the best blend of convention and move parameters (e.g., multi-courses, stream tally, multicast upgrade, replication degree) to augment throughput or limit costs, as indicated by clients arrangements. To approve our methodology, we have actualized the above framework in Over Flow, as a component of the Azure Cloud so applications could utilize it dependent on a Software as a Service approach.

II. RELATED WORK

Title: Overflow: Multi-Site Aware Big Data Management for Scientific workflows on Clouds:

Authors: Radu Tudoran, Member, IEEE, Alexandru Costan, Member, IEEE, and Gabriel Antoniu, Member

Publishing Year: 2015

Method: The worldwide sending of cloud datacenters is empowering huge scale logical work processes to improve execution and convey quick reactions. This exceptional land circulation of the calculation is multiplied by an expansion in the size of the information taken care of by such applications, bringing new moves identified with the effective information the executives crosswise over locales.

Disadvantage:

Information scattering, having the option to decrease the financial expenses and move time by up to multiple times.

Advantage:

Over Flow proposes a lot of pluggable administrations, gathered in an information researcher cloud unit. They give the applications the likelihood to screen the hidden framework, to adventure brilliant information pressure, de duplication, and geo-replication, to assess information the executives costs, to set a tradeoff among cash and time,

and improve the exchange technique in like manner.

Title: Data Transfer Scheduling and Optimization as a Service:

Authors: Tewfik Kosar, Engin Arslan, Brandon Ross, and Bing Zhang

Publishing Year: 2013

Method: Wide-area transfer of large data sets is still a big challenge despite the deployment of high-bandwidth networks with speeds reaching 100Gbps. Most clients neglect to acquire even a small amount of hypothetical paces guaranteed by these systems, an "information move planning and improvement framework as a Cloud-facilitated administration," Stork Cloud, which will mitigate the large-scale end-to-end data movement bottleneck by efficiently utilizing underlying networks and effectively scheduling and optimizing data transfers.

Disadvantage:

Concept but not functionally implemented.

Advantage:

Initial design and prototype implementation of Stork Cloud, and show its effectiveness in large dataset transfers across geographically distant storage sites, data centers, and collaborating institutions.

Title: Inter-Datacenter Bulk Transfers with NetStitcher:

Authors: Nikolas Laoutaris, Michael Sirivianos, Xiaoyuan Yang, and Pablo Rodriguez

Publishing Year: 2011

Method: Huge datacenter administrators with locales at various areas measurement their distinct advantages as per the pinnacle request of the geographic territory that each site covers. Planned, actualized, and approved NetStitcher, a framework that utilizes a system of capacity hubs to join together unutilized transfer

speed, at whatever point and any place it exists.

Disadvantage:

The dimensioning of a site in terms of key resources, such as the number of servers and the amount of transit bandwidth to the Internet, depends highly on the peak demand from the geographic area covered by the site

Advantage:

Contrasted NetStitcher and other mass exchange components utilizing both a tried and a live sending on a genuine CDN. Our tried assessment demonstrates that NetStitcher outflanks every single other system and can save up to multiple times extra datacenter transmission capacity, along these lines making it a significant apparatus for datacenter suppliers.

Title: The cost of a cloud: research problems in data center networks:

Authors: Albert Greenberg, James Hamilton

Publishing Year: 2011

Method: The server farms used to make cloud administrations speak to a huge interest in capital expense and progressing costs. As needs be, we initially look at the expenses of cloud administration server farms today.

Disadvantage:

The cost breakdown uncovers the significance of streamlining work finished per dollar contributed. Shockingly, the assets inside the server farms frequently work at low use because of asset stranding and discontinuity.

Advantage:

Expanding system spryness and giving suitable motivating forces to shape asset utilization. Second, we note that cloud specialist organizations are working out geo-disseminated systems of server farms. Geo-assorted variety brings idleness down to clients and expands

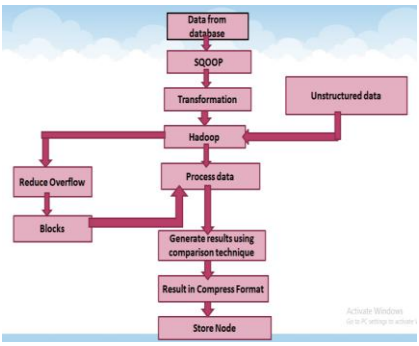
unwavering quality within the sight of a blackout taking out a whole site.

III. PROPOSED WORK

A fully-automated single site software system for scientific workflows data management. Multi-Node Cluster approach for storing away the information with the data with the help of Hadoop. Indexing helps the data the user to have complete access to the data. The multi-route transfer approach across intermediate nodes of multiple data centers. The Compression mechanism is proposed to compress the text data file. Map reduce-Byte Offset algorithm is implemented, which shows the file in an unstructured format large data set. Single site data management for effective sharing and exchange of input/output files between nodes.

Every system has its objectives. It can be either the main objective or sub-objectives. The main objective is to Simplifying the processing of storing the Big Data on a single site data center/cloud. The distribution of nodes is proposed to process the capacity of data on the various nodes across a data center. To compress the data, big data will be divided and stored in different nodes.

The system has the sub goals which are as follows



Big data will be divided and stored in different nodes and processed on the small data sets and large data sets in a structured and unstructured manner.

To process the data, the distribution of nodes can be performed on that data. Distribution of the nodes can be done in the form of blocks based on the data set.

The compression mechanism is applied to reduce the overflow of data problem on a virtual machine. This helps us to compress the text data, which has any repetition of words in the data set and represent in the word power n in matrix form. Analyzing the data can be done by

importing data to geographical location into the analytical platform.

IV.IMPLEMENTATION

System architecture

The existing system is mainly focusing on the data over flow problem in a different geographical locations.

The data over flow problem occurs by getting to the normal shared cloud in different location. When accessing the overall data from all clouds, there may get a chance that the cloud might go down in some location. Providing solution in Data management on cloud with different geographical locations. This causes a serious problem in the efficiency of the system in accessing the data. There will be no Data loss for the data on the nodes. Even we can have the data replication so theta multiple copies of data can be maintained. Processing has a good time. Efficiency increases for storing and processing of the Big Data and Learning about the current framework and techniques of how data is stored and control the overflow. Extracting the business logic - working with new enhancement over the previous statistics and applying the algorithms and methods from previous and current enhanced algorithms and developing Architecture and implementation.

Algorithm:

Step1: The resultant output is divided and distributed over nodes.

Step2: Data is then consolidated to a single file making all the similar words to bag and represented with

word control n and power speak to how many times the word is repeated in the result.

Step3: Each repetition is represented by matrix form man.

Step4: Word ^n[x, y] like happy^3[1,3][2,4][4,5].

Step5: Every word is indexed with the line and place of in the line based on the above method the compression works.

In step1, the resultant yield is detached and disseminated over the nodes; we are compressing the resultant output data because the output will be more than the input size, which causes an overflow problem. In the step2, in the given text data if there are any similar bag of words repeated that represents with that word power of n times. In step3, each repetition of that word is represented in matrix form. In the step4, the formula word ^n[x,y] like happy^3[1,3][2,4][4,5]. In step5, every word is indexed with the line and place of in the line based on the above method the compression works.

Map Reduce – BYTE OFFSET

Step1: Initiate default constructor map().

Step2: Once the map() constructor invokes the method identifies the data and calculates the size of data.

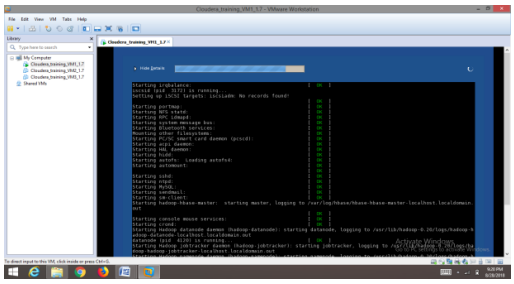
Step3: Divides the data based on configuration size is m GB, then divides m GB/64MB

Step4: => (m * 1024) MB /64mb = x MB files, x is the number of files

Step5: map<key, value>, key => IntWritable, value => text writable

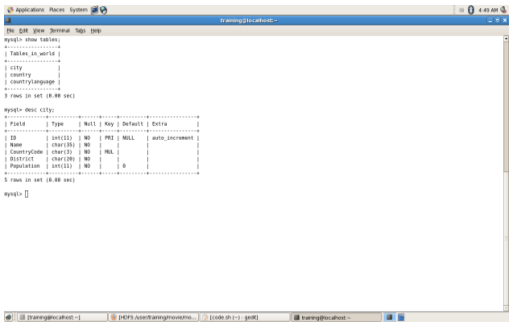
In step1, to run the algorithm, we use the map constructor (). In step2, Once the map() constructor invokes the method identifies the information and computes the size of data. In step3, then the data will be divided based on the configuration size, if it is in 1'm' GB, then it divides m GB/64MB. In Step4, using the

formula (m * 1024) MB /64mb = x MB files, x is number of files. In step5, finally mapping the key and value which speaks to the key => Int Writable, value => text writable.



V. EXPERIMENTS AND RESULTS

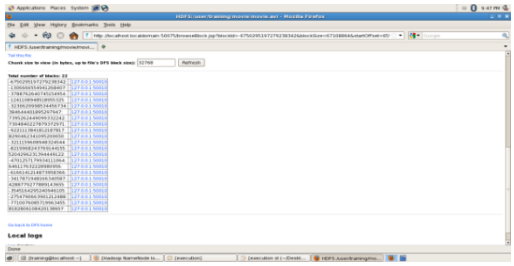
Cloud has been setup by creating the nodes in the network Virtual Machine Work Station. Within the local server virtual machine creating the Cloud era. There will be process the data and finally produce the results.



Access the Nodes: Transformation of the data can be processed to and from the nodes. This process can be performed by importing of the data from MYSQL to Hadoop. Accessing the data to and from Node can be done with any of the datasets. Creating the tables with a large number of fields and also accessing the information of each field. This produces the result in the hdfs file local host with blocks.

Data Pre Process: By processing the data available on the node, the large data file where there will be an overflow problem of the data which we lessen the measure of that data and also distributing that data.

Result Analysis: Finally, generating the reports upon the processed data, which can demonstrate the outcomes in the HDFS file system of all the datasets we are taken to process the data.



Cloud era desktop has been setup within the server which contains some folders in it

Accessing of the nodes can be done by taking sample dataset, and we can know how the information has been accessed and transformed.

This is the training@localhost where we execute the commands in the terminal to process the data, first; make the database in mysql this will load the data from MySQL to Hadoop.

Hadoop fs -copyFromLocal Src ... Dest

This command is utilized to move our file from local file system to HDFS.

To copy the two files in Hadoop

Hadoop fs -copyFromLocal /home/training/Desktop/BX-BooksCorrected.txt /user/training/uncompress/y

File Name	File Size	Number Of Blocks	Block Size
Movie.avi	1.19 GB	22 Blocks	64 MB
BooksConnected.txt	69.96 MB	2 Blocks	64MB
Data.csv	8.56 KB	1 Block	64MB

Files with number of blocks

VI. CONCLUSION AND FUTURE ENHANCEMENTS

The single node cluster approach for storing away the information with the help of Hadoop, which helps us to overcome the overflow problem. The source VM replicates its data to destination VM. For small data sets (69.96 MB brought about less number of blocks), the overflow introduced by our solution makes the transfer less efficient. The outcomes demonstrate that the framework can show precisely in cloud execution. The framework can successfully use high-speed networks connecting the cloud data centers. Working with the overflow idea helps in diminishing the cloud space.

In the future, there will be working on the number of nodes across multiple processors with an efficient result. The overflow problem can be seen with the multiple servers available in any location by using a LAN or Cloud to perform in a real-time environment. For logical work processes dealing with numerous little records, this can turn into a bottleneck, so further wanting to supplant the per-site metadata vaults with a worldwide, various leveled one.

Moreover, an intriguing bearing to investigate is the closer mix between Over Flow and progressing chip away at dealing with floods of information in the cloud, just as other information preparing motors. To this end, an expansion of the semantics of the API is required.

Speech Discrimination-Identifying the Speaker

G. Manasa, M. Tech Student, Department of CSE, Malla Reddy Engineering College(autonomous), District Medchal, Telangana, India.

P.V. Ramana Murthy, Associate Professor, Department of CSE, Malla Reddy Engineering College(autonomous), District Medchal, Telangana, India

Abstract- Despite the recent success of deep learning for many speech processing tasks, single-microphone, speaker-independent speech separation remains challenging for two main reasons. The first reason is the discretionary request of the objective and masker speakers in the blend (change issue), and the second is the obscure number of speakers in the blend (yield measurement issue). We propose a novel profound learning system for discourse detachment that tends to both of these issues. We utilize a neural system to extend the time-recurrence portrayal of the blend signal into a high-dimensional implanting space. A reference point (attractor) is made in the implanting space to speak to every speaker which is defined as the centroid of the speaker in the inserting space. The time-recurrence embeddings of every speaker are then compelled to bunch around the relating attractor point which is utilized to decide the time-recurrence task of the speaker. We propose methods for finding the attractors for each source in the embedding space and compare their advantages and limitations. Identifying the speaker from a mixture of speakers with the help of neural networks with deep learning. The target work for the system is standard sign recreation blunder which empowers start to finish task during both preparing and test stages. We assessed our framework utilizing the voices of clients on two and three speaker blends and report tantamount or preferred execution over other best in class profound learning techniques for discourse partition.

I. INTRODUCTION

Speaker recognition Speaker acknowledgment is a sort of discourse acknowledgment innovation, which acknowledges ID of speaker dependent on discourse parameters in the discourse waveform reflect physiological and social attributes of the speaker[1]. The whole acknowledgment process requires the investigation of information discourse signal, highlight extraction, at long last to decide if the speaker is in preparing speaker accumulation. The exploration of speaker acknowledgment

in speaker acknowledgment framework comprises of highlight extraction and example coordinating [2]. At present the commonest trademark parameters are LPC, LPCC, MFCC [3], etc. The acknowledgment model in like manner use is DTW, VQ, HMM, etc. In current acknowledgment framework, when we extricate the MFCC trademark parameters, we for the most part basically evacuate the first or the initial two element segment, so as to understand the standardization of intensity range. Anyway this strategy doesn't assess other element parts' commitment to the acknowledgment execution. Research demonstrates that distinctive cepstrum coefficient has an alternate commitment to the acknowledgment execution [4]. Along these lines we chose coefficients which contribute fundamentally to the acknowledgment framework to do the exploration in the speaker acknowledgment. At present, there are two techniques to assess the component's commitment to speaker acknowledgment. One is concentrating the commitment of each element part by methods for expanding or diminishing the quantity of highlight segments. The other strategy is characterizing the fisher proportion of each element part to recognize their commitments to acknowledgment [5]. In this paper we receive the second technique.

Voice acknowledgment or speaker acknowledgment alludes to the robotized technique for recognizing or affirming the personality of an individual dependent on his voice.

There are two noteworthy uses of speaker acknowledgment advances and systems. In the event that the speaker professes to be of a specific character and the voice is utilized to confirm this case, this is called confirmation or validation. Then again, recognizable proof is the errand of deciding an obscure speaker's personality. It could be said, speaker confirmation is a 1:1 match where one speaker's voice is coordinated to a specific layout though speaker distinguishing proof is a 1:N match where the voice is looked at against numerous formats.

From a security point of view, distinguishing proof is unique in relation to confirmation. Speaker check is normally utilized as a "guard" so as to give access to a protected framework. These frameworks work with the clients' learning and commonly require their collaboration. Speaker recognizable proof frameworks can likewise be executed clandestinely without the client's information to distinguish

talkers in a dialog, alert computerized frameworks of speaker changes, check if a client is as of now taken a crack at a framework, and so on.

In criminological applications, usually to initially play out a speaker ID procedure to make a rundown of "best matches" and afterward play out a progression of confirmation procedures to decide a definitive match.

II RELATED WORK

Title:

Speaker_independent_Speech_Separation with Deep Attractor_Network :

Authors: Yi Luo, Zhuo Chen, and Nima Mesgarani

Publishing Year: 2018

Method: Speaker-independent speech separation remains challenging, speech separation, the assessed our framework utilizing the Wall Street Journal dataset (WSJo) on two and three speaker blends and report tantamount or preferred execution over other cutting edge profound learning techniques for discourse division.

Disadvantage:

Works with predefined speakers audios sets

No live tracking of audio voices

Advantage:

Speaker identification has been provided

Used as security feature in bio metric applications.

Title: A deep ensemble learning method for monaural speech separation:

Authors: X.-L. Zhang and D. Wang

Publishing Year: 2016

Method: fundamental problem in robust speech processing to address monaural speech separation

Disadvantage:

The first multi-context network averages the outputs of multiple DNNs whose inputs employ different window lengths

Works on single speaker, classifying his audio

Advantage:

Identifies all possible pitchs of the speaker in low high frequency.

Title: A regression approach to single channel speech separation via high-resolution deep neural networks :

Authors: J. Du,Y. Tu, L.-R. Dai,and C.-H. Lee

Publishing Year: 2016

Method: Approach to single-channel speech separation based on deep neural networks (DNNs) to directly model the highly nonlinear relationship between speech features of a mixed signal containing a target speaker and other interfering speakers.

Disadvantage:

Separation of speech of individual from a set of mixed results.

Advantage:

Achieve a better generalization capability than that with output features of only the target speaker

Noise-dependent resolution

Title: Informational and energetic masking effects in the perception of two simultaneous talkers:

Authors: D. S. Brungart.

Publishing Year: 2001

Method: Spatially separated speech signals for identification

Performance in this speech perception task decreased systematically when the level of the target talker was reduced relative to the masking talkers.

Disadvantage:

Problems if the speaker has similar voice characteristics

Advantage:

Works with any decible of audio ratio

Performance evolution in identifying the voice characteristics.

III METHODOLOGY / FRAMEWORK

There are two modules for the project

Speaker Identification

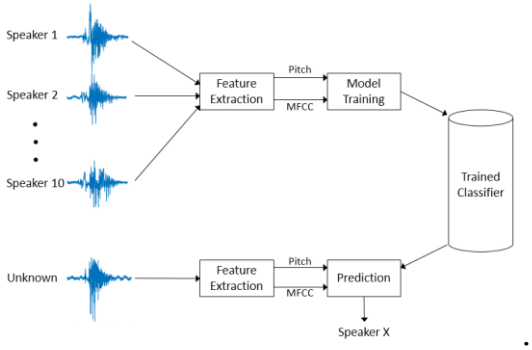
Speaker Detection

Verification versus identification:

There are two noteworthy utilizations of speaker acknowledgment innovations and strategies. In the event that the speaker professes to be of a specific personality and the voice is utilized to confirm this case, this is called confirmation or verification. Then again, recognizable proof is the undertaking of deciding an obscure speaker's personality. As it were speaker confirmation is a 1:1 match where one speaker's voice is coordinated to one layout (likewise called a "voice print" or "voice model") though speaker recognizable proof is a 1: N match where the voice is thought about against N formats.

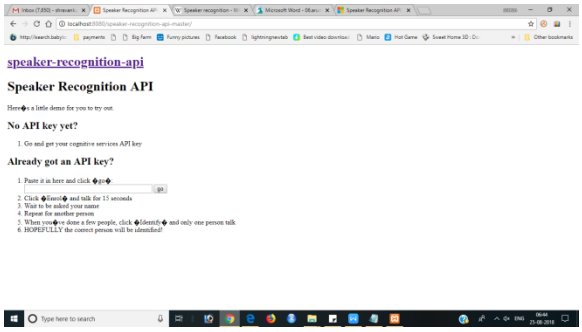
From a security point of view, distinguishing proof is not quite the same as check. For instance, exhibiting your identification at outskirt control is a confirmation procedure: the operator looks at your face to the image in the record. On the other hand, a cop contrasting a sketch of an attacker against a database of recently recorded hoodlums to locate the nearest match(es) is a distinguishing proof procedure.

Speaker confirmation is typically utilized as a "guardian" so as to give access to a protected framework (for example phone banking). These frameworks work with the clients' learning and regularly require their participation. Speaker distinguishing proof frameworks can likewise be actualized clandestinely without the client's learning to recognize talkers in an exchange, alert mechanized frameworks of speaker changes, check if a client is as of now taken on a framework, and so on.



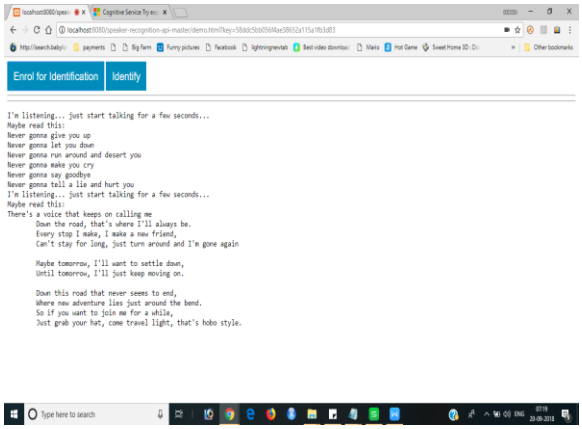
In criminological applications, usually to initially play out a speaker recognizable proof procedure to make a rundown of "best matches" and after that play out a progression of check procedures to decide a convincing match..

IV. RESULTS AND ANALYSIS

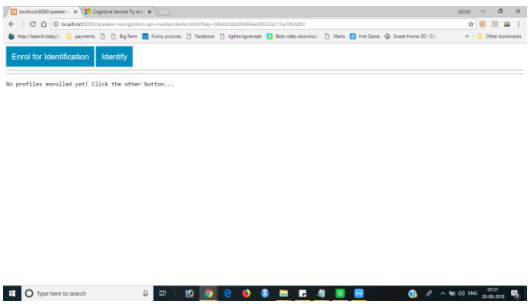


Deep Neural Networks

A deep neural network (DNN) is an artificial neural network (ANN) with multiple hidden layers between the



input and output layers.



Speaker acknowledgment frameworks fall into two classes: content ward and content autonomous.

Speaker can be added with the key

Now read the following content from the screen as we read the user will be enrolled to the application

Based on the previous enrollment we can identify the users

V. CONCLUSION & FUTURE WORK

The mixture of the speech in the audio is isolated by utilizing the DANet which performs profound grouping system by making attractor focuses in the inserting space which force together the embeddings that have a place with a particular speaker. Every attractor in this space is utilized to frame a period recurrence cover for every speaker in the blend. From the blend of the sound subsequent to applying DAN at the discourse is isolated from the blend of speakers and the sign of the every discourse is plotted. The future works incorporate investigating approaches to consolidate speaker data in the estimation of grapple focuses and in the age of the embeddings. These angles can result in both speaker-ward and speaker-autonomous partition by a similar system. Isolating more sources

past discourse flag by making a bigger and progressively instructive inserting space is additionally a fascinating and significant theme, which prompts the likelihood of structuring an all inclusive acoustic source partition system. Additionally a programmed division is required, that separated the sign into portions, contingent upon the quantity of the dynamic speakers. Be that as it may, for this, likewise a dependable location of the dynamic speakers is required. With a programmed division, the speaker acknowledgment could likewise be tried on the information, recorded in a genuine meeting situation.

Department of CSE, Malla Reddy Engineering College(A), RangaReddy, Telangana, India.

Abstract **- Information is an important asset. Appropriate utilization of amazing information can enable individuals to improve forecasts, investigations and choices. Nonetheless, regardless of how much exertion we put into gathering a decent dataset, blunders will definitely crawl into the information, making it vital for information cleaning. This turns into a worry especially when substantial scale heterogeneous information from different sources are incorporated for different purposes. Information cleaning can be confounded, time consuming, and costly, yet it is a vital stride in any information related framework since low quality information may not be appropriate to accomplish the planned purposes. The center of our information cleaning framework is information affiliation and repairing. Affiliation means to recognize a similar question and connection with the most related protests, and repairing is to make a database dependable by fixing blunders in the information. For huge information applications, we don't really need to utilize every one of the information. Much of the time, we just need a little subset of the most applicable information. So the objective of affiliation is to change over huge crude information into a little subset of the most significant information that are most helpful for a specific application. After we acquire a little measure of pertinent information, we additionally need to additionally dissect the information to enable individuals to process the information and transform the information into learning. We utilize various procedures to relate the information to get helpful learning for information repairing. Our exploration demonstrates that information affiliation can viably help with information repairing. To catch the cooperation, we give a uniform structure that unifies the affiliation and repairing process consistently in view of setting designs, use examples, metadata, and repairing rules.**

Keywords- **Data Cleaning, Data Association, Data Repairing.**

I. INTRODUCTION

Data is a valuable resource. Proper use of high-quality data can help people make better predictions, analyses and decisions. Poor-quality data may not be suitable for the intended purposes. Data cleaning is the process of fixing or removing damaged or inaccurate data. This process is necessary and extremely important for Big Data, because erroneous data may lead to poor conclusions and analyses. Data is not always entered properly and needs to be corrected before we use them. Datasets from different data sources need to be cleaned before we combine them together. If data are created for one purpose and are used for another, then the data may not be of sufficient quality for the intended purpose.

Fig 1.1 Different wellsprings of information

Data could be collected from different applications, which may provide data with the same entities, but different identities. Data from social network may arrive with unclear or dishonest information. This becomes a concern particularly when large-scale heterogeneous data from multiple sources are integrated for another purpose. In big data, applications don't necessarily use all the data. In most situations, applications only need a small subset of the most relevant data. Through association between multiple data sources, the big raw data is converted into a small subset of the most relevant data that are most useful for a particular application. After obtaining the small amount of relevant data, the data is further analyzedto help usersdigest the data and turn the data into knowledge. We use a number of techniques to associate the data to get useful knowledge for data repairing. Data association from multiple data sources is a crucial step in data cleaning, because this process can severely influence the outcomes of the data repairing processes. To capture the interaction of users with data, we provide a uniform framework that unifies association and repairing process seamlessly based on context patterns, usage patterns, metadata, and repairing rules. As both context and usage patterns are produced by humans, it tends to have a lot of useful knowledge about people's preferences and opinions. That makes it possible to mine data to discover those latent preferences of people, which could be very useful to build an intelligent system to help clean the data. Our experimental results identify that an efficient data cleaning framework can be constructed using our interactive approach. The first contribution of the paper is a data cleaning framework that

correctsdata errors and ultimately achieves a balance between high quality data and low cleaning cost. The framework first identifies and links associated data; then it ranks them followed by a two phase data cleaning process. Our second contribution is a metadata generation algorithm. The metadata generator generates both structural metadata and descriptive metadata for different kinds of data (structured / semi-structured / unstructured data). The metadata generator is important because it can assist in identifying data items, types and uniqueness for all types of datasets in the proposed framework. Our third contribution consists of two schemas for object.

II. LITREATURE SURVEY

Title: Storing, Tracking, and Querying Provenance in Linked Data:

Authors: Marcin Wylot, Philippe Cudr´e-Mauroux, Manfred Hauswirth and Paul Groth

Publishing Year: 2017

Method: The proliferation of heterogeneous Linked Data on the Web poses new challenges to database systems. In particular, the capacity to store, track, and query provenance data is becoming a pivotal feature of modern triplestores. native RDF store to efficiently handle the storage, tracking, and querying of provenance in RDF data.

Dis advanatage:

Works with structure data with less parameters in imporating and processing of the data.

Advantage:

A reliable and understandable specification of the way results were derived from the data and how particular pieces of data were combined to answer a query. Subsequently, we present techniques to tailor queries with provenance data.

Title: DARE: Cleaning Framework for BigData ----ANINTERACTIVE APPROACH FOR DATA CLEANING:

Authors: Hong Liu, Ashwin Kumar TK, Johnson P Thomas, Xiaofei Hou

Publishing Year: 2016

Method: Data is a valuable resource. Proper use of high-quality data can help people make better predictions, analyses and decisions.Data cleaning can be complicated, timeconsuming, and expensive, but it is a necessary step in any data-related system since poor-quality data may not be suitable to achieve the intended purposes.

Dis advanatage:

Usage of the ETL tools makes lack in the perfomance of the data

Data Associations not performed with more prominance

Advantage:

Uniform framework that unifies the association and repairing process seamlessly based on context patterns, usage patterns, metadata, and repairing rules

Title: A study on data deduplication techniques for optimized storage :

Authors: E. Manogar ; S. Abirami

Publishing Year: 2014

Method: the explosion of the data such as text, image, audio, video, data centers and backup data lead to a lot of problem in both storage and retrieval process. The enterprises invest lot of money for storing the data. Hence, an efficient technique is needed for handling the enormous data. eliminating the redundant data in the storage system such as data deduplication and data reduction

Dis advantage: the disk usage and cost

Advantage:

Various storage optimization techniques, concepts and categories using data deduplication..

Title: An Efficient Versioning File System for Phase-Change Memory:

Authors: Lee Eunji, Jee E. Jang, Taeseok Kim, Hyokyung Bahn

Publishing Year: 2013

Method: Versioning file systems are widely used in modern computer systems as they provide system recovery and old data access functions by retaining previous file system snapshots.

Dis advanatage:

Systems do not perform well with the emerging PCM (phase-change memory) storage, because they are optimized for hard disks. Specifically, a large amount of additional writes incurred by maintaining snapshot degrades the performance of PCM seriously.

Advantage:

Designed for PCM, that reduces the writing overhead of a snapshot significantly

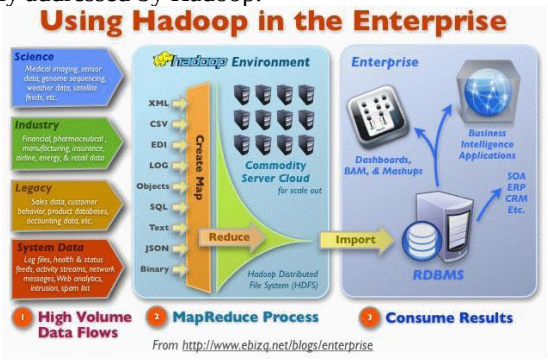
Versioning file systems that incur cascade writes up to the file system root, our scheme breaks the recursive update chain at the immediate parent level.

Quantitative Data Cleaning for Large Databases - Joseph M. Hellerstein

Data collection has become a ubiquitous function of large organizations – not only for record keeping, but to support a variety of data analysis tasks that are critical to the organizational mission. Data analysis typically drives decision-making processes and efficiency optimizations, and in an increasing number of settings is the raison d'etre of entire agencies or firms. Despite the importance of data collection and analysis, data quality remains a pervasive and thorny problem in almost every large organization. The presence of incorrect or inconsistent data can significantly distort the results of analyses, often negating the potential benefits of information-driven approaches. As a result, there has been a variety of research over the last decades on various aspects of data cleaning: computational procedures to automatically or semi-automatically identify – and, when

possible, correct – errors in large data sets. In this report, we survey data cleaning methods that focus on errors in quantitative attributes of large databases, though we also provide references to data cleaning methods forother types of attributes. The discussion is targeted at computer practitioners who managelarge databases of quantitative information, and designers developing data entry and auditing tools for end users. Because of our focus on quantitative data, we take a statistical view of data quality, with an emphasis on intuitive outlier detection and exploratory data analysis methods based in robust statistics [Rousseeuw and Leroy, 1987, Hampel et al., 1986, Huber, 1981]. In addition, we stress algorithms and implementations that can be easily and efficiently implemented in very large databases, and which are easy to understand and visualize graphically. The discussion mixes statistical intuitions and methods, algorithmic building blocks, efficient relational database implementation strategies, and user interface considerations. Throughout the discussion, references are provided for deeper reading on all of these issues.

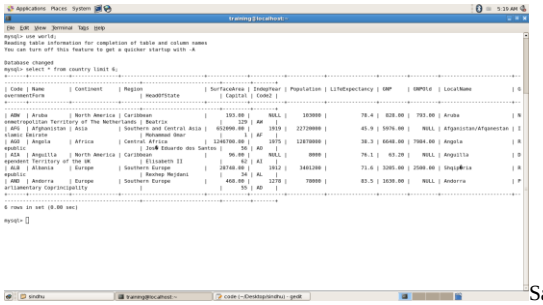
ETL



Hadoop's significance in data warehousing is progressing rapidly as a transitory platform for extract, transform, and load (ETL) processing. Mention about ETL and eyes glaze over Hadoop as a logical platform for data preparation and transformation as it allows them to manage huge volume, variety and velocity of data flawlessly. Hadoop is extensively talked about as the best platform for ETL because it is considered as an all-purpose staging area and landing zone for enterprise big data. To understand the significance of big data and hadoop for ETL professionals read this article to endorse the awareness on why is this the best time to pursue a career in big data hadoop for all data warehousing and ETL professionals.

The spurt of internet users and the adoption of technology by all the conceivable industries through the past two decades began generating data in exponentially expanding volumes. As the data kept growing, owners realized a need to analyze it and thus originated an entirely new domain of Data Warehousing. That laid the foundation for an entirely new domain of ETL (acronym for Extract Transform Load) – a field which continues to dominate the data warehousing to this date.

Data is the foundation of any Information Technology (IT) system and as long as we are prepared to manipulate and consume it, we will keep adding value to the organization. The modern technological ecosystem is run and managed by interconnected systems that can read, copy, aggregate, transform and re – load data from one another. While the initial era of ETL ignited enough sparks and got everyone to sit up, take notice and applaud its capabilities, its usability in the era of Big Data is increasingly coming under the scanner as the CIOs start taking note of its limitations.

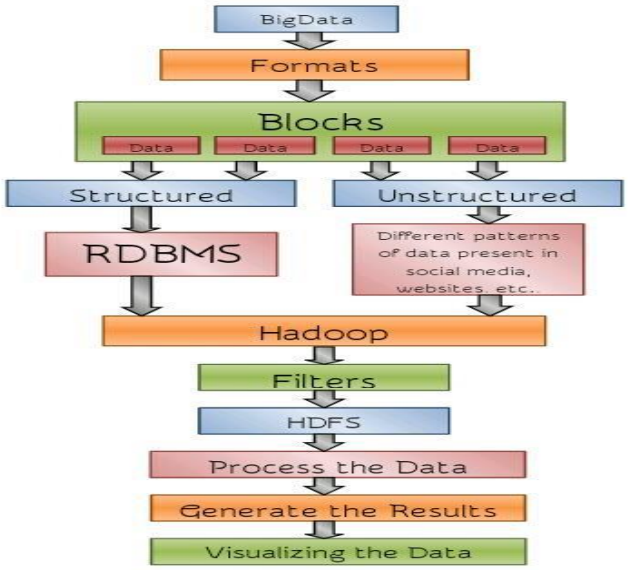


Hadoop for ETL platform

Extract, transform and load processes form the backbone of all the data warehousing tools. This has been the way to parse through huge volumes and data and prepare it for analysis. That notion has been challenged of late, with the rise of Hadoop. A number of Hadoop advocates argue that the only way to manage data in the future is to learn Hadoop. The conventional ETL software and server set up are plagued by problems related to scalability and cost overruns, which are ably addressed by Hadoop.

III. FUNDAMENTALS

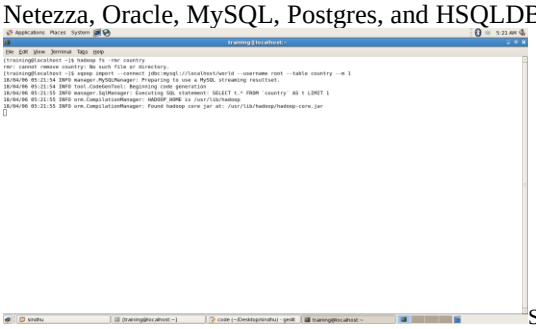
In this work, we focus majorly on three types of functionalists data cleaning in terms of transforming the data by solving the issues in existing ETL tools, hive data loading, data analysis. We use the following data from mysql to carry our work foward.



Sample data from mysql

IV. DESIGN WORK FLOW

Hadoop for ETL platform



Extract, transform and load processes form the backbone of all the data warehousing tools. This has been the way to parse through huge volumes and data and prepare it for analysis. That notion has been challenged of late, with the rise of Hadoop. A number of Hadoop advocates argue that the only way to manage data in the future is to learn Hadoop. The conventional ETL software and server set up are plagued by problems related to scalability and cost overruns, which are ably addressed by Hadoop.

Sqoop

Apache Sqoop efficiently transfers bulk data between Apache Hadoop and structured datastores such as relational databases. Sqoop helps offload certain tasks (such as ETL processing) from the EDW to Hadoop for efficient execution at a much lower cost. Sqoop can also be used to extract data from Hadoop and export it into external structured datastores. Sqoop works with relational databases such as Teradata, Netezza, Oracle, MySQL, Postgres, and HSQLDB

Sqoop command for data import

results in the hadoop platform

V. IMPLEMENTATION METHODOLOGY

Algorithm model:

Start

1) make a working model of the mysql database

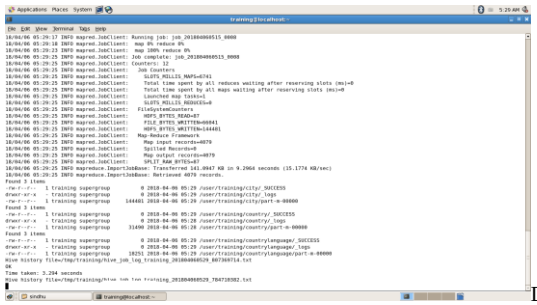
2) Now locate the ip address and the port address.

3) Make a directory in hdfs

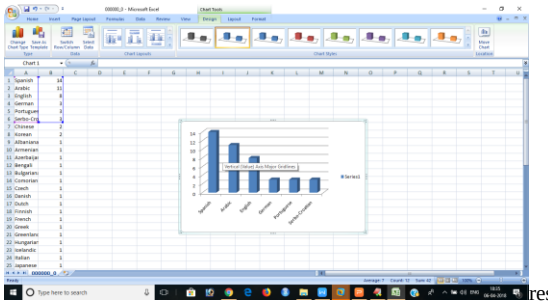
4) Configure the location with Sqoop of hadoop using - sqoop import --connect jdbc:mysql://localhost/world --username root --table country --m 1

5) Perform the filtration using -> sqoop import --connect jdbc:mysql://localhost/world --username root --table city --m 1 --where "countrylanguage where IsOfficial = 'T' and Percentage > '75' "

6) If no results obtained then rmr directory and go to step 3



7) If results obtained pull the data to hive -> load data to hive '/user/location/directory/part-00000'



8) Analyse the data based on the transformed data.

9) Projects the results to the directory.

10) STOP

VI. EXPERIMENT RESULTS

Data from sqoop to hive

results after data filtration

VII. CONCLUSION

Data cleaning is the process of fixing or removing damaged or inaccurate data. This process is necessary and extremely important for Big Data, since incorrect data may lead to poor analysis and thereby yield unsatisfactory conclusions. We develop a data cleaning framework for big data that will improve data quality. In this paper we have i) generated both structural metadata and descriptive metadata for data items and datasets; ii) tracked data usage; iii) harnessed both data context and usage patterns to find similar data items and datasets from multiple data sources and iv) constructed a data association report that can benefit the subsequent data cleaning process and enrich data information in our proposed data cleaning framework. Our experimental results show that our algorithm is effective in improving data quality. Our main finding is that our proposed approach is able to identify data

items and associated datasets which can benefit the subsequent data cleaning process. As future work we intend to further develop our proposed data cleaning framework by building a ranking system which can provide priority based on the value of information and cleaning cost. Moreover, we will construct a cost-based model and interactive approach for data cleaning by using a combination of both machine learning algorithms and human intervention.

Focal Point Analysis in Identifying the Expressions of Human Face

N. Swapna[1], and M. Swami Das[2]

[1]M Tech (CSE) student, Dept. of CSE, MREC, Hyderabad, Telangana State, India.

[2]Associate Professor, Department of CSE, MREC, Hyderabad. Telangana State, India

Abstract— ***By splitting up the images material, the visual final examination construct can anticipate the idea of a image. People who transfer big numbers of accounts in casual organizations, now shifting, like Twitter, Face book, Google Plus and Flickr. These pictures have a key effect on the emotions of communication of customers to casual internet organizations. Consequently, the examination of the view was critical. Some study is focused on the feelings of the written material. The small examination was carried out to generate designs that anticipate the sensory structure's response. In this article, it offers a new graphic assessment framework that uses swap teaching to address predictions. It uses hyper-parameters derived from deep cellular structures in order to implement our process model to prevent overlap. It conducts large tastings on an internet image dataset and shows that the present working point is faster carried out by our model.***

Keywords— Image Analysis, Emotion, Image, Feature Extraction

I. INTRODUCTION

Focal Point Analysis in Identifying the Expressions of Human Face. The personal network online has become an essential component of our daily lives. Users share a bunch of textual and sensory content to convey their feelings and views. These images show the emotions and behaviours of thousands of individuals worldwide. The social networks provide various facilities for the communication and sharing of data by their customers. Users use these facilities to exchange views on various subjects and to demonstrate concern and help for buddies and community. By analysing the user content, we can comprehend and forecast customer conduct. The learning of this information from these technologies can profit several apps, such as predictive modelling, recommendation structures for products and services, internet advertising, etc. This tendency had been identified by researchers and many studies were undertaken to evaluate feelings and opinion mining.

Content from multiple social networks like Face book, Instagram, SnAP, Flickr and Twitter, etc. In recent years have become more popular than linear material. Visual content status or messages often involve a brief or no textual depiction. Thus, most customer feelings convey the graphic characteristics. The pictures are simpler to comprehend and can solve the language limits.

Although a lot of job has been performed to analyse the feeling of verbal material. The sensory feeling assessment study is still in its basic phase. The assessment of visual feelings includes a capacity for the item, image, behaviour and mental background to be recognized. The creation of handmade pictures in order to predict feelings calls for a great deal of personal endeavour and moment. On the opposite hand, monitored Deep teaching and optimization designs require a lot of practice information that is difficult to acquire for photos from various fields. Consequently, in the comparison with other item identification, and monitoring the mental elements of the images are relatively unexplored.

The architectures of deep learning demonstrated enormous success in machine sight field, which is called the Convolutional Neural Networks. In graphic identification, CNN designs approach human level efficiency.

It uses a hyper-parameter transmission teaching strategy. CNN performs better than before in a normal dataset than before.

In these days, it's essential to discover views on the goods, items or activities of any organisation, company, or company. Technology uses verbal material, but not graphic characteristics. Approximately 90-100% of internet personal network information linked to pictures. In the current situation, therefore, people's views or assessments were never regarded as a key aspect. It has 90% of the information on the industry. 60% of the information is in pictures, audios and pictures. This is the result. The unstructured data are not perfectly analysed. To introduce a range of pictures, there is no stronger strategy or technology.

A. Disadvantages of Existing System

The Images contain many feedback about the company or product, which we can't enter to know the reviews. Hadoop even operates with the pictures, but they usually encrypt the picture and send the information.

II. RELATED WORK

Hurricane Sandy is an instance of social media has a positive effect during disasters in 2012. Some instances of how personal communication works in catastrophic situations have been rescued, including Hurricane Irene, the gas crash in 2010. California. A feeling evaluation of personal media disaster-related messages helps to identify pictures which add to the consciousness of the situation and customers ' emotions and worries by defining the polarity of emotions experienced by customers during catastrophes.

Initial research on the assessment of graphic feelings concentrated on handcrafting. Siersdorfer used pixel rank characteristics to predict the feeling of the picture. Borth produced several adjective combinations that express various concentrations of feelings. Resulting pictures are regarded as intermediate characteristics to analyze the feeling of the picture.

III. PROPOSED SYSTEM

The current scheme works with customer feedback that geographically increases the company's output. It examines views and inspections from different locations of research and gathers them for data analysis in a r console. Visual content has become more popular in latest days than verbal content. In the scheme suggested, it presents a way to analyze pictures, such as imaging conduct, which concerns the item or the organization, which enables us to achieve more precise outcomes in the analysis of information.

IV. ADVANTAGES OF PROPOSED SYSTEM

The scheme helps to learn how satisfied customers are with the products. It assists us with brand enhancement. The company's revenues are affected automatically.

The social media text sentiment analysis is quite a challenge. Everyday consumers generate a lot of information in social networks in the age of large information. These information are structured in the shape of brief and an pictures and SMS mix. It is recommended that Hash tags are used for sentimental assessment with powerful favorable and bad views, with ASCII smiley and soft tags. An embedded emotional indicator and correlation system was created to forecast feelings by incorporating emotional cues. For sentimental analyses, a double-recurring neuro-neural network has been suggested to use an forward-looking neural network for Twitter sentiment analysis, created a hybrid model that includes Sustainable Vector Mechanics (SVM), Neural networks Naive Bays, Maximum Entropy and Feed Forward.

Features detection, function extraction and matching are combined in order to resolve common problems of Computer intelligence like item identification and identification, picture recollection in content, face detection and awareness and categorization of texture.

These pictures have multiple colours and pixels. View how the picture is recorded and take each pixel in the matrix as a cell. The cells comprise various strength data, responding to the red, green and blue colors. Thus a 3-D matrix for an RGB picture. The strength of the colours red, blue, and green is every amount.

The use of easy picture pixels in real pictures is not sufficiently descriptions. Two primary steams are to be followed, instead. One is the use of handmade extracting techniques for functions such as sparse coding, auto encoder, restricted Boltzmann machine, PCA, ICA, or K-means, such as SIFT, VLAD, HOG, GIST, LBP.

V. DESIGN OF THE WORKFLOW

Learn how to solve the lacking information issue via current scheme and methods. CNN approach functioned to predict good information by extracting business logic. Development and execution of architecture. The proposed architecture framework is shown in figure1 illustrates that describes the system's architecture by extracting the internet characteristics, Images, labels connecting to classifier and follows sentiment analysis.

VI. METHODOLOGY AND EXPERIMENTAL RESULTS

Download and import information for R. Data. I transform the information and execute the information queries. The plotted figure shown in figure.3 the allocation of information. Figure 2.illustrates that the x-axis represents a person’semotions and the y-axis indicated the emotion rate using gg-plot. Figure 3. Shows emotions such as rage, disregard, disgust, dread, joy, neutrality, and arrow.

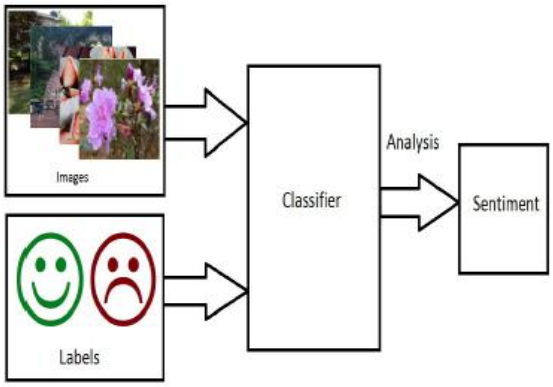

Fig. 1 Diagram of generic visual sentiment analysis framework

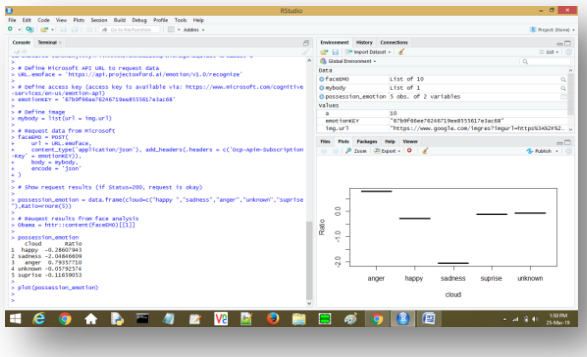

Fig. 2 Result displayed with gg-plot

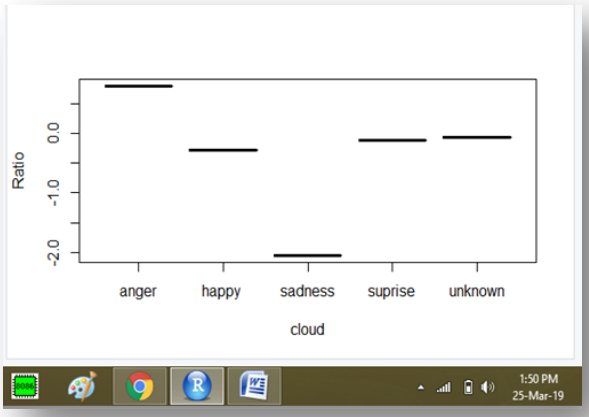

Fig. 3 Report of an Emotion

VII. FUTURE ENHANCEMENT

Addressing the ranking algorithms for extra dominances may also be a further step in this path. Additional limitations to enhance identification precision can be added to the classification algorithms suggested in this job.

VIII. CONCLUSION

Visual social network sentiment analysis can assist customer conduct understanding and provide helpful data analysis information. The article presents a new structure for graphic sense assessment using certain methods such as transition designs and bundles in R-Language, such as gg-plot. The R-Language system is developed with the huge characteristics it utilizes to map the production into a natural understanding. In order to understand customer feedback and publicity, our models can use to evaluate high-scale data-multimedia material. It can be helpful for the emotional surveillance of people with mental wellness problems. Our model is like using audio material sentiment analysis. Finally, it intends to study semi-monitored and unattended ways of deep learning architecture to predict the sensory information impression.

Abstract - *In the last decade, keyword search over relational databases has been extensively studied because it promises to know the users lacking with knowledge of structured languages with query or unaware of the relational database schema on to query the data set in an intuitive approach. The existing works related to about keyword search on the data sets proposed many different approaches and have also gain remarkable results in improvement. However, In most of these new approaches are designed in the centralized setting of where keyword search is used and processed by only the single server. In reality, the scale of data sets increases sharply and the centralized methods are hardly can able to handle keyword queries in and over these large databases. Moreover, processing keyword search over relational databases is a very time-consuming task, and the efficiency of the existing centralized approaches will degrade notably because there are single server which cannot provide enough in computation power for the analysis of keyword search over very huge and large data sets. To address these issues and challenges, we propose the distributed keyword search (DKS) as an approach with R Programming and this approach makes to be well deployed in onto any cluster of data servers to deal with keyword search over large databases in a parallel way..*

Keywords*: - Twitter, sentiment analysis, symbol analysis..*

I INTRODUCTION

The success of search engines on the web service has popularized the use of keyword search, with which untrained clients can find data of enthusiasm from tremendous accumulations of archives/Webpages. Over the previous decade, this achievement has propelled much enthusiasm for contemplating catchphrase seek over databases, and broad methodologies and models are proposed to take care of this issue.

As of late, an ever increasing number of methodologies [1], [2] to catchphrase look over databases receive the information chart to plan the pursuit calculation. These strategies model the database as an information chart , in which hubs compare to tuples and edges compare to essential remote key connections between the tuples. In a large portion of those methodologies, the issue of hunting down outcomes can be come down to finding the Steiner trees [1] that spread all or some of watchwords, which is known to be NP-hard [3]. This paper likewise centers around looking through the Steiner trees dependent on an information diagram to manage catchphrase seek over social databases

Most existing information diagram based works endeavor to plan an efficient brought together answer for the catchphrase seek over databases with the presumption that the entire information chart can fit in primary memory of a solitary server. Nonetheless, with enormous information rising in different fields of the general public, the size of the database is expanding significantly. For this situation, most existing methodologies scarcely can deal with watchword seek on the databases with tremendous volumes. The first reason is that volumes of substantial databases have surpassed the limit of one server and the information diagram for the most part can't fit in the primary memory. Furthermore, finding Steiner trees over the information diagram is a NP-difficult issue and it will devour much registering assets. On the off chance that the size of the database become bigger, the exhibition of existing techniques will corrupt eminently on the grounds that a solitary server can't supply enough calculation control for seeking Steiner trees over a huge information diagram.

To address this test, we propose DKS, a way to deal with circulated catchphrase seek over social databases with MapReduce instrument [4]. MapReduce is a commonplace parallel batchprocessingframeworkthathasbeenusedinso mefamous framework, (for example, HDFS). In any case, our concern can't be illuminated with just two essential tasks: map and diminish, hence we present two sorts of shuffle activities to develop an all-encompassing MapReduce structure that can well help DKS approach. The fundamental standard of DKS is utilizing numerous servers to all the while manage a similar watchword seek, subsequently every server just needs to look through a piece of the database in an appropriated example for decreasing the pursuit time. All the more specifically, we first model the database as an undirected information chart G and accept that G is an associated diagram. To quicken look process, we segment the information diagram G into various subgraphs without cover and allocate these subgraphs to various servers. For a given inquiry q, various servers will find the competitor Steiner trees that will most likely develop into Steiner trees from their neighborhood subgraphs all the while and afterward join the hopeful Steiner trees to produce the total Steiner trees. At last, a specified server will rank the Steiner trees and return the final top-k answers.

II RELATED WORK

Mining Top-k Co-occurrence Data Patterns across Multiple Streams :

FREQUENT Data pattern / itemset mining is a fundamental problem as analysis for many domains, thus has a number of applications, e.g., retail market analysis, bioinformatics, ecology, web click stream mining, network traffic monitoring, and so on. In the Bigdata and IoT era, objects in these applications are often generated in a streaming fashion. Therefore, data mining frequent data pattern/ itemset over data in filtering streams has been data extensively studied. This paper focuses on data as an environment of multiple data streams, and addresses the novel filteration problem of continuous mining of top-k closed data co-occurrence patterns filter across multiple streams.

EXAMPLE 1.2 (WEB USAGE PATTERN MINING). Given a set of click streams generated by multiple users, by mining

cooccurrence patterns, we can find (top-k) typical web search patterns and popular web sites with many users.

EXAMPLE 1.3 (E-COMMERCE). Item browsing and purchase sequences by the same user in an online shop constitute a stream. If a mechanism can detect itemsets appearing in many streams (i.e., users), the owner of the online shop can plot an effective promotion strategy.

EXAMPLE 1.4(ASSOCIATION MINING). Assume that smart phones consecutively generate tuples, each of which is represented by □app-id, loc□. Note that app-id is the identifier of the executed application and loc is the location where the application is executed. Some associations between applications and locations are mined from top-k co-occurrence tuples, since, if a given tuple is observed in many smartphone users, we can see an association between the application and the location.

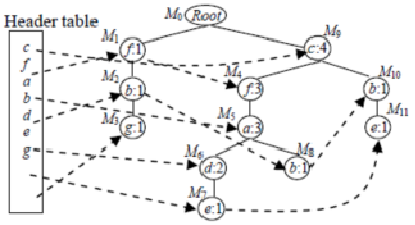

Figure 1. The Pi-Tree for Table 1

III DESIGN OF THE WORKFLOW:

In recent years, more and more approaches [1], [2] to keyword search over databases adopt the data graph to design the search algorithm. These methods model the database as a data graph , in which nodes correspond to tuples and edges correspond to primary-foreign-key relationships between the tuples. In most of those approaches, the problem of searching for results can be boiled down to finding the Steiner trees [1] that cover all or some of keywords, which is known to be NP-hard [3]. This paper also focuses on searching the Steiner trees based on a data graph to deal with keyword search over relational databases

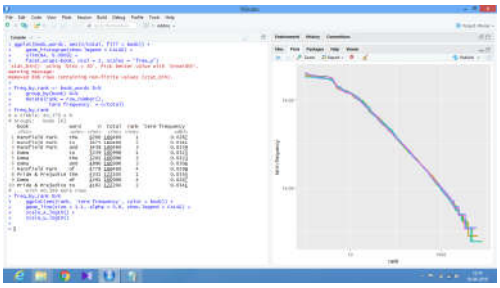
IV METHODOLOGY

Create a dataset

Start working on dataset

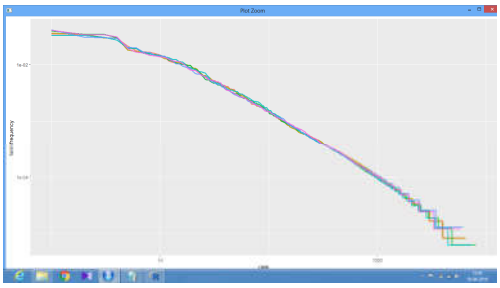
Create a pattern for the data and divide the data with mean

kmeans(x, centers, iter.max = 10, nstart = 1,



algorithm = c("Hartigan-Wong", "Lloyd", "Forgy", "MacQueen"), trace=FALSE)

S3 method for kmeans



fitted(object, method = c("centers","classes"), ...)

V EXPERIMENT RESULTS

Data to console Pattern Matching Executing the MapReduce Partition Nth occur pattern Matching

Frequency Pattern- pattern Matching

word Frequency

Nth Keyword - Overall Nth keywords

VI CONCLUSION

Faced with very large databases, the existing methods to keyword search over relational databases with the centralized setting hardly can process the keyword queries effectively. To solve this problem, we propose DKS, a distributed data-graphbased approach to keyword search over relational databases with MapReduce. In this approach, we first partition the data graph into multiple subgraphs, and then employ a cluster of servers to search the CS-trees within each subgraph in the map operation. After combining the the CS-trees produced by mappers, the combined results will be processed by reducers in a parallel way to construct the Steiner trees. Finally, the top-k results can be found by merging Steiner trees sent by reducers.

VII FUTURE ENCHANCEMENT

In the further, we plan to study some more efficient pruning rules to beforehand cut down the CS-trees that cannot be connected into a Steiner tree in the reduce operation. Furthermore, we will continue to optimize the combine operation of DKS to reduce the cost of transmitting the CS-trees. At last, we will make the DKS approach be more general to distributed keyword search over various very large databases..

Abstract -- In recent years, there has been a huge growth in the use of social networking sites. Currently, social networking sites produce a great deal of information. Millions of individuals convey their views and opinions on a broad range of subjects conveniently through micro blogging pages. In this job, Twitters, where the customer gives their opinions and opinions, is concentrated primarily on extracting feelings from a renowned micro blogging page. Take a feeling assessment of tweets that assist to predict company intelligence. For the handling of information we use R Programming and statistical language. This can be from any industry with the keywords associated to a hash tag #or@. It outcomes when we have attempted to analyze the outcomes in an implementation that continually alters the outcomes. The results of the facebook information feeling assessment will be shown as distinct parts with favorable, bad and neutral feelings.

1. INTRODUCTION

Analysis of the sensation is the method of determining the favorable, bad or neutral content of a reading item. In order to dine weighted tendencies within a phrase or phrase, the assessment structure for text investigations consolidates the distinctive language management of natural language processing (NLP), and artificial intelligence (AI) strategy.

Evaluation research enables informant researchers to verify overall results in comprehensive efforts, guide nuanced statistical surveys, product and product reputation, and to understand customer interactions. In addition, data testing organisations frequently integrate external sentiment investigations APIs with managers, internet networking or stages, so as to communicate useful data to their own customers.

The Internet era has altered the way people convey their views. It is currently performed via blog posts,

conversations about internet speeches, object audit locations, etc. Everything is dependent on this customer's drug. You will examines your polls internet before you take a decision when someone has to buy an object. For a typical customer, measuring the content created by the customer is unreasonably extensive. Various processes to investigate the assumptions are used to robotize this. The two main technologies used in angle inquiry are representative techniques or knowledge foundation approach and machine training processes. A vast database of pre-defined emotions and a competent data picture are needed for learning methodology to distinguish estimates. AI strategy uses an strategy that prepares a classifier of view to arrange ideas. Since the AI strategy does not require a predefined repository of whole emotions, it is preferably less complicated than the basic analysis of knowledge. Different techniques for organizing tweets were used in the current job. Typically, assumption testing is conducted in different sizes from crude to fine.

Comments, polls and important tasks to determine whether a specified population is satisfied with the object, administrations. It helps to anticipate the conclusion of a broad range of people on a particular time, such as the examination of a film, and their evaluation on various subjects which mingle with each other. This data is essential for the inquiry of the evaluation. In order to reach the overall outcome, information retrieval from outlets such as Twitter, Facebook are essential. Blogs. For the supposed inquiry, a tiny blogging interpersonal communication location, Twitter, was focused. Twitter produces enormous information which can not be physically processed to extract some precious data and the programmed characterisation components are therefore necessary.

The progress of Web2.0 and the electronics company has led to a significant quantity increase for the percentage of internet feedback. People should generate surveys of a few components of the stuff with certain critical tendencies and some of them pessimistic. These remarks are business-friendly for suppliers and customers. By the way, the wide range of match plans that are hard to track usually client assumptions. The test by Airtel Tweet utilizes Airtel hash marks on all tweets, and utilizes the twitterR library.

Returning YouTube video through user review feeling assessment.

Disadvantage:

Fundamental information assessment with NLP is accomplished, no choice system or filtration system is implemented.

Advantage:

NLP focused sentimental assessment strategy on customer remarks. natural language processing (NLP). This assessment helps to discover YouTube's most significant and famous google clip.

By collecting tweets using Twitter API, they produced a Twitter inventory and commented on those tweets that use emojis. Using this corpus, a horizontal classifier was created, based on the multinominal Naive Bayes technology that uses features such as ngram and POS labels. The array they used was less efficient because it only includes tweets with emojis. The Naive Bayes bigram system and the Major Entropy model for tweetening have already been updated by Parikh and Movassate (2009) [2]. They discovered that the classification systems of Naive Bayes were far inferior to the Maximum Entropy system.

Go and L.Huang (2009)[3] suggested a response to the hypothesis test of email data through remote monitoring, which included emoji-filled tweets with noisy titles. They produce Naive Bay, MaxEnt and Support Vector Machines (SVM) designs. Its room element consists of unigrams, bigrams and POS. They argued that SVM was successful in various designs and that unigrams became more feasible as hints. The two phase programmed investigative evaluation strategy to purchase tweets was organized by Barbosa et al.(2010)[4]. They organised tweets as goal or concrete, after which they were called good or bad in the second phase. Retweets, Hash Tags, link, accentuation and outcry cards, such as the previous end of phrases or POS, were used for the element room. Twitter gushing data provided by Firehouse API was used by Befit and Frank(2010)[5], which provided all the customer emails that are constantly voluntarily available. They studied healthy multinomial bays, stubborn tendency, and the Hoeffding tree. They hit on the basis that the Stochastic Gradient Descent (SGD) system was the inferior to anything the remainder had been used when used with the appropriate teaching pace. Agarwal et al. (2011)[6] have developed a 3-way system to order beneficial, bad and impartial class assumptions. They attempted various stuff, such as the unigram model, a component model and a tree fragment model. They talked like a tree to tweets for a tree part model. The model includes 100 images and more than 10,000 parts are used by the uniconstruct model. They ended up with points that are of great importance and play a important part in the ordering process, joining previous phrases with their parts (pos-)labels. The model centered on the tree part defeated the two others.

Davidov et al., (2010)[7] suggested a method to cope to the use of tweet clients of Twitter described totems as an accentuation, single word, n-gram and sample sensation style structure as different kinds of components that are then combined as the final element vector. They used K-Nearest Neighbor methodology in the preparing and experiment range to assign points by creating a part vector for each model.

The Twitter API was used by Po-Wei Liang et.al.(2014)[6] to collect facebook. They have three distinctive classes (photo, motion-picture, mobile) for the preparing of their data. The data is indicated as favorable, bad and unassuming. Separated tweets comprising sensations. Unigram Naive Bayes model and the Naive Bayes assumption of liberty was performed. Additionally, the reciprocal information and chi square removal approach have provided us with inefficient hints.

Paul and. And. al.[7] showed Naive Bayes classification types for distinction of English tweets. In specific, Baseline (ready to label tweets as favorable, negative and impartial) and Binary (uses a language of extremity and commands as beneficial and bad) were produced two separate variants in Naive Bayes classification. The examples of the classificators were Lemmas (items, phrases, descriptors, verbs modifiers), Lexicons of polarity and multi-word from different perspectives and Valence Shifters. Turney et al.[1] used a sack of letters approach for an evaluation study, which did not take account of the links between phrases, and an archive was talked about simply as a collection of phrases. The concept for the whole study has been settled by assessing each term and adding these characteristics with certain complete capabilities.

Kemps et al[2] used WordNet's lexical database in multiple dimensions to determine a word's enthusiastic content. On WordNet, you built a separation metric and chose the semantical extremity of the descriptors. Xia et al.[3] used the sentiment classification collection scheme which was developed through the consolidation of various capacities and groupings. In their job they used two types of capacities (Part-of-Speech Data and Word Relationships) and three basic classification systems. They linked methods to collectivity like set mix, weighted mix and meta-classification for placing sensation and improved accuracy.

Luoet.-Luoet. Al.[14] had problems and efficient means of mining Twitter tweets ' feelings. Spam and furiously fluctuating vocabulary allows final retrieval within Twitter screening.

The word lexicon with feeling phrases is used in vocabulary[2] and is matched with data to determine the extreme. It gives an assessment of the sense statements that show how the word in the lexicon is positive, negative and objective. The wordings compiled rely mainly on methodologies relating to a sense of vocabulary, i.e., a collection of recognized and precompiled words, statements and even maxims, produced by the Opinion Finder dictionary for standard communication courses, for instance;

Word-based mention: it relies on the usage of physically collected and remarked conditions (plants). This collection is developed through the corresponding phrases and lexicon anthonyms. One example of the WordNet lexicon is used for the development of a SentiWordNet thesaurus.

Corpus-based: The corpus approach aims to give a specific region of lexicons. These lexicons are generated from a number of seed concluding concepts that are used to use descriptive and semanticized schemes by hunting for associated phrases.

The use of similar phrases, antonyms or links from thesaurus, for instance, based on semantic methods like WordNet, may also talk to an fascinating scheme.

According to the show projections such as the accuracy and review, we are examining current evaluation mining approaches including AI, vocabulary methods, cross-sectional and language methodologies, etc.

3. METHODOLOGY

The embedding techniques for studying feelings in this chapter. Describe the conventional neural network context-based techniques for term embedding teaching. Then enter our expansion to collect the polarity of sentiments in phrases before you present hybrid designs that encode data on both feeling and background basis. Then define term tier data inclusion for embedded teaching.

3.1 Notation

The significance of the factors used in this document have been noted. We are talking in specific about one phrase, the key of which I in a phrase is, these are background phrases of Wi, i.e. the embedding vector of Wi. In this job, the neural network methods were implemented with certain fundamental wireless levels, including search, hT, linear and smooth tmax. Olayer implies the input matrix for each cellular cell. These levels can be implemented at: www:/ir.hit.edu.cn / dytang.

The purpose of term depiction is to depict elements of the significance of the term. One easy way to use is the one-hot encoding of a term WI, whose vocabulary size is 1 in place and zeros elsewhere. However, such a warm term image codes only the index of phrases in a vocabulary, without the wealthy relationship framework of the lexicon. The use of word-clusters[2],[6] is a popular method to discovering resemblance between phrases. Each term is related to a discreet category and in some ways the phrases in the same category are comparable. This contributes to a warm image over a narrower vocabulary. The aim of numerous scientists to find a continuous and reliable vector for each term, also recognized as term embedding, is not to characterize similarities with an discrete variable depending on a clustering outcomes that corre-sponds with a smooth or harsh part of phrase range. In the existing embedding study algorithms, distributional hypotheses[3] are mainly focused on which terms have comparable significance in different situations. Many techniques of matrix factorization can be considered as term depictions. For instance, Late Semantic Indexing (LSI)[7] can be considered a direct embedding that utilizes a vector of "thermal text" stats, for instance, where each line is one word or phrase and each column is

a single text in a database. Hyperspace Analog to Language[2] uses a matrix of' term' s-statistics co-existing, in which both lines and columns match the term and the inputs indicate the amount of occasions that a term in the framework of anot/her phrase happens. Hellinger PCA[2] also investigates term embedding in coincidence statistics on "term-term." A rise of research research has brought about term embedding with cellular network with the reactivation of concern in profound teaching and cellular network[30],[1] and[2]. Bengio et al.[6] are giving a pioneering job in this area. They present a cellular probabilistic linguistic system, which at the same time teaches a constant phrase and term sequence description feature depending on the sentences displayed. Due to a phrase and its previous background phrases, the machine first links a mutual lookup chart to each background phrase for its constant matrix. Context term signals are then transmitted to a forward-looking wireless network with Softmax as an input element to forecast the next word's conditional probability. The neural network and the survey panel parameters are taught together with rear propagation. After the job of Bengio et al.[6], many ap-proaches are being suggested to accelerate instruction or capture greater semantic data. Bengio et al.[3] present sensory architectures by unifying background variables with the present term, and use selection of significance to optimize the system efficiently with the' favorable test' detected and "adverse specimens" selected. In order to decompose Morin and Bengio [4], hierarchy is developed

4. SENTIWORDNET:

The papers dealt with four distinct variants of SENTIWORDNET:

1. SENTIWORDNET 1.0 submitted and published for study reasons in (Esuli and Sebastiani 2006) ;

2. SENTIWORDNET 1.1, only discussed in a technical report (Esuli and Sebastian, 2007b) that never reached the publication stage;

3. SENTIWORDNET 2.0, Only addressed in the PhD Thesis of the second author (Esuli, 2008);,

4. SENTIWORDNET 3.0. The first presentation will be Since in commonly recognized official journals releases 1.1 and 2.0 have not been discussed, we will discuss the variations between variants 1.0 and 3.0. The principal distinctions are:

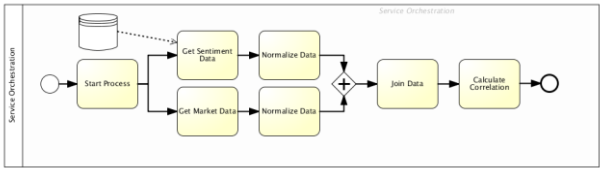
1. In variant 1.0 (including 1,1 and 2.0) the previous WORDNET 2.0 is annoted, and in variant 3.0 the latest WORDNET 3.0 is annoted.

2. The weak-supervised, semi-supervised teaching scheme for SENTIWORDNET 1.0 (and 1.1) adaptive annotation was held out. Conversely, the findings of this half monitored teaching algorithm for SEN-TIWORDNET (2.0 and 3.0) represent only the midway stage of the annotation method since they are supplied to an iterative and convergent random walking system. After convergence is

reached, the SENTIWORDNET (2.0 and) 3.0 is the random walk system function.

3. Version 1.0 (and 1.1) utilizes the WORDNET symbols glosses as visual depictions of the synsets when a semi-controlled method of classifying the (glosses) sunsets in classes Pos, Neg and Obj is mentioned. In variant 2.0, this is the initial phase; in the second step, not pure glosses but their automatically sensed ambiguous EXTENDEDWORDNET variants have been used in the random walk method stated previously (Harabagiu et al., 1999) In both SENTIWORDNET 3.0, we use individually disambiguated glosses from the Princeton WordNet Gloss Corpus 2 in the semi-supervised learning phase (1st phase) and random walking (2st phase), which we suppose to be more exact than the glow of EXTENDEDWORDNET.

Generating SENTIWORDNET 3.0



The instant annotation method under SENTIWORDNET 3.0 is hereby summarized in more depth. This is a two-step method: (1) a weak, semi-supervised, and random, teaching stage.

5. CONCLUSION

In this document we study feeling-specific term embedding (called feeling embedding). Unlike most exiting studies, which only encode language contexts in term embeddings, we make it easy to foster the ability to embed word in terms of feeling semántics when recording word similarity. In the sense-inbedroom the phrases can therefore be isolated with comparable backgrounds, but with the reverse feelings polarity-labels like "good" and "evil." In order to code background and feeling tier information efficiently, we bring several neural networks into phrase embedding concurrently in a single manner. Three sentiment analysis jobs empirically test the efficacy of feeling embedding. In the analyzes of feelings on a term stage, we demonstrate that feeling inlays are helpful in finding similarity between feeling phrases. Sensitivity embedding in the ranking of phrases helps to capture discriminatory characteristics to predict the feelings of phrases. For lexical tasks such as constructing a lexicon for feelings, embedding of feelings are helpful to measure similitudes between phrases. The finest artists on all three assignments are hybrid designs that collect both background and feeling data.

Abstract—***Due to huge information advance in biomedical and human services networks, exact investigation of restorative information benefits early malady acknowledgment, tolerant consideration and network administrations. At the point when the nature of therapeutic information is inadequate the precision of study is decreased. Besides, various areas show one of a kind appearances of certain territorial infections, which may brings about debilitating the forecast of illness episodes. In the proposed framework, it gives AI calculations to powerful forecast of different sickness events in illness visit social orders. It analyze the changed gauge models over genuine medical clinic information gathered. To beat the trouble of fragmented information, it utilize an inactive factor model to remake the missing information. It probe a local endless ailment of heart infections. Utilizing organized and unstructured information from medical clinic it use Machine Learning calculation. As far as we could possibly know in the territory of therapeutic huge information investigation none of the current work concentrated on the two information types. Contrasted with a few run of the mill gauge calculations, the figuring precision of our proposed calculation achieves 80% exactness with a union speed which is quicker than that of the irregular woodland malady chance expectation calculation.***

Keywords: Big data analytics, machine learning, healthcare.

I. INTRODUCTION

It is evaluated that over 70% of individuals in India are inclined to general body ailments like viral, flu, cough, cold and so forth, in like clockwork. Since numerous individuals don't understand that the general body maladies could be side effects to something progressively destructive, 25 % of the populace surrenders to death on account of overlooking the early broad body side effects. This could be a perilous circumstance for the populace and can be are disturbing. Thus distinguishing or anticipating the malady at the soonest is imperative to keep away from any undesirable losses. The presently accessible frameworks are the frameworks that are either devoted to a specific malady or are in research stage for calculations with regards to summed up sickness. The motivation behind this framework is to give forecast to the general and all the more regularly happening sickness that when unchecked can transform into lethal illness. The framework applies information mining methods and ID3 choice tree calculations. This framework will foresee the most conceivable malady dependent on the given side effects and careful steps required to evade the hostility of ailment, it will likewise enable the specialists to dissect the example of quality of infections in the general public. In this task, the infection expectation framework will complete information mining in its primer stages, the framework will be prepared utilizing AI and information mining.

II. RELATED WORK

With the development of enormous information examination gear, more dedication has been paid to infection desire from the view of huge information request, different investigates have been led by picking the highlights precisely from countless information to improve reality of threat arrangement as opposed to the previously chose physiognomies. In any case, those overall work for the most part estimated organized information. Along these lines, chance association dependent on enormous information investigation, the accompanying undertakings remain: How should the lost information be addressed? In what manner should the fundamental unending infections in a positive area and the primary essences of the malady in the district be abrasive? In what capacity can huge information investigation ability be utilized to gauge the sickness and create a superior strategy?

To tackle these issues, it see the organized and unstructured information in human services field to evaluate the danger of illness. To begin with, the framework use Decision tree map calculation to create the example and reasons for sickness. It obviously demonstrates the infections and sub sicknesses. Second, by utilizing Map Reduce calculation for apportioning the information to such an extent that a question will be dissected distinctly in a particular parcel, which will expand the operational proficiency yet decrease inquiry recovery time. Guide decreasing calculation is utilized for apportioning the therapeutic information dependent on the yield of Decision Tree map calculation. Contrasted with a few run of the mill expectation calculations, the forecast exactness of our proposed calculation increments.

The creators of this venture, Narender Kumar and Sabita Khatri [1], have looked into and made examinations of various calculations, for example, k-NN, Naïve Bayes, Random Forest, J48, utilizing execution estimates like ROC, kappa insights, RMSE and MAE in WEKA instruments, and furthermore thought about the classifiers on different precision measures. The end came to of this examination was that Random Forest has better exactness for constant kidney dataset that was utilized. In this venture the creators, Monika Gandhi and Dr. Shailendra Singh [2], have investigated various information mining calculations like Naïve Bayes, Neural system and choice tree calculations for their precision on forecast of Heart Disease. The creators Marija Sultana, Afrin Haider and Md.Shorif Uddin [3], have broke down calculations, for example, K-star, J48, SMO, Bayes Net and Multilayer Perceptron Network utilizing WEKA instruments for coronary illness expectation dataset. The presentation of these datamining strategies in obtained by mix of consequences of measures, for example, prescient precision, ROC bend and AUC esteem. The outcome acquired is the SMO and Bayes system show more ideal outcome than their other referenced partners. In this task, the creators Girija D.K, Dr. M.S. Shashidhara and M.Giri [4], utilize neural systems to make forecasts with respect to nearness of uterine fibroid ailment. The test results demonstrate an exactness of 98% utilizing the Multilayer perceptron neural system and information mining. This undertaking centers around the most widely recognized type of disease present in ladies for example Bosom Cancer and its repeat. The creators Uma Ojha and Dr. Savita Goel, in this venture have inquired about on numerous information mining calculations in both order and grouping types. They achieved a watched end that, C5.0 and Fuzzy C-implies give most astounding and least exactness among all the utilized calculations, individually. While C5.0 is most astounding with 81% exactness on the given information, Fuzzy C-implies is least with 37% precision. The other summed up end came to is that Classification calculations give better exactness over Clustering calculations [5]. Information mining has been utilized to reveal designs from the huge measure of put away data and hence used to manufacture prescient models. Restorative field contains enormous measure of information that are should have been handled. Information mining in restorative field improves the nature of patient consideration and the forecast of medicinal services designs. Information mining apparatuses encourages us to find obscure examples, bunch the related things and basic leadership of social insurance arranged issues. Restorative consideration is need; it gives patient and trust in a productive life. The gathered information when distributed is utilized for social causes without hurting the poise of the patients. Early location of illness can build the survivability of patients[1]. Information mining procedures, for example, order and expectation, grouping, affiliation principle mining and different mining strategies can be helpful to apply on restorative information. The gathered information as pictures can likewise be utilized to mine human services information. These days, many picture mining procedures improved the ailment forecast and medicinal services basic leadership task as most effortless. This paper introduces the use of information mining calculations in field of medication.

III. METHODOLOGY

Heart disease is an umbrella term for a confusion that influences the heart. Coronary illness implies equivalent to heart malady yet not cardiovascular infection. Cardiovascular infection alludes to clutters of the veins and heart, while coronary illness alludes to simply the heart. According to WHO (World Health Organization) and the CDC, coronary illness is the main source of death in the UK, USA, Canada and Australia [4]. The affiliation's 2015 Heart sickness and Stroke update aggregated by the American Heart Association, the Centers for Disease Control and Prevention, the National Institutes of Health and other government sources shows that Cardiovascular ailment is the main worldwide reason for death, representing 17.3 million passings for each year, a number that is required to develop to more than 23.6 million by 2030. From 2001 to 2011, the demise rate from coronary illness has fallen around 39 % – however the weight and hazard components remain alarmingly high. The hazard variables of coronary illness are smoking, overweight, cholesterol, hypertension, diabetes, unfortunate eating regimen and physical activity[5]. T. Revathi and S. Jeevitha [6] investigated the information mining calculations on forecast of coronary illness. The clinical information identified with coronary illness is utilized for investigation. The consequences of Neural Network, Naïve Bayes, and Decision Tree calculations are thought about, Neural Network accomplished great exactness. Devendra Ratnaparkhi, Tushar Mahajan and Vishal Jadhav [7] proposed a coronary illness forecast framework utilizing Naïve Bayes and contrasted the outcomes and Neural Network and Decision Tree calculations. As indicated by that technique, Naïve Bayes calculation gives great expectation.

IV. DATA TRANSFORMATION

In this progression, the dataset is investigated and fundamental information is chosen and the dataset is changed over into machine justifiable structure. Highlight Extraction - Feature extraction is the procedure to diminish the size of information in order to just take instructive, non-repetitive and significant information, in order to encourage resulting learning and speculation venture to procure better human elucidation. The ID3 calculation is utilized in this venture, for preparing of the illness forecast model. At the point when the calculation is connected, it produces a standard set dependent on the watched example of information. Based on this standard set, the framework preparing is done and the model is made.

A. Usage

Information Description: Factual Observation: Based on the informational collections, a measurable methodology is confined from the information. (Straight Regression). Preparing Dataset: From every one of the outcomes, we apply the irregular backwoods calculation in discovering all the conceivable choice trees and foresee the outcomes.

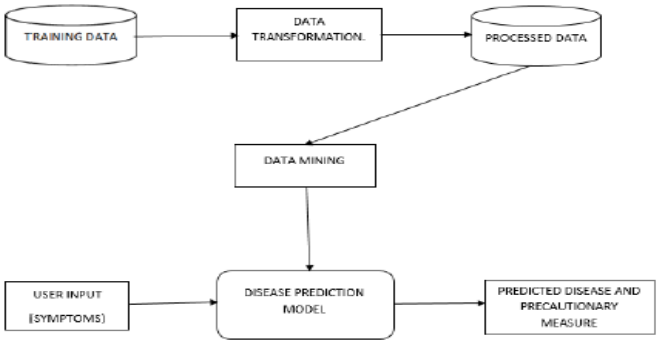

Fig.1 Data Transformation

B. Algorithm Steps

Linear Regression

1) Load the data to console
2) Check for any missing values
   If any missing values:
      Replace them with #999
      then step 1
   else:
   continue
3) Sort the combination columns
4) Correlation over the columns
5) Test the data

Logistic Regression:

6) Train the data on minimum dataset
7) Check the results
8) Apply on the complete dataset
9) Generate the results from the model.

Algorithms for Logistic regression and random forest:

Step 1: Train the data on minimum dataset.
Step 2: Check the results.
Step 3: Apply on the complete dataset.
Step 4: Generate the results from the model.

C. Reports: Form the above outcomes produce the reports as far as conduct of the information.

V. RESULTS AND DISCUSSIONS

The implementation is executed with the example information accessible from a nearby site. The information is first sorted and after that the centre parameters are been recognized from the dataset. The measurable examination of the information is executed. When the parameters are recognizable later we have actualized with strategic relapse model for the forecast of the heart sicknesses and contrasted our model and the Random timberland model for the precision computation. In this procedure the information is been ordered into testing information and preparing information and discovered the outcomes to be precise and discovered that the strategic model gave better outcomes thought about irregular woodland. The barplot depicts most affected sex for the given dataset. As appeared in the above barplot generally male is affecting the illness. Speaking to the precision barplot for preparing and testing dataset as appeared in the above figure, it depicts about the expectation exactness for preparing and testing datasets .It speaks to the expectation exactness for the dataset with various calculations which are performed at different interims of the dataset with preparing and testing information.

VI. CONCLUSIONS

A random forest model based multimodal ailment chance forecast calculation utilizing organized information from clinic. As far as we could possibly know, none of the current work concentrated on the two information types in the zone of medicinal enormous information examination. Examining the sickness elements dependent on the social insurance information. Missing qualities issue can be settled utilizing AI calculations. Malady forecast should be possible

dependent on kind of the sickness and sort of infection, locale and hazard dimension of the patient's ailment by the accessibility of the information.

Analysis of Efficient Active Learning-based SVM approach for Unlabeled Data

Rapolu Jyothirmai[1], S. Ajay Kumar[2]

[1]M. Tech., Student, Department of CSE, Malla Reddy Engineering College (Autonomous), Secunderabad, Telangana, India.

[2]Associate Professor, Department of CSE, Malla Reddy Engineering College (Autonomous), Secunderabad, Telangana, India.

Abstract— ***Over the last century, keywords in relation documents have been thoroughly investigated as they promise that customers with a query-related application system absence organized language knowledge to consult data laid down for a approach will be understood. Current research of keyword searches for information collections has a number of distinct methods and significant advances. However, the majority of latest methods are distributed, where a keyword query by only one server has been utilized and handled. Additionally, it takes a lot of time to process keyword query in relation databases. In order to tackle the type of questions and problems, we suggest that Disparted Keyword Search (DKS) for any group of information servers is an R programming strategy that allows finding keywords easier to implement over big databases.***

Keywords— Classification, Clustering, Active Learning, Support Vector Machines

I. INTRODUCTION

The capacity of a computer to understand by itself is learning tools. With no human interface the device can accomplish tasks. Machine Learning is artificial intelligence software which automatically allows the user to benefit from clearly programmed knowledge and enhance it. ML relies on computer programs for teaching information access and use. In complicated supervised learning tasks [1], the instance is rare and expensive to achieve. Where it takes time and energy to obtain Zhu's real world labels, as is the case with language recognition, [2] indicating that it takes 10 times longer to get words than the duration of the address.

The most commonly-used computer training technique is regression with a wide range of apps, including sensation analysis, spam identification, danger evaluation and picture classification. Classification is the information category prediction method. Classes are referred to as objectives or classifications or marks. It is a predictive system that is used in order to approximate and map (f) from data entry (X) to separate factors in production (Y). Classification is part of the controlled teaching class where information were also included in the objectives.

K-means is among the most easiest and most common methods for clustering. The technique is called machine learning algorithms in uncontrolled techniques with k-means. Uncontrolled [3] models produce data collections that generally only use entry coordinates without knowing norlabel results. The main objective of the algorithm k-means is to find and examine models from a collection of the same information items. K-means testing for a certain amount (k) of nodes in a dataset to achieve this purpose. A group relates to the set of the aggregated information items because of certain differences.Decide the destination range k for the amount of centers the dataset needs. The nucleus of the fictional group is a centroid.

The designs used to enhance teaching efficiency by use of unstated cases are active learning [4] and semi-supervised learning [5]. Active training is also known as query learning [6], which allows the software to select "interesting" cases and then works faster. Synthesis methods [7], steam-based limited sampling of affiliation queries.

One of the least challenging and uncontrolled methods is clustering of k-means. Unmonitored calculations produce data sets inductions that only use data vectors without understanding or specifying the outcomes. To achieve an object, K- involves looking for an organizational fixed number (k) of a dataset. The K-includes calculation describing in distinct phrases the number of centroids to the nearest unit, while keeping the centroids fairly expected. The K-includes calculations.Using the self-learning method in the semicircular concept of teaching. For example: first use Some of the instances that have been labeled and select the most confident instances to enter a teaching concept.

II. RELATED WORKS

A. K-means based on Active Learning for Support Vector Machine

Unlabeled information is collected easily and cheaply from the destination, but it is quite difficult and costly to obtain a large number of labeled information. Therefore, for many real-world applications, the way marked and unlisted data are used to improve educational effectiveness. Active learning and semi-monitored learning and intensive research from different perspectives are the right approaches. The first says that the learner can control the entire data set simultaneously and constantly check the tags.

They used the helpful learning strategy of SVM (KA-SVM) in this document. K-means were used to build a pre-selection system centered on an hypothesis of the classes which would provide a subset of major teaching courses. SVM can then be taught on this portion instead of a whole sub-set optimally. The results demonstrate the excellent efficiency of this approach, these techniques and laboratory results.

B. A Sequential Algorithm for Training Text Classifiers

For the content analysis and information recovery, natural language processing, and for other activity containing partly or fully linear data, the ability to practice classifying texts cheaply is essential. A linear sample algorithm has been created and evaluated on a venture that categorizes content from wire media during the teaching of statistical classifiers.

III. ALGORITHM

A. K-means

One of the easiest and most commonly used systems could be clustered via k-means between any unattended training algorithm. In summary, k-means clustering tries to determine that every information location is assigned to the nearest center and to minimize the total gaps between such tasks.

Step 1: Initialization of the cluster core.

Step 2: Assign findings to the closest node centres.

Step 3: Cluster centres should be examined as an median of findings.

Step 4: Repeat steps 2 and 3 until they become convergent.

Steps on K-means

The algorithm K-means becomes an optimal local. The results of k-means are therefore not strictly the greatest. It is essential to initiate the core to detect the value of the alternative. There is a better K-means initialization technique, providing a more secure clustering alternative. The customer has to select a top of moment for the amount of nodes.

B. Support Vector Machine

The boundary with the closest observer is known as the optimal hyper-plane. It guarantees that the design is suitable and robust. Use the previous formula to locate the optimal hyper aircraft.

a.x+b=0.

A.x+b=0.

where, a.x= sum of a andx scalar.

The two previous criteria must be met in this equation.

• The A and B categories must be very good so that the f(x) = a.x+b function is poor only if x is A.

• F(x) < = 0 if only B is x.

It is feasible (robustness of the model) from every observation. Hyperflight therefore relies on the sources of support known as the closest points. With reduced support points, the SVM generalization capacity is increasing.

IV. DESIGN OF WORK FLOW

Figure 1 shows the method of analysis by classifying data into data provision and data preparation. First, the data is collected and then a linear regression system is used for information and the row combination is discovered. For example: If we need students in schools who earn more than 70 per cent of points in the last semester. The pupil numbers are three hundred.

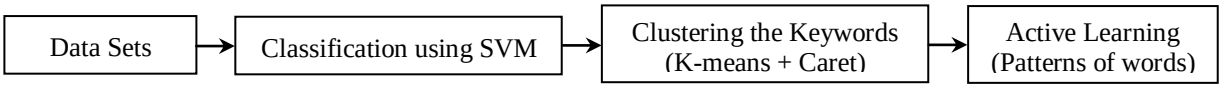

Fig. 1 Architecture for Searching the Word

A. Dataset:

Dataset is a mixture of the corresponding information products, which can be viewed or handled as a whole or separately or together.

B. Data Classification:

The most effective and efficient method of information categorization is information classification. We have used information classification techniques to divide them into 2 components. Security requirements after the classification scheme for each class has been created. The information are split into two phases.

C. Support Vector Machine:

An SVM is a classifying classification that is officially described by a separate hyperplane. The algorithm provides an ideal hyperplane that categorizes fresh instances thanks to labeled training data. The AnSVM model shows instances of the classifications separated by a certain cluster as broad as feasible. The first stage rejects most of the unwanted data, since it is completely underneath.

D. Clustering the keywords:

Data is more than 50 times in the second phase. It could have used and outdated information in these information. Thus the second phase K-means applicable. More than 70% of students can be calculated easily.

Iterate trough products for a certain amount of iterations:

i. Find the closest way to the item.

ii. Specify the mean object. Medium = 70 attribute

iii. Mean update.

iv. Repeat phase 3.

Repeat the method for a few iterations and we have our nodes.

E. Caret

Training in classification and regression is a series of features that aim to simplify the predictive model creation method. Now more than 70% of students have the information. These learners can finally relocate to the university.

V. EXPERIMENTAL RESULTS

Here, the "word cloud" library stores all the related which user wants by using "janeastenr" library. Figure 2 is showing that all the related words for a search word "miss." All these words are built in the library called "word cloud."

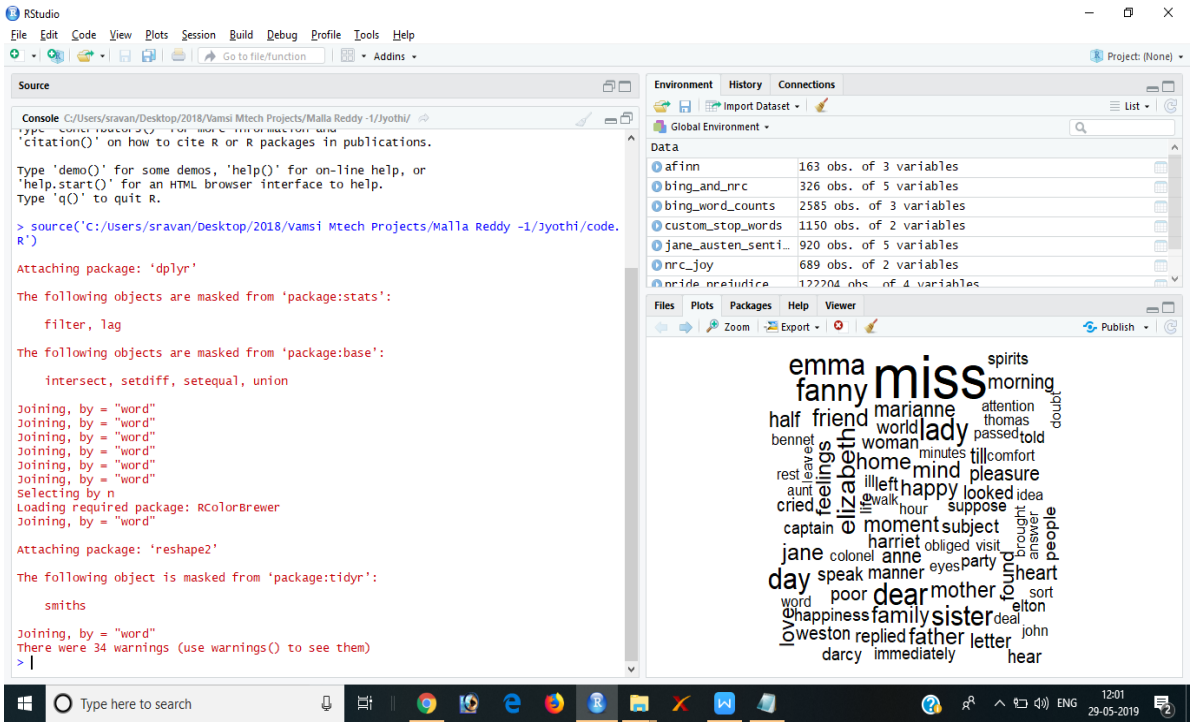

Fig. 2 Showing related words to miss

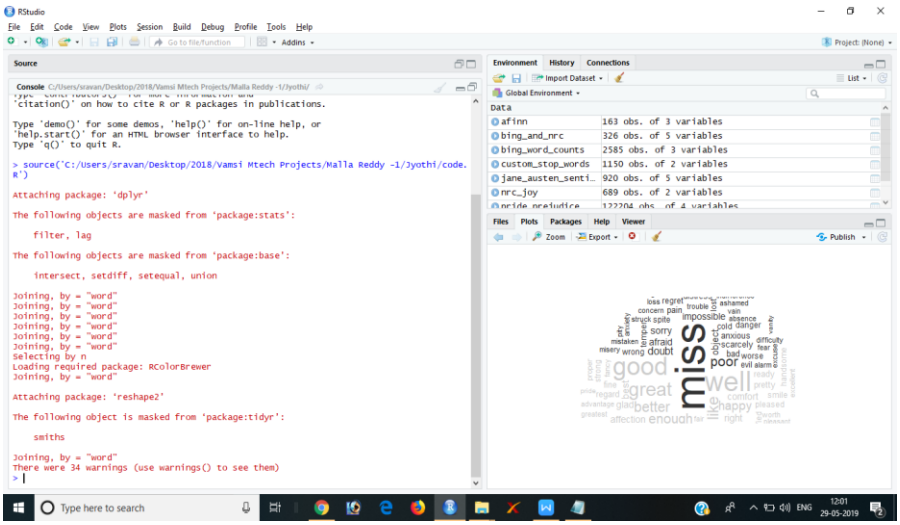

Fig. 3 Differentiating the word “miss”

Figure 3 is showing the results after applying k-means and SVM algorithms. First, it classified the data by using “tidytext” and “tidyr” libraries. And then, unstructured data has found. So, it applied “janeastenr” library. The janeastenr library is having an unstructured data which is used for analyzing. At last, we get the results for searching the word “miss” in black color. The eliminated or duplicate words are in another color.

VI. CONCLUSIONS

The K-means and SVM algorithms have been used. The k-mean model is centered around the theory of a group where SVM is a ranking method. K-means were also used for the construction of classifications on the basis of an active vector mapping training (KA-SVM). The customer wishes to send an e-mail container.

A Scalable Framework for Stylometric Analysis on a Speech Data

K. Vijaya Lakshmi[1], Dr. S Dhana Lakshmi[2]

[1]M. Tech Student, Department of CSE, Malla Reddy Engineering College, (A), Ranga Reddy, Telangana, India.

[2]Professor, Department of CSE, Malla Reddy Engineering College, (A), Ranga Reddy, Telangana, India.

Abstract— ***Stylometry is a region of research where the examination can be connected on the client discourse investigation, recognizing the conduct of the speaker. Stylometric additionally incorporates the investigation of the creator distinguishing proof dependent on the vocabulary correlation from creator to creator. Here we present 'Stylometry with R' (stylo), a flexible R bundle for the abnormal state complex investigation of content accumulations. This bundle unequivocally looks to further add to the ongoing improvement in the field towards a further developed degree of replicability and benchmarking in the field. We speak to the writings as high dimensional vectors and we envision the similitudes between them utilizing multidimensional scaling. We presume that the length of writings is a factor that influences the oppressive limit of the stylometric factors. We additionally discovered that there are sure factors that are superior to others to distinguish explicit creators and explicit content types.***

Keywords— Stylometry, Data Analysis, Speech, Behavior Analysis.

I. INTRODUCTION

Stylometry is the investigation of etymological style, this implies taking a gander at examples in language to diagram standards or qualities of the subject of study. Stylometry is frequently used to decide origin to unknown compositions, yet the standards of Stylometry can likewise be utilized in different regions, for example, the investigation of music. Stylometrists look for a reasonable quantifiable quality that can be utilized to make authoritative determinations about a creator. It is conceivable, notwithstanding, that such a component does not exist. Notwithstanding, as the inquiry advances, analysts discover factual properties and create devices that, when utilized related to one another, enable solid ends to be attracted origin questions.The nuts and bolts of stylometry were built up by the Polish savant Wincenty Lutoslawski in 1890. Previously, this control was exceptionally restricted on the grounds that people needed to physically play out the majority of the information examination on the writings they were considering. With the approach of PCs, be that as it may, specialists are liberated from information examination jobs to concentrate on the hypothesis fundamental the information connections. Stylometry picked up fame from renaissance dramatization creation questions. This enthusiasm for deciding creation in renaissance works set up stylometry's believability in the territory of origin attributions. A basic idea in any case in stylometry is the possibility of the author invariant. This is a composition trademark that has a place with a particular creator. The thought is that, the writer of an archive has highlights of his or her composition which are reliable over all reports composed and that all writers have their own interesting invariants. Subsequently, recognizable proof of this credit can figure out who composed an archive. It is concurred that these sorts of qualities do exist between creators, yet inconvenience exists in recognizing which parts of the content ought to or ought not to add to this invariant. There are three unique classifications which general stylometry can be broken into. These are: origin attribution, portrayal, and check. Origin attribution is deciding the right creator out of a little gathering of creators. Origin Characterization includes deciding the physical characteristics of an author such as age, gender, or race. Authorship verification is determined if a document was written by a specific individual. The differences between verification and attribution are much nuanced. If the reader wishes to learn more about the differences, the paper Authorship verification for short messages using Stylometry (Computer, Information and Telecommunication Systems (CITS), 2013 International Conference on. IEEE, 2013.) by Brocardo is a good start. Most research in stylometry falls into the category of attribution, with verification being the least developed, having been studied almost exclusively in the context of plagiarism.

Stylometric tests are generally targeted at long documents being unreliable on short documents. A long document is a fairly general term often dependent upon the study. Short documents are more easily described as documents one or two paragraphs in length. The ability of Stylometry to analyse these short documents is a

developing interest area. Stylometry's success on works such as novels and plays has raised interest in its merits in modern contexts where online document length is much shorter. Examples of the focus of modern stylometry are email or forum posts. These document sources provide additional challenges beyond their length because they are often poorly structured or written. This is an important area of development because reliable stylometric tools for short online documents can be useful in criminal cases giving law implementation more devices to arraign hoodlums. These new applications for stylometry have raised protection worries that keep on being examined. In the event that the peruser is keen on getting familiar with the security worries around Stylometry.

II. RELATED WORKS

R contents can be depended on for doing the entire work themselves, from controlling writings (ordinarily, to create word records) right to charting the outcomes (and that in an extraordinary assortment).

These abilities were put to use in the investigation of Delta's reliance on concentrated writings' sizes (Eder 2010), and on the conduct of Delta at an assortment of interims in the word recurrence rank records in an assortment of dialects (Rybicki and Eder 2011). The R condition allowed us to cover immense measurements at exceptional rates (regularly a great many Delta emphases every hour in corpora of a hundred full-estimate books). It likewise allowed us to utilize other factual strategies, for example, PCA, CA or MDS, or those once in a while utilized so far in this field –, for example, bootstrap accord trees dependent on an investigation of Papuan dialects by Dunn et al. (2005, cited in Baayen 2008: 143-47). Likewise, the whole investigation – from stacking writings to conclusive outcomes in numeric and realistic structure – can be practiced with a solitary content. Our Delta content, for instance, did fundamentally everything: it took care of electronic works to make a summary of the extensive number of words used in all compositions pondered, with their frequencies in the individual compositions; institutionalized the frequencies with z-scores (if proper); picked words from communicated repeat ranges for examination; played out additional frameworks that (regularly) improve attribution, for instance, Hoover's customized dropping of individual pronouns and isolating (modified removal of words absurdly trademark for individual works); took a gander at the results for individual works; played out an arrangement of multivariate examinations; showed the comparable qualities/detachments gained in tree graphs; finally, made the recently referenced accord tree – another chart that joined many tree diagrams for a collection of parameter regards. It was our plan to build up a general stage for multi-emphasis attribution tests; for example, substitute content created heat maps to demonstrate the level of Delta's accomplishment in attribution at different interims of the word recurrence positioning rundown. Stylometry: Recognizing creators of writings utilizing R: Barely any individuals anticipate that government officials should compose each word they express themselves; dependence on speech specialists and talked people is a since a long time ago settled political practice. All things considered, it's intriguing to know which articulations are really the government official's own words, and which are driven basically by counsels or influencers. By taking a gander at the parts of semantic style (word/sentence length, recurrence of word pairings, utilization of accentuation, and so on.) of the talks we can able to find out the behaviour of the person.

A Stylometric Approach to Identity-Level Identification and Behaviour Detection. Lexical features describes the semantics of the words used by the author. Vocabulary richness and word-length distributions are classic examples. Syntactic features: Such kind of features rely on an analysis of typical sentence structure considering elements like function words, punctuation, and part-of-speech tags. Structural features: Structural feature targets the actual composition of the text discussing its organization and layout. Due to the short extracts without any further information, this seems not applicable here. Content-specific features: This type of features based on an analysis of essential keywords and phrases on specific topics like in scientific publication. Like the feature set before not applicable in our context.

III. PROPOSED WORK

Stylometry or the investigation of quantifiable alternatives of (artistic) vogue, similar to sentence length, vocabulary extravagance and various frequencies (of words, word lengths, word shapes, and so on) has been around at least since the focal point of nineteenth century, and has discovered arranged reasonable applications in origin attribution examination.

The examination in most recent couple of decades on use of language factual investigation is developing in a quick manner. Present day stylometry pulls in vigorously on the assistance of PCs for measurable examination just as the computerized reasoning and furthermore giving access to the developing corpus of content archives open through the Internet. Our primary objective is to exhibit and break down the discourse by the despot's vocabulary and after that investigating the information so as to extend the factual examples. Stylometry to distinguish if moves in elaborate examples are seen crosswise over different talks, utilizing computational instruments. The pivotal examination with stylometry is this: There exist propensities for every individual, framed unwittingly, concerning words and Language use. These decide the despot's structure, decent variety, and word decision in every individual's works, shaping a Stylistic mark.

Stylometry became out of before procedures of examining writings for proof of credibility, authorial character and builds the vocabulary wealth. Applying the stylometry to the discourses of the speakers in examining the discourse conveyed to the group of spectators. To assess the productivity in examining the discourses, we contrast and required strategies. Breaking down the discourse content by means of huge archives. These huge scale reports help us to find out about the speaker from his discourse or the vocabulary utilized and the method for his methodology over the discourse conveyances. To exhibit and break down the conduct of the despot. Research dependent on the examination of writings may assist the researchers with gaining full control of the conduct of the person. The term stylometry draws the conduct of the client from every one of the addresses conveyed by the speaker. The proposed framework gives the factual items from the speaker information, for example, positive negative and enthusiastic terms. The conduct of the individual speaker could be investigated from the feelings dependent on the specific discourse information. Utilizations of the customary articulation make the data characterization a great deal well disposed and bring progressively proficient outcomes. Utilizations NLP Algorithms can be executed on any sort of information.

IV. IMPLEMENTATION

Stylometric investigation errands can be sorted out into two kinds, creation distinguishing proof and composing style closeness identification. Each assignment is comprise of two stages (i) finding proper stylometric highlights (ii) framing productive ways to deal with apply on these highlights. The target of creation recognizable proof errand is to analyze question writings against the composition tests of the hopeful writers. An outstanding case of creation distinguishing proof is the Federalist papers in which 12 debated/unknown expositions were looked at against composing tests of Alexander Hamilton and James Madison. Since, all hopeful creators (conceivable classes) are known an earlier, the initiation recognizable proof errand can utilize regulated or unsupervised order procedures. Stylometric highlights are composing style-markers or traits that are compelling discriminators of creation. A huge range of stylometric highlights have been proposed so far including lexical, syntactic and basic. Lexical highlights are character based and word-based factual proportions of lexical varieties. These incorporate word and character lengths, sentence lengths. Syntactic highlights incorporate capacity words, grammatical feature label n-grams. Auxiliary highlights incorporate the style-markers identified with the format and association of content. For instance, number of words in sentence and number of words in passage. Existing examinations utilized the equivalent size of the content to look at for origin recognizable proof. This is a test in genuine datasets. This is on the grounds that, a database of understudy assignments may contain records with various lengths composed by a wide range of understudies. In this examination we use creator bunch level stylometric highlights to make our framework altogether quicker than existing procedures with sensible precision. In this work, we utilize 56 stylometric highlights which are ordered into three kinds: lexical, syntactic and auxiliary. The lexical highlights can be further subcategories into 14 character-based and 13 word-based highlights. We utilize 27 syntactic highlights, which incorporate capacity words, grammatical form. There are 2 auxiliary highlights, the quantity of words in sentence and the quantity of words in passage.

Behavior analysis is a characteristic science that tries to comprehend the conduct of people. That is, conduct investigators think about how natural, pharmacological, and experiential variables impact the conduct of people and nonhuman creatures. Perceiving that conduct is something that people do, conduct experts place uncommon accentuation on contemplating factors that dependably impact the conduct of people, an accentuation that functions admirably when the objective is to secure versatile conduct or improve issue conduct. The study of conduct examination has made disclosures that have demonstrated valuable in tending to socially significant conduct, for example, speaking, medicate taking, good dieting, work environment wellbeing, instruction, and the treatment of unavoidable formative handicaps (e.g., mental imbalance).

This field of science is worried about portraying, understanding, foreseeing, and evolving conduct. They look for answers by taking a gander at the organic and ecological components, in spite of the fact that they are principally inspired by the job of condition in conduct change. There are three principle branches to the field: Conceptual Behavior Analysis, Experimental Behavior Analysis, and Applied Behavior Analysis. The Conceptual branch centres around the philosophical, hypothetical, chronicled, and methodological issues that underlie the field. Trial Behavior Analysis includes essential research expected to add to the assemblage of information about marvels that control and impact conduct. Connected Behaviour Analysis is centred on the utilization of the standards of conduct to the requirements of people to advance conduct change and improve personal satisfaction. The engineering portrays the idea of examining the discourse reports from the essential advances. The principal way is we gather the reports, separate the words, apply the extremity feeling to keep an eye on the words, and after that at long last produce the conduct out from the information.

A. Identify Parameters:

At First the information is taken into the R support. At that point the information is shown with the view strategy in the R language. The size of the information might be 1 Gb or 1Tb. Ideally the unstructured information is taken. In this module we use KNN calculation for characterizing the watchwords with assistance

of normal articulations. The customary articulations encourage to expel the pointless information, for example, stop words or blaw words. Presently the stemming is finished once and the KNN is connected subsequently to remove the spaces between the words, to make one report. The Term-Document Matrix is utilized to outline the arranged words into the report and this is the place we apply the stemming for the words.

B. Stemming

Stemming is a system of lessening words. To the specific content record we apply stemming procedure to evacuate the spaces, punctualities, stop words. At that point the archive with the positive and negative terms is acquired. After this procedure a proper report is shaped.

C. Steps for KNN Algorithm:

Step 1: Determine the parameters K=numbe of nearest neighbours. k = how many keywords – one, two, three words.

Step 2: Calculate the number of keywords between the query-instance and the data.

Step 3: Sort all the keywords and determine the count of the keywords.

Step 4: Gather all the categories of the keywords.

Step 5: Use simple majority of the category of keywords as the prediction value of the query instance.

D. Classify Keywords

In view of the consequences of the watchwords from the principal module, and after that apply the bayes calculation according to the necessity. The catchphrases got subsequent to applying KNN is named as preparing informational collection. Gather all the catchphrases to a variable. Apply the bayes calculation and sort the watchwords according to positive and negative terms. When catchphrases are arranged, order the feeling of words in the particulars of glad, miserable, dread, terrible. Undertake the outcomes according to the grouped words.

E. Steps for Naïve Bayes Algorithm

Step 1: Collect all the key words to a variable.

Step 2: Apply the bayes algorithm and categorise the keywords as per positive and negative terms.

Step 3: Once keywords are categorised.

Step 4: Classifying the emotion of the words as happy, sad, fear, bad.

Step 5: Project the results.

F. Behaviour Analysis

Conduct examination is a characteristic science that looks to comprehend the conduct of people. The study of conduct examination has made revelations which have been demonstrated valuable in tending to socially significant conduct, for example, talking, sedate taking, smart dieting, working environment security, culture, and the treatment of inescapable formative incapacities (e.g., mental imbalance).

There are three principle branches to the field: Conceptual conduct examination, test conduct investigation, and connected conduct examination. The calculated branch centres around the philosophical, hypothetical, authentic, and methodological issues will underlie the field. Trial conduct investigation includes essential research expected to add to the assemblage of learning about marvels that control and impact conduct. Connected conduct investigation is centred around the use of the standards of conduct to the requirements of people to advance conduct change and improve personal satisfaction. From all the above prerequisites we investigate the information utilizing the stylo techniques for anticipating the conduct of the information. Presently to whole informational index apply stylo strategies. Computing the feelings from past module, this strategy demonstrates the conduct of the speaker. In the wake of finding the conduct we get the outcome as reports that bring about the conduct investigation.

G. Stylo:

The third program to encourage stylometry that is examined was the R stylometry bundle: This toolset works inside the R programming condition and highlights a GUI for clients who might not want to utilize the programming backing of R. For clients that desire to exploit R's capacity, Stylo incorporates extra capacities and approaches to join them into different projects. Stylo likewise highlights support for AI which underlines the extent of the toolset. Since stylo works inside R, setting it up and utilizing the essential highlights turns out to be marginally increasingly hard for clients unversed in programming dialects. When arrangement is finished, be that as it may, stylo incorporates a GUI to help armature examination. The stylo manual was complete and strolled through the majority of the various parts and how they work.

V. EXPERIMENT AND RESULTS

The execution is made with the ten unique addresses from an individual and numerous speaker and the found that the outcomes are the depicting the conduct of the speaker at the best to the connected strategies. The outcome manages distinguishing the catchphrases, unigram, bigram, trigram words from the discourse record. At that point later creates the extremity from the watchwords and the feelings are been ordered from the discourse content. At long last the conduct of the speaker over the crowd has been ordered and discovered that outcomes were precise and explanation is distinguished. A model content report to break down the conduct of

the speaker. Here Pakistan president commented on discourse archive is taken. Speaking to the quantity of lines alongside words in an archive recognizing two parameters from the content record. At first we locate the quantity of words in the content report. There are around 1929 words and 75 lines in the content archive the specific content archive is partitioned into single words. Indeed, even it recognizes how often a specific word is repeated. Representing the expressions of unigram list. The archive is separated into single words then the stemming procedure is connected. At that point it evacuates the superfluous words, spaces and so on. Presently the archive contains just positive terms and negative terms. Speaking to the extremity (arranging into positive and negative terms) after the correlation between the positive and negative words, a different rundown of positive and negative words is ordered.

Characterizing feelings from positive and negative words, in the wake of getting the rundown of positive and negative words, feelings are arranged from the words. Speaking to the conduct from the feelings, the conduct of the individual is gotten from the feelings. In this way we can locate the conduct classification of the individual.

VI. CONCLUSION

Stylometry is connected to discover the conduct of the speaker through his speech. Results help us in examining the conduct of the speakers and their vocabulary. The discourse is taken in the content organization. Hence the conduct of the specific speaker through his discourse is dissected by distinguishing watchwords and next the feeling of got words must be found. Later the feeling will be disregarded the stylo, in grouping the conduct of the individual. We will investigate the conduct dependent on the feeling. From the ongoing after effects of extremity and the feelings from the discourse information, we presently arrange the outcomes to work out the conduct of the speaker dependent on the passionate class. Arranging the feelings dependent on the sort of extremity, we can recognize the conduct of individual.

[2]Professor, Department of CSE, Malla Reddy Engineering College, (A), Ranga Reddy, Telangana, India.

Abstract— ***Sentiment analysis of text is a valuable tool used to identify and classify bodies of text for various purposes, including public sentiment detection in political campaigns, spam detection and threat assessment. In this paper, we examine the effectiveness of incorporating Emoji data for Twitter data emotion classification. We conducted experiments using Multinomial Naïve Bayes (MNB) and Support Vector Machine (SVM) classification methods, with automatically labeled Twitter data. We compare the accuracy of these classification methods with and without the Emoji data included over varying vocabulary sizes. We find that MNB outperforms SVM on the data for large vocabulary sizes, and both classifiers perform slightly better with the Emoji data included.***

Keywords—Sentiment analysis, Twitter, Emoji, Supervised Learning.

I. INTRODUCTION

Natural language processing (NLP) is a field within artificial intelligence that overlaps heavily with linguistics and focuses on understanding data from raw text. It relies heavily on statistical measures to evaluate sources of information and understand text. NLP is employed throughout software today for various purposes, including syntax and spelling evaluation for word processors, human-computer interaction and automatic language translation. With the growing use of the Internet, a largely text based communication media, NLP has grown in interest for security and management solutions, such as spam detection in emails and identification of improper languages in social media postings.

Sentiment analysis, closely related to natural language processing. attempts to identify sentiment (positive, negative, neutral) or emotion from texts and/or social media. It is a challenging task for machines and can even challenge humans occasionally. The structure of the English language, combined with sarcastic tones and ambiguous grammar, can often be misleading for those without an intuitive understanding of the language. Interest in emotion/sentiment detection, however, has grown alongside the field of artificial intelligence, particularly with the increase in emotional communication over the Internet. The advent of social media in the past decade has led many more individuals than ever before to communicate about personal and emotional matters, social and political viewpoints through both private and public messaging platforms. The social media thus has become a rich source of information about public sentiments in many aspects of the society. Developing automated methods for sentiment detection can provide valuable tools for many useful applications, including public sentiment detection for political campaigns such as the US presidential election, and automated detection of abusive communications on social media that is highly desired by social media companies such as Facebook.

II. RELATED WORK

A. Sentiment Analysis

The process of sentiment analysis typically follows a common framework: collect raw data, preprocess the data to remove noise, represent the cleaned textual data in suitable form (typically in a feature vector) for computation, label the data for training purposes, and then feed the data to train a classifier. Preprocessing is necessary due to the ambiguity inherent in language and human tendency to deviate from standard grammatical structures. This results in very noisy data that is difficult to classify. The cleaning process removes some of this noise, resulting in data that is easier to work with. This can involve removing certain punctuation, trimming words of their various endings to result in only root words (stemming), or filtering the data points by keywords or length. Data representation typically takes the form of a vector of features, with the most common feature being the frequency count of a word. This is often called "Bag of Words"(BoW) representation. Most classification relies on supervised learning, where training is required to teach the system how to recognize the various classes. This requires labeling data with class labels prior to training the system. The labeling process can be done manually by a human to ensure maximum accuracy, though this is slow and subjective. Other methods involve identifying the most prevalent keywords in text and labeling them, though these automatic

methods must then be verified by a human to be accurate. If the dataset itself is not labeled accurately, any classification will also be inaccurate.

B. Classification

Sentiment analysis of texts essentially amounts to classifying textual documents into sentiment/emotional classes. Various types of classifiers have been used for text classification. The two most commonly used classifiers for text are the Naïve Bayes classifier and the Support Vector Machine (SVM). Both rely on supervised learning, being trained on one dataset with the data points labeled with proper classes and then tested on a disjoint dataset with the class labels withheld. Both classifiers learn the features that define each class and then attempt to find which class fits the unlabeled data of the testing dataset. Space consideration limits. In recent years, use of deep learning neural networks for text classification. In this study we intend to keep the classifiers simple and thus we do not consider using deep learning neural networks here. But we intend to investigate the use of deep networks for sentiment/emotion analysis in the near future. The Naïve Bayes classifier considered in this study is based on the Bayes' theorem of probability, and the Naïve Bayes Assumption which assumes that the features of an object are conditionally independent, given the class label of the object. There are many variations on the model, such as the Multinomial Naïve Bayes, the Gaussian Naïve Bayes and the Bernoulli Naïve Bayes, all of which operate on the probability of the occurrence of words in the text. By comparison, SVM is a non-probabilistic classifier. A linear SVM is a binary classifier that aims at finding the maximal margin hyper plane that separates the data points in one class from the data points in the other class such that the "margin" is maximized. This ensures the greatest margin of error for the hyperplane and thus the lowest misclassification rate.

Documents into sections that can be identified by their opinions, allowing for observing how sentiment changes throughout a document [6], or classifying individual phrases by their positivity and negativity [13]. In this way, sentiment analysis can be used for summarizing reviews for products in a comparable manner, detecting whether a given user review is positive or negative for a product. Other work has been done to identify the subjectivity of documents, and whether they should be classified as fact or opinion [5]. In the last decade research has increased involving social media, resulting in many experiments on mining political and subjective opinions from blogs and news articles [4, 8]. There has also been other research into the use of Twitter as a source of data [7, 10], and how sentiment analysis can be executed to accurately identify emotion through these short statements [1, 3]. This is like our work, though we include Emoji data in the tweets that is typically unaddressed in these works.

III. METHODOLOGY

A. Data Collection

The first step of sentiment analysis is acquiring a large corpus of high quality textual data for training and testing. The advent of social media in the past decade has brought a new source of highly emotional human text. Many individuals use Facebook, Twitter, or other social media sites every day and post emotional information or opinions. Studies show that upwards of 80% of individuals in the United States with internet access have Facebook accounts, while between 2530% of these individuals have accounts on various other media websites (Pinterest, Twitter and Instagram for example) [2]. These sites act as an aggregator for this emotional information that researchers can then access and use for experimentation.

For our study, we collected data purely from social media. Specifically, we collected "tweets" from Twitter, which are usually short (less than 140 characters) messages posted by individuals that contain various opinions and emotions. Twitter provides an API for programmers to access their data, requiring a Twitter developer account. We used a package for Python called "twitter" [9] to utilize the API Twitter offers to access their databases and collect the raw tweet data. In this data, all personal identifying information is removed. To collect specific tweets, we chose to follow the model of Wang et al [11], who tested the viability of tagged tweets as auto-classified textual data. On Twitter, many people use these "hashtags" to mark their tweet as pertaining to a certain topic. For instance, during the 2016 presidential election, many people tagged tweets in favor of candidate Hillary Clinton with "#ImWithHer." This allows for tweets to be grouped and viewed by their tags to quickly access information, and allows for easy classification of tweets. Our tweets were collected from seven broad emotional classes: Sad, Angry, Happy, Scared, Thankful, Surprised, and Love. For each class, we define a set of key words that are indicative of the emotions in that class. For example, for the "Happy" class, the set includes key words such as "joy", "pleased", "glad", "happy", etc. Then in collecting tweets, a tweet is selected if it contains at least one hashtag for a key word from one of the seven emotion classes.

Emoji Data The non-standard characters however are of interest for our study due to the recent inclusion of "Emoji" characters in social media. These characters display as certain faces, as seen in Fig 2. Their primary use is to display various emotions such as happiness, anger, sadness and love. Typically the use of these Emoji characters provides very direct and strong suggestions of the emotion included in the text, even though they are commonly thrown away. This is like the case for punctuation, which is often trimmed in many applications except for sentiment analysis, where question marks and exclamation points can provide insight into the

emotions of the writer. The purpose of our experimentation here is thus to investigate the influence that including Emoji data within text can have on the accuracy of emotion classifiers.

TABLE I: DISTRUBITION OF CLASSES AFTER CLEANING

Class	Number of Viable Tweets
Sad	23121
Angry	7672
Happy	7710
Scared	4791
Thankful	4525
Surprised	2167
Love	4075
Total	54061

Fig. 2 Sample of Emoji Characters

These Emoji characters are represented in the text as various Unicode values. Web browsers then map these Unicode sequences into the associated images to display. The same process can also be used when collecting the purely textual data – collect the Unicode values and map them to the correct Emoji faces. An example of the Emoji encoding scheme is shown below in Fig 3. For example, the Unicode sequence U+1F600 results in a smiling face, while U+1F622 results in a crying face. Instead of mapping the Unicode back into an image, since our plan is to work solely with textual data, we can map the Unicode sequences into specific textual sequences, such as <ANGRYFACE> for a mad face and so forth. This allows us to capture the Emoji data in a human recognizable form in text.

IV. RESULTS AND DISCUSSIONS

- For each of the experimental cases, measured the classification accuracy of the system using the given vector size by running each trial ten times and averaging the accuracy to remove variation.
- It represent how this code will generate the results from the last lines in the image we can identify the scores of positivity and negativity and more number of emoji's used in the data to describe the customer emotion.
- It describes about predefined code which is written for identifying the smileys and analysing them.

V. CONCLUSIONS

Micro-blogging like twitter nowadays became one of the major types of the communication. The large amount of information contained in these web-sites makes them an attractive source of data for opinion mining and sentiment analysis. Most text based methods of analysis may not be useful for sentiment analysis in these domains. To make a significant progress, we still need novel ideas. Using twitter names and hash-tags to collect training data can provide better results. Also adding symbol analysis using emoticons and emoji characters can significantly increase the precision of recognizing of emotions. The most successful algorithms will be probably integration of natural language processing methods and symbol analysis.

Abstract— ***Bitcoin was improving its market share and struggling with real currency in the actual world. In this sense, there is the amount of applications developed for the cryptocurrencies and general applications that can be able to worn in a disseminated situation is increasing. The cryptocurrencies used in blockchain, such as Bitcoin, also has become popular for other apps. The website like Ethereum's got its assistance for creating apps of this kind. In this document, Bitcoin focuses on cryptocurrency and failure scrutiny on economic information. It is suggested that an algorithm should have a regression analysis. The document also offers the dynamics of Bitcoin with the aim of using it as a cryptocurrency. It also sheds light on the opinion of software growth using Ethereum. Ethereum is a scheme to generate distributed applications where millions of pcs and customers can engage in safe interactions. The conclusion indicated that the Ethereum system was helpful and the failure study showed the efficiency dynamics discovered in the monetary information.***

Keywords— Cryptocurrency, security, ethereum, cryptography, ethereum applications.

I. INTRODUCTION

The statement currency has two wide definitions. They are a material currency in the shape of coins or notes measured in, for instance, Euros and electronic money that are not tangible in nature. unconventional currencies are dissimilar forms of electronic currency other than physical currency. Bitcoin has appeared as moreover electronic currency or electronic cash. It is a decentralized digital legal tender that does not have need of a central bank or a governing body. In other phrases, bitcoin is a unmarked type of cash with an advanced payment network. Many variables influence the trade rate of physical currencies such as the euro. These variables embrace rise, political stability, financial circumstances, recession and trade levels. The objective of this thesis is to look at the hypothesis that "the variables influencing traditional macro-finance do not guide the charge of Bitcoin." To this conclusion, a methodology is residential with an abstract structure desirable to finish the study. From the evaluation of the results of the studies, it is recognized that Bitcoin rates are not linear as they are in the situation of conventional currencies. Its existence in the digital shape is lone of the fundamental reasons why the Bitcoin legal tender is not influenced by variables that influence the normal currency. Another significant remark in the explore is that there are various other variables, for instance press, talk of hand and advertising, affecting the charge of Bitcoin. The remaining of the document offers more in sequence on Bitcoin and cryptocurrency and offers failure study in count to the scheme of creating distributed applications by means of the Ethereum engine. Crypt currency has turn out to be a truth with many instances, such as Bitcoin. It is not comparable to the established currency, the presence of which is not physical and is not controlled by governments. However, it is highly thought as Bitcoin competes with the established currency on the stock markets as well. Cryptocurrency has well-built protection assistance with Blockchain technology. Blockchain technology offers a centralized ledger that retains all operations as a sequence of chunks. This can assist mine and figure out whether operations are performed out credibly. Blockchain technology and cryptocurrency have drawn several studies in this field. In this document, we provide significant perspectives into the cryptocurrency and the Ethereum development environment that could be used to construct cryptocurrency apps.

II. RELATED WORKS

This subdivision offers a outline of the appropriate cryptocurrency literature and associated plays.

The theory of substitute currency According to Levy & Glimcher [8], the speech "supplementary or alternate monetary" is primarily used to indicate any money that is used as a unchanging choice to the corporate or dominant domestic monetary scheme. Patel et al. [10] acknowledged that substitute currencies are over and over again generated by a corporation, an individual or an organization. Moreover, this category of currency can be developed by moreover local or state governments [11]. Luther and White [9] argued that an substitute currency scheme could evolve obviously when individuals imagine using a precise service as a currency. Modern prose offers many argumentative reasons for the perception of substitute currency. Levy & Glimcher [8] argued that an extra or

supplementary currency could behave like a firm means of return (replacing additional cash for the conventional euro and vice versa) which is certainly not a recognized monetary of the country. However, it is believed of or regarded as a currency scheme that promotes the count of national currencies.

However, according to Levy & Glimcher [8], the additional exchange is rarely regarded as a legal instrument. A lawful tender is a deposit tool that is acknowledged by the lawful system and is generally applicable transversely to the nation. For illustration, euro loose change or banknotes are measured to be legal tenders in the European amalgamation. The implementation of the supplementary currency shall be governed by an arrangement between two separate parties which may authorize the exchange of currency. Luther and White [9] insisted on the view of the conception of complementary currencies to boost, safeguard or guide the nation's economy. Substitute currency is regarded to be an instrument used to promote any particular monetary, artistic and political objective (Burnside, Eichenbaum & Rebelo, 2016). Experts such as Patel and others [10] have identified several interchangeable definitions used to denote options monetarily. One such instance would be the word "group monetary or local currency." Several specialists often find more than a few classified currencies to be alternative currencies, most of which are published by different personal companies. Kim & Dilts [8] argued that fresh taxation is largely inserted into the environment for a plethora of reasons. Besides, Luther and White [9] illustrated several such reasons in their study process. The specialist argued that substitute currency must be issued when a country intends to increase its economic safety and stability [8]. Xiao et al. [11] championed the use of substitute currency in circumstances where a country or a specific society has no proper connections to specified financial capital. Cryptocurrency details, for instance Bitcoin, are further reviewed in [12]-[20]. The upper row is that Bitcoin has turn out to be popular as a cryptocurrency.

III. PROPOSED WORK

Thorough knowledge of interchange Currency is desirable to discover the outcome of substitute currency and its end product on the economic sector. The innovation, arrival, and impact of currencies for instance bitcoin and other forms are explored in aspect in this section. Bitcoin is coupled with substitute currency and has attracted focus to a whole host of areas, from cryptography to economics and mainframe knowledge, as well as economic aspects [3].

Bitcoin is lone of the the majority successful cryptocurrencies in the globe. It was first brought to the orb by the genius psyche of Nakamoto[5], who used the' linear organizational design' for this purpose[3]."The main issue with standard cash is all the confidence that is considered necessary to create it function. The innermost bank must be instructed not to lower the currency, but the past of fiat currencies is inclusive of violations of that trust."[5] The aim of the bitcoin is its decentralized philosophy. It is an evolving skill that attacks standard trading currencies. Bitcoin is one of the opening forms of cryptocurrency to emerge, slowly altering the ways of wealth. Currency at its initiation in 2008 to its present shape in 2018 has urbanized to reach astounding facts of roughly $330 per bitcoin. It is therefore crucial to concentrate on the investigate of this transaction currency swapped for fiat currencies[5]. There are quite a few elements to this distinctive currency. First and foremost, the digital legal tender had its past. But the distinction that Nakamoto[5] has made to this legal tender is that the distinctive notion of' public-key cryptography' has been worn to compose these electronic cryptocurrencies [5]. The aim of Bitcoin, for Nakamoto, was to separate currency schemes from government influence and consequently decentralization that is far distinct from the' statutory currencies' worn by innermost banks in the in attendance scheme. The ideology is to create' confidence' flanked by the bitcoin industry respondents all through the phase of building block system engineering using two main outputs–(A) Cryptography techniques and (B) Hash features. The fruition of this scheme has extended theoretical study in this knowledge and is evolving as a sophisticated level of PC learning[5]. Although Nakamoto's continuation is wearing a veil in privacy, his white paper has been tested for a moment, and Bitcoin remains to be a cryptocurrency scenario[3]. Nakamoto acknowledged in his seminal job,' Bitcoin: Peer-to-Peer Electronic notes System,' that the key characteristic of this legal tender is the exercise of the Ledger system for payments finished in the approach of a blockchain. The main elements of Bitcoin as suggested by Nakamoto are 1) Blockchain or Ledger for all operations (2) Mining–the skill of the decentralized agency to authenticate operations. This scheme is commonly referred to as mining records [3].

A. Legalization by Users

The principle taken for the intent of validation is the opinion of' mining.' Users will start by validating the creation and its validity before introducing it to the blockchain. The validation scheme is very costly, as it includes encryption and the use of complicated alphanumeric buttons. As shortly as the customer, who is as well called the miner, conducts the validity inspection of all operations and connects them to the blockchain, the patron will conduct the pulling out operation. These efforts are rewarded by the BTC legal tender and thus the bitcoin or legal tender is created or the records are generated [3].

Bitcoin Enabling Technology; the swap over tempo is gritty by fiat currencies. Bitcoin rates are in the connection connecting the real exchanges as well as the Bitcoin exchanges. The distinction is therefore in the industry for bitcoin and the legal tender markets. Since Bitcoin is a practical currency and depends on blockchain techniques, factors or financial sizes E, Velocity V and the facility of the Bitcoin industry, B is closely linked where business variables are measurable. They are seized from the Blockchain system. Thus, if P is the cost level

of products and facilities, it can be determined horizontally by captivating into description the worldwide macro-economic indexes in real time[4]. Hence the value of Bitcoin (PB) = PE (Price in financial size)/VB or Bitcoin flow speed[4].PB = PE/ VB

Blockchain; devolution is the appearance that cryptocurrencies follow and is contrary to the fiat currencies that are appreciated by the innermost banks. A debate on decentralization sets away the preceding target structure on (1) the submission register must be retained and controlled (2) the authority to make lawful operations must be treated at the appeal of the purchaser (3) The expansion of fresh bitcoin ought to be controlled. The rejoinder to these objectives was discovered only in blockchain technology[4]. The finances that are produced in the blockchain are therefore immediately affianced in the trading and advance of bitcoin. They are immediately exaggerated by Bitcoin's deliver and command. Thus, blockchain technologies associated to the Bitcoin bazaar are a pattern of how to toil seamlessly between high-level cryptography and market economy[1]. The key to the above objectives is to include the participant as fraction of the Bitcoin system itself. The person will offer the required hardware funds through his laptop. These are referred to as' managed schemes.' The relay or the allocation and act of cash is addressed by P2P networks. The blockchain then registers the background of trading and is then communicated on the set of connections. The full background of the prior action is then checked by each network member. The device is also called the' bank' and will provide every scale of the recent operation and the nearly all significant hash value. This score is extracted from the' prior block' and the effort is made to produce irreversible in order that operates with the attribute and suggests the subsequently block[4]. The fundamental assumption of blockchain expertise is the validation by customers themselves, thus eliminating the necessitate for third parties or governments to remotely corroborate the batch of currency. Instead, each patron has already validated the invent or the delivery or spring of life of the coin. The benefit of bitcoin is that it enables the set-up member to conduct the pulling out method. Each operation then becomes a further node or block where further activities are conceded out and a decentralized stage is established. Actions or events are autonomous and transmitted separately or from both person in the association to each other on the arrangement. This method will carry on until all operations are distributed transversely to the system. The blockchain is thus cloned or transmitted to all the respondents in the net and becomes a' complete node' separately from recording each record [3].

IV. IMPLEMENTATION

Ethereum is a scheme to easily form decentralized apps. Such apps have distributed architecture and perform particular aims. These apps offers for associations between distinct sides. It promotes the API worn by Bitcoin and BitTorrent to include peer-to-peer networks that be able to be worn by customers transversely the globe. Ethereum also promotes black-chain expertise that can be worn to safeguard financial and other apps during a dispersed setting. Ethereum Virtual Machine (EVM) is a shared implicit mechanism in which millions of pcs can engage. It promotes two types of records, namely external records (EOAs) and agreements. The contracts can serve different purposes like maintaining a figures store, serving as an account, manage Contracts can join distinct aims, such as keeping a data store, acting as an email, managing associations between many customers, and providing library features. In a betting implementation, the sides concerned may have secure communication by means of the Ethereum implementation as revealed in Figure 1.

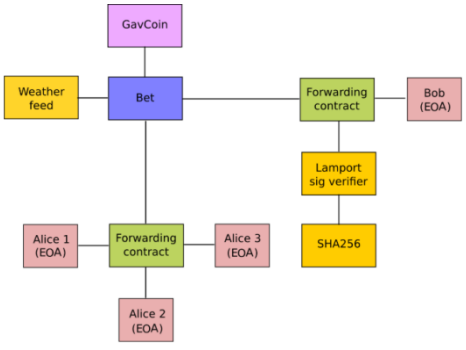

Fig. 1 Distributed relationships during the software Ethereum

As revealed in Figure 1, here are safe associations among distinct sides in the order of the orb in a betting implementation. The Ethereum implementation can assist to accomplish such complicated relationships through the establish of safety. Bitcoin dealings are a complicated method. As revealed in Figure 2, nearby is a contract between Bob and Alice. Bob is a merchant who takes the bitcoins as payment while Alice is a purchaser of goods or services and agreeable to forfeit the bitcoin amount. Bob and Alice are also desired to comprise Bitcoin wallets in their scheme. Wallets are effectively machine documents that refer to various bit signatures references. A bitcoin email is produced out of bed of words and numbers. Each email represents the equilibrium of the bitcoin (Jain & Paras, n.d).

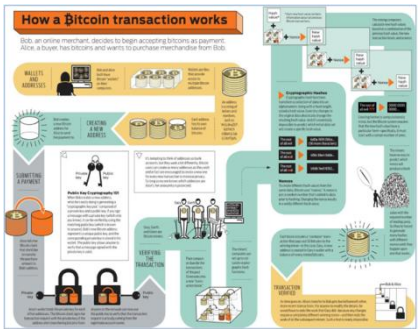

Figure 2: Procedure followed in a Bitcoin contract

To start operations, Bob is starting to create a unsullied Bitcoin financial credit for Alice to obtain a deposit. Alice then tells its Bitcoin client that it has decisive to submit the necessary buy quantity to Bob's Bitcoin email. Alice's wallet is linked to a concealed key. The BitCoin Client utilizes a private key to register a payment application. Any consumer on the Bitcoin network can now verify the payment application to understand whether it comes from a lawful proprietor fresh application block is created accessible to other internet customers to assist them mine accounts. Computers that mine are capable of computing cryptographic hash functions. Bitcoin consumers can generate many addresses that are used to perform operations. Cryptographic hash functions provide data in a transformed form that can not be attacked by opponents. Bitcoins use the notion of nonces or random digits for greater safety. A fresh application block is created accessible to other internet customers to assist them in my accounts. Computers that mine are capable of computing cryptographic hash functions. Bitcoin consumers can generate several addresses that are used to perform operations. Cryptographic hash functions provide data in a transformed form that can not be attacked by opponents. Bitcoins use the notion of nonces or random digits for greater safety. Mining machines can produce fresh hash values that can be used to mix with prior hash values in an attempt to have a fresh application row (Jain & Paras, n.d).

Creating hashes is computationally insignificant, but for hashes, Bitcoin requires a particular shape. There's no data to miners about it. As a result, miners need to produce various hashes from which one can operate. Each bank has a coin foundation operation that charges 50 bitcoins to a miner's winnings. A fresh email is thus established in Gary's wallet, which contains freshly minted bitcoins. Transaction verification requires position and ancient operations are placed under old ones and therefore the payments are not irreversible (Jain & Paras, n.d).

A. Bitcoin Mining Process

Bitcoin can be mined with distinct hardware accessible on the industry. It also requires software programs that can assist with mining and benefits. However, the mining method is distinct for each accessible cryptocurrency. Figure 3 demonstrates the Bitcoin mining method.

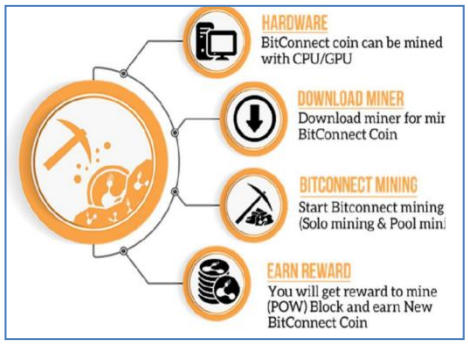

Figure 3: Illustrates the Bitcoin mining method (Kalyani, 2018)

The method used to mine the Bitcoin currency is shown. There is some hardware needed for the mining method. You can buy it from e-Commerce websites like Amazon. The mining method can be performed either by CPU or GPU. After hardware acquisition, it is essential to have the software needed for the mining method. The software requires to be purchased for the Bitconnect coin mining operation. There are two processes in place, such as single mining and tube mining. Once the mining is done, the award will be provided to the miners. Miners are therefore getting fresh BitConnect currency (Kalyani, 2018).

V. EXPERIMENT AND RESULTS

A. Data Used for Regression Analysis

Data has been collected from http://fundforpeace.org/fsi/ that contains the price details of Bitcoin besides the Fragile States Index. The data reflect different attributes like Year, Bitcoin Price, USD/EUR/ and GoldUSD. It also

provides other attributes related to fragile states index for countries like the USA, Kuwait, Latvia, United Kingdom, and Switzerland. An excerpt of the data collected is presented in Table 1.

TABLE 1: SHOWS DATASET USED FOR REGRESSION ANALYSIS

Year	Bitcoin	USD/EUR	GoldUSD	USA	Kuwait	Latvia	United Kingdom	Switzerland
2014	854.0	1.4	1292.0	35.4	59.0	48.0	34.3	23.3
2015	229.0	1.1	1150.0	35.4	57.5	48.5	33.4	22.3
2016	409.0	1.1	1339.0	34.0	58.5	47.4	32.4	21.8
2017	1197.0	1.1	1318.0	35.6	58.5	46.4	33.2	21.1
2018	9521.0	1.2	1316.0	37.7	58.5	46.4	33.2	21.1

The information reflects the characteristics mentioned above for the years 2014 to 2018. The information demonstrates how Bitcoin value increased from 2014 to 2018. It also demonstrates the efficiency of GoldUSD over the years. The USD / ERU proportion is also expressed in the information.

Regression Analysis The regression analysis was conducted to analyze Bitcoin and Euro prices and the factors that drive the same prices or exchange rates. Data from some nations are regarded for the assessment of information as indicated above. Various variables affecting the fiat currency, such as the euro, are analyzed. In the same way, Bitcoin yields are guided by certain variables. For Bitcoin, the factors that influence the euro may not be the same. This is the component of the hypothesized model that has been tried in this section. Gold prices are also regarded for stronger assessment. The predictability of the fiat currency and the unpredictability of Bitcoin according to the hypothesized model are assessed. Irrational behavioral hypothesis, as mentioned in the literature, is used to cope with variables that cause Bitcoin's cost. The rationale behind this is that, according to the literature, Bitcoin is affected by various variables such as press, fame, and the use of technology and the customer population. The statistical modeling method recognized as the Regression Analysis is used to forecast or assess the connection between distinct factors. If there is a statistically significant connection between variable pairs, it can be identified by regression analysis. In other phrases, the connection between the factors is modeled using regression analysis. It uses the notion of independent variables and dependent variables. Independent variables are considered to be predictors. Reveals the adjustments in the valuation of the dependent variable when the independent variables are subject to change. The model used for independent variables is called a regression function. As a result, it enables predict important interactions or forecasting, in other terms.

The regression analysis requires the correct training of the information that is made the care of in this thesis. The information described in Table 1 is used properly in the regression analysis. The regression analysis instrument is used in the spreadsheet application recognized as Microsoft Excel. The regression analysis uses formulas linked to the total of numbers, the degree of liberty, the average square, the F function, and the importance or the P-value. Based on the P-value, it is feasible to understand how two series of factors are considerably linked. The sum of the squares is computed as, the degree of freedom is computed as m-1, the mean square is computed as SSB / m-1, the F value is computed as (SSB /m-1)/(SSE /n-m) and finally the meaning is computed where m is the number of columns, while n is the number of reactions considered. There is a notion between organizations and organizations regarded externally for regression analysis. The matrix R and the adapted matrix R are measured as in the Eq. Well, 1 and Eq. 2 and 2 respectively.

$$R^2 = \frac{F*(m-1)}{(n-m)+(F*(m-1)} \quad (1)$$

$$\text{Adjusted } R^2 = 1 - \frac{(n-1)(1-R^2)}{(n-m)} \quad (2)$$

In the process of regression analysis mean and standard deviation are computed as in Eq. 3 and Eq. 4.

$$\text{Mean } \mu = \frac{\text{Sum of values}}{\text{the total number of elements}} \quad (3)$$

$$\text{Standard Deviation } \sigma = \sqrt{\frac{(x_i-\mu)^2}{N}} \quad (4)$$

B. Result Analysis

TABLE 2: PROVIDES RESULTS OF REGRESSION ANALYSIS

VI. CONCLUSION

During this document, we concentrated on knowing Bitcoin and its developments and dynamics in the genuine orb. It sheds light on the distinct elements connected with the legal tender of the crypt. They include Bitcoin, BlockChain, and Ethereum. Bitcoin is a practical currency produced using cryptography technology. Its activities are shielded by Blockchain in collaborative peer-to-peer settings. Ethereum is worn to construct distributed applications so as to use safety primitives that are worn in Bitcoin and BitTorrent as integrated P2P apps to Bitcoin. It is recognized that Bitcoin is like a cryptocurrency technique has been progressively developed straight commencing its beginnings. The empiric research also disclosed the effectiveness of the Ethereum system for constructing P2P integrated apps that provide safe associations between many customers in the region of the globe. During the future, we propose to operate on the edifice of an Ethereum implementation. An algorithm is suggested and applied to carry out a failure study of financial information linked to blockchain skill that can be worn to protect biomedical records in a dispersed multi-user situation.

Abstract-Irregular backwoods technique is a standout amongst the most generally connected grouping calculations at introduce. From the genuine huge information scene and prerequisites, the utilization of arbitrary backwoods technique in the huge information condition to direct inside and out investigation. Because of the huge information requirements to process countless in the meantime, and the information design changes always after some time, the exactness of a arbitrary woodland calculation without self-recharging and versatile calculation will steadily decrease after some time. Going for this issue, examination on the qualities of arbitrary woodland strategy, exhibits how to understand the self-adjustment capacity with irregular timberland technique in comparative circumstances, and checked the attainability of the new technique for utilizing the genuine information, and examination and discourse of how to additionally inquire about and enhance the arbitrary woods strategy in huge information condition.

***Keywords*— Decision tree, Random Forest, Big Data**

I. INTRODUCTION

Big Data is one of the major challenges of statistical science and has numerous consequences from algorithmic and theoretical viewpoints. Big Data always involve massive data but they also often include online data and data heterogeneity. Recently some statistical methods have been adapted to process Big Data, like linear regression models, clustering methods and bootstrapping schemes. Based on decision trees combined with aggregation and bootstrap ideas, random forests were introduced by Breiman in 2001. They are a powerful nonparametric statistical method allowing to consider in a single and versatile framework regression problems, as well as two-class and multi-class classification problems. Focusing on classification problems, this paper proposes a selective review of available proposals that deal with scaling random forests to Big Data problems. These proposals rely on parallel environments or on online adaptations of random forests. also describe how out-of-bag error is addressed in these methods. Then, we formulate various remarks for random forests in the Big Data context. Finally, we experiment five variants on two massive datasets (15 and 120 millions of

observations), a simulated one as well as real world data. One variant relies on subsampling while three others are related to parallel implementations of random forests and involve either various adaptations of bootstrap to Big Data or “divide-and-conquer” approaches. The fifth variant is related to online learning of random forests. These numerical experiments lead to highlight the relative performance of the different variants, as well as some of their limitations.

Big Data always involve massive data but they also often include online data and data heterogeneity. Recently some statistical methods have been adapted to process Big Data, like linear regression models, clustering methods and bootstrapping schemes. Based on decision trees combined with aggregation and bootstrap ideas, random forests were introduced by Breiman in 2001. They are a powerful nonparametric statistical method allowing to consider in a single and versatile framework regression problems, as well as two-class and multi-class classification problems. Focusing on classification problems, this paper proposes a selective review of available proposals that deal with scaling random forests to Big Data problems. These proposals rely on parallel environments or on online adaptations of random forests. We also describe how related quantities -- such as out-of-bag error and variable importance -- are addressed in these methods. Then, we formulate various remarks for random forests in the Big Data context. Finally, we experiment five variants on two massive datasets (15 and 120 millions of observations), a simulated one as well as real world data. One variant relies on subsampling while three others are related to parallel implementations of random forests and involve either various adaptations of bootstrap to Big Data or to "divide-and-conquer" approaches. The fifth variant relates on online learning of random forests. These numerical experiments lead to highlight the relative performance of the different variants, as well as some of their limitations.

Random forests or random decision forests are an ensemble learning method for classification, regression and other tasks that operates by constructing a multitude of decision trees at training time and outputting the class that is the mode of the classes (classification) or mean prediction (regression) of the individual trees. Random decision forests correct for decision trees' habit of overfitting to their training set.

The first algorithm for random decision forests was created by Tin Kam Ho[1] using the random subspace method,[2] which, in Ho's formulation, is a way to implement the "stochastic discrimination" approach to classification proposed by Eugene Kleinberg.

An extension of the algorithm was developed by Leo Breiman and Adele Cutler, who registered "Random Forests" as a trademark (as of 2019, owned by Minitab, Inc.). The extension combines Breiman's "bagging" idea and random selection of features, introduced first by Ho[1] and later independently by Amit and Geman in order to construct a collection of decision trees with controlled variance.

The general method of random decision forests was first proposed by Ho in 1995.[1] Ho established that forests of trees splitting with oblique hyperplanes can gain accuracy as they grow without suffering from overtraining, as long as the forests are randomly restricted to be sensitive to only selected feature dimensions. A subsequent work along the same lines concluded that other splitting methods, as long as they are randomly forced to be insensitive to some feature dimensions, behave similarly. Note that this observation of a more complex classifier (a larger forest) getting more accurate nearly monotonically is in sharp contrast to the common belief that the

complexity of a classifier can only grow to a certain level of accuracy before being hurt by overfitting. The explanation of the forest method's resistance to overtraining can be found in Kleinberg's theory of stochastic discrimination.

The early development of Breiman's notion of random forests was influenced by the work of Amit and Geman who introduced the idea of searching over a random subset of the available decisions when splitting a node, in the context of growing a single tree. The idea of random subspace selection from Ho[2] was also influential in the design of random forests. In this method a forest of trees is grown, and variation among the trees is introduced by projecting the training data into a randomly chosen subspace before fitting each tree or each node. Finally, the idea of randomized node optimization, where the decision at each node is selected by a randomized procedure, rather than a deterministic optimization was first introduced by Dietterich.

II RELATED WORK

Title: An Ensemble Random Forest Algorithm for Insurance Big Data Analysis

Problem Statement:A sampling approach combined with the ensemble learning algorithm on the large-scale insurance business data mining

Solution: An ensemble random forest algorithm that uses the parallel computing capability and memory cache mechanism optimized by Spark

Advancement: Exploring the proposed algorithm to different types of big data analytic, combining deep learning into the proposed algorithm to improve the accuracy of prediction based on big data analysis

Disadvantages:A lot imbalances in the data as discussed in paper, for which we can propose model with linear regression.

Title: Data Mining based on Random Forest Model to Predict the California ISO Day-ahead Market Prices

Problem Statement: In this paper,an ensemble learning model,namelythe random forest (RF) model, is used to predict both the exact values as well as the class labels of 24 hourly prices in the California Independent System Operator (CAISO)’s day-ahead electricity market

Solution:AThe focus is on predicting the prices for the Pacific Gas and Company (PG&E) default load aggregation point (DLAP). Several effective features, such as the historical hourly prices at different locations, calender data, and new ancillary service requirements are engineered and the model is trained in order to capture the best relations between the features and the target electricity price variables

Advancement: The future research would be on introducing the new efficient features to capture the price characteristics in the hour with high price fluctuations more appropriately

Disadvantages: It is also interesting if Consider the impact of other features, such as temperature and fuel prices, on exact value prediction as well as on the classification.

Title:ENSEMBLE CLASSIFIER WITH RANDOM FOREST ALGORITHM TO DEAL WITH IMBALANCED HEALTHCARE DATA

Advancement:work can be extended by combining Random Forest algorithm and various multiclassifier algorithms such as OVA (One-Vs-All) randomization algorithm to get higher performance

Disadvantages:A lot imbalances in the data as discussed in paper, for which we can propose model with linear regression.

Introduction of Random Forest Method

Random Forest strategy is a mix order technique proposed by Breiman in 2001. Utilizing sacking technique, irregular backwoods strategy will draw various preparing test sets that are not quite the same as each other. Each and every example set forms a choice tree with haphazardly chosen attributes[9].

Irregular timberland utilizes CART calculation for building trees. Thinking about the extensive number of manufactured trees, irregular backwoods technique is portrayed with great capacity to oppose clamor and extraordinary execution in the arrangement ability.

Random forest method is defined as a set of decision trees $\{h(x,\theta k),k=1,\ldots\}$, where $h(x,\theta k)$ is a meta-classifier, namely, a unpruned decision tree created using CART calculation; x fills in as the info vector, while $\{\theta k\}$ is an autonomous and indistinguishably dispersed arbitrary vector.

They decide the development procedure of every choice tree. As per the info information, every choice tree will give a result; joining of numerous outcomes will give the last yield of an irregular woodland. In the irregular woodland, the development procedure of a solitary choice tree is as per the following:

1. For the first preparing sets, packing technique is used to choose irregular information with substitution and in this manner shape preparing sets with contrast.

2. The highlights are likewise chosen utilizing examining approach. On the off chance that it is expected that an informational collection has N highlights, at that point M highlights will be examined from N, where M<<N. For each removed preparing set, just haphazardly chose M includes as opposed to all N highlights will be utilized for hub part in building trees.

3. All fabricated choice trees will develop openly without pruning.

The last outcome can be incorporated utilizing straightforward larger part voting strategy (for arrangement issues) or numerical normal strategy (for relapse issues) performed among the aftereffects of the choice trees.

Advantages of Random Forest Method

Random Forest technique can be regarded as a consolidating classifier calculation or a blend of choice trees. It joins the benefits of stowing and irregular element determination [10]:

1. Packing can evaluate not just the significance of each component yet additionally speculation mistake;

2. The trees of irregular timberland strategy are fabricated utilizing Truck calculation, which is perfect with the treatment of nonstop traits and discrete properties;

3. Irregular timberland strategy can successfully settle the issue of uneven grouping;

4. Arbitrary woodland strategy has astounding clamor resistance what's more, high grouping precision.

With regards to huge information condition, arbitrary woods technique is additionally portrayed with following favorable circumstances:

1. From the point of view of the enormous measure of huge information, the irregular timberland strategy can be skillful;

2. The moderately straightforward choice trees created by arbitrary woodland technique encourages business examiners to decipher its importance;

3. Arbitrary woodland technique is reasonable for circulated and parallel condition, demonstrating a decent adaptability;

4. The straightforward classifier made by choice trees can process information productively, which is pertinent to the attributes of fast information revive rate in the huge information condition.

Disadvantages of Random Forest Method

In spite of the previously mentioned favorable circumstances, arbitrary woods strategy is additionally confronting new difficulties in the mode of enormous information:

To begin with, in the enormous information condition, the information refresh rate is quick, so are the refresh rates of information attributes what's more, modes covered up in information.

Choice trees in view of preparing sets information will end up outdated and less exact in ordering information after a specific timeframe.

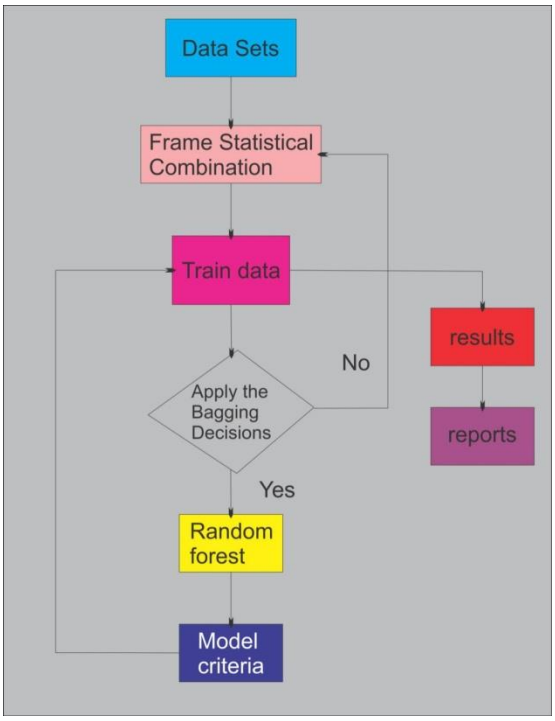
This requires calculations in the enormous information condition to have information versatility. In the interim, this capacity ought to additionally be immediately reflected in the classifier, while the typical lead of business or the stream-shape entry of information through the classifier ought not be influenced.

Furthermore, the choice tree, truth be told, is an insatiable calculation that effectively prompts unsteadiness and over fitting. Tackling this issue has an incredible importance for enhancing the exactness of choice tree. Thirdly, the backwoods scale built up by arbitrary timberland has not been unmistakably characterized; larger than average scale may result in repetition and hence lessen the productivity and exactness of characterization.

III METHODOLOGY / FRAMEWORK

Accuracy and Pruning of Decision Trees

With a specific end goal to address the issues in the enormous information condition, enhanced calculation ought to have the accompanying qualities:



1. It can rapidly produce a classifier on a given information preparing set;

2. The subsequent classifier can rapidly order new spilling information;

3. A calculation ought to be of flexibility to react to the adjustments in information modes and certification its exactness;

4. It should restrain the scale, to be specific, the quantity of trees, which will, from one perspective, guarantee the productivity of the calculation, while then again, will likewise ensure its precision.

Complexity International Journal (CIJ)
Volume 23, Issue 03, Sep 2019
Impact Factor (2019): 5.6 ISSN: 1320-0682

IV. RESULTS AND ANALYSIS

Testing Data Set

Informational indexes utilized in the test are begun from genuine client information of money related industry. The information sum represents 200,000 pieces with around 10,000 bits of information from each quarter, which was inspected from a bigger unique 5-year informational index.

The informational index contains an objective class and 16 include characteristics, which incorporates both the persistent numerical characteristics and discrete properties. Irregular woodland unit in R dialect form was utilized in the test.

So as to confirm the viability of previously mentioned changes, we utilized 10000 bits of information of the first quarter in the main year as the instated preparing set and utilize them to set up the underlying irregular woodland, where the number of trees levels with 100.

Data Inventory: The data is taken from a source and the same is loaded to the r console. This helps us to understand more about the data and how to analyze it.

Training Data: The second step is to find the combination out from the data so like which combinations can provide us the best results for prediction

Data Bagging: Number of decision trees is framed for the training data for the analysis. From this we will take the best possible combinations of the decision trees for the prediction

Results: from the above decision tress we frame a model which works for the prediction

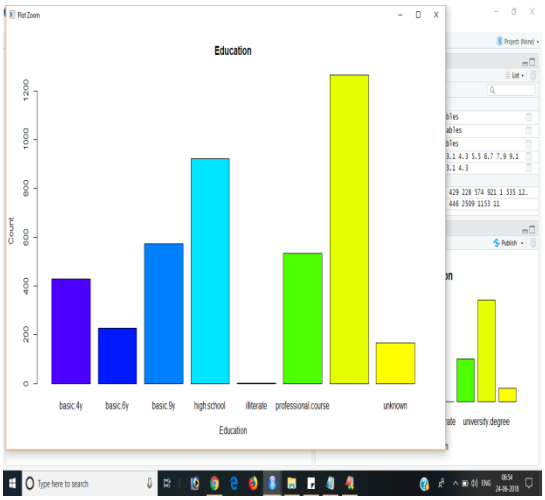


Fig 7.5 Education

- The graphs representing the education of the clients whose data has been considered for the analysis.
- Based on their qualification of the person the loan is issued.

V. CONCLUSION & FUTURE WORK

In light of the first arbitrary backwoods technique, this article proposed another enhanced model for the calculation. After change, it works well in the present enormous information mode. Particularly, its information examples will likewise change continuously with time, which enables it to give a superior play in the enormous information situations.

In the respect of process, the enhanced technique needs not to check the prepared information once more. Rather, it as it were requires to record the preparing consequences of every choice tree when utilizing classifier for handling information and to record the wrongly handled example information when creating the last outcomes. It has better practicability and possibility because of this variety and its low required capacity and calculation costs.

The enhanced strategy likewise has a decent execution in confirmation by utilizing genuine budgetary industry information. In any case, it ought to be noticed that it requires inside and out investigation on different angles. For instance, regardless of whether can it be embraced to different kinds of informational collections? Regardless of whether can the pruning choice capacities be made strides? What is the proper extent of the new choice trees? All of these inquiries should be additionally investigated in consequent contemplates.

ABSTRACT

Deliberate or inadvertent escape of classified data is undoubtedly one among the premier extreme security dangers that associations look inside the advanced period. The risk right now stretches out to the private lives: an abundance of private information is out there to interpersonal organizations and great telephone providers and is in a roundabout way exchanged to undependable outsider and fourth gathering applications. amid this work, a bland data genealogy structure LIME (Data Lineage in the Malicious Environment), is utilized for data stream over different elements that take two trademark, guideline parts (i.e., proprietor and buyer). It characterizes the exact security ensures required by such a data heredity component toward recognizable proof of a blameworthy substance, and decide the disentangling non-denial and trustworthiness suspicions. At that point create and break down a totally special dependable data exchange convention between two substances among noxious surroundings by expanding upon unmindful exchange, solid watermarking, and mark natives. At long last, an exploratory investigation to exhibit the helpfulness of convention what's more, apply structure to the important data run projections of learning outsourcing and the informal organizations. In general, LIME(Data Lineage in the Malicious Environment),lineage structure for information exchange, to be a key advance towards accomplishing responsibility by plan.

Keywords: Classified Data, LIME, Trademark, Malicious Environment, Micro Benchmarking, Pairing Based Cryptography, GNU

I. INTRODUCTION

Data Extraction avoidance is the type of solutions which can help an institute to apply control for the prevention of unwanted, unintentional or leakage of specific information to illegal entities inside or outside the institute. Here specific information may refer to the institute's internal processing of documents, tactical business plans, academic property, economic statements, security policy, network architecture, blueprints etc.

In the past few decades there has been an exponential growth in technology in which the major part was the revolution of computers. This revolution has taken upon every aspect both resourcefully and individually, this growth has surely changed our lives by making it much easier. In the process of this growth there has been a severe risk which everyone may not be conscious of which is data extraction. Data extraction is basically a scenario where any intruder will access our personal data and make the extracted data public or the intruder might use it for any other intentions. Today we have a huge access of smartphones and gadgets which makes data

extraction much easy as the impostor can now easily transfer the data.

We as a consumer find many apps on internet and we knowingly handle our data to the respective organizations but is our data really safe in the hands of the organization, what if any employee of the fellow organization decides to make a step that ruins the organizations name, what if any employee wantedly access your data and misuses it. The answer to that problem is represented in the following work which will determine the guilty entity with proof and held for explanation if any data extraction occurs. There are few safety mechanisms such associate secret writing of valuable data, however it's a proactive measure that cannot verify the info leak once it happens. Once the intruder decrypts the information then there's no potential live which will prevent the info leak of the personal data and business data by any desired measures. Following are few measures that we often see and there are a number of situations where the event is determined.

1. We should take facebook for instance wherever we can see assortment of outsiders that approaches our insight, if any outsider is experienced in learning spill it winds up impractical to call attention to or see that wherever extremely the data was misused as there square measure a few outsiders advertised.
2. Consultancies have all the valuable data of representatives/applicants caning to seek out work which outsider contracts another outsider then all the three organizations will right now approach the individual information then it may turn out to be horrendously difficult to undeniably relate one the three partnerships for learning spill, in each the circumstances witnesses can either don't target the exact learning safety or the intruder may attentively reveal classified data which cannot be tied to any of the handlers. At times there comes experience the explanatory procedures however it's horribly expensive and it also doesn't create a terribly sensible outcome .Amid this distribution the prerequisite for general answerability instrument in learning exchange is demonstrated which may specially go with confirmable measures and control the condemn blameworthy. This philosophy of identification is named as learning root. Endeavors are made by numerous associations to utilize learning source inside the type of watermarking or including of false information or data in specially appointed way has not been that flourishing.

II. EXISTING SYSTEM

In the digital era, data outflow during intentional exposures, or un-intentional damage by untruthful staff and harmful external entities, always provide serious threats to organizations. it's not laborious to believe that this is simply the edge of an iceberg, as in most cases information of knowledge outflow go unreported thanks to concern of loss of client confidence or restraining penalties huge amount of digital data can be derived at nearly no price and might be unfold through the net in terribly short time to boot, the risk of obtaining or getting caught for information outflow or the extraction is very low, as there square measure presently nearly no answerableness mechanisms. For these reasons, the matter of information loss has reached a replacement dimension these days.

2.1 Disadvantages

Even with access management mechanisms, wherever access to sensitive information is restricted, a malicious approved user will publish the valuable information as soon as he receives it. Primitives like coding provide protection solely as long because the info of interest is encrypted, however once the recipient decrypts a message, nothing will stop him from publication the decrypted content. Therefore it looks not possible to stop information outpouring proactively.

2.2 Proposed System

In this work, the requirement for a general answerability mechanism in information transfers is got wind. This answerability are often directly related to demonstrably detective work a transmission history of information across multiple entities ranging from its origin. This can be called information place of origin, information lineage or supply tracing.

Here the matter is dignified of practically associating the problem to the extraction, and work on the information lineage methodologies to unravel the matter of knowledge leak in numerous leak situations. This system defines LIME, a generic information lineage framework for information flow across multiple entities within the malicious atmosphere.

Here it's observe that entities in information flows assume one amongst 2 roles: owner or shopper and introduce an extra role within the sort of auditor, whose task is to see a problem for any data extraction, and summarize the accurate properties for communication between these roles.In the process Associate in nursing non-mandatory non-repudiation assumption created between two house owners, Associate in nursing and non-mandatory trust (honesty) assumption created by the auditor concerning the house owners.

The second contribution, associate in nursing responsible for information transfer protocol to provably and securely transfer valuable information between the two parties is bestowed. It deals with associate in nursing and untrusted sender, associate in nursing and untrusted receiver situation related to data transfer between any two customers, the protocol we use is an interesting combination of the sturdy watermarking, oblivious transfer, and signature primitives.

2.2.1 Advantages of Proposed System

The key advantage of this representation is that it applies answerableness right from design; i.e., it drives the system designer to contemplate doable information leakages and also the corresponding answerableness constraints at the look stage. This helps to beat the prevailing state of affairs wherever most lineage mechanisms ar applied solely once an escape went on.

III. MODULES

3.1 Data Owner

In this module owner uploads their pictures with their contents data to the net server. For the safety purpose to the information, owner assigns the digital sign and stores it inside the internet and in addition performs the subsequent operations to transfer image with its digital signature with supported title, description

Below are the few operations an Owner can perform

1 .Upload image or a file,

2. Verify image or file details

3. View Consumer requests and

4. Deleted image details

3.2 Web Server

The Web service supplier manages an internet to supply information storage service. And performs the subsequent operations reminiscent of Storing all image files with their signature, read all image Files with its details, view all image comments, and view all information house owners and Users, read all attackers.

A web server will be monitoring the system held responsible for a secure login including analyzing of all the data that has been transferred between two entities

The basic operations that are performed by the web server are as follows

1. View Owner and consumer Details

2. View all the files details
3. View the attacked files
4. View Download history

3.3 Auditor

Auditor has capability to access, manage or monitor the transferred knowledge or data beneath the entrustment of information of owner, auditor has experience and capabilities that a standard user doesn't have, for occasionally auditing the outsourced knowledge. This audit service is considerably necessary for digital forensics and credibleness in Web and performs the subsequent operations

1.View image/file details
2. View Attacked files
3. Block or unblock an attacker
4. View messages from a consumer

3.4 Data Consumer

The net user of an Organization encompasses a great quantity of data to be stored in servers and have the permissions to access and manipulate and keep image and its data.

The consumer can search information and accessing the image data if he's approved and performs the subsequent operations

1.View all the files
2. Download a file
3. Send download request
4. Send message to the auditor

IV. TECHNIQUES USED

4.1 Micro Benchmarking

The execution of the convention is done in as a proof-of-idea and to determine its result. For the unaware exchange sub-convention is executed to the convention utilizing the PBC library, which itself makes utilization of the GMP library. For marks BLS plot is executed, likewise utilizing the PBC library. For symmetric encryption a usage of AES from the Crypto++ library is utilized. For watermarking a usage of the Cox calculation is utilized for vigorous picture and set the negative factor, which decides the quality of the watermark, to a estimation of 0.1.Now execute the explore different avenues regarding diverse parameters to examine the execution. The sender and beneficiary piece of the convention will be executed in a similar program, i.e., don't break down system sending, yet just computational execution.

4.2 PBC (Pairing Based Cryptography)

Blending based cryptography is a generally youthful territory of cryptography that rotates around a certain capacity with exceptional properties.

The PBC (Pairing-Based-Cryptography) library is a free C library based on the GMP library that plays out the numeric activities and fundamental matching based on cryptosystems.

The PBC library is planned to be the foundation of executions of matching based cryptosystems, in this manner speed and portability are key objectives. It provides schedules by comparing it to the elliptic bend era, elliptic bend number juggling and blending calculation. Due to the GMP library, in spite of being composed in C, pairings times are shabby. On a 1GHz Pentium III:

- Fastest matching is 11ms
- Short matching is 31ms

The API is sufficiently dynamic that the PBC library will be used despite of the fact that the associated researcher has exclusively a rudimentary comprehension of pairings. There’s no must be constrained to get some answers concerning elliptic bends or a significant measure of collection hypothesis. (The base necessity is a few information of cyclic gatherings and properties of the blending.)

The PBC library can likewise be utilized to construct customary cryptosystems.

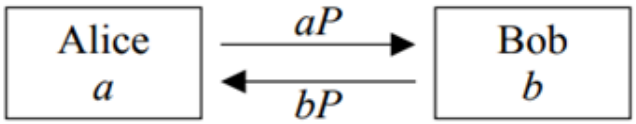

Fig 1. Two party one round key agreement protocol

3.3 The GNU Multiple Precision Arithmatic Library

GMP is attentively designed to be fast for small operands as well as for large operands. The speed is accumulated by use of adequate words as basic arithmatic type, by use of quick algorithms, with immensely advanced assembly code for the most familiar inner loops for a lot of CPUs, by a general insistence on speed.

GMP could be a free library for subjective accuracy number juggling, in task on marked whole numbers, objective numbers, and gliding point numbers. there's no sensible cutoff to the accuracy aside from those verifiable by the available memory inside the machine GMP keeps running on. GMP highlights a made arrangement of capacities, and furthermore the capacities have a regular interface. The fundamental target applications for GMP are cryptography applications and investigation, web security applications, unadulterated science frameworks, process unadulterated arithmetic examination, and so forth.

GMP is thoroughly intended to be as brisk as feasible, each for little operands and for huge operands. The speed is accomplished by exploitation full words in light of the fact that the fundamental number juggling sort, by exploitation brisk calculations, with to a great degree enhanced gathering code for the principal regular inward circles for loads of CPUs, and by a general weight on speed. The primary GMP unharness was made in 1991. it's consistently created and kept up, with a substitution unharness concerning once every year. Since variant about six, GMP is appropriated beneath the twin licenses, wildebeest LGPL v3 and wildebeest GPL v2. These licenses make the library freed to utilize, share, and enhance, and allow you to kick the bucket the outcome. The wildebeest licenses offer flexibilities, however conjointly set firm limitations on the use with without non programs. GMP's primary target stages are Unix-type frameworks, reminiscent of GNU/Linux, Solaris, HP-UX, waterproof OS X/Darwin, BSD, AIX, and so on. It is additionally celebrated internationally to figure on Windows in each 32-bit furthermore, 64-bit mode.

3.4 BLS Scheme

In cryptography, the Boneh– Lynn– Shacham (BLS) signature topic allows a client to confirm that an endorser is bona fide. The subject uses a straight blending for confirmation, Associate in nursing marks square measure segments of an elliptic bend group. working in Associate in Nursing elliptic bend bunch gives some safeguard against list math assaults (with the proviso that such assaults square measure still achievable inside the objective bunch of the matching), allowing shorter marks than FDH marks for an indistinguishable level of security. Marks made by the BLS signature subject square measure normally talked as short marks, BLS short marks, or just BLS marks. The mark subject is undeniably secure.

3.5 Cox Algorithm

The Cox– Zucker machine is a calculation made by David A. Cox and Steven Zucker. This calculation decides whether a given arrangement of areas gives a premise (up to torsion) for the Mordell– Weil gathering of an elliptic surface E → S where S is isomorphic to the projective line. The recipe was introductory uncovered inside the 1979 paper "Crossing point quantities of segments of elliptic surfaces" by Cox and Zucker and it totally was later

named the "Cox– Zucker machine" by Charles Schwartz in 1984.

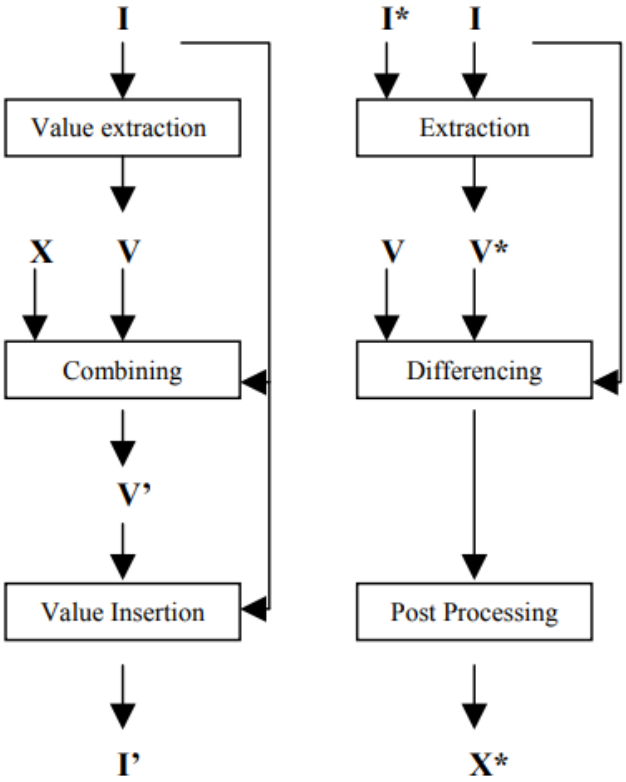

Fig 2. Working of cox algorithm

3.6 Possible Data Distortion

Here a simple cacophonic algorithmic program is utilized. Here the picture is spilt into n similarly estimated squares. In any case, once utilized a powerful watermark for the modest components (that will be that the - issue used by the Cox algorithmic program is zero.5), varieties between neighboring components ended up noticeable in spite of the way that the one watermarks zone unit in cognoscible.This outcome turns out to be considerably more grounded when numerous emphases as decided. Now and again, this bending would potentially affect the ease of use of the record. The Cox algorithmic program is utilized with relates alpha issue of zero.1 and no mutilation is noticeable. It would entrance to examine if this drawback are regularly dodged by exploitation extra detailed cacophonic calculations. As most watermarking plans assemble utilization of the nearness of information inside the archive, this can be not an inconsequential assignment.

VI. CONCLUSION AND FUTURE ENHANCEMENT

We are blessing LIME, a model for capable data exchange over different elements. We tend to plot teaming up parties, their interrelationships and give a solid inner portrayal for a data exchange convention utilizing a novel blend of negligent exchange, strong watermarking and computerized marks. We have a tendency to demonstrate its rightness and show that it's feasible by giving little seat checking comes about. By introducing a general relevant structure, we have a tendency to present answerableness as right on time as inside the style area of a data exchange foundation. Despite the fact that LIME doesn't effectively prevent data release, it presents responsive answerableness. Along these lines, it'll deflect vindictive gatherings from unseaworthy individual reports and can energize legitimate (however reckless) gatherings to create the predefined assurance for touchy data. LIME is adaptable as we have a tendency to separate between beyond any doubt senders (typically proprietors) and untrusted senders (generally buyers). Inside the instance of the beyond any doubt sender, a dreadfully simple convention with next to no overhead is achievable. The untrusted sender needs a considerable measure of modern convention, however the outcomes don't appear to be bolstered put stock in presumptions furthermore, along these lines they should be prepared to change over an unbiased substance (e.g. a judge). Our work conjointly rouses any investigation on data release recognition procedures for differed report sorts furthermore, projections. To Illustrate, it'll be a propelling future examination heading to style a certain ancestry convention for determined data.

Defended Data Transmission Using Attribute Based Encryption In The Recoverable-Storage Cloud

Mr.Rajashekar Vasari[1], Dr.K.Rama Krishna Reddy[2]
[1] M.Tech Student, Department of CSE, Malla Reddy Engineering College (A), Telangana, India
[2]Associate Professor, Project Guide, Department of CSE, Malla Reddy Engineering College (A) Telangana, India

Abstract— Cloud computing gives an adaptable and advantageous route for information sharing, which brings different advantages for both the general public and people. Be that as it may, there exists a characteristic resistance for clients to specifically outsource the common information to the cloud server since the information regularly contain important data. Accordingly, it is important to put cryptographically upgraded get to control on the common information. Identity-based encryption is a promising cryptographical primitive to assemble a pragmatic information sharing framework. Nonetheless, get to control is not static. That is, the point at which some client's approval is terminated, there ought to be a component that can expel him/her from the framework. Thus, the renounced client can't get to both the beforehand and along these lines shared information. To this end, we propose an idea called revocable-capacity identity-based encryption (RS-IBE), which can give the forward/in reverse security of ciphertext by presenting the functionalities of client disavowal and ciphertext refresh all the while. Besides, we exhibit a solid development of RS-IBE, and demonstrate its security in the characterized security show. The execution examinations show that the proposed RS-IBE conspire has points of interest regarding usefulness and proficiency, and in this manner is plausible for a viable and practical information sharing framework. At last, we give execution aftereffects of the proposed plan to exhibit its practicability.

Index Terms—Cloud computing, data sharing, revocation, Identity-based encryption, ciphertext update, decryption key exposure.

1 INTRODUCTION

CLOUD computing is a worldview that gives huge calculation limit and tremendous memory space requiring little to no effort [1]. It empowers clients to get expected administrations independent of time and area over numerous stages (e.g., cell phones, PCs), and hence conveys extraordinary comfort to cloud clients. Among various administrations given by cloud computing, cloud stockpiling administration, for example, Apple's iCloud [2], Microsoft's Azure [3] and Amazon's S3 [4], can offer a more adaptable and simple approach to share information over the Internet, which gives different advantages to our general public [5], [6]. In any case, it likewise experiences a few security dangers, which are the essential worries of cloud clients [7].

Right off the bat, outsourcing information to cloud server suggests that information is out control of clients. This may cause clients' wavering since the outsourced information more often than not contain profitable and delicate data. Also, information sharing is frequently executed in an open and unfriendly condition, and cloud server would turn into an objective of assaults. Far more detestable, cloud server itself may uncover clients' information for illicit benefit. Thirdly, information sharing is not static. That is, the point at which a client's approval gets lapsed, he/she should never again have the benefit of getting to the already and thusly shared information. Hence, while outsourcing information to cloud server, clients likewise need to control access to these information with the end goal that exclusive those right now approved clients can share the outsourced information.

A characteristic answer for overcome the previously mentioned prob-lem is to utilize cryptographically upheld get to control, for example, identity-based encryption (IBE). Besides, to defeat the above security dangers, such sort of identity-construct get to control put in light of the mutual information should meet the accompanying security objectives:

Data confidentiality: Unapproved clients ought to be kept from getting to the plaintext of the common information put away in the cloud server. What's more, the cloud server, which should be straightforward yet inquisitive, ought to likewise be dissuaded from knowing plaintext of the common information.

In reverse mystery: Backward mystery implies that, when a client's approval is lapsed, or a client's mystery key is bargained, he/she ought to be kept from getting to the plaintext of the thusly shared information that are still encrypted under his/her identity.

Forward mystery: Forward mystery implies that, when a client's power is terminated, or a client's mystery key is traded off, he/she ought to be kept from getting to the plaintext of the mutual information that can be beforehand gotten to by him/her.

The particular issue tended to in this paper is the means by which to build a major identity-based cryptographical instrument to accomplish the above security objectives. We likewise take note of that there exist other security issues that are similarly critical for a viable arrangement of information sharing, for example, the genuineness and accessibility of the mutual information [8], [9], [10], [11], [12]. Be that as it may, the exploration on these issues is past the extent of this paper.

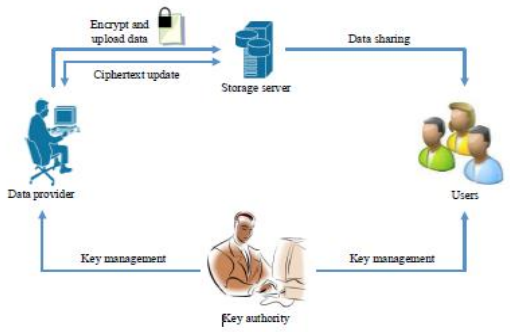

Fig. 1. A natural RIBE-based data sharing system
Clearly, such an information sharing framework can give privacy and in reverse mystery. Besides, the strategy for decrypting and re-encrypting all the mutual information can guarantee forward mystery. In any case, this brings new difficulties. Note that the procedure of decrypt-then-re-encrypt fundamentally includes clients' mystery key data, which makes the general information sharing framework helpless against new assaults. As a rule, the utilization of mystery key ought to be constrained to just regular decryption, and it is ill advised to refresh the ciphertext intermittently by utilizing mystery key.

Another test originates from effectiveness. To refresh the ciphertext of the mutual information, the information supplier needs to habitually complete the system of download-decrypt-reencrypt-transfer. This procedure brings incredible correspondence and calculation cost, and accordingly is unwieldy and undesirable for cloud clients with low limit of computatio and capacity. One strategy to stay away from this issue is to requirethe cloud server to straightforwardly re-encrypt the ciphertext of the mutual information. Be that as it may, this may present ciphertext extension,namely, the measure of the ciphertext of the mutual information is direct in the quantity of times the common information have been refreshed. What's more, the strategy of intermediary re-encryption can likewise be utilized to vanquish the previously mentioned issue of proficiency. Tragically, it additionally obliges clients to associate with the cloud server so as to refresh the ciphertext of the mutual information.

1.2 Related work

1.2.1 Revocable identity-based encryption

The possibility of identity-based encryption was exhibited by Shamir [13], and supportively instantiated by Boneh and Franklin [14]. IBE takes out the necessity for giving an open key system (PKI). Despite the setting of IBE or PKI, there must be an approach to manage disavow customers from the system when fundamental, e.g., the master of some customer is slipped by or the puzzle key of some customer is revealed. In the standard PKI setting, the issue of repudiation has been particularly mulled over [15], [16], [17], [18], [19], and a couple of techniques are for the most part supported, for instance, revelation foreswearing list or fastening authenticity periods to confirmations. In any case, there are only two or three focuses on disavowal in the setting of IBE.

Boneh and Franklin [14] first proposed a trademark revocation course for IBE. They added the present period to the ciphertext, and non-denied customers once in a while got private keys for every day and age from the key expert. Grievously, such an answer is not flexible, since it requires the key expert to perform straight work in the amount of non-repudiated customers. In addition, a protected channel is fundamental for the key master and non-revoked customers to transmit new keys. To conquer this issue, Boldyreva, Goyal and Kumar [20] familiar a novel approach with fulfill beneficial denial. They used a matched tree to manage identity to such a degree, to the point that their RIBE scheme reduces the multifaceted design of key denial to logarithmic (instead of direct) in the most outrageous number of structure customers.

1.2.2 Forward-secure cryptosystems

In 1997, Anderson [28] presented the thought of forward security in the setting of mark to restrict the harm of key presentation. The center thought is isolating the entire lifetime of a private key into T

discrete eras, with the end goal that the trade off of the private key for current day and age can't empower a foe to create legitimate marks for past eras. In this manner, Bellare and Miner gave formal meanings of forward-secure mark and exhibited functional arrangements.

2 PRELIMINARIES

In this segment, we first quickly display the fundamental ideas onbilinear matching and decisional ℓ-BDHE suspicion. At that point, a calculation used to perform productive disavowal is presented.

2.1 Bilinear pairing and complexity assumption

Definition 1 (Bilinear pairing). *Let G_1 and G_2 be two cyclic groups with prime order q, and g be a generator of G_1. A bilinear pairing is a map $e : G_1 \times G_1 \to G_2$ with the following properties:*

- *Bilinearity: $e(u^a, h^b) = e(u,h)^{ab}$ for all $u, h \in G_1$, $a, b \in \mathbb{Z}_q^*$.*
- *Non-degeneracy: $e(g,g) \neq 1$.*
- *Computability: There exists an efficient algorithm to compute $e(u,h)$ for any $u, h \in G_1$.*

Definition 2 (Decisional ℓ-BDHE Assumption). *The decisional ℓ-BDHE problem is formalized as follows. Choose a group G_1 with prime order p according to the security parameter λ. Select a generator g of G_1 and $a, s \xleftarrow{R} \mathbb{Z}_p$, and let $f_i = g^{a^i}$. Provide the vector $\boldsymbol{f} = (g, g^s, f_1, ..., f_\ell, f_{\ell+2}, ..., f_{2\ell})$ and an element $D \in G_2$ to a probabilistic polynomial-time (PPT) algorithm $\mathcal{C}$, it outputs 0 to indicate that $D = e(g^s, g^{a^{\ell+1}})$, and outputs 1 to indicate that D is a random element from G_2.*

The advantage of $\mathcal{C}$ solving the decisional ℓ-BDHE problem in G_1 is defined as follows:

$$\mathbf{Adv}_{\mathcal{C}}^{\ell\text{-dBDHE}}(\lambda) = \left|\Pr[\mathcal{C}(\boldsymbol{f}, D = e(g^s, g^{a^{\ell+1}})) = 0] - \Pr[\mathcal{C}(\boldsymbol{f}, D \xleftarrow{R} G_2) = 0]\right|.$$

We say that the decisional ℓ-BDHE presumption holds in G1 gave that no PPT calculation can take care of the decisional ℓ-BDHE issue with a non-insignificant favorable position.

2.2 KUNodes algorithm

Our RS-IBE conspire utilizes a similar parallel tree structure presented by Boldyreva, Goyal and Kumar [20] to accomplish proficient repudiation. To portray the repudiation component, we initially display a few documentations. Indicate by ε the root hub of the twofold tree BT , and Path(η) the arrangement of hubs on the way from ε to the leaf hub η (counting ε and η). For a non-leaf hub θ, we let θl and θr remain for its left and right youngster, separately. Given a day and age t and disavowals list RL, which is included the tuples (ηi, ti) demonstrating that the hub ηi was repudiated at day and age ti, the calculation KUNodes(BT ,RL, t) yields the littlest subset Y of hubs of BT with the end goal that Y contains a progenitor for every hub that is not denied before the day and age t.

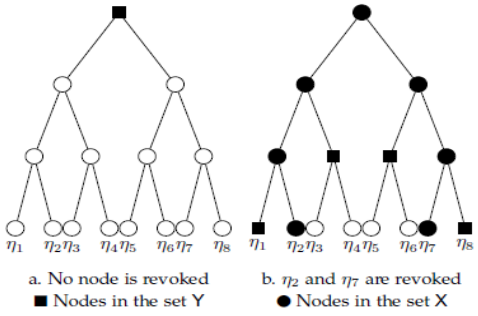

Fig. 2. An instance of the algorithm KUNodes

Casually, to recognize the set Y, the calculation initially denotes every one of the predecessors of denied hubs as repudiated, at that point yields all the non-renounced offspring of disavowed hubs. For instance, we exhibit two cases of the calculation KUNodes in Figure 2. The formal portrayal is given underneath.

Algorithm 1 KUNodes($\mathcal{BT}, RL, t$)

```
X,Y ← ∅
for all (η_i, t_i) ∈ RL do
    if t_i ≤ t then
        Add Path(η_i) to X
    end if
end for
for all θ ∈ X do
    if θ_l ∉ X then
        Add θ_l to Y
    end if
    if θ_r ∉ X then
        Add θ_r to Y
    end if
end for
if Y = ∅ then
    Add the root node ε to Y
end if
return Y
```

3 DEFINITION AND SECURITY MODEL OF RS-IBE

In this segment, we initially give the formal meaning of RSIBE, and afterward give the relating security display.

3.1 Syntax of RS-IBE

Definition 3 (Revocable-Storage Identity-Based Encryption).
A revocable-stockpiling identity-based encryption conspire with message space M, identity space I and aggregate number of eras T is involved the accompanying seven polynomial time calculations:

• Setup(1λ, T,N): The setup calculation takes as information the security parameter λ, the time bound T and the most extreme number of framework clients N, and it yields people in general parameter PP and the ace mystery key MSK, related with the underlying renouncement list RL = ∅ and state st. PKGen(PP,MSK, ID): The private key era calculation takes as info PP, MSK and an identity ID ∈ I, and it creates a private key SKID for ID and a refreshed state st. • KeyUpdate(PP,MSK,RL, t, st): The key refresh calculation takes as information PP,MSK, the present denial list RL, the key refresh time t ≤ T and the state st, it yields the key refresh KUt. • DKGen(PP, SKID,KUt): The decryption key era calculation takes as info PP, SKID and KUt, and it creates a decryption key DKID,t for ID with era t or an image ⊥ to outline that ID has been already disavowed.

• Encrypt(PP, ID, t,M): The encryption calculation takes as information PP, an identity ID, an era t ≤ T , what's more, a message M ∈ M to be encrypted, and yields a ciphertext CTID,t.
• CTUpdate(PP,CTID,t, t′): The ciphertext refresh calculation takes as information PP, CTID,t and another day and age t′ ≥ t, and it yields a refreshed ciphertext CTID,t′ .

• Decrypt(PP,CTID,t,DKID,t′): The decryption calculation takes as information PP, CTID,t, DKID,t′ , and it recoups the encrypted message M or a recognized image ⊥ showing that CTID,t is an invalid ciphertext.

• Revoke(PP, ID,RL, t, st): The repudiation calculation takes as info PP, an identity ID ∈ I to be renounced, the present repudiation list RL, a state st and denial day and age t ≤ T , and it refreshes RL to another one.

3.2 Security model

Definition 5 (IND-RID-CPA). A RS-IBE conspire is INDRID-CPA secure gave that to any PPT foe An, it has immaterial preferred standpoint in the accompanying security diversion between a challenger C and the enemy A:

• Setup. C performs Setup(1λ, T,N) → (PP,MSK) and sends PP to A;

• Phase 1. A makes the accompanying inquiries in a versatile way:

a. OSK(ID): C performs PKGen(PP,MSK, ID) → (Slide, st) and returns SKID to A;

b. OKU(t): C runs KeyUpdate(PP,MSK,RL, t, st) → Ut and returns KUt;

c. ODK(ID, t): C runs PKGen(PP,MSK, ID) → (Slide, st) and DKGen(PP, SKID,KUt) → DKID,t, at that point advances DKID,t to A;

d. ORV (ID, t): C refreshes the present disavowal list RL by running Revoke(PP, ID,RL, t, st) → RL and returns the refreshed RL to A;

• Challenge. A signs the inquiry is finished and sends (M0,M1, ID∗, t∗, st) to C subject to the limitation that M0,M1 ∈ M and |M0| = |M1|. At that point, C picks an arbitrary piece β R ←− {0, 1} and restores the tested ciphertext CTID∗,t∗ ← Encrypt(PP, ID∗, t∗,Mb) to

A;

• Phase 2. A starts another inquiry stage as stage 1;• Guess. A yields a bit β′ as a figure of β; The confinements expressly made on A's questions in the amusement are as per the following:

1) OKU(t) and ORV (ID, t) must be questioned in a consecutive request in time. That is, the time t ought to be more prominent than or equivalent to the season of all past questions;

2) ORV (ID, t) can't be questioned if OKU(t) was questioned;

3) If OSK(ID∗) was questioned then ORV (ID∗, t) must be questioned, where t ≤ t∗;

4) ODK(ID, t) can't be questioned before OKU(t) was questioned;

5) ODK(ID∗, t∗) can't be questioned

.

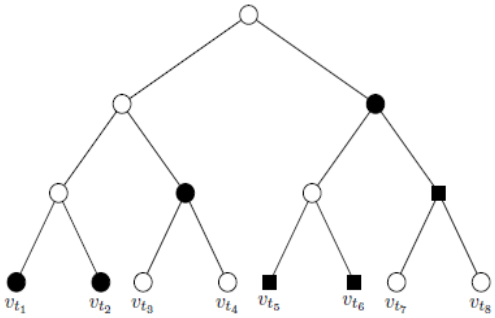
The adversary A's advantage in the above game is defined as

$$\mathbf{Adv}^{\text{IND-RID-CPA}}_{\text{RS-IBE},\mathcal{A}}(\lambda,T,N)=\left|\Pr[\beta'=\beta]-\frac{1}{2}\right|$$

Remark 1. In the security game above, we do not provide a query oracle for the ciphertext update algorithm **CTUpdate** since the adversary can run it to a ciphertext just by using the public parameter PP.

4 RS-IBE RESISTANT TO DECRYPTION KEY EXPOSURE

In this segment, we initially introduce a solid development of RSIBE impervious to decryption key introduction, and after that examine its security and execution.



4.1 Construction

Our development includes two parallel trees BT and T to oversee identity and day and age, separately. More

accurately, for identity renouncement, we take after Boldyreva et al's. [20] methodology. That is, given an identity ID, we arbitrarily store it in a leaf hub η of BT , and produce the relating mystery key SKID = {(θ, SKID,θ)}θ∈Path(η) as in past RIBE plans [20], [24]. On the off chance that the client ID is not denied at day and age t, there exists a hub θ ∈ Path(η) ∩ KUNodes(BT ,RL, t). Subsequently, given the refresh key KUt = {(θ,KUt,θ)}θ∈KUNodes(BT ,RL,t), the client

a hub v of T , let bv ∈ {0, 1}≤ℓ be the twofold grouping

relating to the way from the root hub of T to v, where 0 and 1 show that the way goes through the left and right offspring of the parent hub, individually. On the other hand, given a string b ∈ {0, 1}≤ℓ, let vb be the hub that has a way b from the root hub to it. Moreover, mean by bv[j] and ti[j] the j-th bit of bv and ti separately, and |bv| the length of bv. What's more, for each leaf hub vt of the paired T , we characterize the accompanying set: Tt = {v|Parent(v) ∈ Path(vt), v/∈ Path(vt)} ∪ {vt}, where Parent(v) signifies by the parent hub of v. As exhibited in [34], such a set components the accompanying property:

l Nodes in the set Tt1 n Nodes in the set Tt5

Fig. 3. An example of T with depth 3

Property 1. Given two eras t and t′ with the end goal that t < t′, for every hub v′ ∈ Tt′ , there exists a hub v ∈ Tt to such an extent that bv is a prefix of bv′ . At the end of the day, there exists a string b′ ∈ {0, 1}l with the end goal that bv′ = bv||b′, where l = |bv′ | − |bv|.

As displayed along these lines, the above property empowers us to refresh the ciphertext from eras t to t′. For logical reason, we give a twofold tree with profundity 3, which implies that the aggregate number of era is 8. As appeared in Figure 3, the furthest left and furthest right leaf hubs vt1 and vt8 relate to the strings 03 and 13 separately. The sets Tt1 = {v1, v01, vt2 , vt1} and Tt5 = {v11, vt6 , vt5}.

We introduce the solid development underneath

• Setup(1λ, T,N): Given a security parameter λ, the

add up to number of eras T = 2ℓ, the most extreme number

of clients N, this calculation executes as takes after:

1) Choose bilinear gatherings (G1,G2) with prime request p > 2λ and the comparing bilinear guide e : G1 × G1 → G2.

2) Select gathering components g, g2 R ←− G1 and a number α R ←− Z∗ p, and set g1 = gα. Moreover, pick two

random vectors $\boldsymbol{u} = (u_0, u_1, ..., u_n) \in G_1^{n+1}$ and $\boldsymbol{h} = (h_0, h_1, ..., h_\ell) \in G_1^{\ell+1}$, and for each $ID \in \mathcal{I} = \{0,1\}^n$ and $t \in \{0,1\}^\ell$, define the following two functions[3]:

$$F_u(ID) = u_0 \prod_{i=1}^{n} u_i^{ID[i]}, \quad F_h(t) = h_0 \prod_{j=1}^{\ell} h_j^{t[j]}.$$

Here, ID[i] is the ith bit of ID.

3) Let the ace mystery key be MSK = gα 2 , and instate the state st with a double tree BT of profundity log(N) and the repudiation list RL = ∅.

4) Publish the general population parameter as

• PKGen(PP,MSK, ID): For an identity ID ∈ I, this calculation creates its mystery key as indicated by the accompanying way

4.3 Performance discussions

In this segment, we talk about the execution of the proposed RS-IBE plot by contrasting it and past

works as far as correspondence and capacity cost, time many-sided quality and functionalities, which are compressed in Table 1, Table 2 and Table 3.

From Table 1 we can see that the sizes of private key and refresh enter in plans [22], [24] and our plan are all upper limited by O(r logN/r), since these plans all use parallel information structure to accomplish repudiation. Then again, Liang et al's. [26] plot includes a communicate encryption plan to appropriate refresh key with the end goal that their plan has consistent sizes of private key and refresh key. Moreover, by appointing the era of re-encryption key to the key expert, the ciphertext size of their plan likewise accomplishes steady. In any case, to this end, the key specialist needs to keep up an information table for every client to store the client's mystery key forever periods, which brings O(T)τG1

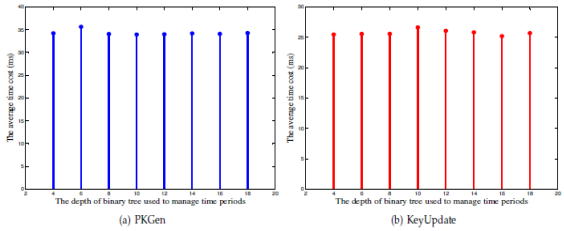


Fig. 5. The time costs of the algorithms **PKGen** and **KeyUpdate**.

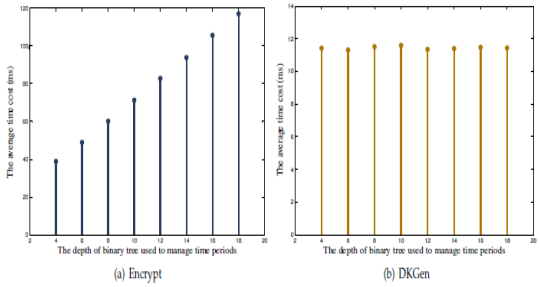

Fig. 6. The time costs of the algorithms **Encrypt** and **DKGen**.

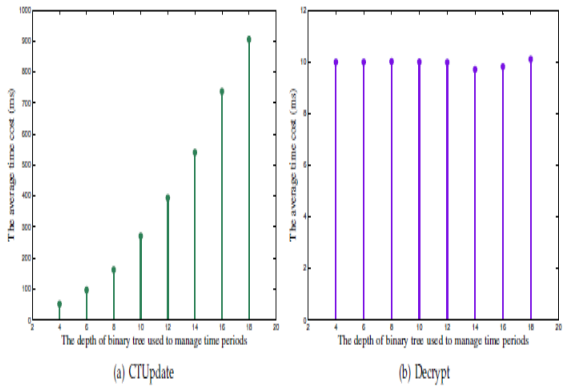

Fig. 7. The time costs of the algorithms **CTUpdate** and **Decrypt**.

capacity taken a toll for the key specialist. On the other hand, the ciphertext size of our plan is recently direct in log(T)2. Moreover, we take note of that in every recorded plan, the private key generator needs to occasionally create a refresh key, it must be on the web if each era is fairly short, e.g., 60 minutes. Be that as it may, from the point of view of useful applications, the recurrence of refreshing clients' decryption keys ought not be too little. A day and age like seven days, a large portion of a month or a moth is more alluring. As a result, the private key generator simply needs to create a refresh key for the following time frame when the present day and age is finished. In this manner the PKG does not should be constantly on the web. Another restriction of these recorded plans is that the produced ciphertext has the size direct with the quantity of collectors. To defeat this issue, a characteristic way is to develop a comparable plan in the setting of communicate encryption.

4.4 Implementation

To demonstrate the useful materialness of the proposed RSIBE conspire, we additionally actualize it utilizing codes from the Pairing-Based Cryptography library variant 0.5.14 [39]. In particular, we utilize the symmetric supersingular bend y2 = x3 + x, where the base field measure is 512-piece and the installing degree is 2. The usage is gone up against a Linux-like framework (Win7 + MinGW) with an Intel(R) Core(TM) i5 CPU (650@3.20GHz) and 4.00 GB RAM. In the usage, we set the quantity of clients to be N = 8 and the denied uses to be R = 4 (the hubs η2, η3, η4, η7 in Figure 2 are repudiated). In Figure 5, Figure 6 and Figure 7, we display the running time of the fundamental calculations, i.e., PKGen, KeyUpdate, DKGen, Encrypt, CTUpdate and Decrypt, for various decision of the aggregate number of eras T ∈ {24, 26, 28, 210, 212, 214, 216, 218}. To produce the exploratory

outcomes, we execute as the accompanying system: create the private key and encrypt a message

5 CONCLUSIONS

Cloud computing brings incredible accommodation for individuals. Especially, it consummately matches the expanded need of sharing information over the Internet. In this paper, to manufacture a financially savvy and secure information sharing framework in cloud computing, we proposed an idea called RS-IBE, which bolsters identity disavowal and ciphertext refresh at the same time with the end goal that a repudiated client is kept from getting to already shared information, and in addition in this manner shared information. Besides, a solid development of RS-IBE is exhibited. The proposed RS-IBE conspire is demonstrated versatile secure in the standard model, under the decisional ℓ-DBHE supposition. The examination comes about show that our plan has points of interest as far as effectiveness and usefulness, and along these lines is more achievable for down to earth applications.

STYLOMETRIC ANALYSIS OF ANNOTATED SPEECH TO STUDY BEHAVIOUR OF THE SPEAKER

[1]K Vijaya Lakshmi, [2]Dr. S Dhanalakshmi

[1]M. Tech Student, Department of CSE, , Malla Reddy Engineering College(Autonomous), RangaReddy, Telangana, India.

[2]Professor, Department of CSE, Malla Reddy Engineering College(Autonomous), RangaReddy, Telangana, India.

Abstract- *Stylometry is an area of research where the analysis can be applied on the user speech analysis, identifying the behaviour of the speaker. Stylometric also includes the analysis of the author identification based on the vocabulary comparison from author to author. Here we introduce 'Stylometry with R' (stylo), a flexible R package for the high-level stylistic analysis of text collections. This package explicitly seeks to further contribute to the recent development in the field towards a more advanced level of replicability and benchmarking in the field. Stylometry is a multidisciplinary research endeavor, attracting contributions from divergent scientific domains, which include researchers from Computer Science – with a fairly technical background as well as experts from the humanities who might lack the computational skills which would allow them easy access to the state-of-the-art methods in the field.*

Keywords:- *Stylometry, Data Analysis, Speech, Behaviour Analysis.*

I INTRODUCTION

Stylometric contemplates, in the entirety of their assortment of material and technique, share two basic highlights: the electronic writings they examine must be urged by one way or another to yield numbers, and the numbers themselves must be handled with factual programming. In some cases, the two activities are two free pieces of a given report. To give the least difficult precedent, one bit of programming is utilized exclusively to aggregate word recurrence records; at that point, one of the numerous business measurements bundles takes over to separate significance from this mass of words, draw diagrams and so forth.

This methodology works if standard factual systems are connected to the information. For multivariate word-recurrence based creation attribution, for example, when free AntConc produces word records with frequencies, costly (yet regularly college authorized) SAS, SPSS or Statistica can be utilized to deliver relative frequencies and relationship grids thereof, and one of their numerous modules can thus deliver Principal Components (PCA), Cluster (CA), or Multidimensional Scaling (MDS) investigations. This is now an entirely agreeable circumstance when contrasted with what Burrows needed to depend on in his fundamental work on Jane Austen's style (Burrows 1987).

However, as stylometrists have started to create factual strategies for their own – to give some examples, Burrows' Delta, Zeta and Iota (Burrows 2002, 2006) and their changes by different researchers (Argamon 2008, Craig and Kinney 2009, Hoover 2004a, 2004b) – business programming, regardless of its wide exhibit of available techniques, progresses toward becoming

something of a straitjacket. This is the reason various devoted stylometric arrangements have showed up, focusing on the particular examinations much of the time utilized in this network.

Hoover's Delta, Zeta and Iota Excel spreadsheets are a spearheading and great case of this methodology (Hoover 2004b). Always created since somewhere around 2004 (when one of the writers of this introduction got a CD-ROM with an early form), they have no less than two noteworthy resources: they do precisely what the stylometrist needs (with a few discretionary methods) and they just require spreadsheet programming that has progressed toward becoming (regardless) the standard on most PCs on the planet today. This has been particularly useful for utilizations in authority workshops and study halls; the understudy just needs extra (and, frequently, free) programming to create word recurrence records and he/she is prepared to go. However Excel forces one confinement: it is pointless excess regarding memory use, which results in the gradualness of its preparing. Likewise, the two-organize nature of the procedure (a different bit of programming gets ready word records that can be later naturally brought into the spreadsheet) may be something of an issue basically in light of the fact that it would take an accomplished Visual Basic software engineer to make Excel arrange the word records themselves.

II RELATED WORK

R contents can be depended on for doing the entire work themselves, from controlling writings (ordinarily, to create word records) right to charting the outcomes (and that in an extraordinary assortment).

These abilities were put tu use in the investigation of Delta's reliance on concentrated writings' sizes (Eder 2010), and on the conduct of Delta at an assortment of interims in the word recurrence rank records in an assortment of dialects (Rybicki and Eder 2011). The R condition allowed us to cover immense measurements at exceptional rates (regularly a great many Delta emphasess every hour in corpora of a hundred full-estimate books). It likewise allowed us to utilize other factual strategies, for example, PCA, CA or MDS, or those once in a while utilized so far in this field –, for example, bootstrap accord trees dependent on an investigation of Papuan dialects by Dunn et al. (2005, cited in Baayen 2008: 143-47). Likewise, the whole investigation – from stacking writings to conclusive outcomes in numeric and realistic structure – can be practiced with a solitary content. Our Delta content, for example, did basically everything: it handled electronic writings to make a rundown of the considerable number of words utilized in all writings contemplated, with their frequencies in the individual writings; standardized the frequencies with z-scores (if appropriate); chose words from expressed recurrence ranges for investigation; played out extra systems that (typically) improve attribution, for example, Hoover's programmed cancellation of individual pronouns and separating (programmed expulsion of words unreasonably trademark for individual writings); looked at the outcomes for individual writings; played out an assortment of multivariate examinations; displayed the similitudes/separations acquired in tree charts; at long last, created the previously mentioned accord tree – another diagram that joined many tree outlines for an assortment of parameter esteems. It was our plan to build up a general stage for multi-emphasis attribution tests; for example, a substitute content created heatmaps to demonstrate the level of Delta's accomplishment in attribution at different interims of the word recurrence positioning rundown.

Stylometry: Identifying authors of texts using R:

Few people expect politicians to write every word they utter themselves; reliance on speechwriters and spoke persons is a long-established political practice. Still, it's interesting to know which statements are truly the politician's own words, and which are driven primarily by advisors or influencers. By looking at the aspects of linguistic style (word/sentence length, frequency of word pairings, use of punctuation, etc.) of the speeches we can able to find out the behaviour of the person.

A Stylometric Approach to Identity-Level Identification and Behaviour Detection:

Lexical features: Lexical features describes the semantics of the words used by the author. Vocabulary richness and word-length distributions are classic examples.

Syntactic features: Such kind of features rely on an analysis of typical sentence structure considering elements like function words, punctuation, and part-of-speech tags.

Structural features: Structural features targets the actual composition of the text discussing its organization and layout. Due to the short extracts without any further information, this seems not applicable here.

Content-specific features: This type of features based on an analysis of essential keywords and phrases on specific topics like in scientific publication. Like the feature set before not applicable in our context.

Idiosyncratic features: Individual usage anomalies like misspellings and grammatical mistakes are taken into consideration. After the editing process of all the texts, it is unlikely that any valuable results remain.

Title: A Scalable Framework for Stylometric Analysis Query Processing:

Authors : Sarana Nutanong Chenyun Yu Raheem Sarwar Peter Xu Dickson Chow

Publishing Year: 2016

Method: Stylometry is the statistical analyses of variations in the author's literary style. The technique has been used in many linguistic analysis applications, such as, author profiling, authorship identification, and authorship verification.

Dis advanatage:

However, these studies are generally limited to (i) a small number of candidate authors, and (ii) documents with similar lengths.

Advantage:

larger number of documents of different lengths written by a larger pool of candidate authors with a high accuracy

Title: A survey of modern authorship attribution methods:

Authors :E. Stamatatos, JASIST

Publishing Year: 2009

Method: The main idea behind statistically or computationally-supported authorship attribution is that by measuring some textual features we can distinguish between texts written by different authors. The first attempts to quantify the writing style go back to 19th century, with the pioneering study.

Dis advanatage:

computational requirements and settings rather than linguistic or literary issues.

Advantage:

authorship attribution studies

text representation and text classification.

Title: Overview and Comparison of Plagiarism Detection Tools :

Authors : Asim M. El Tahir Ali, Hussam M. Dahwa Abdulla

Publishing Year: 2011

Method: An overview of effective plagiarism detection methods that have been used for natural language text plagiarism detection, external plagiarism detection, clustering-base plagiarism detection and some methods used in code source plagiarism detection

Dis advanatage:

Comparision Models with all softwares.

No development of the models

Advantage:

Author citing on the articles made easy.

user intendation over the articles are accessed easly and secured over the authors.

Title: Does size matter? Authorship attribution, small samples, big problem:

Authors : Maciej Eder.

Publishing Year: 2013

Method: find such a minimal size of text samples for authorship attribution that would provide stable results independent of random noise.

Dis advanatage:

method of sampling: contrary to common sense, randomly excerpted 'bags of words' turned out to be much more effective than the classical solution, i.e. using original sequences of words ('passages') of desired size.

Advantage:

k-NN applied to most frequent words, character 3-grams, character 4-grams, and parts-of-speech-tag 3-grams.

III Proposed Work:

Stylometry or the study of measurable options of (literary) vogue, like sentence length, vocabulary richness and numerous frequencies (of words, word lengths, word forms, etc) has been around a minimum of since the center of nineteenth century, and has found assorted sensible applications in authorship attribution analysis.

The research in last few decades on usage of language statistical analysis is growing in a rapid way. Modern stylometry attracts heavily on the help of computers for statistical analysis as well as the artificial intelligence and also providing access to the growing corpus of text documents accessible via the Internet. Our main goal is to demonstrate and analyse the speech by the dictator's vocabulary and then analyzing the data in order to project the statistical patterns. Stylometry to identify if shifts in stylistic patterns are observed across various speeches, using computational tools. The crucial analysis with stylometry is this: There exist habits for each person, formed unconsciously, in regards to words and Language usage. These determine the dictator's structure, diversity, and word choice in each person's writings, forming a Stylistic signature.

Stylometry grew out of earlier techniques of analyzing texts for evidence of authenticity, authorial identity.

Increases the vocabulary richness.

Applying the stylometry to the speeches of the speakers in analyzing the speech delivered to the audience.

To evaluate the efficiency in analyzing the speeches, we compare with required methods.

Analyzing the speech text via large documents.

These large scale documents help us to know more about the speaker from his speech or the vocabulary used and the way of his approach over the speech deliveries.

To demonstrate and analyze the behaviour of the dictator.

Research based on the analysis of texts might help the scientists to gain full control of the behaviour of the individual.

The term stylometry draws the behaviour of the user from all the speeches delivered by the speaker.

The proposed system provides the statistical objects from the speaker data such as positive negative and emotional terms.

The behaviour of the individual speaker could be analyzed from the emotions based on the particular speech data.

Usages of the regular expression make the information classification a lot friendly and fetch more efficient results.

Uses NLP Algorithms can be implemented on any kind of data.

IV IMPLEMENTATION

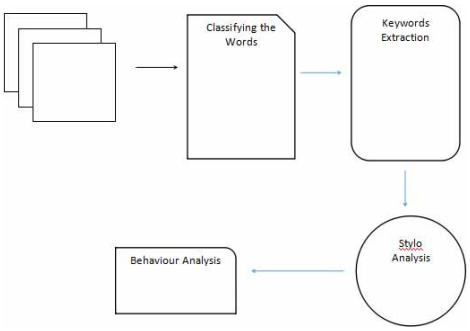
Stylometry

Stylometric investigation errands can be sorted out into two kinds, creation distinguishing proof and composing style closeness identification [1]. Each assignment is comprise of two stages (I) finding proper stylometric highlights (ii) framing productive ways to deal with apply on these highlights. The target of creation recognizable proof errand is to analyze question writings against the composition tests of the hopeful writers. An outstanding case of creation distinguishing proof is the Federalist papers [12] in which 12 debated/unknown expositions were looked at against composing tests of Alexander Hamilton and James Madison.

Since, all hopeful creators (conceivable classes) are known an earlier, the initiation recognizable proof errand can utilize regulated or unsupervised order procedures. Stylometric highlights are composing style-markers or traits that are compelling discriminators of creation. A huge range of stylometric highlights have been proposed so far including lexical, syntactic and basic. Lexical highlights are character based and word-based factual proportions of lexical varieties. These incorporate word and character lengths, sentence lengths [6]. Syntactic highlights incorporate capacity words [12], grammatical feature label n-grams [2]. Auxiliary highlights incorporate the style-markers identified with the format and association of content. For instance, number of words in sentence and number of words in passage.

Existing examinations utilized the equivalent size of the content to look at for origin recognizable proof [3], [2]. This is a test in genuine datasets. This is on the grounds that, a database of understudy assignments may contain records with various lengths composed by a wide range of understudies. In this examination we use creator bunch level stylometric highlights to make our framework altogether quicker than existing procedures with sensible precision. In this work, we utilize 56 stylometric highlights which are ordered into three kinds: lexical, syntactic and auxiliary. The lexical highlights can be further subcategories into 14 character-based and 13 word-based highlights [6]. We utilize 27 syntactic

highlights, which incorporate capacity words [1], grammatical form [2]. There 2 auxiliary highlights, the quantity of words in sentence and the quantity of words in passage.



Behavior Analysis:

Behavior analysis is a characteristic science that tries to comprehend the conduct of people.

That is, conduct investigators think about how natural, pharmacological, and experiential variables impact the conduct of people and nonhuman creatures. Perceiving that conduct is something that people do, conduct experts place uncommon accentuation on contemplating factors that dependably impact the conduct of people, an accentuation that functions admirably when the objective is to secure versatile conduct or improve issue conduct. The study of conduct examination has made disclosures that have demonstrated valuable in tending to socially significant conduct, for example, speeking, medicate taking, good dieting, work environment wellbeing, instruction, and the treatment of unavoidable formative handicaps (e.g., mental imbalance).

This field of science is worried about portraying, understanding, foreseeing, and evolving conduct. They look for answers by taking a gander at the organic and ecological components, in spite of the fact that they are principally inspired by the job of condition in conduct change.

There are three principle branches to the field: Conceptual Behavior Analysis, Experimental Behavior Analysis, and Applied Behavior Analysis. The Conceptual branch centers around the philosophical, hypothetical, chronicled, and methodological issues that underlie the field. Trial Behavior Analysis includes essential research expected to add to the assemblage of information about marvels that control and impact conduct. Connected Behavior Analysis is centered around the utilization of the standards of conduct to the requirements of people to advance conduct change and improve personal satisfaction.

The architecture describes the concept of analyzing the speech documents from the basic steps. The first way is we collect the documents, extract the words, apply the polarity emotion to check on the words, and then finally generate the behaviour out from the data.

IDENTIFY PARAMETERS

At First the data is taken into the R console. Then the data is displayed with the view method in the R language. The size of the data may be 1 Gb or 1Tb. Preferably the unstructured data is taken. In this module we use KNN algorithm for classifying the keywords with help of regular expressions. The regular expressions facilitate to remove the unnecessary data such as stop words or blaw words.

Now the stemming is completed once and the KNN is applied therefore to take away the spaces between the words, to create one document.

The Term-Document Matrix is used to frame the sorted words into the document and this is where we apply the stemming for the words.

Stemming

Stemming is a procedure of reducing words. To the particular text document we apply stemming process to remove the

spaces, punctualities, stop words. Then the document with the positive and negative terms is obtained. After this process an appropriate document is formed.

Steps for KNN Algorithm

Step 1: Determine the parameters K = number of nearest neighbours.

k = how many keywords - one, two, three words

Step 2: Calculate the number of keyword between the query-instance and the data.

Step 3: Sort all the keywords and determine the count of the keywords.

Step 4: Gather all the categories of the keywords.

Step 5: Use simple majority of the category of keywords as the prediction value of the query instance.

CLASSIFY KEYWORDS

Based on the results of the keywords from the first module, and then apply the bayes algorithm as per the requirement. The keywords obtained after applying KNN is named as training data set. Collect all the key words to a variable. Apply the bayes algorithm and categorise the keywords as per positive and negative terms. Once keywords are categorised, classify the emotion of words in the terms of happy, sad, fear, bad. Project the results as per the classified words.

Steps for Naive Bayes Algorithm

Step 1: Collect all the key words to a variable.

Step 2: Apply the bayes algorithm and categorise the keywords as per positive and negative terms.

Step 3: Once keywords are categorised.

Step 4: Classifying the emotion of the words as happy, sad, fear, bad.

Step 5: Project the results.

BEHAVIOUR ANALYSIS

Behaviour analysis is a natural science that seeks to understand the behaviour of individuals. The science of behaviour analysis has made discoveries which have been proved useful in addressing socially important behaviour such as speaking, drug taking, healthy eating, workplace safety, culture, and the treatment of pervasive developmental disabilities (e.g., autism).

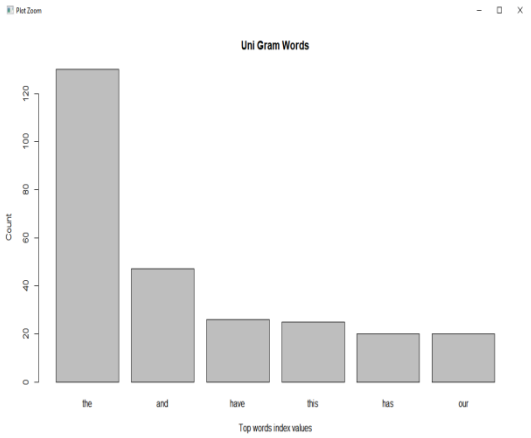
There are three main branches to the field: Conceptual behaviour analysis, experimental behaviour analysis, and applied behaviour analysis. The conceptual branch focuses on the philosophical, theoretical, historical, and methodological issues will underlie the field. Experimental behaviour analysis involves vital research intended to add to the body of knowledge about phenomena that control and influence behaviour. Applied behaviour analysis is focused on the application of the principles of behaviour to the needs of individuals to promote behaviour change and improve quality of life.

From all the above requirements we analyse the data using the stylo methods for projecting the behaviour of the data. Now to entire data set apply stylo methods. Calculating the emotions from previous module, this method shows the behaviour of the speaker. After finding the behaviour we get the result in the form of reports. Resulting in the behaviour analysis.

Stylo

The third program to facilitate stylometry that is investigated was the R stylometry package: This toolset operates within the R programming environment and features a GUI for users who would not like to use the programming support of R. For users that wish to take advantage of R's power, Stylo includes additional functions and ways to incorporate them into the other programs. Stylo also features support for machine learning which emphasizes the scope of the toolset. Because stylo works within R, setting it up and using the basic features becomes slightly more difficult for users unversed in programming languages. Once setup is complete, however, stylo includes a GUI to aid armature analysis. The stylo manual was very comprehensive and walked through all of the different components and how they work.

V EXPERIMENT AND RESULTS



The implementation is made with the ten different speeches from a individual and multiple speaker and the found that the results are the describing the behaviour of the speaker at the best to the applied methods. The results deals with identifying the keywords, unigram, bigram, trigram words from the speech document. Then later produces the polarity from the keywords and the emotions are been classified from the speech content. Finally the behaviour of the speaker over the audience has been classified and found that results were accurate and clarification is identified.

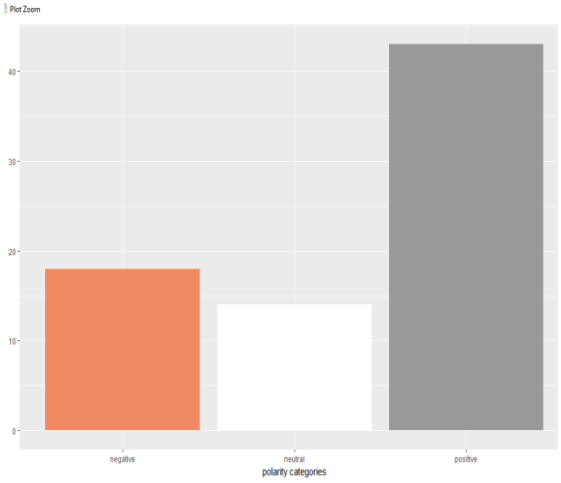
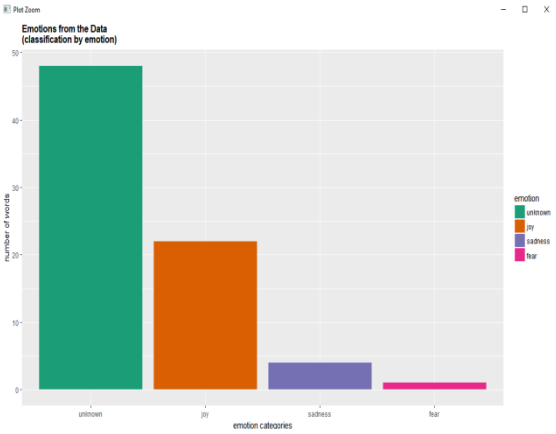
an example text document to analyze the behaviour of the speaker. Here Pakistan president annotated speech document is taken.

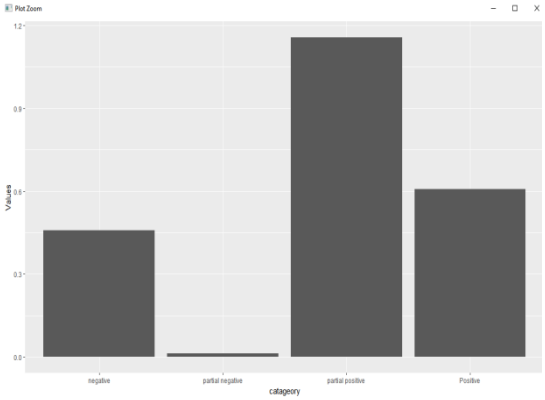
Values	
blDat	chr [1:75] "Honourable President, Respecte…
blg	Classes 'file', 'connection' atomic [1:1] 3
blgLinesCnt	75L
blgWordCnt	1929
data	chr [1:75] "Honourable President, Respecte…



Representing the number of lines along with words in a documentidentifying two parameters from the text document. At first we find the number of words in the text document. There are about 1929 words and 75 lines in the text document.



the particular text document is divided into single words. Even it identifies how many times a particular word is repeated.Representing the words of unigram list.



The document is divided into single words then the stemming process is applied. Then it helps to remove the unnecessary words, spaces etc. Now the document contains only positive terms and negative terms.

Representing the polarity (categorizing into positive and negative terms) after the comparison between the positive and negative words, a separate list of positive and negative words is categorized.

Classifying emotions from positive and negative words, after obtaining the list of positive and negative words, emotions are classified from the words.

```
> behaviour
          catageory     Values
1          Positive 0.60691818
2          negative 0.45848241
3 partial positive 1.15669018
4 partial negative 0.01389334
```

Representing the behaviour from the emotions, the behaviour of the person is obtained from the emotions. Thus we can find the behavioral category of the person.

VI CONCLUSION

Stylometry is applied to find the behaviour of the speaker through his speech.Results help us in analysing the behaviour of the speakers and their vocabulary. The speech is taken in the text format. Thus the behaviour of the particular speaker through his speech is analysed by identifying keywords and next the emotion of obtained words has to be

found. Later the emotion will be passed over the stylo, in classifying the behaviour of the person.We will analyse the behaviour based on the emotion.

From the recent results of polarity and the emotions from the speech data, we now classify the results to work out the behaviour of the speaker based on the emotional category. Classifying the emotions based on the type of polarity, we can detect the behaviour of person.

A Heuristic Model for Predicting Human Fall Detection using Machine Learning Techniques

Mohammed Inayathulla, PA Hima Kiran, M Chandana Sri, M Deepika

Abstract*: *It is very obvious that human fall due to unconsciousness is a very common health problem in every human being. With the evolution of many smart health devices, we should contribute the technological advancement of machine learning into it. Different techniques are already used in order to detect human fall detection in human beings. In this paper we have studied the patterns of falling of human through the fall detection dataset while this human was performing various motions. By understanding all these we have generated the prediction protocol which estimates the fall of a person using fall detection dataset. Machine Learning classifiers were used to predict the human fall and a comparative study of various algorithms used was developed to find out the best classifier.

Keywords*: *Classification, Fall Prediction, Machine Learning, Random Forest.

I. INTRODUCTION

The term fall can be defined as an unintentional event in which the body moves from its initial position to a lower level. This would cause some serious injuries also in adverse conditions. Hence a fall prediction system would be really useful in such conditions where it can predict the human fall prior to falling so that required remedies can be carried out. A fall detection system can be defined as a usable device whose main motive is to alert when a fall action has occurred. The fall alert detectors can estimate when the user was about to fall by detecting the sudden changes of body movements. Old age people have high degree of risk of death or injury resulting from falls. As the density of population is increasing human fall prediction system can be very handy. The aim of this paper is to implement a fall detection model by using different machine learning techniques. Human fall prediction can be considered as a typical classification problem of machine learning. To carry out this work data is collected from publicly available datasets. Supervised classifiers are then implemented on the collected data. All the features available in the dataset are used to build the classifier. After the classifier was built its accuracy was built on the unseen data. Several researchers have been working in this field to expose the importance of machine learning. As the current work is based on supervised schematic studies this also can be extended in computer vision where the data is collected by using visual sensors and based upon the data collected machine learning can be applied to identify the human fall detection. The structure of the paper is as follows in the next section related work is discussed then implementation details are discussed followed by results and conclusions.

II. LITERATURE SURVEY

In [1] the authors worked on visual surveillance for detecting the fall detection. Their approach was a two step process ellipse approximation and motion history image. In [2] the authors used an embedded camera in human body to identify the joint movements and there by classifying whether the person will classify or not. SVM classifier was used by the authors. In [3] the authors proposed a step by step process for identifying the fall detection. The critical steps were feature extraction human identification and fall detection. Histograms of Oriented Gradients and Local Binary pattern were used in combination of deep learning techniques to expose the human fall detection by authors in [4]. In [5] the authors worked on mobifall dataset with five different classifiers and proved that KNN classifier outperformed the other classifiers used. In [6] the authors used a smartphone based approach to identify the fall detection and thereby generating an alarm to the responsible of the victim. Three point based technique was employed to identify the fall detection in indoor video surveillance[7]. CHLAC features with skeletal image sequences were extracted using a mobile robot and KNN algorithm was used as a classifier for fall detection [8]. Deep Learning LSTM neural network method was used [9] with a smart phone as a sensor for fall detection. Convolutional Neural Networks was used in [10] in order to identify the fall detection with respect to the furniture and human characteristic relationships.

III. PROPOSED METHODOLOGY

The aim of this paper is to implement the classification scheme to identify the fall detection of a person. The algorithms used are Random Forest, K-Nearest Neighbor, Decision Tree and Naive Bayes. Fall detection prediction system can be categorized into four stages: Data Collection, Data Cleaning, Implementation, Prediction.

The main recognition of this paper is to identify the sophisticated among those mentioned classification algorithms. The methodology is described in figure 1.

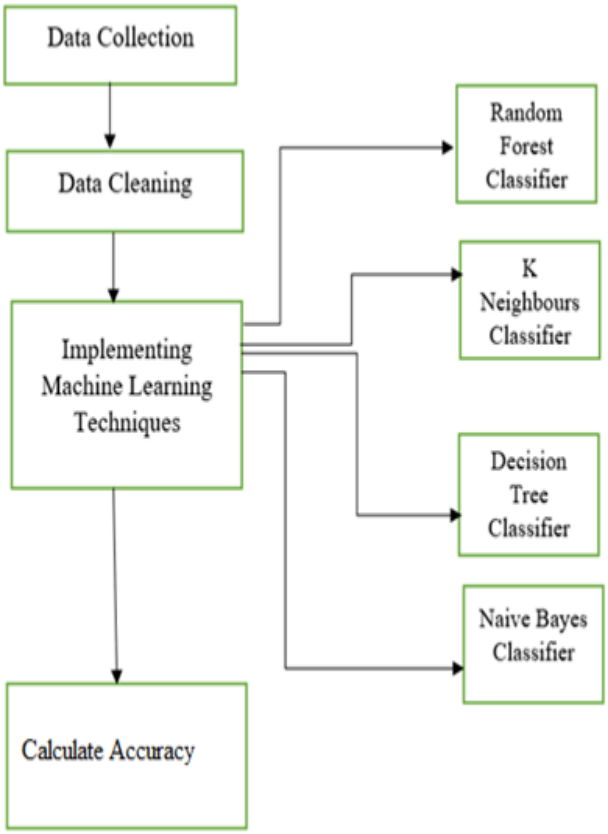

Fig 1: Fall Detection Prediction Model

Data Collection:

The "fall detection" dataset[11]is used for fall detection prediction which is used has the China Activity of elderly patients along with their medical information". The dataset consists of following features: Time, Sugar level, EEG monitoring rate, Blood pressure, Heart beat rate, Blood circulation.

Data Cleaning:

Data cleaning is the important phase as the erroneous data would significantly impact the overall performance of the system. In this phase data is thoroughly inspected to find out any missing values null values and standard statistical measures are used to deal with the null values and missing values.

Implementation and Accuracy:

Fall Prediction Model was implemented in python. After loading the dataset split the data into training and testing data. Using the training dataset train the model using the machine learning classifiers. Confusion matrix is used to test the model. All the features were used to built the classifier. The data split was performed in the ratio of 80 and 20 were 80% was used to training and 20% for testing. For decision tree entropy was used as the splitting criteria. In KNN 7 neighbours were worked for each unseen instance. When building random forest 500 trees were grown. Accuracy was computed based on the confusion matrix which is the familiar metric to evaluate the classifier and the accuracy values of each classifier are shown in the table 1.

IV. RESULTS

Table: 1 Accuracy scores of various classifiers used.

Classifiers	Accuracy
Naive Bayes Classifier	0.83
Decision Tree Classifier	0.89
K NN Classifier	0.7
Random Forest Classifier	0.92

The above table shows the accuracy values of each classifier and Random Forest has outperformed the other classifiers used with an accuracy of 92%. For every classifier the train test split ratio was 80 and 20 respectively as mentioned above.

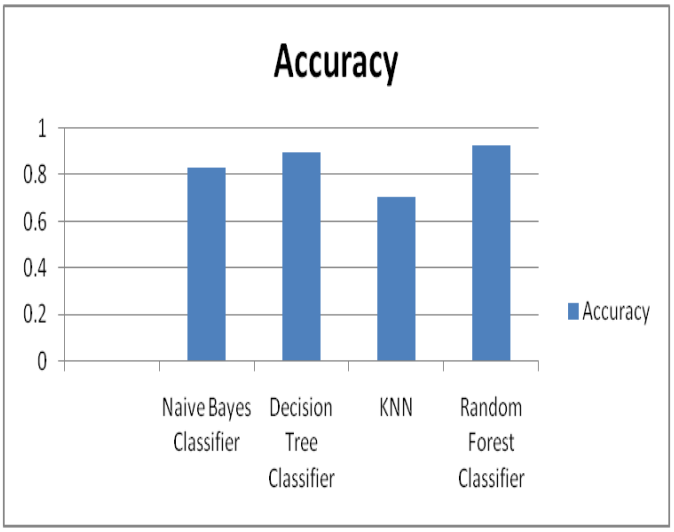

Fig 2: Comparision Chart of accuracy of classifiers

V. CONCLUSION

Out of the four learning algorithms used Decision tree and Random Forest have shown the better results. In future fall detection prediction system can be used to work in real time with regularly modernized datasets from distinct devices in various conditions. Deep Learning Techniques can be used to explore the surveillance data collected of various patients thereby predicting the human fall detection in real time.

SPATIO-TEMPORAL DEPTH MOTION DESCRIPTOR FOR ACTION RECOGNITION UISNG 2D CONVOLUTIONAL NEURAL NETWORKS

S. Sandhya Rani[1], Dr. G. Appa Rao Naidu[2],Dr.V. Usha Shree[3]

[1]Research Scholar, Department of CSE,JNTUH, India

[2]Professor, Department of CSE,JBIET, India

[3]Principal, Department of ECE, JBREC, India

Abstract: *This paper proposes a new Human Action Recognition Framework by fusing the Motion History with Depth Motion information. Firstly, Difference Depth Motion Map (D^2MM) is proposed to capture the shape and motion cues of action. Particularly, D^2MM nullifies the side effects like body shaking movements and Ghost Shadows. Secondly, Modified Motion History Image (M^2HI) is proposed to identify the real ad fake movements in human body and to encode motion information effectively. Before the action representation, this work employed temporal segmentation in which the entire sequence of frames of a depth video is segmented into different sets with different frame lengths. Then the proposed two action representation methods are applied over the segments. For feature extraction and classification, we have employed a simple 2D Convolutional Neural Network (2D-CNN) in two phases and the results are fused to obtain final classification score. Simulation experiments are conducted over MSR action 3D dataset and MSR daily activity 3D dataset, shows the effectiveness of proposed method.*

Keywords: Action Recognition, Depth data, Depth Motion Map, Convolutional Neural Network, Late fusion, MSR action dataset, Accuracy.

I. INTRODUCTION

In recent years, vision based action recognition has gained a great research interest due to its widespread applicability in several applications including context based video retrieval, autonomous driving vehicle, human-computer interactions, intelligent surveillance systems [1] [2], and gaming applications [3]. In earlier several approaches are proposed to recognize human action but most of them considered the traditional RGB videos which were captured through normal cameras [4], [5]. However, the traditional RGB videos have several constraints such as different lighting conditions, varying backgrounds, color and textural variations etc., due to which the action recognition has become a challenging task in computer vision.

In recent years, with the advent of low-cost depth cameras like Microsoft Kinect [6], the action recognition research has entered into a new phase in which the input videos of an action recognition system are RGB Depth (RGB-D) videos. The depth cameras ensure depth data as well as color images sequence in real time, which makes the action recognition system more realistic and solves the traditional problems with RGB videos. The RGB-D videos are more advantageous than the traditional RGB videos in several aspects: (1) the depth cues in RGB-D videos are insensitive to illuminations variations and they can capture the videos even in dark environments also. (2) Depth videos can provide depth data while the traditional ones can't. (3) Texture and color variations are not present in the depth videos which make the action unit detection easier [7].

Considering the advantages of depth videos, an extensive research effort has been made to achieve better recognition results. Among the earlier developed action representation methods, Depth Motion Maps (DMM) [8] and Motion History Images (MHI) [9] have gained better performance in the recognition of human actions. However, they are susceptible for cluttered backgrounds, small body shaking movements, jumbled objects and low resolution depth videos. Moreover, in the depth map construction, the DMM process considers the entire frames of depth video by which the detailed temporal information in the subset of images can't be captured.

To solve these problems, in this paper, we have developed a new action recognition framework based on the combination of DMM and MHI. Two new action representation schemes namely, Difference Depth Motion Map (D^2MM) and Modified Motion History Image (M^2HI) are proposed to represent the 3D depth action video in 2D image format. Before action representation, to acquire detailed motion information, this paper employed temporal segmentation at different levels. Further for feature extraction and classification we have employed 2D Convolutional Neural Network (2D-CNN) model and the final action label is evaluated based on late fusion. At the late fusion, we have considered three different fusion techniques such as Maximum fusion, Product fusion and linear fusion. Simulation experiments are conducted over MSR action 3D dataset and MSR daily activity 3D dataset and the performance is measured through recognition accuracy.

Remaining paper is organized as follows; Section II demonstrates the details of literature survey. Section III explores the details of proposed action recognition model. Simulation experiments details are demonstrated in section IV and the concluding remarks are shown in section V.

II. LITERATURE SURVEY

Due to the great success of depth action video sin action recognition, lot of research works has been conducted in this orientation. A detailed literature survey on action recognition methods can be found at [10-12]. In this section, the recent works related to the paper, including, action segmentation, and action representation are briefly reviewed.

A. Segmentation

Generally, most of the earlier developed action recognition works have assumed that the individual instances of action in the frame or image are already isolated or segmented. In the case of continuous action recognition from depth videos, the input stream generally contains unknown number of frames, unknown number of objects, and unknown boundaries of actions and to this problem has to be solved at the same time. Means, the feature extraction or action representation or action recognition method has to solve this problem, which is highly complex and also results in less quality.

With respect to action segmentation, Dynamic Time Wrapping (DTW) is one of the widely employed techniques to determine the delimiting frames of individual actions [13], [14]. In this approach, for a given action sequence, initially difference images are extracted by subtracting the successive grayscale images. Next, the difference images are divided into small blocks of size 3×3 and every block is represented with an average value of pixels within the block. Then the final feature of each frame, called as motion feature is calculated by flattening the blocks in the difference image, excluding the final frame. This process is accompanied for both training and testing videos. Finally the action is segmented by comparing the motion features and analyzed through Viterbi algorithm [15]. However, the DTW based segmentation makes it difficult to obtain more distinct feature when a filter with small size is applied over the images. Let's consider two different difference images of two different actions. If we apply a filter with size 3×3 over them, then the obtained motion features may not differ much because at the starting, the two action frames have similar features.

Another possible method of action segmentation is based on appearance. Based on the general assumption about the similar characteristics of starting and ending frames, D. Wu et al., [16] accomplished Histogram of Gradient (HoG) with correlation coefficient and K-Nearest Neighbor (K-NN) [17] to identify the first and last frames of an action video.

Though these methods applied segmentation for action detection, they are not focused over the detection of key frames. All of these methods are applied spatial segmentation which resides within the frame but not reveals about the temporal motion information between frames. Every actor has his/her own speed and ends up the video with varying number of frames. For example, a slow action is completed in larger time and acquired in larger number of frames, which creates a he computational burden over further processes. Hence the frames are need to be segmented temporally through the temporal motion information will also get preserved.

B. Action representation

Most of the previous works focused on the extraction of Spatio-temporal features to represent an action in depth videos. The most popular approaches are HOG3D [18], 3D EMOSIFT [19], Acionlet [38], HON4D [20], Depth Motion Maps (DMM) [23] and Motion History Images (MHI) [30]. In particular, Yang et al., [8] employed DMMs to acquire cues of capture motion from dissimilar viewpoints (top, side, and front) and they employed HOGs to represent an action. Similarly, Chen et al., [21] accomplished Local Binary patterns for feature extraction after representing the depth action video with DMM from three projection views such as Front view, side view and top view. Kernel Based Extreme Learning Machine (KELM) is employed for action

classification. This method also had shown its contribution at fusion level by applying two levels of fusions such as feature level fusion and decision level fusion. At feature level the LBP features are fused and at decision level, soft max rule is applied to combine classification scores. Further, the same author, Chen et al., [22] generated the DMMs are segment level at which the depth video sequence is segmented into several overlapping segments. Then each segment is characterized by DMM followed by LBP to extract the location rotation invariant information. In the final stage, Fisher kernel is accomplished to generate a compact feature vector for every action. ELM is applied for action classification.

Next, focusing over the segmentation and motion information, M. A1-faris et al., [24] proposed a new version of DMM, called as "Fuzzy weighted multi-resolution DMMs (FWMDMMs)". This model focused over the creation of multiple DMMS at multiple levels by segmenting the temporal action frames at different levels. After DMMs representation, to find the significance, this method employed fuzzy weight function in three orientations such as Linear, reverse and central. Finally the FWMDMMs are fed to deep CNN model for classification [25]. Further, the main aim of Xu Weiyao et al., [26] is to exploit the frame selection and towards such, a new "Multilevel Frame Select Sampling (MFSS)" method is proposed to generate three levels of temporal samples from input depth sequences. Then they are represented through Motion and Static Mapping (MSM) followed by Block based and LBP and Fisher kernel representation. KELM is accomplished for action classification. Further extending the LBP to "Discriminative Completed LBP (DiscLBP)", Wu Li et a., [27] proposed DMM assisted action recognition with two classifiers such as ELM and collaborative representation classification (CRC).

Next, MHI is also a basic representation of an action image which can also determines the motion information at every pixel. Based on this fact, Watanabe et al., [28] extracted shift invariant features based on "Higher Order Local Correlation (HOLC)" from the MHI for action recognition. Next, Y.L. Tian et al., [29] considered MHIs as a basic action representation and over the obtained MHI they employed a global and location filtration method to eliminate the unaltered motions. "Gaussian Mixture Model (GMM)" based classifier is employed for action classification. Next, combining the Static History Image with MHI, E. Chen et al., [31] proposed an action recognition framework in which LBP is applied for feature extraction. Support Vector Machine is accomplished for classification. Further, D. Kim et al., [32] projected the depth map into two orthogonal planes such as front and side view. And then applied two descriptors namely, "Depth Motion History (DMH)" and "Depth Motion Appearance (DMA)" for action representation and finally applied SVM for classification.

III. PROPSOED APPROACH

3.1 Overview

In this paper, we have a novel deep learning based action recognition framework to recognize human actions form depth action videos. This framework employs Spatio-temporal features from depth videos for action recognition. Here the Spatio-temporal data is incorporated with two different action representation techniques: Temporal Difference Depth Motion Map (TD^2MM) and Temporal Modified Motion History Image (TM^2HI). Each of the method provides explicit action movements in the form of certain shape and motion cues. Further the feature extraction and classification is employed through 2D-Convolutional Neural Network (2D-CNN). Two 2D-CNN models are trained on these two action representations and the obtained classification results are fused to derive the ultimate classification label. Figure.1 shows the block diagram of proposed action recognition framework. The major contributions of this work are outlined as follows;

1. We didn't rely on the handcrafted features through which the system will consume additional time to extract the features form every action model. Instead of that we directly used CNN to extract the Spatio-temporal information from data.

2. Unlike the conventional DMM which consider all the frames, we have considered only few set of frames for DMMs construction. Moreover, the proposed TD^2MM nullifies the extra side effects like ghost shadows, and small body shake movements.

3. Unlike the conventional MHI which can't determine the whether the pixel belongs to the moving portion of human body or a fake moving pixel, the proposed TM^2HI can differentiate between these two effectively.

4. At decision level, we have employed late fusion get the final decision regarding classification label. This makes the recognition system to train different models simultaneously.

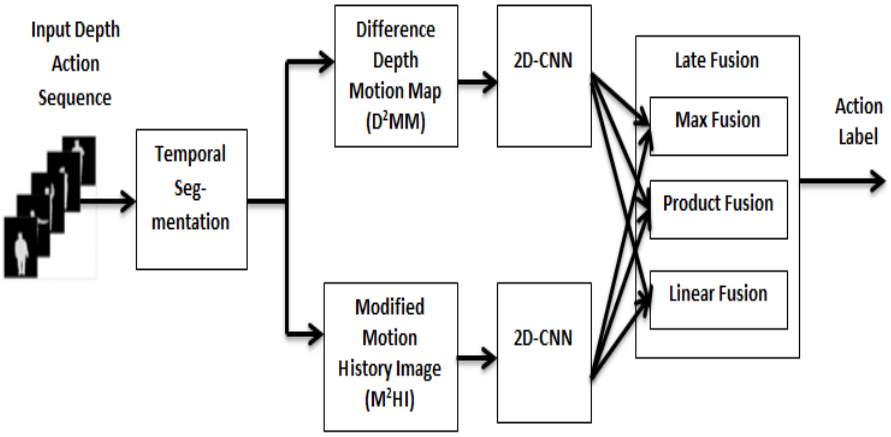

Figure.1 Block diagram of proposed action recognition model

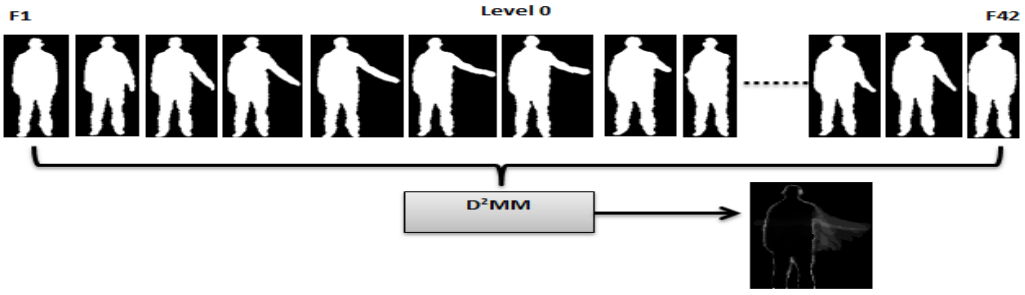
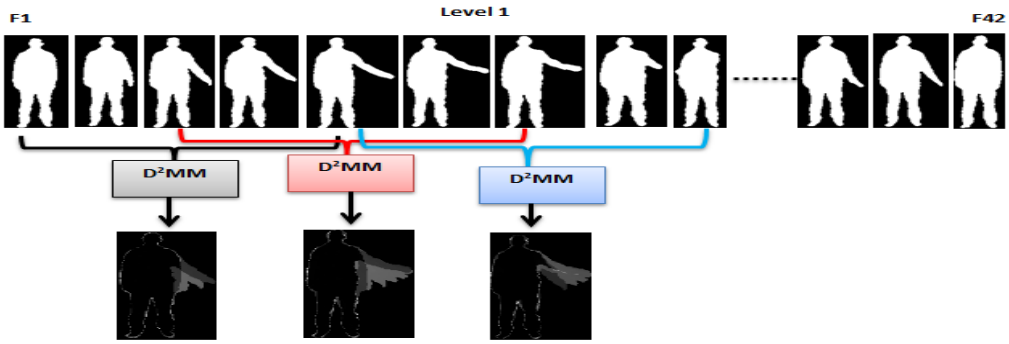


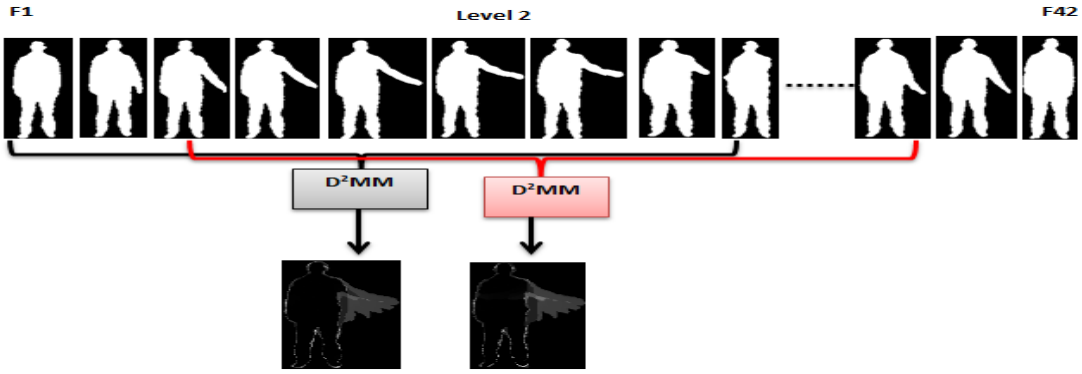
3.2 Action Representation

Action representation is an important task in the action recognition model. Representing an action with motion information is one of the significant way in which an entire video can be represented in a single 2D image. In our model, we have employed two different action representation techniques such as TD^2MM and TM^2HI. DMM and MHI are the base sources of these two techniques which have gained significant importance in the action representation with motion information. DMM and MHI are sensitive to noise caused by several side effects such as cluttered background, jumbled objects and low resolution cameras. Hence the DMM is extended to D^2MM and MHI is extended to M^2HI to remove the external noises thus the quality of DMM and MHI will get enhanced.



3.2.1 TD^2MM

DMM has gained much importance in the representation of human actions in depth videos. In DMM, the 3D action video is transformed into a 2D motion image and has been successfully applied for action recognition. DMMs are basically used to determine the motion and shape information of a depth action video. Generally the DMM is obtained by the accumulation of difference between the frames of an action sequence. Actually the DMM is constructed by considering all the frames into the process. However, this process may not be able to capture more and detailed temporal information. Hence to capture more and effective motion information, we have employed temporal segmentation in which the depth video sequence is divided into several temporal and overlapped set of segments with equivalent number of frames in every set. Then DMM is applied over these segments to obtain 2D motion image. Since the actions performed by different people have different variations like speed and number, consideration of entire frames or equal number of frames for computation of DMM is not a suggestible technique. Hence we have employed three different levels and at level, we have considered different number of frames for DMM computation. Further, we have considered a uniform overlapped frames to segment the video sequence into several sets of segments, i.e., the segmentation will maintain a constant number of overlapping frames between every two successive segments.



Under this temporal segmentation, we have considered tally three levels such as L_0, L_1 and L_2. At the level L_0, the process considers entire set of frames for depth map constriction. Next at level L_1, the process considers five frames with an overlapping factor R = 3. Further at level L_2, the process considers ten frames with same overlapping factor. A simple demonstration about temporal segmentation is depicted in figure.2.

(a)

(b)

(c)

Figure.2 Temporal Segmentation (a) Level 0, (b) Level 1 and (c) Level 3

As shown in figure.2, the depth video sequence is composed of 42 frames. Figure.2(a) demonstrates the original depth map construction at level L_0 in which the entire set of frame are considered. Next, Figure.2(b) shows the depth map construction at level L_1 in which the entire action sequence is segmented in several sets and every set is composed of five frames. Here we have employed the overlapping factor as 3. For example, the first set consists of frames starting from F1 to F5, the second set consists of frames starting from F3 to F7. Hence the common frames between set 1 and set 2 are F3, F4 and F5. In this way entire sequence is segmented at level L_1. Next, at level L_2, the entire action sequence is segmented in several sets and every set is composed of five frames, as shown in Figure.2(c). Here also we have employed the overlapping factor as 3. For example, the first set consists of frames starting from F1 to F10, the second set consists of frames starting from F3 to F12. Hence the common frames between set 1 and set 2 starts from F3, and ends at F10. In this way entire sequence is segmented at level L_2.

Once the frames are segmented into different segments, then they are subjected to depth map construction through D^2MM according to the method described in [33]. Even though the traditional DMM can acquire shape and motion cues of an action effectively, several side effects present in the depth action sequence like ghost shadows, and small body shaking movements' results in some unidentifiable energy regions in DMM. To suppress these external regions, D^2MM initially computes a binary motion image based the difference between consecutive frames. Next, it measures a weighted motion score of a binary image through sliding window and based on that score, a new difference map is constructed. Finally the D^2MM is obtained by the accumulation of all the difference maps. An example output of DMM and D^2MM is shown in figure.3.

(a) (b) (c)

Figure.3 (a) Original Depth action frame, (b) DMM and (c) D^{2}MM

3.1.2TM^{2}HI

Similar to the temporal segmentation employed at TD^{2}MM, here also initially the input depth action sequence is segmented into different segments at various levels. Once the temporal segments are obtained, then they are subjected to M^{2}HI, an extension of tradition MHI. MHI was initially introduced by Bobick and Davis [34]. MHI records the temporal variations history at every pixel in the action frames of a video. MHI is a very simple and effective encoding scheme that encodes the spatial distributions of movements of an action. For this computation, MHI considers the pixel intensities of a pixel located at *(x, y)* in a temporal frame at time *t, (x, y, t).* The proposed M^{2}HI is employed over grayscale images because the grayscale images preserve the compact motion information and also makes the M^{2}HI less sensitive to noise and illumination variations. Consider an RGB-D action image sequence, with N frames, initially it is converted into grayscale image sequence and let it be $F(x,y,t), t = 0,1, \dots N-1$. Next, convert the grayscale image sequence into binary motion image sequence $B_m(x,y,t), t = 0,1, \dots N-1$, by the computation of difference between consecutive frames $F(x,y,t)$ and $F(x,y,t+1)$. Mathematically the $B_m(x,y,t)$ is obtained as;

$$B_m(x,y,t) = \begin{cases} 1, & if\ |F(x,y,t) - F(x,y,t+1)| > \tau \\ 0, & Otherwise \end{cases} \quad (1)$$

Where $F(x,y,t)$ is the pixel located at position (x,y) in a frame F at time *t*, $F(x,y,t+1)$ is the pixel located at position (x,y) in a frame F at time *t+1*. The Binary motion image can be simply defined as a temporal difference image which has larger deviations in pixel intensities. Next, τ is a pre-determined threshold that signifies the motion variations. For larger value of τ, the binary motion image obtains only the pixel which have larger deviations in their pixel intensities in the consecutive frames and vice versa. Hence the value of τ is to be determined experimentally. In our work, we have set the value of τ as 40, that means the pixels in the binary motion image will become 1 if the difference between the pixels at the same location in two consecutive frames will be greater than 40. Based on the obtained binary motion image, the MHI is computed as;

$$MHI = \sum_{t=0}^{N-2} \omega_t . B_m(x,y,t) \quad (2)$$

Where ω_t is the weight of a $B_m(x,y,t)$ at time t and is computed as

$$\omega_t = (t+1).{}^{255}/_{N} \quad (3)$$

Here ω_t follows a linearly increasing characteristic with time *t*. It signifies that the recent binary motion image has higher significance than the oldest binary motion image. This is valid only for some times because as the time progresses, the action will reach to peak and then slowly ends up. After the peak frame, the motion won't have any significance. Moreover, the frames after the peak frame won't contribute much motion information. Hence consideration of an entire set of frames for MHI construction won't have much significance in the provision of more motion information. This problem is solved by considering only a set of frames which is handled through eh temporal segmentation as described in the above subsection.

Note: the temporal segmentation is done up to 3 levels only because more number of levels constitutes an increased computational burden and less number of levels can't explore motion information effectively. Further, the speed of an action is also unknown, hence we have employed only up to three levels. For an action with high speed, the entire motion information is covered with less number of frames and vice versa. The segmented sets of frames can achieve better results in both cases due to the multi-level temporal segmentation.

In the traditional MHI, the motion region is identified through pixel-wise difference which results in some unidentified regions due to object boundaries and small body shaking movements. Such kind of undefined regions are treated as noises in the binary image sequence $B_m(x,y,t), t = 0,1, \dots, N-2$, resulting in a poor

quality MHI. To solve this problem, we have proposed a simple and effective method to remove these noises in the $B_m(x,y,t), t = 0,1,\dots,N-2$, called as Modified Motion History image (M^2HI). M^2HI employs a 2D sliding window at every pixel location (x,y,t) to decide whether the pixel belongs to the moving portion of human body or a unconnected fake moving pixel. Generally in the action image, the movement of human body occupies a larger number of pixels which results in a more number of connected pixels. In the case of binary image, the real movement of human body occupies a larger region with no-zero pixels. In other words, if the movement at pixel location (x,y,t) is a real movement (having pixel intensity 1), then the neighbor pixels within the 2D sliding window also have pixel intensities 1 only. Otherwise if the pixel at location (x,y,t) is not a real movement and if it is fake movement, then then relative pixels in its neighborhood won't have any significance, i.e., they will be 0's. to compute the motion significance of a pixel at location (x,y,t), we have computed a new score called significant motion score ($S_M(x,y,t)$) for every moving pixel in the binary image $B_m(x,y,t)$, as follows;

$$S_M(x,y,t) = \frac{1}{(w+1)^2}\sum_{i=x-(w/2)}^{x+(w/2)}\sum_{j=y-(w/2)}^{y+(w/2)} B_M(i,j,t) \qquad (4)$$

Where w is the size of sliding window, i.e., height and width. In our work, we have set the height and width value as 6, i.e., $w = 6$. After the computation of significant motion score at every pixel, then the $S_M(x,y,t)$ is checked for the significance, i.e., whether it is significant or not. This is done by comparing the $S_M(x,y,t)$ with a pre-defined threshold φ. Generally, for a fake moving pixe1, the neighbor pixels differ and the $S_M(x,y,t)$will be close to 0. Unlike, for a real movement, the neighbor pixels also have same value and the $S_M(x,y,t)$ value will be close to 1. But we can't consider only the pixels with $S_M(x,y,t) = 1$ as significant because some real movements are also exists which have $S_M(x,y,t) \approx 1\ (> 0.6)$. Hence, we have employed a threshold based decision to find the some more pixels with real movements which have $S_M(x,y,t) > \varphi$. In this phase, the $S_M(x,y,t)$ is compared with the predefined threshold, φ. If it is found to be greater than the threshold, then that pixel value is assigned as 1 otherwise zero. Based on this strategy, a new binary motion image $B_M'(x,y,t)$ is computed as follows;

$$B_M'(x,y,t) = \begin{cases} 1, & if\ B_m(x,y,t) = 1\ and\ S_M(x,y,t) > \varphi \\ 0, & otherwise \end{cases} \qquad (5)$$

In our experiments, we have set the threshold $\varphi = 0.6$. Further the new MHI, i.e., M^2HI is constructed based on the obtained new binary motion image $B_M'(x,y,t), t = 0,1,\dots,N-2$ using Eq.(2). The output of this process is a grayscale image with only real movements of the human body where the real moving pixels are more brighter and remaining are less brighter. Figure.4 shows an example of outputs obtained through MHI and M^2HI.

3.3 CNN Model

Once the human action representation is completed through TD^2MM and TM^2HI, the next step is to extract Spatio-temporal features. Here to extract such type of features, we have employed a CNN model according to the CNN model described in our earlier work [33]. The architecture of CNN model is shown in figure.5 which consist of five convolutional layers ad three pooling layers. The structural details such as number of filters and filter size of every layer are described in table.1.

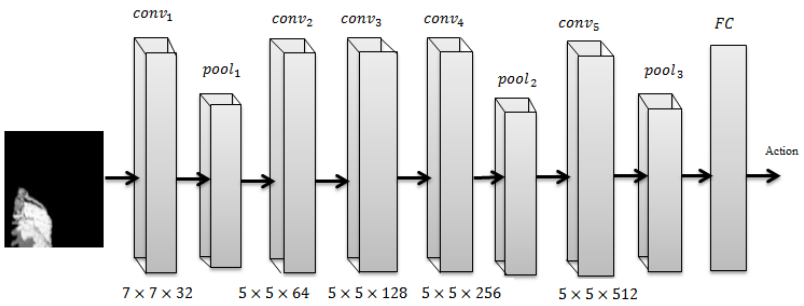

Figure.5 CNN model for action recognition

Table.1 CNN structures

Layer	Filter Size	Stride	Pad
$\boldsymbol{Conv_1}$	7×7	2×2	0
$\boldsymbol{Pool_1}$	-	2×2	-
$\boldsymbol{Conv_2}$	5×5	1×1	0
$\boldsymbol{Conv_3}$	5×5	1×1	0
$\boldsymbol{Conv_4}$	5×5	1×1	0
$\boldsymbol{Pool_2}$	-	2×2	-
$\boldsymbol{Conv_5}$	3×3	2×2	0
$\boldsymbol{Pool_3}$	-	2×2	-

3.4 Fusion for Classification

Information fusion is an important aspect in multi-modal action recognition. Basically, the fusion strategies are of three types and they are defined based on the stage at which the fusion is employed. The three types are: Early fusion (fusion of multiple data modals), Intermediate fusion (fusion of multiple features) and late fusion (fusion of multiple decisions). The early fusion needs multi modal data which have some distinct features, which is not our case since we have employed only one model. Next, the intermediate fusion is employed a feature level and it fuses different feature extracted through different feature extraction methods. This is also not suitable for our work because we didn't apply any feature extraction techniques. We have employed different action representations only. The feature extraction is done with CNN only. If we employ intermediate fusion, we have to fuse the motion maps and motion history image obtained through TD^{2}MM and TM^{2}HI, but the size of the feature maps obtained are of very large (almost equal to the size of original frame). This process required a huge memory and also this constitutes a more computation burden at classification level. Hence we have adopted late fusion and here we compute the probabilities for final fusion result calculation. The main advantage of late fusion is the possibility of simultaneous training of data of different feature maps.

In general, late fusion can be employed in two ways: unsupervised fashion and supervised fashion [34]. The supervised decision necessitates an extra training on the obtained outputs at different models. Moreover, according to [35], an additional training of classifier necessitates an extra memory usage and some distinct parameters are needed to set, which is not suitable for our work. SVM and Neural Networks (NN) are the best example for supervised learning. Unlike the supervised learning, the unsupervised learning didn't require any additional training. Majority voting is a best example for unsupervised decision strategy. In unsupervised decision making, the additional memory and additional parameter setting won't come into picture. Hence we have employed an unsupervised decision making strategy to find the final classification score.

Let's consider an action A, each of CNN model produces for each class $C_l, 1 \leq l \leq C$, a class membership probability $P(C_l|A)$. Further let's assume the probability of class membership obtained through TD^{2}MM + CNN is $P_{CD}(C_l|A^{CD})$ and the probability of class membership obtained through TM^{2}HI + CNN is $P_{CM}(C_l|A^{CM})$. Then the final probability of class membership is derived by providing a simple linear relation between $P_{CD}(C_l|A^{CD})$ and $P_{CM}(C_l|A^{CM})$, as

$$P(C_l|A) = \alpha . P_{CD}(C_l|A^{CD}) + (1 - \alpha) . P_{CM}(C_l|A^{CM}) \qquad (6)$$

Here the additional parameter α controls the significance of each model and it is determined experimentally. Along with this fusion, we also have employed two additional and most popular fusions such as product fusion and maximum fusion. Based on the obtained fused results, the final class label $\hat{C}_l$ is determined as the one which have maximum probability of class membership, obtained as;

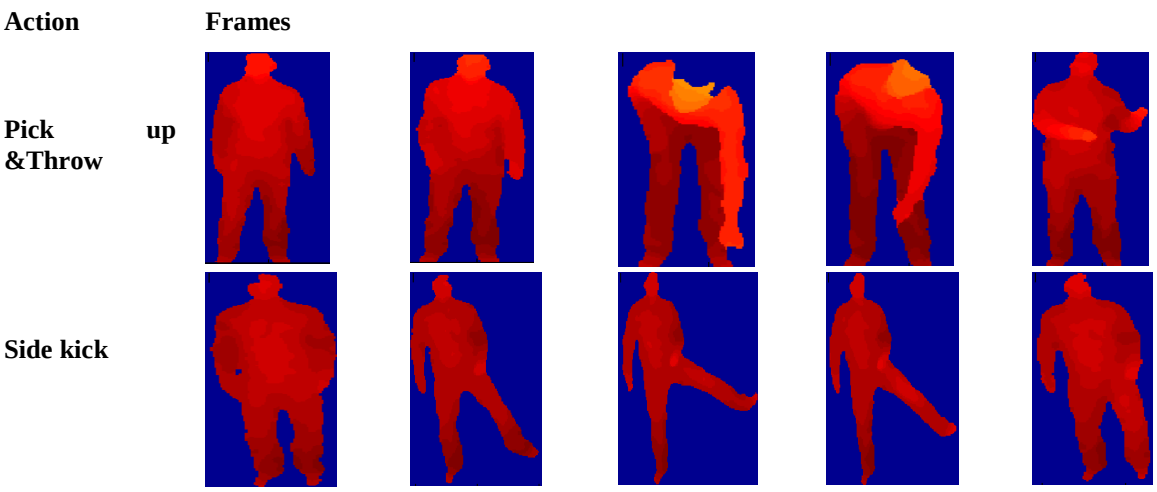
$$\hat{C}_l = \text{argmax}_{1 \leq l \leq C}\left(P(C_l|A)\right) \quad (7)$$

IV. SIMULATION EXPERIMENTS

To evaluate the proposed action recognition model, we have used totally two standard datasets and the performance is measured at several instances. Initially this section describes the details of datasets. Next, the details of performance metrics such as Recall, Positive Predictive Value (PPV), F-Score, False Negative Rate (FNR) and False Discovery Rate (FDR) are illustrated. Finally this section explores the comparison between prosed and earlier approaches.

4.1 Datasets

A. MSRAction3D dataset [36]



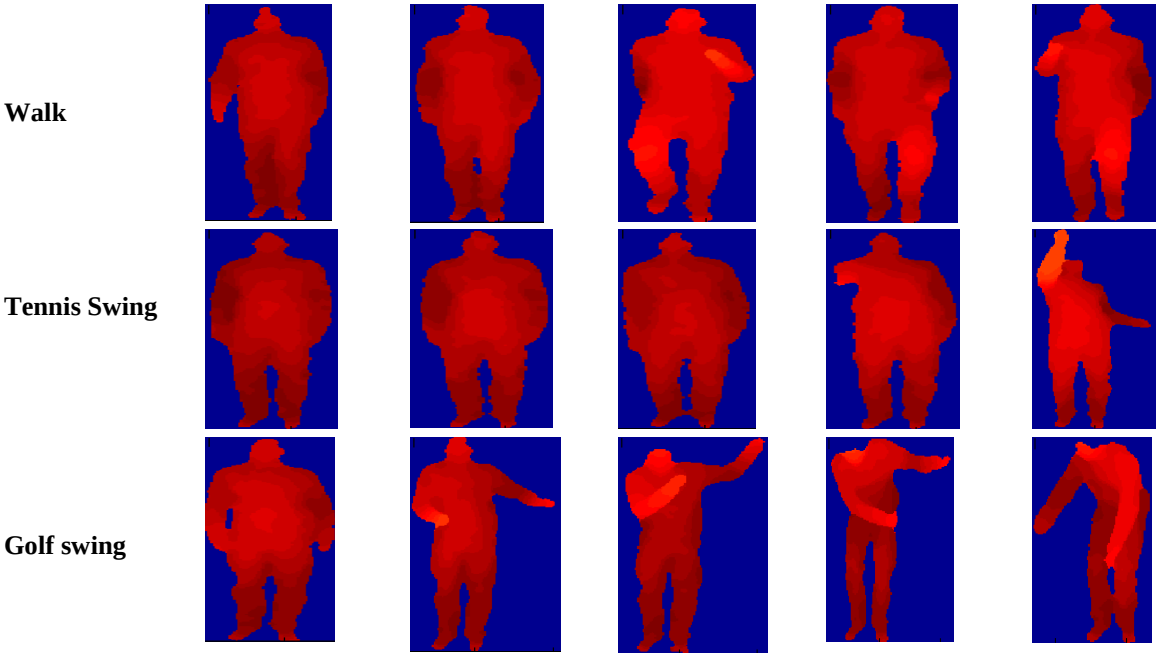
This dataset is of the most popular depth videos dataset and most of the earlier works used this dataset for validation. Totally this dataset consists of 20 different actions: “horizontal arm wave”, “high arm wave”, “high throw”, “forward punch”, “hand catch”, “hammer”, “draw tick”, “draw cross”, “draw circle”, “side boxing”, “two hand wave”, “hand clap”, “jogging”, “side kick”, “forward kick”, “bend”, “pick up & throw”, “golf swing”, and “tennis swing”. A depth camera is used to capture all these actions facing the action with front view. Totally 10 actors are used for this dataset creation and they performed each action 2 to 3 times. Since every actor has his/her own speed, the action videos of this dataset are very challenging. For example the two actions such as Draw tick and Draw cross are much similar and they are differed by just hand movement. Some samples of this dataset are shown in figure.6.

B. MSRDailyActivity3D dataset [37]

This dataset is a daily activity dataset consists of totally 16 daily activities: “Call cellphone”, “read book”, “eat”, “drink”, “cheer up”, “use vacuum cleaner”, “use laptop”, “write on paper”, “sit down”, “stand up”, “play guitar”, “walk”, “lay down on sofa”, “play game”, “toss paper”, and “sit still”. Every action is performed under two positions; one is in standby position and another is sitting in sofa position. The total number of depth videos present in this dataset is 320. This dataset contains noises and cluttered backgrounds.

4.2 Results

The simulation was done according to the even and odd basis, i.e., for ten subjects of MSR action 3D dataset, the action performed by even number actors are trained and the actions performed by odd number actors are tested. This type of validation is called as cross action validation means the trained and tested actions are not same. Here the actions with actor numbers 1, 3, 5 7 and 9 are trained and the actions with actor numbers 2, 4, 6, 8 and 10 are tested. After testing, the performance is measured through several performance metrics and they are shown in the following table.2 andtable.3.



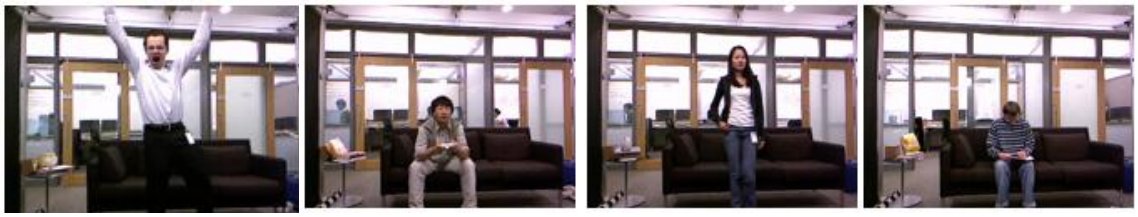


Figure.6 some samples of MSRAction3D dataset

Figure.7 some samples of MSR Daily Activity 3D dataset (a) Cheer up, (b) Play game (c) Stand up, and (d) Read book

Table.2 Performance Metrics of MSR action 3D dataset for different actions

Action/Metric	**TPR (%)**	**PPV (%)**	**F-Score (%)**	**FNR (%)**	**FDR (%)**
High Arm Wave	86.0459	100.00	92.4996	13.9541	0000
Horizontal Arm Wave	94.9294	86.5292	90.5348	5.07060	13.4708
Hammer	100.00	100.00	100.00	0000	0000
Hand Catch	79.28922	90.9392	84.7155	20.7107	9.0608
Forward Punch	89.27212	100.00	94.3320	10.7278	0000
High Throw	96.22742	92.4931	94.3233	3.77258	7.5069
Draw Cross	83.29362	93.9394	88.2967	16.7063	6.0605
Draw Tick	95.48432	89.0622	92.1615	4.51568	10.9378
Draw Circle	95.68222	100.00	97.7934	4.31778	0000
Hand Clap	96.59922	87.2936	91.7109	3.40078	12.7064
Two-Hand Wave	100.00	94.8575	97.2254	0000	5.1425
Side-boxing	100.00	100.00	100.00	0000	0000
Bend	87.2547	90.2364	88.7205	12.7452	9.7636
Forward Kick	100.00	97.1294	98.5437	0000	2.8706
Side Kick	100.00	93.2215	96.8854	0000	6.7785

Jogging	100.00	100.00	100.00	0000	0000
Tennis Swing	95.5336	89.0598	92.1831	4.46639	10.9402
Tennis Serve	95.2725	91.4785	93.3369	4.72750	8.5215
Golf Swing	93.1294	97.5992	95.3119	6.87060	2.4008
Pick Up & Throw	91.5992	98.4500	95.6154	8.40080	1.5523

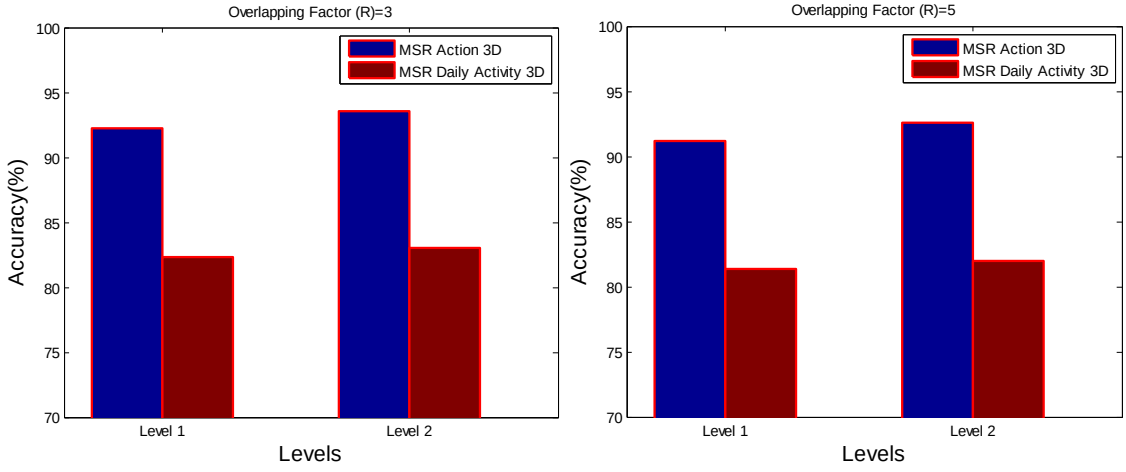

Table.2 shows the details of performance metrics obtained after the simulation of proposed recognition framework over MSR action 3D dataset. The performance evaluation is accomplished totally throng fie metrics such as Recall, PPV, F-score, FNR and FDR. From the results shown in the above table, we have noticed that the maximum recall (100%) is obtained for totally six actions and they are Jogging, Side kick, Forward kick, Two-hand wave, side boxing and Hammer. And the minimum recall is noticed for Hand catch (79.28922%). The next minimum s achieved for Draw cross action (83.29362%). Next, the maximum PPV (100%) is achieved for totally six actions and they are Jogging, side boxing, draw circle, forward punch, hammer and high arm wave. And the minimum PPV is noticed for Horizontal Arm Wave (86.5292%). The next minimum s achieved for Draw Tick action (89.0622%). The main reason behind the les recall rate or less PPV of draw cross and draw circle actions is the structural similarity between them. The three actions namely Draw Tick, Draw cross and Draw circle have almost same movements expect the hand movements and this this main of less PPV. For a given draw cross action frame, the system recognized it as either draw circle or draw tick and hence it has less recall rate. Similarly for a given other inputs like Draw Circle and Draw Cross actions, the system mostly recognized them as draw ticks and hence it has less PPV.

Next, the maximum F-Score (100%) is observed at totally three actions they are hammer, jogging and side boxing. And minimum F-Score is noticed for Hand catch action (84.7155%). The next metrics such as FN and FDR follows an inverse relation with Recall and PPV respectively. Hence for an action which has gained maximum recall will have less FNR and the action which has gained maximum PPV will have less FDR. Based on this we have noticed the minimum FNR (0%) for six actions and they are Jogging, Side kick, Forward kick, Two-hand wave, side boxing and Hammer. And maximum FNR is observed for Hand catch (20.7107%). Similarly, the minimum FDR (0%) is observed for totally six actions and they are Jogging, side boxing, draw circle, forward punch, hammer and high arm wave. And the maximum FDR is noticed for Horizontal Arm Wave (13.4708%).

Table.3 Performance Metrics of MSR daily activity 3D dataset for different actions

Action/Metric	**TPR (%)**	**PPV (%)**	**F-Score (%)**	**FNR (%)**	**FDR (%)**
Drink	86.2234	71.4458	78.1421	13.7765	28.5542
Eat	85.4127	90.1147	87.7007	14.5873	9.88530
Read book	95.2252	82.6693	88.5861	4.58480	17.3307
Call cellphone	66.3145	65.2471	65.7764	33.6855	34.7529
Write on a paper	92.1345	86.3312	89.2226	7.68550	13.6688
Use laptop	93.1124	75.4214	83.3383	6.88760	24.5786
Use vacuum cleaner	89.2341	92.3312	90.8495	10.5853	7.66880
Cheer up	76.4147	95.4574	84.8811	23.5853	4.54259
Sit still	96.0032	84.4414	89.8518	3.99679	15.5586
Toss paper	66.1457	89.4578	76.0554	33.8543	10.5422
Play game	50.2345	85.3369	63.2413	49.7655	14.6631
Lay down on sofa	89.4574	75.4878	81.8810	10.5426	24.5122
Walk	85.7741	88.6996	87.2123	14.2259	11.3004
Play guitar	90.3336	75.8858	82.4817	9.66640	24.1142
Stand up	88.8854	85.6653	87.2456	11.1146	14.3347
Sit down	89.4175	92.4578	90.9122	10.5825	7.54219

Table.3 shows the obtained Performance Metrics after the simulation of proposed recognition framework over MSR daily activity 3D dataset. Towards this simulation, we have considered both set of action depth videos (action videos captured under two positions such as Standby and siting in sofa position) for training and testing. Similar to the above simulation, here also the validation is done through cross subjects, i.e., the subjects of 1, 3, 5, 7, 9 are trained and the subjects of 2, 4, 6, 8, and 10 are tested. In this simulation we have noticed that some actions like read book, use laptop, play guitar and sit still has very much less movements and hence they can be considered as 3D video with static motions. These actions are also processed for simulation and we observed maximum recognition performance. From the table.3, we have noticed that that maximum recall (96.0032%), precision (95.4574%), and F-Score (90.9122%), are obtained for actions sit still, cheer up, and sit down respectively. Next the minimum recall (50.2345%), precision (65.2471%), and F-Score (63.2413%), are obtained for actions Play game, Call cellphone, and play game respectively. Next, the maximum FNR (49.7655%) and FDR (34.7529%) are observed for actions play game and call cell phone respectively. Finally the minimum FNR (3.9967%) and FDR (4.54259%) are observed for actions sit still and cheer up respectively.

(a) **(b)**

Figure.8 Accuracy at different overlapping factors (a) R = 3, and (b) R = 5

To alleviate the effectiveness of temporal segmentation, we have simulated the proposed action recognition model with varying overlapping factors (R) at both Level 1 and Level. At level, the frames length is considered as 5 and at level 2, the frame length is considered as 10. Initially at both level, we have segmented the frames with overlapping factor R=3 and next with overlapping factor R = 5. After the simulation though these parameters, the obtained accuracy are shown in figure.8, where 8(a) is the accuracy at R = 3 and the 8(b) is the accuracy at R = 5. From these results we have noticed that as the frame length increases, the accuracy also increase but up to certain extent only. For example, the accuracy at level 1 (frame length = 5) for MSR action 3D dataset is observed as (92.2212% whereas it is of 93.5568% at level 2 (frame length = 10).

Similarly the accuracy at level 1 for MSR daily activity 3D dataset is observed as 82.3452% whereas it is of 83.0012% at level 2. Further we have noticed that as the overlapping factor, R value increases, the accuracy reduces. This is illustrates with the following values; the accuracy obtained for MSR action 3D dataset at R=3 and level 1 is observed as 92.2212% whereas it is of 91.2212% at R = 5 at the same level. Similarly the accuracy of MSR action 3D dataset at R=3 and level 2 is observed as 93.5568% whereas it is of 92.1023% at R = 5 at the same level. The similar nature of accuracy results are observed for MSR daily activity 3D dataset also. For instance, the accuracy of MSR daily activity 3D dataset at R=3 and level 1 is observed as 82.3452% whereas it is of 81.3321% at R = 5 at the same level. Similarly the accuracy of MSR daily activity 3D dataset at R=3 and level 2 is observed as 83.0012% whereas it is of 82.3214% at R = 5 at the same level.

4.3 Comparison

Table.4 shows the comparison between the proposed and conventional approaches through recognition accuracy on the both MSR action 3D and MSR daily activity 3D datasets. LOP [38] and actionlet [38] are the two typical features which are mainly focused on the encoding of depth data. These methods have limited accuracies, which reflects the challenges (e.g. cluttered backgrounds and noises) of the dataset especially MSR Daily Activity 3D dataset. Using DMM with HOG, X. Yang et al., [8] achieved an accuracy of 88.73% while this approach is not able to capture the body shaking movements due to the simple DMM. Next, combining the

DMM with DMA, Kim D et al., [32] achieved an accuracy of 90.4500% which is more sensitive to the noise and textural variations in the depth action videos. To overcome this problem, Chen et al., [21], [23] employed LBP over the obtained DMM and every action is represented with a fisher kernel vector. Though these methods have gained a better recognition performance, they are not focused over the presence of fake moving pixels in the DMM. These fake moving pixels are derived due to several reasons like small body shaking movements, cluttered backgrounds and low resolution cameras. The conventional DMM cannot capture such kind of noises and hence the proposed approach has better performance compared to them. On an average the recognition accuracy of DMM + LBP methods is noticed as 91.20% while the proposed D^2MM+M^2HI+CNN is noticed as 93.6410%, shows an improvement of 2.44% in recognition accuracy.

Table.4 Comparative analysis through accuracy

Method	**Dataset**	**Accuracy (%)**
DTW [16]	MSR Action 3D	63.8900
DMM + HOG [8]	MSR Action 3D	88.7300
HON4D [20]	MSR Action 3D	88.9300
DMA + DMH + HOG [32]	MSR Action 3D	90.4500
Actionlet Ensemble [38]	MSR Daily Activity 3D	74.2200
STIPs (Harris3D+HOG3D) [18]	MSR Daily Activity 3D	60.6000
DMM + LBP [23]	MSR Action 3D	90.5000
DMM + LBP + FV [21]	MSR Daily Activity 3D	84.000
DMM + LBP+ LF [21]	MSR Action 3D	91.9000
LOP Features [38]	MSR Daily Activity 3D	42.5000
D^2MM-CNN [33]	MSR Action 3D	91.5900
D^2MM-CNN	MSR Daily Activity 3D	**85.2330**
M^2HI-CNN	MSR Action 3D	**90.3620**
M^2HI-CNN	MSR Daily Activity 3D	**83.3320**
D^2MM+ M^2HI+CNN	MSR Daily Activity 3D	**87.7850**
D^2MM+ M^2HI+CNN	MSR Action 3D	**93.6410**

Our recent method, i.e., D^2MM-CNN [33] has developed an extension to the conventional and DMM obtained an accuracy of 91.5900% after the simulation over MSR Action 3D dataset. Here the same method is applied over the MSR Daily Activity 3D dataset and the recognition accuracy is observe as 85.2330% while for conventional approaches, like STIPs (Harris3D+HOG3D) [18] and Actionlet Ensemble [38], it is of 60.6000% and 74.2200% which is very less. Next, Chen at al., [21] also applied the DMM + LBP+ FV method over MSR Daily Activity 3D dataset and obtained an accuracy of 84.000% which is 1.233% less than the proposed D^2MM-CNN.

Next, another proposed method, M^2HI-CNN applied over two dataset and gained an accuracy of 90.3620% and 83.3320%. Compared to the conventional approaches, this method also gained a better performance because it has efficiently encoded the motion information by finding the face movements in the human body. Finally the average accuracy of integrated method (i.e., D^2MM+ M^2HI+CNN) has obtained an accuracy of 93.6410% and 87.7850% after its accomplishment over the MSR Action 3D and MSR Daily Activity 3D datasets respectively, which is high, compared to all the earlier methods. The main reason is that the proposed action representation model is more resilient to the side effects present in the actions videos such as body movements and cluttered backgrounds etc.

V. CONCLUSION

In this paper, we have proposed a new action descriptor which can identify the real and fake motions in the actions videos and encodes the temporal information between sequences of frames. The proposed descriptor is an integrated form which was constructed by combining depth motion map and motion history information of a depth video. The newly proposed Difference Depth Motion Map can remove the cluttered backgrounds

effectively and can also derive the motion information in the low resolution videos. Further the newly proposed Modified Motion History Image can differentiate the real movements from fake movements and can represent the motion image much effectively. Before the action representation, to include much motion information, a new segmentation called a temporal segmentation s employed at different levels. Simulation experiments are conducted over MSR action 3D dataset and MSR daily activity 3D dataset and the obtained results out-performs the state-of-art methods.

Abstract

Psychological wellness conditions influence a noteworthy level of the world's population every year. The stress investigation of emotional wellness phenomena in openly accessible social networking sites like Twitter, Sina Weibo and Facebook. A set of stress-related textual, visual, and social attributes from various aspects are first defined and then propose a novel hybrid model. The work has demonstrated the utility of online social information for contemplating despondency, be that as it may, there have been limited assessments of other mental wellbeing conditions. It is not easy to access the user posts on their Facebook page. In order to obtain the user data from Facebook, system have to get the access token from Facebook developer page. The API act as an intermediate system that will help the system to analysis the user information from the Facebook page. The system will also help to Recommending users with different links for psychological counselling centers, soft music or articles to help release their stress according to users' stress level

Key words: *Stress detection, social media, microblog, access tokens, and face book.*

1. Introduction

More and more teenagers today are overloaded with adolescent stress from different aspects: academic future, self-cognition, interpersonal, and affection. Long-lasting stress may lead to anxiety, withdrawal, aggression, or poor coping skills such as drug and alcohol use, threatening teenagers' health and development. Hence, it is important for both teenagers and their guardians/teachers to be aware of the stress in advance and manage the stress before it becomes severe and starts causing health problems. The current social media micro-blog offers an open channel for us to timely and unobtrusively sense teenager's stress based on his/her tweeting contents and behaviours. This study describes a framework to further predict teenager's future adolescent stress level from micro-blog and discusses how we address the challenges (data incompleteness and multifaceted prediction) using machine learning and multi-variant time series prediction techniques. Forthcoming events that may possibly influence teenager's stress levels are also incorporated into our prediction method. Our experimental results demonstrate the effectiveness of considering correlated features and event influence in prediction. To the best of our knowledge, this is the first work on predicting teenager's future stress level via micro-blog. College can be stressful for many freshmen as they cope with a variety of academic, personal, and social pressures. Although not all stress is negative, a certain level of stress can be beneficial to help improve performance. However, too much stress can adversely affect health in the annual survey of the American Freshman; the number of students reported feeling overwhelmed and stressed has increased steadily in the last decade. Over 50% of college students suffer significant levels of stress during a typical college semester.

 Copyright © 2020 Authors

Consequently, there is a need to find innovative and cost-effective strategies to help identify those students experiencing high levels of stress and negative emotions early on so that they can receive the appropriate treatment in order to prevent future mental illnesses. Social media use, such as Twitter and Facebook, has been rapidly growing, and research has already shown that data from these technologies can be used for novel approaches to public health surveillance . Twitter usage among young adults has increased 16% from 2012 to 2014. Currently, 32% of adults of the ages 18-29 years use Twitter, and the usage is expected to increase steadily in the future. People often have the need to share their emotions and experiences . Researchers have theorized that emotional sharing may fulfil a socio-affective need by eliciting attention, affection, and social support. Consequently, this may help individuals cope with their emotions and provide an immediate relief . Users often share their thoughts, feelings, and opinions on these social media platforms, and as a result, social media data may be used to provide real-time monitoring of stress and emotional state among college students.

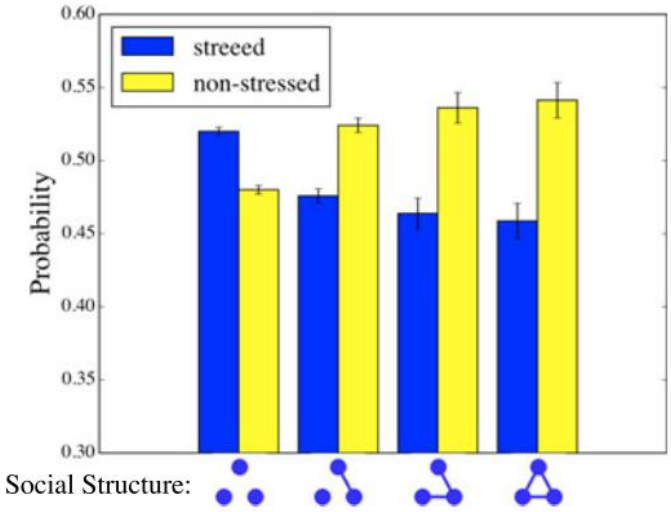

Figure 1. The sampling test results of the diversity of the user's social structures form Sina Weibo

Previous studies have shown that Twitter data can be used to monitor a wide range of health outcomes, such as detecting human immunodeficiency virus infection outbreaks and predicting an individual's risk of depression . For example, De Choudhury et al conducted one of the first studies that used an individual's tweets to predict the risk of depression . The authors found that certain features extracted from a person's tweets collected over a 1-year period were highly associated with the risk of depression in adults, such as raised negative sentiment in the tweets, frequent mentions of antidepressant medication, and greater expression of religious involvement. Currently, no studies have examined whether Twitter data can be used to monitor stress level and emotional state among college students. Studying this topic is important because the large amount of social media data from college students' frequent use of social media can be used to help university officials and researchers monitor and reduce stress among college students.

2. Proposed System

Inspired by psychological theories, we first define a set of attributes for stress detection from tweet-level and user-level aspects respectively: 1) tweet-level attributes from content of user's single tweet, and 2) user level attributes from user's weekly tweets. The tweet-level attributes are mainly composed of linguistic, visual, and social attention (i.e., being liked, retweeted, or commented) attributes extracted from a single-tweet's text, image, and attention list. The user-level attributes however are composed of: (a) posting

 Copyright © 2020 Authors

behavior attributes as summarized from a user's weekly tweet postings; and (b) social interaction attributes extracted from a user's social interactions with friends. In particular, the social interaction attributes can further be broken into: (i) social interaction content attributes extracted from the content of users' social interactions with friends; and (ii) social interaction structure attributes extracted from the structures of users' social interactions with friends.

2.1. Advantages

Experimental results show that by exploiting the users' social interaction attributes, the proposed model can improve the detection performance (F1-score) by 6-9% over that of the state-of-art methods. This indicates that the proposed attributes can serve as good cues in tackling the data sparsity and ambiguity problem. Moreover, the proposed model can also efficiently combine tweet content and social interaction to enhance the stress detection performance.

Beyond user's tweeting contents, we analyzed the correlation of users' stress states and their social interactions on the networks, and address the problem from the standpoints of:

(1) social interaction content, by investigating the content differences between stressed and non-stressed users' social interactions; and

(2) social interaction structure, by investigating the structure differences in terms of structural diversity, social influence, and strong/weak tie.

We build several stressed-twitter-posting datasets by different ground-truth labelling methods from several popular social media platforms and thoroughly evaluate our proposed method on multiple aspects.

We carry out in-depth studies on a real-world large-scale dataset and gain insights on correlations between social interactions and stress, as well as social structures of stressed users.

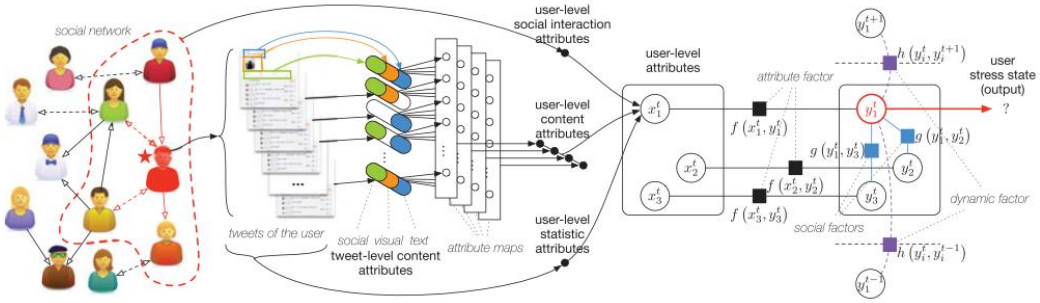

Figure. 2 Architecture of proposed stress detection model

3. Implementation

3.1. System Framework

In this framework we propose a novel hybrid model - a factor graph model combined with Convolution Neural Network to leverage tweet content and social interaction information for stress detection. Experimental results show that the proposed model can improve the detection performance by 6-9% in F1-score. By further analysing the social interaction data, we also discover several intriguing phenomena, i.e. the number of social structures of sparse connections (i.e. with no delta connections) of stressed users is around 14% higher than that of non-stressed users, indicating that the social structure of stressed users' friends tend to be less connected and less complicated than that of non-stressed users.

 Copyright © 2020 Authors

3.2. Social Interactions

We analyzed the correlation of users' stress states and their social interactions on the networks, and address the problem from the standpoints of:

(1) social interaction content, by investigating the content differences between stressed and non-stressed users' social interactions; and

(2) social interaction structure, by investigating the structure differences in terms of structural diversity, social influence, and strong/weak tie. Our investigation unveils some intriguing social phenomena. For example, we find that the number of social structures of sparse connection (i.e. with no delta connections4) of stressed users is around 14% higher than that of non-stressed users, indicating that the social structure of stressed users' friends tend to be less connected and complicated, compared to that of non-stressed users.

3.3. Attributes categorization

We first define two sets of attributes to measure the differences of the stressed and non-stressed users on social media platforms: 1) tweet-level attributes from a user's single tweet; 2) user level attributes summarized from a user's weekly tweets.

3.4. Tweet-level Attributes

Tweet-level attributes describe the linguistic and visual content, as well as social attention factors (being liked, commented, and retweeted) of a single tweet. We can classify words into different categories, e.g. positive/negative emotion words, degree adverbs. Furthermore, we extract linguistic attributes of emoticons, so we can map the keyword in square brackets to find the emoticons. Twitter adopts Unicode as the representation for all emojis, which can be extracted directly.

3.5. User-Level Attributes

Compared to tweet-level attributes extracted from a single tweet, user-level attributes are extracted from a list of user's tweets in a specific sampling period. We use one week as the sampling period in this paper. On one hand, psychological stress often results from cumulative events or mental states. On the other hand, users may express their chronic stress in a series of tweets rather than one. Besides, the social interaction patterns of users in a period also contain useful information for stress detection. Moreover, as aforementioned, the information in tweets is limited and sparse. We need to integrate more complementary information around tweets, e.g., users' social interactions with friends.

4. Conclusion

Psychological stress is threatening people's health. It is non-trivial to detect stress timely for proactive care. Therefore, we have presented a framework for detecting user's psychological stress states from user's monthly social media data, leveraging Facebook post content as well as user's social interactions. Employing real-world social media data as the basis, we studied the correlation between user's psychological stress states and their social interaction behaviours. We recommend the user for health consultant or doctor. We show the hospitals for further treatment on a graph which locate shortest path from current location of user to that hospital. We recommended the user for health precaution and send mail for user interaction purpose.

Abstract

Agriculture aims at cultivating crops to gratify the human needs. A study claims that nearly 50% of crops are being affected with diseases in early stages. Even though there exists many traditional approaches to eradicate the early stage diseases, the implication of digital technology lays a foundation in a efficient manner. Early diagnosis not only reduces time and money, also avoids spread of diseases to other crops, in turn improving the overall production. By considering this fact in the mind (as the focal area), the paper proposes an approach to categorize diseases in the tomato plant leaf at an early stage(s). The proposed method adopts clustering technique to cluster the disease affected regions and extract the features from those regions subject to classification process. The techniques adopted for clustering, feature extraction and classification are K-Means, Discrete Wavelet Transform (DWT) followed by Gray Level Co-occurrence Matrix (GLCM) and Neural Networks (NN) respectively. The proposed approach is assessed on the standard dataset images from Kaggle repository. Among various classes of leaf categories, randomly 50 images are chosen from each category to evaluate the proposed method. Experimental findings unfold that the proposed disease identification plays a vital role in early stages that the existing state-of-the-algorithms.

1. Introduction

The planet earth is crammed with plant life irrespective of the location in the world. Plant life, one of the parts in eco-system, makes the world sustain. Unlike various land forms-hills, mountains, plains, plateaus and basins, the plants that grow in these land forms also show discrepancy. An apple tree that grows in temperate zone cannot be grown in tropical zone. The flora depends upon the land form of specific region. To develop a conservative and sustainable eco-system for future generation, humanity should preserve the flora of each and every landform.

The humanity is dependent on agriculture for its daily livelihood. The boom of computer vision in fields of communication, science and technology, transportation ended up with numerous contemporary techniques such as Biometrics, Artificial intelligence, drones and many more. Computer vision needs to be extended in the field of agriculture too.

Agriculture aims at cultivating quality crops to gratify the human needs. In turn, the crops are qualitative if and only if the plants are not diseased. 50% of overall plant life in agriculture is diseased. Certain traditional technique in eradication of the diseases is suitable for meager plant diseases. Identification of diseases in early stage avoids further spread of disease in plants. At this

Copyright ⓒ2020 SERSC

juncture, Image Processing Technique contributes production of quality plants to achieve increased yield.

The diseases affected in plants might be due to biotic or abiotic factors. For instance, symptom like disease reflection in leaf of the plants (which is not the only symptom) are well analyzed by a farmer based on prior experience. Other symptoms that aid in identification include soil analysis and pH measurement, microscopic examination, and microscopic methods [4]. Early diagnosis of diseases, help the farmers to

- Identify disease causing agent.
- Minimize waste of time and money, and
- Prevent irreparable damage even before visualizing.

To achieve aforesaid advantages, scientific diagnosis techniques such as Multilayer Perceptron (MLP) Neural Network , Thresholding, Dual-segmented regression, Color-based, Quantification, Fuzzy-logic, Feature-based, Knowledge-based, Discriminant analysis, Region growing techniques, Third party image processing packages, Support Vector Machine and many more are used [5].

2. Existing Methods

The following section summarizes the salient features of existing (tomato) plant leaf classification disease

Hiteshawari Sabrol and Satish Kumar [6] studied Gray-Level Spatial Dependence-based approach for Feature Extraction to recognize the plant disease with Adaptive Neuro Fuzzy classifier to classify the diseased plants. When the method was tested on TDPS1.0 and BPDS 1.0 dataset recognition accuracy of 90.7% and 98% was achieved for tomato and brinjal/eggplant, respectively. Ning Fu, Chong Wang, and Xiaowen Ji [7] examined corn leaf spot disease through Fuzzy technology. The corn lesions were clearly identified from the sample images which were classified as Class A –maize leaf spot identification, Class B – corn leaf spot disease recognition, Class C – disease identification by patch superimposition and the recognition accuracy was 89.76, 87.43, and 85.6 respectively. The authors measured real time data samples including plant foliage via image processing thus enhancing the efficiency of the study.

Amrita Tulshan and Natasha Raul [8] identified plant leaf disease using Machine Learning – KNN classifier the type of plant disease were also identified. The plant leaf images underwent pre-processing, segmentation and feature extraction stages and the outputs of every stage processed in KNN classifier by the textural feature based algorithm classified the diseased leaf as well as its type. The results of the algorithm used for the study when compared with SVM classifier yielded 98.56% accuracy for 75 leaf images. Sammy Militante, Bobby Gerardo and Nanette DIonisio [9] utilized Deep learning to detect and recognize the diseases in plant leaves. 35,000 images of the Plant Village Repository were used for the testing. The images acquired were resized into 96X96 resolutions for processing. The multi layered convolution neural network classified the infected diseases with the accuracy rate of 96.5%. The model also yielded more than 99% accuracy result for plants like tomato, grape and apple plants.

Sherly Annabel, Annapoorani and Deepalakshmi [10] reviewed machine learning techniques for detecting the plant leaf disease followed by classification. The authors' detected disease in various plant leaves such as rice, grape, cotton, soybean, sugarcane via machine learning algorithms like SVM, Multi SVM, K-Means clustering, Fuzzy C-Means, CNN, ANN, Back propagation neural network, Decision tree, Multi layer perceptrons and many more. The comparative chart designed by the authors revealed the type of disease detected in the respective methods. Further, the comparison of classification algorithms not only disclosed the accuracy of algorithms but also the pros and cons of using each algorithm. Akshay Kumar and Vani [11] detected the diseases affected from tomato leaf images by means of Convolutional Neural Network (CNN). 14,803 images from Plant village dataset were studied. Among various architectures in CNN, LeNet, VGGNet, ResNet50 and Xception architectures were investigated. During investigation, VGGNet achieved an accuracy rate of 99.25%.

Copyright ⓒ2020 SERSC

Rath and Meher [12] detected brown spot and blast diseases in rice plants by the method of computation. The dataset images include normal, brown spot and blast diseased rice plants obtained from the crop fields and other public domains among which 100 images were used as the training dataset. PCA preprocesses the images, Gabor Filtering technique extracted shape and texture features and finally to detect the diseases Radial Basis Function Neural Network classifier was used. The performance of the aforesaid steps when evaluated using metrics such as accuracy, recall and precision was 95%, 95% and 97%, respectively. Santhana Hari, Sivakumar, Renuga, Karthikeyan and Suriya [13] identified and detected plant diseases from the images through the technique of Convolutional Neural Network. The put forth Plant Disease Detection Neural Network (PDDNN) has 16 layers like input layer, convolutional, maxpooling, ReLu activation layer and fully connected layer. The dataset includes defected images of various plants and 400 images were treated as training dataset. Accuracy rate of 86% was achieved when the performance was evaluated.

Rishabh Yadav, Yogesh and Sushama [14] exploited Particle Swarm Optimization technique to identify, detect and classify diseases that occurs in plant leaves. The acquired 8750 plant leaf images from Plant Village dataset were pre-processed and resized to 250X250 pixel size. With the aid of Alexnet, the features were extracted from the resized images and passed into PSO to deduce and optimize the extracted features. Finally, the leaf diseases were classified by the classifiers like XGBoost, Random Forest, KNN and SVM classifiers among which SVM classifier classified the images with the cross validation accuracy of 99.07%. Mosin, Bhavesh and Krina [15] utilized drones based Precision Farming method in the field to identify disease affected area and minimized the usage of pesticide based on leaf category such as good, bad or average. To categorize the leaf images from drones, the inception model in CNN trained the dataset. The model achieved accuracy of 99% on 2600 images procured from internet and local farms.

3. Materials and Methods

This section unfolds the procedure for early disease identification of tomato plant leaves adopted in the proposed approach and incorporates the clustering based and feature selection methods for extracting the disease affected regions of the tomato plant leaf. The plant village dataset is collected from [1], which consists of ten class of tomato leaf classes namely, (1) class 1: leaf affected with target spot (2) class 2: leaf affected with mosaic virus (3) class 3: leaf affected with yellow leaf curl virus (4) class 4: leaf affected with bacterial spot (5) class 5: leaf affected with early blight (6) class 6: healthy leaf (7) class 7: leaf affected with late blight (8) class 8: leaf affected with mold (9) class 9: leaf affected with Septoria leaf spot and (10) class 10: leaf affected with two spotted spider mite disease. Table 1 shows the dataset specification details with respect to tomato leaf diseases. Various classes of tomato plant leaves from Class 1 to Class 10 is illustrated from (a) to (j), respectively. Figure 1 shows few tomato leaves affected various diseases collected from [1].

Table 1. Dataset Description

Sl . No	Class Names	Total Count	No. of Images chosen randomly

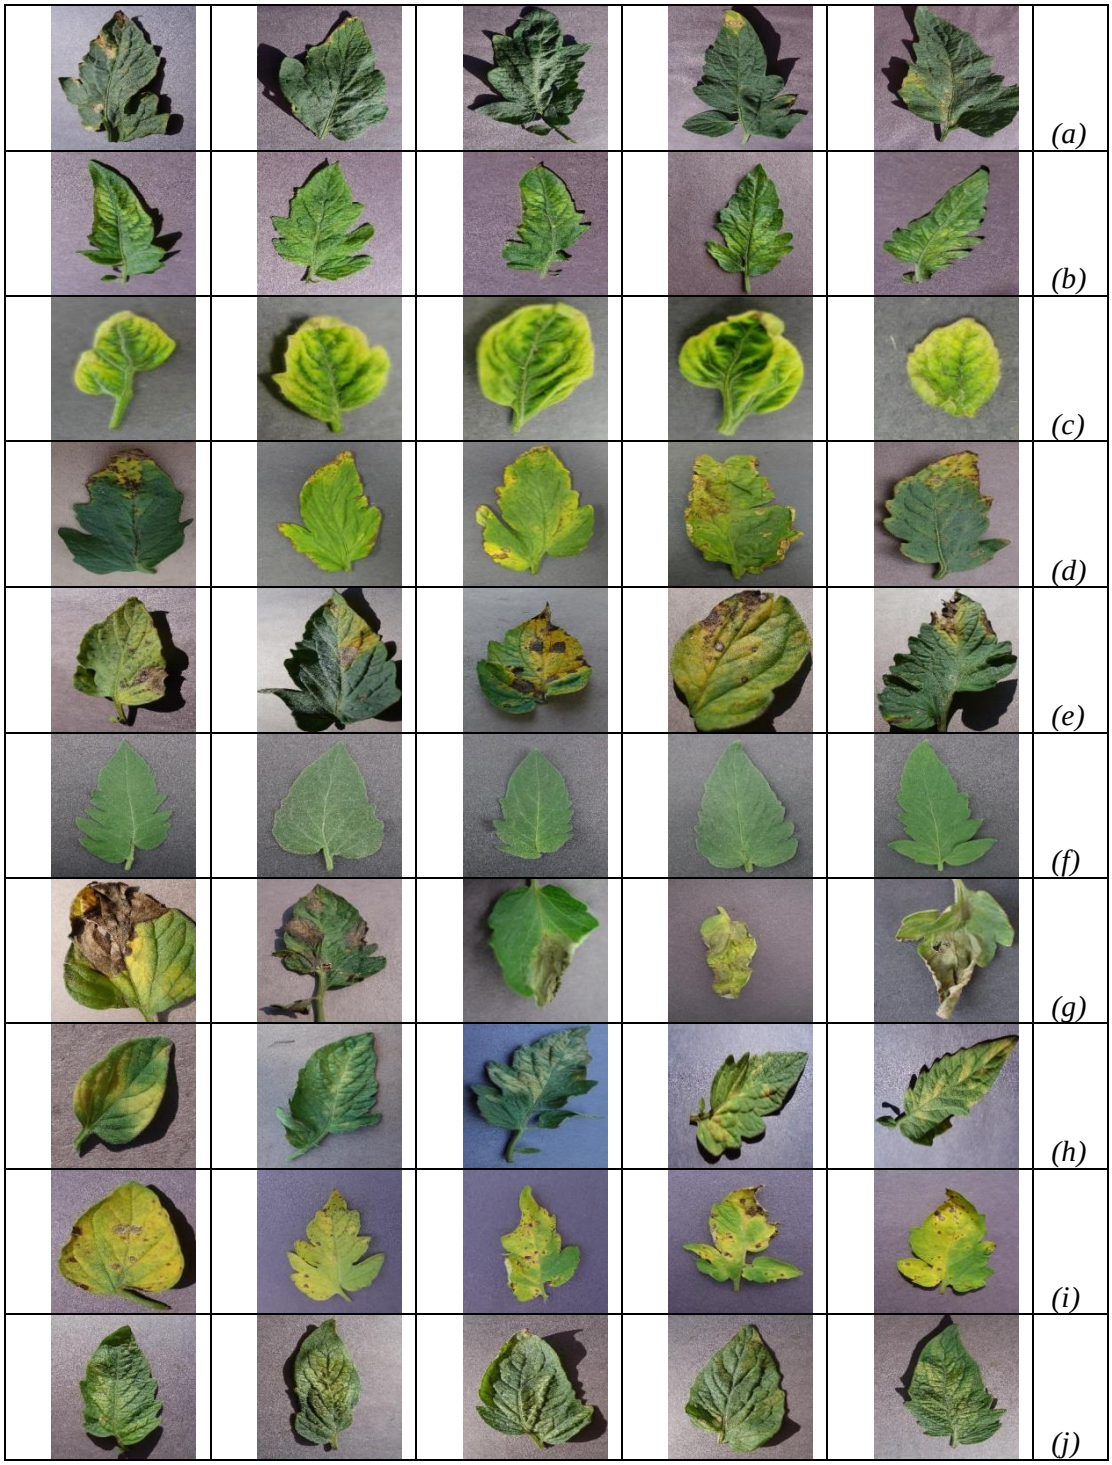

Figure 1. Samples tomato plant leaves affected with various diseases collected from [1]

3.1 Approach

The proposed method has three steps namely, (1) Clustering (2) Feature Extraction (FE) and (3) Classification. The techniques adopted in the proposed method are K-Means for Clustering, Discrete Wavelet Transform (DWT) and GLCM for FE and finally the Neural Networks (NN) for classification. Figure 2 shows the pseudo code of the proposed tomato leaf disease detection method.

Input: Leaf Image

Output: Disease Category

Read the Input Image.

2. Cluster the affected region using K-Means Clustering Technique.
3. From the resultant clustered image, choose the leaf affected cluster area and repeat the following:
   a. Extract the DCT features.
   b. Extract GLCM features from the resultant image.
   c. Apply the Neural Networks (with the specified features) on the extracted GLCM features.
   d. Maximum value in the corresponding row (index) determines the corresponding type of disease.

Figure 2. Pseudo Code for the

Proposed Tomato Leaf Disease Detection Method

The simplest clustering technique, K-Means Clustering, is adopted in the proposed method to cluster the disease affected regions in the tomato plant leaves. It includes the following steps summarized from [16]:

a) Initially, random points are selected (in this case, the product of rows and columns in the input image is considered) as cluster center.

b) Number of random centroid is chosen as ten.

c) Based on the distance between the chosen centroid and the other points, those points are clustered to the concern centroid(s) with respect to the minimum distance.

d) The cluster center(s) are revised in accordance with the mean of designated observations.

e) The above two steps (step (c) and step (d)) are repeated till the convergence occurs.

Finally, the outcome of K-Means Clustering approach is the clustered regions of disease affected and unaffected regions in the input tomato plant leaf. Figure 3 shows the resultant of clustering operations for a sample image from [1], where the Figure 3 (a), (b), (c), (d) and (e) represents the input image, clustering operations, Clustered Region 1 (CR1 – the clustering of leaf portion affected with disease), CR2 - unaffected leaf portion and CR3 - the clustered leaf, respectively.

Input Image (a) | **Clustering Operation (b)** | **CR1 (c)** | **CR2 (d)** | **CR3 (e)**

Figure 3. Resultant of Clustering operations for a sample image

Copyright ⓒ2020 SERSC

In the FE method, the proposed method adopts DWT and GLCM approaches for extracting the predominant features of the input tomato leaf. In general, one dimensional (1D) DWT perform operations on vector, which is of length 2x, (where x ranges from 2, 3, and so on) and produces a transformed vector of same size. Initially, the input vector is filtered with Low Pass Filter (LPF) and High Pass Filter (HPF) of specific size and stored in the first half and second half of the transformed vector, respectively. Thus, ends up with one-level wavelet transform of input vector. Subsequently, these steps are repeated for three iterations, resulting in a three level 1-D DWT. With respect to two dimensional (2D) DWT, one level 1-D DWT is applied along the rows followed by columns subsequently. As a result, low-low, low-high, high-high and high-low bands of transformed images are generated. Subsequently, these steps are repeated for three iterations, resulting in a three level 2-D DWT [2]. Followed by DWT, GLCM and Haralick features are extracted. The features examined in the proposed method are Contrast, Correlation, Energy, Homogeneity, Mean, Variance, Entropy, Standard Deviation, Smoothness, Kurtosis, Skewness, Inverse Difference Moment (IDM) and Root Mean Square (RMS) Values and determined using the Equations from (1) to (13), respectively.

$$\sum_{i,j=0}^{N-1} P_{i,j}(i-j)^2 \tag{1}$$

$$\sum_{i,j=0}^{N-1} P_{i,j}\left[\frac{(i-\mu_i)(j-\mu_j)}{\sqrt{(\sigma_i^2)(\sigma_j^2)}}\right] \tag{2}$$

$$\sum_{i,j=0}^{N-1} P_{i,j}^2 \tag{3}$$

$$\sum_{i,j=0}^{N-1} \frac{P_{i,j}}{1+(i-j)^2} \tag{4}$$

$$\mu_i = \sum_{i,j=0}^{N-1} i(P_{i,j}),\ \mu_j = \sum_{i,j=0}^{N-1} j(P_{i,j}) \tag{5}$$

$$\sigma_i^2 = \sum_{i,j=0}^{N-1} P_{i,j}(i-\mu_i)^2,\ \sigma_j^2 = \sum_{i,j=0}^{N-1} P_{i,j}(j-\mu_j)^2 \tag{6}$$

$$\sum_{i,j=0}^{N-1} P_{i,j}(-\ln P_{i,j}) \tag{7}$$

$$\sigma_i = \sqrt{\sigma_i^2},\ \sigma_j = \sqrt{\sigma_j^2} \tag{8}$$

$$R = 1 - \frac{1}{1+\sigma^2} \tag{9}$$

Copyright ⓒ2020 SERSC

$$K = \{\frac{1}{MN}\sum_{i=1}^{M}\sum_{j=1}^{N}[\frac{p(i,j)-\mu}{\sigma}]^4\} - 3 \quad (10)$$

$$S = \frac{1}{MN}\sum_{i=1}^{M}\sum_{j=1}^{N}[\frac{p(i,j)-\mu}{\sigma}]^3 \quad (11)$$

$$H = \sum_{i,j}\frac{P(i,j)}{1+|(i-j)|} \quad (12)$$

$$y = \sqrt{\frac{\sum_{i=1}^{M}|u_{ij}|^2}{M}} \quad (13)$$

where,

N and P_{ij} denotes the rows/columns and probability of points,

- σ, σ_i and σ_j denotes the standard deviation (SD) and SD of rows and columns,
- μ, μ_i and μ_j denotes the mean (M), and M of rows and columns,
- R, K and S denotes the contrast measure, kurtosis and skewness,
- H and y denotes the IDM and RMS

Table 2 illustrates the dimension variations of input image during the feature extraction phase.

Table 2. Image Dimensions after Features Extraction

Sl. No	Input image dimensions (in pixels)	Image dimensions after applying (in pixels)	
		DWT	GLCM
1	256 x 256	38 x 152	1 x 13

Followed by the feature extraction, classification of plant leaf diseases is accomplished through the Neural Network (NN) with following specifications:

- Number of sample selected for training = 80%
- Number of sample selected for testing = 10%
- Number of sample selected for validation = 10%
- Number of hidden layers (chosen) = 15
- Training function adopted in the pattern recognition network is Bayesian Regularization Back Propagation ('trainbr'). The significance of this network lies in updating the weight and subsequent bias values with respect to Levenberg-Marquardt Optimization technique. Moreover, it reduces the consolidation of weights and squared error [3] and then regulates the appropriate combination to improvise the network performance. This type of network is referred as Bayesian Regularization (BR).

4. Experimental Results

The proposed method of tomato plant leaf disease detection approach is evaluated on the sample leaf images collected from plant village dataset [1]. The dataset consists of ten classes of tomato leaf categories (nine affected classes and one healthy class) resulting in 16,012 number of images. Randomly, 50 images are selected from each category resulting to 500 images for evaluating the proposed method. As an initial step, K-Means Clustering is applied on the input image and clustered images are resulted for leaf regions and disease affected regions. Upon choosing the disease affected region cluster, the feature extraction process is carried out using 2D-DWT and GLCM approaches. Thus, the input image of uniform size (256 x 256) pixels are subjected to feature reductions of 38 x152 pixels and 1 x 13 pixels due to DWT and GLCM approaches, respectively. Later, resultant features are classified using NN of specified specifications. Table 3 unfolds the proposed method's performance with respect to classification accuracy and metrics used to evaluate are Sensitivity and Specificity.

Equations 14, 15 and 16 are used to determine the Sensitivity, Specificity and Classification Accuracy respectively.

$$\text{Sensitivity} = \frac{TP}{TP+FN} * 100 \tag{14}$$

$$\text{Specificity} = \frac{TN}{TN+FP} * 100 \tag{15}$$

$$\text{Classification Accuracy (CA)} = \frac{TP+TN}{TP+TN+FP+FN} * 100 \tag{16}$$

Here, the variables TP, TN, FP and FN denote the True Positive, True Negative, False Positive and False Negative respectively. Further, the best training performance is 5.029e-10 at 45 epochs. When compared to the existing tomato plant leaf disease classification approaches namely, [6], [7], [8] and [13], the proposed classification has significantly higher performance in terms of classification accuracy.

Table 3. Performance Measures

Number of images	TP	FN	TN	FP	Sensitivity	Specificity	Classification Accuracy
500	445	5	48	2	98.88	96.0	98.6

5. Conclusion

The proposed method of tomato plant leaf disease identification approach has three phases namely (1) Clustering of affected and healthy regions using K-Means approach (2) Feature Extraction through DWT and GLCM and (3) Classification using NN. The proposed work was evaluated on Plant Village Dataset with randomly selected 500 images comprising of ten classes. When compared with the performance of the existing approaches, the proposed method has significant classification accuracy. The proposed model can be enhanced with the real dataset and evaluated with different NN architectures (such as AlexNet and GoogLeNet). Further, the scope may be extended to imperatively suggest the remedial measures for the concern leaf diseases.

Abstract

Currently, college-going students would take more time over their parental generations. Further, in the united States, the six-year graduation rate need been 59% for decades. Moving forward that educational quality by preparing better-prepared learners who could effectively propose over an auspicious way may be basic also too to anticipate that part. Faultlessly foreseeing students' occupation part clinched alongside future need pulled in substantially consideration as it could assistance distinguish good way might make given will them on time by advisors. Former Look into once students' part prediction incorporate shallow straight models; however, students' scholastics and investment will be a Exceptionally mind boggling transform that includes those amassing of information crosswise over an arrangement for parts that could not be sufficiently displayed by these straight models. What's more to that, former methodologies concentrate on prediction precision without recognizing prediction uncertainty, which may be key to advising and choice making. In this work, we avail recurrent neural network (RNN). These c's models need aid In light of those suspicion that former information of the scholar can provide people for future occupation part thus that evaluations from claiming former courses could make used to anticipate evaluations in An future course. The MLP ignores the transient flow from claiming students' information advancement. Hence, we recommend RNN to students' execution prediction. Should assess those execution of the suggested models, we performed broad investigations ahead information gathered. Those test Outcomes indicate that the recommended models accomplish finer execution over former state-of-the-craft methodologies and give more exact outcomes as a result.

1. INTRODUCTION

In the educational data mining field Academic students' performance is one of the most important topics. It can be a very useful factor for both students and teachers. Data mining conception basically extract the meaningful data from the raw information and the Educational Data Mining (EDM) is a developing technique which extracts meaningful knowledge in the context of educational field. Researchers contributed a lot on EDM theory to learn and investigate educational psychology and also data sciences that closely related to the learning analytics. Many different machine learning approaches are there to forecast a student's presentation using the student's family details as well as educational background. Particularly, these machine learning method enable to detect the student, who is at the risk i.e. who is likely to fail or drop out from the class. This helps a teacher to provide a remedy to the weak student. It can also help to identify the high performer student in the class. Decision Tree [1] and Naive Bayes [2] algorithm is highly used in Educational Data Mining. Havan Agrawal [3] stated limitation of these algorithms, the accuracy of the Bayesian classification model reduces when input is provided in a continuous range. Artificial Neural Network is a powerful tool to make a prediction. Deep learning is the state of art [4] for artificial intelligent research. Currently deep learning concept is highly used in voice/sound recognition [5], Natural Language Processing [6], computer vision [7]. Here proposed Recurrent Neural Network (RNN) classifier model to predict the students' Job. RNN is a different of a neural network. It obtains the output value based on the past and the current information using the recurrent loop of the network. The proposed RNN model aims to predict a

student Suitable Job through logistic classification analysis. One hidden layer with Relu activation function is implemented. The proposed model is able to predict a student Job with the accuracy of around 85%.

II. LITERATURE SURVEY

Kyndt [8] Utilized neural network to predict academic execution of the first year b.tech student, In light of students' motivation, methodologies with learning, attempting memory limit and consideration.

Ioannis E. Livieris, et al. [9] Here the studytells about the performance of students in Mathematics using an Artificial Neural Network (ANN) classifier. They Discovered that the changed ghastly perquisite prepared simulated neural system performs finer arrangement contrasted with different classifiers in this context.

S. Kotsiantis, [10] investigated indistance learning using machine learning techniques for dropout prediction of students. Their study made an important contribution as it was a pioneer and helped to carve the pathway for educational data mining.

Moucary, [11] utilized anhybrid strategy on K-Means clustering Also simulated neural system to foreseeing those execution about people of higher training about new outside dialect. They utilized neural system to foresee the student's execution et cetera fitting them for An specific cluster utilizing the K-Means calculation. This clustering aided the instructors to distinguish a student's abilities throughout their right on time phases for scholastics.

Mukta Also Usha[12] predicted those academic execution from claiming business school graduates utilizing neural networks And accepted Factual systems they recognized the underlying constructs of a accepted business school educational program Also exhibited its significance for those different components of confirmation transform.

Amrieh, [13] suggested a prediction model for students' execution In view of information mining routines. Those model might have been assessed previously, three diverse classifiers; Naïve Bayesian, simulated neural system Also choice tree. The classifier's execution might have been enhanced by utilizing irregular forest, packing and boosting as a cluster system. Those model attained dependent upon 22. 1% that's only the tip of the iceberg in correctness compared The point when behavioural Characteristics were uprooted and precision will be expanded up to 25. 8% after utilizing those cluster systems.

III. IMPLEMENTATION

A Recurrent Neural Network (RNN) Is An class of artificial neural system the place associations the middle of units form a graph chart along an arrangement. It is mainly used to handle the time series data. RNN may be on settle on utilization of consecutive majority of the data. RNNs are called repetitive a result they perform those same undertaking for each component of a grouping. RNN can be described in other way to say that has "memory" to capture the data that is calculated till now. Figure 1 (a) shows a graphical illustration of a structure of an RNN. Figure 1 (b) shows the recitation by the time of working out of an RNN

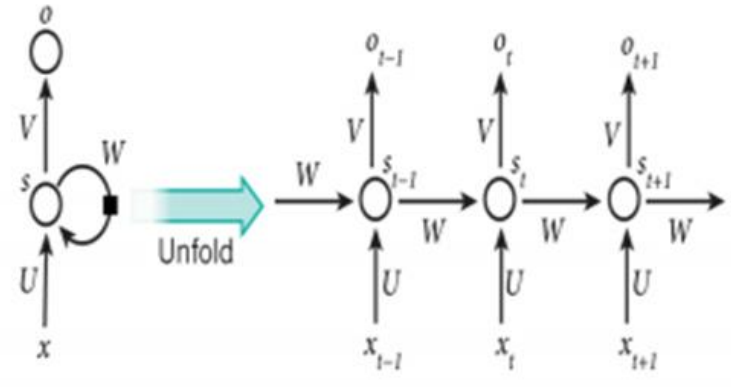

Figure.1. Structure of the recurrent neural network

Those forward pas of the RNN may be Just about same Likewise that from claiming an MLP with single hidden layer but that actuation arrives in those hidden layer from both the present outside information and the hidden layer activations particular case venture once more in time. To the information to hidden units we have:

Copyright ⓒ 2020 SERSC

$$a_h^t = \sum_{i=1}^{I} w_{ih} x_i^t + \sum_{h=1}^{H} w_{hh} b_h^{t-1}$$

$$b_h^t = \theta_h(a_h^t)$$

The output unit has:

$$a_k^t = \sum_{h=1}^{H} w_{hk} b_h^t$$

The back propagation of the RNN is just the standard back propagation. Those complete arrangement for delta terms could make computed toward beginning In t = t and recursively applying those The following functions, decrementing t In each step. Note that δj T+1= 0, ∀j, since no slip is gained from past the limit of the arrangement.

$$\delta_h^t = \theta^j(a_h^t)(\sum_{k=1}^{K} \delta_k^t w_{hk} + \sum_{h'=1}^{H} \delta_{h'}^{t+1} w_{hh'}$$

$$\delta_h^t = \frac{\partial O}{\partial a_j^t}$$

IV. DATA PROCESSING

It is an educational data set together since a learning management system. The data set is little bit updated by adding two more features with the existing data set. The data set contains record for total 480 students. The modified data set contains total of 34 features as below

1. Academic percentage in Operating Systems
2. percentage in Algorithms
3. Percentage in Programming Concepts
4. Percentage in Software Engineering
5. Percentage in Computer Networks
6. Percentage in Electronics Subjects
7. Percentage in Computer Architecture
8. Percentage in Mathematics
9. Percentage in Communication skills
10. Hours working per day
11. Logical quotient rating hackathons
12. coding skills rating
13. public speaking points
14. can work long time before system?
15. self-learning capability?
16. Extra-courses did
17. certifications
18. workshops
19. talent tests taken?

30. Management or Technical Salary/work
31. hard/smart worker
32. worked in teams ever?
33. Introvert
34. Suggested Job Role

mark in range 60%-80% is class 'Medium' and mark below 60% is 'Low'. Data processing is essential to recover the eminence of the dataset. Text data type attributes Gender, Parent Responsible, Parent Answering, Parent Satisfaction ,Student Absence Days are transformed to binary data '0' and '1'. Other Text data type attributes Nationality, PlaceofBirth, Stage, Grades, SectionID, Topic, Class in 1st Term and Class in 2nd Term are transformed to numerical data type.

V. METHODOLOGY

In this paper, a modified vanilla RNN is used to make the prediction of a student's performance. After building the proposed system, a comparative study is made with the Deep neural network (DNN) which is proposed by the Prabu P, et al.[14]. The whole implementation is done in PYTHON. Once the data pre-processing is completed, the whole data set is classified into two parts. One is training set and another one is the testing set. The data set is divided into the ratio of 3:1(Train/Test). The class variable is one-hot encoded for both train and test dataset. The class variable is represented in the numerical format as below

Classes	One-Hot Encoding Format
Low	[1,0,0]
Medium	[0,1,0]
High	[0,0,1]

The proposed neural network contains three layers. The first layer is the input layer and the seventeen features are given as input in the system. The final result of the student is produced as output from the output layer. The hidden layer is located in between the input and the output layer. The hidden layer consists of 40 neurons. One recursive path is there in between the hidden layer neurons to make the neural network recurrent. Random initialization of weights w and bias b to every interconnected layers. This initialization is specifically proposed for hidden nodes with Rectified Linear Unit (ReLU) non linearity. The ReLu activation function is defined as the positive part of its argument. It is represented by

$$f(x) = x+ = max(0,x) \quad \text{Where } x \text{ is the input to a neuron.}$$

VI. RESULT

The proposed method is applied to a dataset of 480 students. 360 data is used for training and the rest 120 data is used for testing. The proposed RNN is able to achieve the accuracy of 85.4% in predicting of a student's final grade. The performance of the training data is determined using the mean square error. After completing the 200 epochs, the mean square error of the training data set is determined as 0.11.

Copyright ⓒ 2020 SERSC

Classification Results:-

Classifier	Accuracy (%)
Artificial Neural Network	77.8
Deep Neural Network	83.7
Recurrent Neural Network	85.4

VII. CONCLUSION

Here a method is presented to forecast a student presentation utilizing Recurrent Neural Network with Rectified Linear Unit (ReLU) initiation purpose. RNN is suitable for analysis of the time series data. In this paper, student's ultimate term class is projected utilizing first two term class along side by other fifteen features. Here it is assumed that the student's final class is a sequential output of other two term class. The projected ideal achieved an exactness of 85.4% that outperformed the other machine learning algorithm. Higher accuracy can be obtained with larger dataset and features. This model can be used to predict student's performance and help to identify the students who have higher chance of failing. As a part the future work, the model can be tested with larger data set by adding more features. A clustering technique can be used to categorize the students at the very early phase, which will help to deal with the cold start problem. The proposed method can also be used in the intelligent tutorial system (ITS) to predict a student performance and based on that ITS can provide proper feedback to the students.

Abstract.
This paper proposes protecting data by using data security and it is considered to introduce alteration, inspection, intrusion, and footage. Cloud computing may be a kind of online based computing that grants approaches of PC and various devices depending on resources and necessary information. It is an ideal that empowers entirely on the prevention and control of configurable computing resources. Now a days security is a major problem in developing cloud computing so efficient debugging of cloud computing is a successful model by security in cloud presentations. The present work is a part of cryptography in cloud computing for getting better information safety. Here we approach another security for cryptography to get secured information at cloud data centers.

Keywords: *Sensitive data management, Information security, Cryptography.*

1. Introduction

In the recent network Data Prevention is a main concern for the business organization. Prevention of sensitive data from unauthorized entities and monitoring the data flow to avoid more security risks are the main goals of the security domain. Unapproved prevention has severe concerns by organization in both long term and short term. To prevent from the unwanted access and transaction from trendy, an structured effort is wanted to control the data flow inside and outside the organization. Data Prevention and prevention process are the important research issue, which is not always possible because several reasons. Recent news and reports indicates 50 % of data's are leaked in the business sector either partially or fully [1]. This is very difficult to identify the exact details of leaked data and the leaker. However, the data Prevention has many channels to leak. So monitoring every channel is an impossible task, and thus creates many serious issues. There is numerous detection and prevention schemes like Intrusion Detection System (IDS), firewall, and virtual private networks are the common security systems used to detect or prevent some unwanted access. These

ISSN: 2233-7857 IJFGCN
Copyright ⓒ2020 SERSC

schemes can perform well if the rules are properly defined.

However, the rules can be violated from dissimilar manageable channels such as email, prompt messaging, and via other social media supplements. To overcome this problem, Data Prevention (DP) systems are deployed. There are less adequate researches introduced to thwart the DP issue, so there is a need and challenge to design and develop a new DP mechanism with detection ability. Motivated by the DP field of study, a survey on the Data Prevention and Prevention approaches are presented in this paper. The paper provides the basic process of DP along with the recent techniques under the data Prevention process. The paper finally contributes the problem and challenges of the recent techniques with future work.

2. Data Prevention and Standards

Numerous studies conducted to define the area of Data Prevention and prevention in the literature. But the definition of data or information leakage and prevention is the process of content watching and protective by the misuse [2]. Although researches on Information Avoidance are growing is small problem on the detection of information Prevention by the perception of employer behavior [3]. Writers in [4] reviewed DP methods and its problems by appropriate description. The DP procedure comprises three phases such as collecting data, analyzing and remedial action phases as shown in Fig 1.0. The data collection is starting by the user internet or intranet logs and the database sources. The collected data's are imported in the DP analysis phase, which performs rule matching, policy verification, content and context verification processes. The setting confirmation extracts the sender, wellspring id, timings of the information access, organization and extent starting with those header majority of the data and so forth throughout this way, observing and stock arrangement of all instrumentation may be the content may be the pre-processed information from standard statement and tagging transform. That identification also classifying the information under those predefined population generally uses those security strategies What's more preparing tests. At long last the DP schemes determines the issue by choice suitable medicinal activities like alerting, blocking, permitting Furthermore finishing some other activities in the security arrangement standard situated.

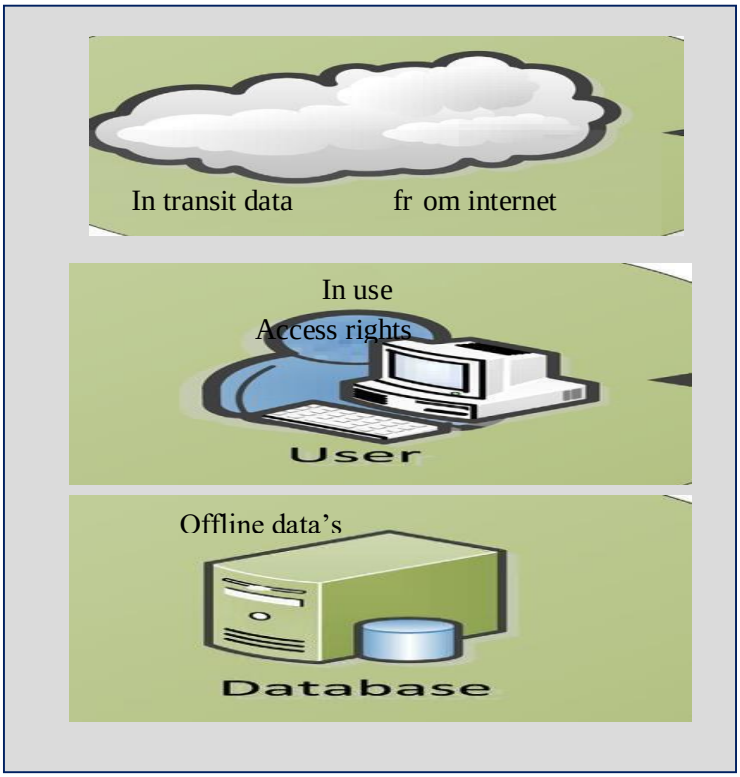

Fig 1 Deployment of DP

ISSN: 2233-7857 IJFGCN
Copyright ⓒ2020 SERSC

Fig. 1 shows the simplified deployment of a DP, where the exposure and avoidance qualities and investigation, recognition and corrective activities. That dataset methodology incorporates the web data's alternately on travel data's, client entry privileges also logged off recorded information starting with the database. These three sorts about data's are by and large gathered to the DP transform. That fig 2.0 indicates the information sorts utilized to the DP. Information clinched alongside travel is those information being transmitted manifestation particular case hub should in turn inside the same system alternately different networks. Information being used is those data, which will be receptive of the clients clinched alongside record organization or email formats inside the requisitions. Those information being used organization is not encrypted Also this might be effectively deciphered. Those third database data's need aid typically organized Furthermore secured with solid entry controls.

The content based DP monitors delicate data by regular expressions for identifying the arrangement. For sample account number, phone number and other delicate details are monitored. According to this type, authors in [5] proposed a DP with regular expression. But the technique is not successful and creates high false positive rates.

The DP are performed by agent who has the ability to alter the availability of confidential data. Author in [6] identified dissimilar leaky channels while data is transferred. This includes the portable Media such as USB, memory cards and several more. Author's audits the actions associated to the sensitive data access and restricts according to the audit report.

The categories of DP techniques are summarized in fig , which has different types of methods to prevent data Prevention and maintain the Proprietorship and identification utilizing behavioral Investigation and so forth throughout this way, observing and stock arrangement of all instrumentation may be etc. , those practically prominent methodologies under DP is the utilization from claiming cryptographic Also watermarking techniques, this abstains from the information starting with the unapproved clients. In the identification process, those information also behavioral examinations for quick mining need several developments.

3. Challenges Facing DP

Similar to the other data protection and security techniques, the DP face several issues while detecting and preventing the data Prevention. There are seven main challenges were identified from the earlier work [7] such as listed below.

- The first challenge is the data transaction may happen in many channels and many ways. If the data transmitted via the desired application then it can be detected or protected. But, if the data channel is other than the specific application like email, USB and other format then it will be a challenging task.
- The second challenge is the data modification, where the data can be modified and that can be partially leaked to the users. Sometimes many approaches find the whole pattern of the sensitive content. So it is failed to detect the partial and full data Prevention with or without modification.
- The third challenge is determining and providing appropriate access rights to the specific users according to their security level is more complicate. The improper guidelines and policies may affect the DP accuracy. The access controls should be properly configured.
- The fourth challenge is the process of encryption and steganography process, this technique can protect the data from the unauthorized user, but it difficult to analyze the data content when the strong encryption techniques are used.
- The use of watermarking concepts preserves the ownership and thus avoids the data Prevention. But the watermarking contents are unreliable for all type of data. And moreover, the watermarked contents are easily recoverable. This creates many challenging issues.
- The scalability and integration for vast domain is certainly impossible. This creates a scalability issue. When the network size is huge, then the policy matching, monitoring and access specifications are difficult one.
- Finally the detection of data Prevention from the log needs a complete supervised learning process. This creates many uncertainties and cause several issues over sensitive data. These challenges are commonly noted from the literature. Based on these challengers many researches made and that is described in the following section.

4. Literature survey

Wang, l. , Tao, j. , & Kunze, m. In their investigate paper "Scientific cloud computing: early meaning

ISSN: 2233-7857 IJFGCN
Copyright ⓒ2020 SERSC

and experience" says that, registering clouds equips clients for benefits will get hardware, software, and information asset. Some clouds administration models are:.

i) HaaS: Hardware as service fittings likewise an administration might have been recommended conceivably toward 2006. Likewise an outgrowth of fast developments for fittings virtualization, it mechanization and more utilization metering Furthermore pricing, clients Might purchase it fittings - or actually a whole information centre/computer center- as a pay-as-you-go membership administration. Those HaaS Might make flexible, versatile Also reasonability will meet your needs.

ii) SaaS: Software as a service product or provision will be facilitated Concerning illustration An administration Also furnished with clients over those Internet, which excludes the prerequisite with introduce What's more run those provision on the customer's nearby machine. SaaS accordingly changes that customer's cerebral pain about product maintenance, furthermore declines the overhead for product buys by once interest estimating.

iii) DaaS: information as a administration information clinched alongside Different formats, from Different sources, Might a chance to be accessed by means of benefits with clients on the organize. Customers could, to instance, control remote data essentially like worth of effort around neighborhood circle alternately get information semantically on the web. 2. Er. Sharanjit Singh and Er. Rasneet Kaur Chauhan, "Introduction will Crypto cloud clinched alongside cloud registering "proposes cryptographic calculations as: 1) information encryption norms (DES) 2) propelled encryption guidelines (AES) 3) triple – des 4) RSA 5) blowfish These calculations camwood a chance to be connected effectively to cloud earth.

Nelson Gonzalez, Charles Miers, Fernando Redígolo, Tereza Carvalho, Marcos Simplicio, Mats Näslundy and Makan Pourzandi clinched alongside their exploration paper, "An measurable Investigation for current security worries What's more results for cloud computing" says that pointing should c the majority of the data identified with cloud security have recognize the principle issues in those region Furthermore assembled them under a model made of eight categories: Compliance, Trust, Architecture, personality card Furthermore Access, availability, episode response, information security Furthermore governance.

Fig. 2. Cloud computing environment

A. Historical backdrop also description cloud computing bursts similarly as a hot point starting with the late from claiming 2007 because of its abilities from claiming rendering versatile propelling it organizations, QoS guaranteed registering situations and configurable product administrations [3]. The cloud computing gives registering again those web furthermore this statement is essentially propelled eventually Tom's perusing the climate cloud. On cloud, information will be put away toward remote area What's more may be accessible with respect to interest. It permits customers to utilize requisition product without introducing those document in whatever machine locally, for web connectivity. Toward information outsourcing client might get those required data starting with anyplace a greater amount effectively Also need no cerebral pain for storage room also could skip those additional costs with respect to software, hardware, Also data assets What's more information upkeep [2].

B. Current cloud tasks at present various undertakings starting with business Furthermore academia is projected, to example, supply undertaking [4] - IBM What's more european union joint exploration

ISSN: 2233-7857 IJFGCN
Copyright ⓒ2020 SERSC

activity to cloud computing, amazon versatile figure cloud [5], IBM's blue Cloud[6], experimental cloud undertakings for example, aura [7] Furthermore Stratus[8], OpenNEbula [9].

C. Categorization of clouds. Clouds might be arranged comprehensively as: i) state funded Cloud: hosted, worked Also figured out how Eventually Tom's perusing outsider merchant from person alternately more information focuses. Ii) Private Cloud: figured out how or claimed Toward an organization, giving work to administrations inside an association. Iii) mixture Cloud: comprised both those private and open cloud models the place association might run non - center requisition done a government funded cloud, same time administering center requisitions Also delicate information in-house over An private cloud.
D. What's more On-Demand organization cloud registering depends When association at oneself What's more on-demand organization models. It ought should for enable the individuals client with fellow team member with the cloud ought to perform assignments over building, deploying, managing, Moreover arranging. The client ought with respect to need the capacity will get to figuring abilities Concerning illustration Besides during they might required and a greater amount to no alliance starting with the cloud organization supplier. This could assistance clients will an opportunity to make secured close by control, getting deftness their work, Furthermore will settle on better choices with respect to the present also future necessities.
E. Broad network entry abilities need aid open again those system Furthermore got with through standard components that development utilization Eventually Tom's perusing heterogeneous slim alternately thick customer phases (e. G. , cell phones, tablets, convenient Pcs furthermore workstations).
F. Measured services cloud frameworks thus control and more, overhaul asset use toward using an metering capacity at exactly level from claiming reflection best possible of the sort from claiming management (e. G. Stockpiling capacity, processing, diffusion limit Furthermore vigorous customer accounts). Asset use could make monitored, regulated and more reported, giving straightforwardness of the supplier Wand more purchaser.
G. Rapid adaptability capabilities might make flexibly provisioned also discharged, every so often naturally, proportional fast outward also inner proportionate for interest of the customer, those capacities open to provisioning consistently need every last one of earmarks about continuously limitless and might be appropriated for any amount at whatever point.

5. Implementation

Elliptical curved cryptography in cloud computing will be efficiently utilized similarly as an contact from claiming get ready with instant public key cryptography resolutions, for example implementing keys furthermore digital signatures. There would different inspirations overdue vitality from claiming utilizing elliptic curves Likewise they offer that's only the tip of the iceberg minimal key sizes and more workable implementations [11]. ECC is a sort about open cryptosystem like RSA. A chance to be that as it may, its snappier propelling breaking point Furthermore by giving engaging What's more alternative approach to masters about cryptographic computation impacts it on difference from RSA. An comparable security level offered toward RSA, could a chance to be also provided for toward ECC, that similarly for more diminutive key sizes. To example, "the 1024 bit security quality of a RSA Might a chance to be decreased on 163 bit security quality from claiming ecc with those same level. Separated starting with this, ecc will be particularly great suiting for remote communications, like portable phones, PDAs, keen cards Also sensor networks".

Ecc utilization purpose of duplication operation, which need been discovered with make computationally that's only the tip of the iceberg proficient over RSA exponentiation [12]. Ecc need drawn a great part consideration Likewise those security results to remote networks for example, such that Clouds, because of the little way measure and more rearranged calculation [13].
Elliptic bend compelling reason An fascinating property that makes it fit for utilization done cryptography previously, cloud registering i. E. Its energy with make whatever two keeps tabs ahead An specific curve, incorporate them together Additionally get An third reason for existing on the same twist. The fundamental operation bolted in for ecc might make reason for existing multiplication, i. E. Extension of a scalar k for toward whatever associate p on the twist to get an additional side of the

ISSN: 2233-7857 IJFGCN
Copyright ⓒ2020 SERSC

side of the point Q on the same twist [14]. The general scientific articulation for a elliptic bend is:.

$$y2+axy+by=x3+cx2+dx+e \quad (1)$$

Here a, b, c, d and e are actual figures
Where x and y are a set of actual numbers. In its simplest form, an elliptic curve equations can gives as

$$y2\text{-}x8+dx+e \quad (2)$$

A statistical investigation, exhibits that An similar level starting with security rendered Toward a RSA-based diagram to an enormous modulus could aggravate proficient for An extensively more diminutive elliptic bend group, i. E. An 163 touch enter of ecc might make thought will make concerning delineation secure Similarly as 1024 odds enter for RSA. Likewise ecc utilization more diminutive way sizes, which impacts On quicker calculations, more level control consumptions, sparing memory What's more transfer speed. Ecc In this way clubbed for cloud registering will doubtlessly provide a significant part more secure nature's domain alongside velocity and sparing about Numerous intangible/indirect assets. Ecc connected to cloud will bring about All the more consideration paid towards how with evade information duplications, how on use information and benefits proficiently what's more entryway should attain expense profit investigation results. Additionally ECC employments more diminutive way sizes, which impacts on quicker calculations, low power consumptions, saving memory also band width. ECC in this way clubbed with cloud computing can provide secure environment including speed and saving of many intangible resources.

6. Conclussion

Data prevention is a main problem in the area of information safety. There are numbers of researches from different domains is constantly operational to emerging data avoidance and prevention approaches to alleviate this issue. Protecting confidential and sensitive information is more important. Cloud prevention will be used to service-based information security. Will plough with respect to cloud computing, those group must take genuine also committed measures to ensure security. A development proceeds will receive widespread guidelines (for example, open source) to guarantee interoperability around service providers. ECC can a chance to be used likewise and only portable computing, remote sensor systems, also server based encryption, picture encryption and its provision previously, each field of correspondence. Cloud computing for ECC may be a completely new region and need enormous degree from extent research. The worry here is data security with elliptic curve cryptography to provide for mystery furthermore affirmation about information the middle of clouds. Over future, security issues about cloud computing could make cantered a greater amount also a endeavour could a chance to be produced with find exceptional results using elliptical curve cryptography.

Abstract
Nowadays, Dynamic industries like tourism is a enhance to boost many countries economy in recent years. The hotel sector leads to a significant role among all aspects of the tourism industry. Online travel platforms, in association with hotel management, are a part of hotel E-tourism that helps users to make travel plans online, suggest precise recommendations in consideration with the earlier feedbacks upon hotel stay. From the past few months, the user roaming ratio falls rapidly due to the COVID-19 Pandemic across the globe. In a business concern, this Pandemic affects all tourism sectors, specifically in the hotels' occupancy. To retain business positions and attract the users in these problematic scenarios, hotel and travel platform management concerns about past preferences of users, which have a significant impact on gratification for a comfortable stay. The current market trends show that user reviews are playing a vital role to select a hotel based on a safe location. Our work tries to find and recommend the dimensions that contribute more towards higher satisfaction levels of users in Asian continental top tourism city hotels listed by the Master and VISA Inc survey with item collaborative filtering and regression techniques based on Tripadvisor reviews from social media in recent times. The outcome of the work is helpful for Asian continental hotel management to concentrate more on the dimensions for obtaining better reviews. From an online travel platform perspective, this work suggests the contexts for the travel recommender system to gain things effectively from users.

Keywords: Tourism, Travel platforms, Hotel management, Hotel class, Travel purpose, Context, Collaborative, Recommender System.

1.Introduction.

Because of its influence and significance in e-commerce and the achievement of superior consumer acceptance, in the current days of growth, web technologies, the recommended systems (RS) have twisted the notice of business people and the common man to itself. Nowadays everyone wants to refresh themselves in the vacation by visiting the locations across the globe, mainly in the categories of middle and upper sections of users. At least once a year, these sections plan their vacations due to an increase in socioeconomic factors. Online Travel platform is one such opportunity for fulfilling their desires. Figure 1 shows the traditional recommender system architecture how it is working to fill fill customer needs.

Burke[7] talked about various matters. Types of algorithms suggested. It clarified there that Two methods of suggestion. Collaborative cooperation is first, Filtering (CF), and content-based filtering (CBF), respectively. The mixer of each of these algorithms is called hybrid filtering. The internet is a platform in which one can express the views and opinions among a community of users who are located globally[5]. The content generated by users through the internet encompasses diversity in different web domains and also in media[7]. Ratings and Reviews are a part of online content created by a user. The analyses and ratings provided by customers are one of the most prevalent and accessible information in the electronic World of Mouth[1,2]. In the vacation industry sector, eWOM helps users in decision making about the selection of a hotel to stay with the availability of online content. In the hospitality and tourism sectors, social media play a significant role[6][9].

The significant and widespread online activity in the tourism industry is the information searched by the travellers [10]. Many tourism studies indicate that the user relies on the information available in the online tourist platforms for planning their trips. In online travellers' decision making, user-generated information leads to a vital role. User choices about travel plans are affected by the increase in the growth of online generated content. Before planning their trips, 50 per cent of travel planners depend on the content generated by previous users[8,20]. Opinion platforms are increasing in recent years, offering their users to create reviews and ratings online. TripAdvisor is one of the travel opinion platforms that allows users to express views and ratings regarding the hotel stayed experience.

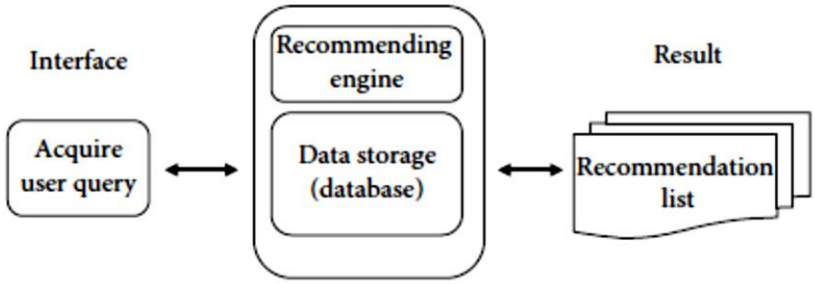

Figure 1: A generic architecture of recommender system

2.Literature Survey

Prior studies on the recommender method Discussed in the segment above. Previous research identifies similar factors Recommenders' principles, such as the filtering of information and Recommendation algorithms used previously for the development of Recommendation of systems[20] which aid to know and to understand Comprehend the need of web-based recommenders in the modern age Techno. Technology.

2.1. Recommender Systems.

Helping to end recommendation systems Users to help them locate goods and essential customer services that they are Searching. Tan and He[13] tabled a necessary proposal Echo process, called resonance similitude (RES), a novel approach. Superior is the book resemblance. Predictive accuracy vs similar conventional Tourism means an overnight stay away from the regular place of residence. Tourism and hospitality sectors generate significant revenue in many country's economies. In recent years numerous e-commerce applications developed related to tourism and hospitality for attracting the users[12]. Current statistics indicate that majority of hotel room bookings related to travel are done online with a percentage of 71 by individual users[15]. [18] Fasahte et al. Discussed if unrated products could be suggested and Using various filtering techniques, expected, and Using the Trip Advisor dataset, did tests. They also demonstrated a hybrid approach using ranking To predict user behaviour, data and textual content. Crespo Crespo Explain that Sem-Fit uses the experience of customers[16] point of view to apply the fuzzy logic technique to the relation between customers and hotels.

Hotels must concentrate on many vital aspects to obtain profitable revenues. One of the critical elements of the hotels is their presence online. Online reviews perform a significant role in knowing about the reputation of hotels, which act as an interface between users and providers of service offering useful information to make decisions about hotel stays[1][11]. To choose their accommodation in hotels, majority users depend on reputed online traveler platforms like Tripadvisor, Trivago, and Yelp, who provides the previous guest opinions based on social networks[15].[A recent study by Barclays indicates the potential growth of acquiring an additional 3.2 billion

dollars earnings by the hotel sector's income next decade if they pay more attention to online reviews those reviews to analyse and find out the best recommendations based on machine learning techniques[14,15].

Asia and the Pacific have been standing at the forefront of tourism development, having one-third of the world's economy. The hotel sector in this continent offers attractive tour packages in different hotel classes for users throughout the year. Hotel class and Trip-Type of a user take part in a crucial role in the selection of hotels to stay who have varied socioeconomic backgrounds[4,14]. Generalised Context-aware Recommender Systems is also one of the simple methods for acquiring views of previous users[3,15]. To build a customised hotel recommendation by Lin et al.[10], The techniques for text mining are used in combination with monitoring and browsing.

Rianthong et al.[13] It is concluded that the review ranking, prices and usefulness of the hotels must be taken on the upper side of the series in order to minimise the search expense of the customers. Using multiple regression analysis, a helpful model of stochastic programming was used. The most common and significant features for the classification of feelings are defined by Baghel and Lal[11] and grouped into seven classes, identified as basic features, seed word features, TF-IDF, punctuation-based features, phrase-based features, N-grams, and POS lexicons. Sharma et al., and Sharma, respectively.

Unfortunately, from the last three months in the entire world, the tourist roaming ratio falls due to the COVID-19 Pandemic[23]. Since most users rely on traveler domains in the selection of hotels they want to stay. To sustain the business and attract the users continuously, one of the crucial factors taken into consideration by the traveler domains is users' past opinions for that hotel class and Trip-type along with the location. Users view changes from one location to another; many factors influence the satisfaction level, like hotel class and travel purpose[25]. This study tries to find the impact of trip-type on hotel class.[26] This research article tries to find the contextual segments which have a high impact on user overall rating from different hotel classes, trip-types in Asian continent hotels of top tourism cities, and recommends these contexts to both hotel management, traveler domains for future improvement[27].

3.Methodology:

The approach suggested uses the heterogeneous nature (textual and numerical) of data crawled in from social media. Data is collected from selected hotel websites (data sources) containing the keywords that are present in the active user search query. For the download of the requested data, a web crawler was used, and data for further processing was stored in the NoSQL Cassandra database. Numbers (such as votes, ranks, and a number of video views) and text (such as ratings and comments) typically contain E data. To obtain accurate recommendations, our system used ranks, votes, and feedback data to extract hotel features from it. In two simultaneous instances, the scheme works. Numericranks and hotel votes are normalised from each chosen source of data. Analysis info, on the other hand, is processed using the natural language processing kit for review mining and highlights are extracted in the form of a matrix of hotel functions. Furthermore, for these extracted functions, numerical polarity scores are computed using SentiWordNet, and the average polarity score is calculated. Weighted average polarity scores are now determined by aggregating the normalised rank score, voting score, and polarity score. Lastly, suggestions are co-recommendations. Regression approaches for machine learning techniques. To calculate the final score to find out the type of guest (solo, family, company, friends, couple, etc.) for the hotel, we have

described a collaborative filtering other machine learning technique. The hotel recommendation method proposed is shown in Figure 2. In each of the five separate classes, the hotels' final recommendations are shown based on a specific guest category.

3.1. Feature Extraction Process.

The reviews are extracting from Tripadvisor, one of the leading e-tourism travel platforms. The data set consists of 37 cities across the Asian continent from different hotel classes having 15,977 reviews. From each city, we select 30 top hotels, at least with 200 to 1000 records. Maximum of reviews are coming from the last two recent years. This review contains the contextual dimensions Room, Location, Value, Cleanliness, Service, Sleep-Quality, and overall rating of the hotel. The item-item collaborative filtering recommendation algorithm used here replaces missing values of some contexts in this data set and backword elimination method in multiple regression algorithm which uses to obtain the significant impact of contextual dimensions on user overall satisfaction.

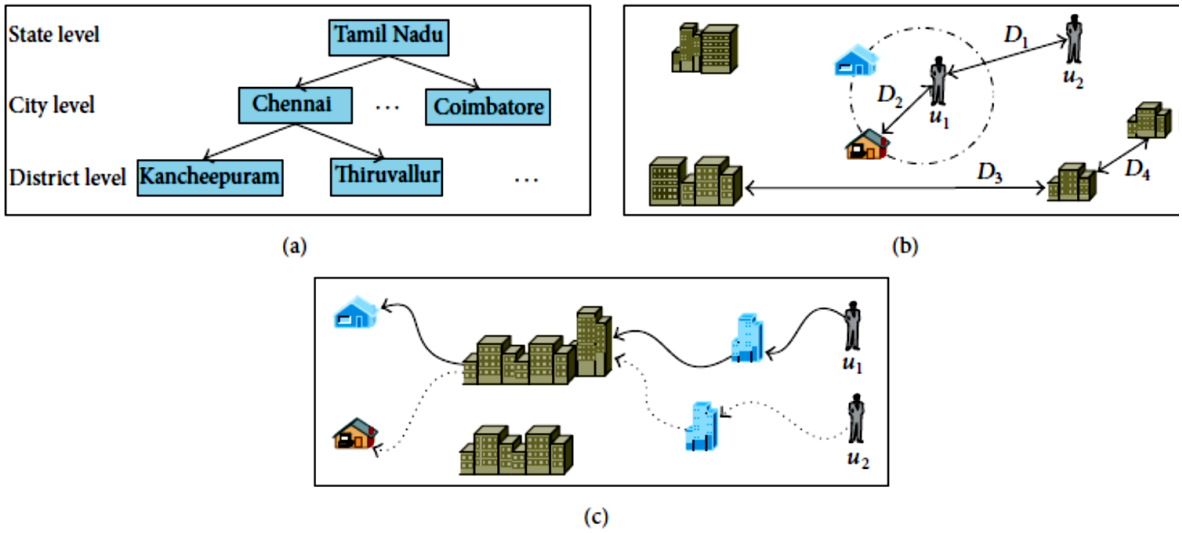

Figure 2:The proposed system for hotel Recommendation
(a)Location hierarchy (b)location Distance(c)location sequence

4. Results

After applying the O.L.S regression model to predict the significant contextual attributes on the overall user satisfaction level on different classes of hotels ranging from 1-5, The following screenshots show the results.

Table 4.1: List of cities in the Asian continent in consideration to extract reviews

S.NO	CITY	COUNTRY
1	Agra	India
2	Amman	Jordon
3	Bali	Indonesia
4	Bangkok	Thailand
5	Bangalore(Bengaluru)	India
6	Beirut	Lebanon
7	Chennai	India
8	Cochin	India
9	Delhi	India
10	Denspar	Indonesia
11	Dubai	U.A.E
12	Galle	Srilanka
13	Giza	Egypt
14	Hongkong	Hongkong
15	Hyderabad	India
16	Istanbul	Turkey
17	Jaipur	India
18	Japan	Japan
19	Johor Bahru	Malaysia
20	Kuala Lumpur	Malaysia
21	Katmandu	Nepal
22	Kuta	Indonesia
23	Macau	China
24	Mecca	Saudi Arabia
25	Medina	Saudi Arabia
26	Mumbai	India
27	Osaka	Japan

28	Pattaya	Thailand
29	Phuket	Thailand
30	Riyadh	Saudi Arabia
31	Seoul	South Korea
32	Sharjah	U.A.E
33	Singapore	Singapore
34	Taipei	Republic of China(Taiwan)
35	Tehran	Iran
36	Vijayawada	India
37	Vishakapatnam	India

Hotel class-1(*)

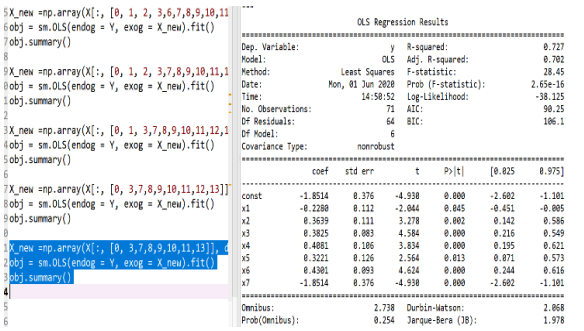

Figure 3: Hotel class-2(**)

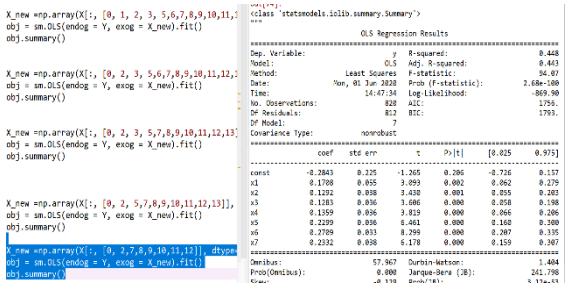

Figure 4:Hotel class-3(***)

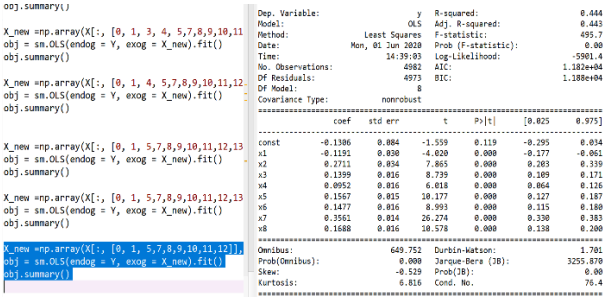

Figure 5:Hotel class-4(****)

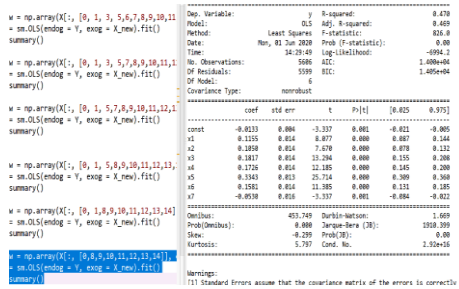

Figure 6:Hotel class-5(*****)

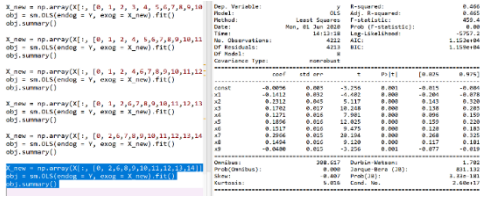

Figure 7: Durbin-Watson is also in suggestable range for all hotel classes from 1.5 to 2.5.

The above results indicate that all contextual segments make a significant contribution to the user gratification level in a hotel stay on several star hotels having in a range from 0.000 to 0.05, and Durbin-Watson is also in suggestable range for all hotel classes from 1.5 to 2.5. From the above observations of several hotel categories we rank, the contextual dimensions contribute more towards user happiness, also recommending these contexts to the recommender system to obtain valid recommendations is shown in the below table.

Table 4.2: Impact of contextual dimensions on overall rating in several star hotels

IMPACT RANK	*	**	***	****	*****
1	Service	Service	Service	Service	Service
2	Value	Sleep-Quality	Sleep-Quality	Value	Value
3	Location	Room	Value	Room	Cleanliness
4	Cleanliness	Value	Room	Sleep-Quality	Room

5	Room	Location	Cleanliness	Cleanliness	Sleep-Quality
6		Cleanliness	Location	Location	Location

Based on the rankings in above, all classes of hotels users are giving more importance to the context "Service" while in two, three-star hotels quality of the bed, i.e., Sleep-Quality, in one, four and five-star hotels amount spent for a room(Value) Have more impact in the user view. The context Cleanliness has an impact in one-star hotels, whereas least for the ambiance of a room(Room) since the user spent less amount comparing with other star hotels, so they give the least importance. The context Location does not make an impact on 3,4 and five-star hotels.
Since users stay in hotels for various travel concerns, this study tries to explore the same context significance in several trip-types. Below are the results of the same trip-type in different star hotels.

Hotel class-2

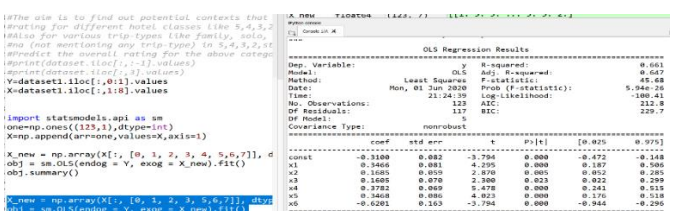

Figure 8: Trip-Type: Family

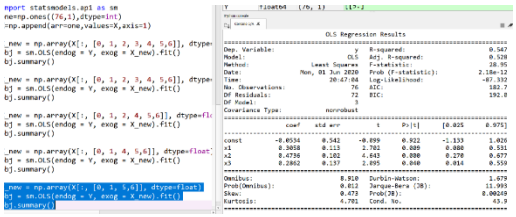

Figure 9: Trip-Type: Couple

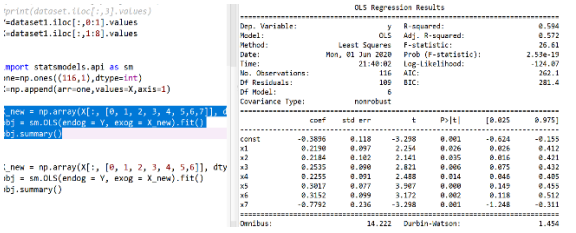

Figure 10: Trip-Type: Friends

Hotel class-4

TRIP	**	***	****	*****
FAMILY	1.Service 2. Sleep-Quality 3. Cleanliness 4. Location 5. Value	1. Service 2. Value 3. Sleep-Quality 4. Location 5. Room 6. Cleanliness	1. Service 2. Value 3. Room 4. Location 5. Cleanliness 6. Sleep-Quality	1. Service 2. Value 3. Cleanliness 4. Room 5. Location

Table 4.3: Significant contextual segments in Trip-Typ: Family

Table 4.4: Significant contextual segments in Trip-Type: Couple

Trip	**	***	****	*****
Couple	1.Sleep-Quality 2. Room 3. Service	1. Service 2. Value 3. Cleanliness 4.Sleep-Quality 5. Location	1. Service 2. Room 3. Value 4. Sleep-Quality 5. Location 6. Cleanliness	1. Service 2. Value 3. Room 4. Cleanliness 5. Location

Table 4.5: Significant contextual segments in Trip-Type: Business

Trip	**	***	****	*****
Business	1. Service 2. Cleanliness 3. Sleep-Quality	1.Service 2.Sleep-Quality 3.Room 4.Location 5.Cleanliness	1. Service 2. Value 3. Sleep-Quality 4. Cleanliness 5. Room 6. Location	1. Service 2. Value 3. Cleanliness 4. Sleep-Quality 5. Room 6. Location

Table 4.6: Significant contextual segments in Trip-Type: Solo

Trip	**	***	****	*****
Friends	Service 1.Ser 1.Sleep-Quality Room 2.Sle 2.Service Value 3.Roo 3.Value 4.Val 4.Room 5.Cle 5.Location 6.Cleanliness	1.Service 2.Location 3.Sleep-Quality 4.Room 5.Cleanliness 6.Value	leep-Quality 1.Sleep-Quality ervice 2.Room oom 3.Value alue 4.Location leanliness 5.Service ocation	1.Service 2.Sleep-Quality 3.Location 4.Cleanliness 5.Room 6.Value

Table 4.7: Significant contextual segments in Trip-Type: Friends

Table 4.8: Significant contextual segments in Trip-Type: N.A(Not Answer)

Trip	**	***	****	*****
N.A	1.Room 2.Service	1.Room 2.Sleep-Quality 3.Value 4.Location 5.Service	1.Service 2.Sleep-Quality 3.Room 4.Cleanliness	1.Cleanliness 2.Sleep-Quality 3.Value 4.Room 5.Location

Table 4.9: Impact Trip-Types on Hotel classes

**	***	****	*****

1.Couple	1.Business 2.N.A	----	1.Business 2. N.A

Tables from 4.3 to 4.8 reflect the significant contextual segments in several travel purposes. From the above observations, Trip-Type makes a considerable impact on contextual segments in hotel classes. Contexts priority changes from one Trip-Type to another also its impact on user overall gratification. According to the results in table 4.9 in two-star hotels, Couple, four, five-star hotels Business and N.A trip-types shows a significant impact on user overall satisfaction.

5.Conclusion

In e-Tourism, the role of online travel platforms is a significant one that offers services and makes recommendations to their users for a comfortable stay in hotels upon prior views. The type of recommendations made by travel platforms is also vital in the hotel management eye in a business concern. To reach user dynamic satisfaction levels, every travel recommender system periodically broadly assesses the users' views identify the things influencing more towards the expectation level, and makes necessary changes in the recommendation model. In this paper, we analysed user opinions of top tourism destinations in the Asian continent identified the contexts and travel purposes that show more interest in the user view to opt high gratification levels in several classes of hotels. Our observations indicate that user preferences vary with hotel classes and travel purposes.

Future Extension

Users are traveling around the world for several reasons; their preferences vary from one continent to another regarding the hotel stays. In the future, we will analyse other continent user opinions.

Abstract:
In distributed computing, clients can get to cloud administrations using the web. In present days, in superior registering and cloud frameworks, disappointment is an inexorably significant issue. Alleviating the impact of misfortune and making stable conjectures with excellent lead time stays an overwhelming exploration issue as huge scope frameworks keep on creating in scale and multifaceted nature. Because of the advancing unpredictability of elite figuring frameworks, specific current adaptation to internal failure procedures, for Example, successive registration and replication are not adequate. It includes the significance of having a productive and useful way to deal with disappointment the executives set up to relieve the impacts of disappointment inside the framework. With the approach of AI methods, the capacity to gain from past data to anticipate future personal conduct standards makes it conceivable to foresee potential framework disappointment all the more precisely. Along these lines, in this paper, by applying a few calculations to improve the exactness of disappointment forecast, we investigate the prescient capacities of AI. We have set up an expectation of disappointment. The fundamental analysis that we have Random backwoods (RF), SVM, Classification and Regression Trees (CART) considered). Exploratory discoveries show that comparative with different calculations, the typical expectation precision of our paradigm utilising SVM while foreseeing breakdown is 92% exact and productive. This discovering implies that all likely future device and application disappointments can be viably imagined by our cycle inside.

Keywords: Cloud Computing, Reliability, Fault Tree, random forest, SVM, CART.

1. Introduction

Distributed computing relies upon assets sharing to achieve intelligence and versatile economies, similar to a public utility. Non-business applications utilised in the logical space are displayed as work process applications request significant computational assets, and these requests can be productively satisfied using a cloud stage. One of the absolute highlights of the dispersed figuring phase; for

Content from this work may be used under the terms of the Creative Commons Attribution 3.0 licence. Any further distribution of this work must maintain attribution to the author(s) and the title of the work, journal citation and DOI.
Published under licence by IOP Publishing Ltd

Example, the cloud is disappointment taking care of the cloud must store the customer's information when it is running on a customer side application.

Inside the field of processing, disappointment forecast utilising AI is a massive region of intrigue has expanded significant thought since it is a central point in the first-class appropriated figuring condition and expect a crucial part in the organisation of gainful variation to inside disappointment. Investigation in gigantic degree enlisting relies upon an escalated and significant appreciation of what system frustrations in trademark structures appear to be to be equivalent. For Example, earlier information on disappointment qualities can be utilised to improve the framework and hub accessibility using asset assignment [3, 5].

It takes a basic comprehension of the highlights of real gadget disappointments to construct a helpful disappointment expectation model. Additionally, some measurable disappointment properties can help Designers of adaptation to internal failure framework create to assess and build up a proficient and powerful technique for transformation to internal failure [3-5]—the size of equipment stockpiling frameworks in current superior, enormous scope foundation processing. Even though there are numerous standard methodologies of adaptation to internal failure for adapting to and limiting the impact of disappointments, the potential disappointment pattern and conduct of existing frameworks [1, 4] should be seen fundamentally. It is crucial to observe that all of the three layers of circulated figuring, Infrastructure as a Service (IaaS), Platform as a Service (PaaS) and s, are made sure about by our cycle.

In [3], creators utilise fractional Critical Path (PCP) given the high reliance of the errands. After finding the PCPs, planning is done with the end goal that each PCP is appointed to an alternate asset type dependent on the heartiness of the asset. Authors [4] have proposed a C-HEFT calculation, an augmentation of HEFT, where the disappointment of assignments during execution is tended. The flat bunching technique utilised by the creators blends the capacities in a similar even degree of the application. After the misfortune, just the bombed assignments of that specific level bunch are executed as opposed to running the whole application the figure1 and figure 2 are demonstrated the standard college cloud organisation and disappointment cloud network the log record can create a wide range of deficiencies and disappointments.

*1.2 problem statement***:**

Medical or scientifical applications utilised in different examination space are made out of ward assignments and may likewise include multi-step information move among the capacities. Work processes are the straightforward technique for speaking to reliance limitation in appropriated frameworks, and the information structure utilised for an inward portrayal of these applications is regularly done using DAG (Coordinated Acyclic Graphs). The type of work process is Pipeline, Split, Merge and Diamond structures, grouped dependent on conditions. There are two modules in proposed models. The underlying model expectation of the errand disappointment with learning calculations is

completed. The following strategy is utilised to amend the happened blow proactively.

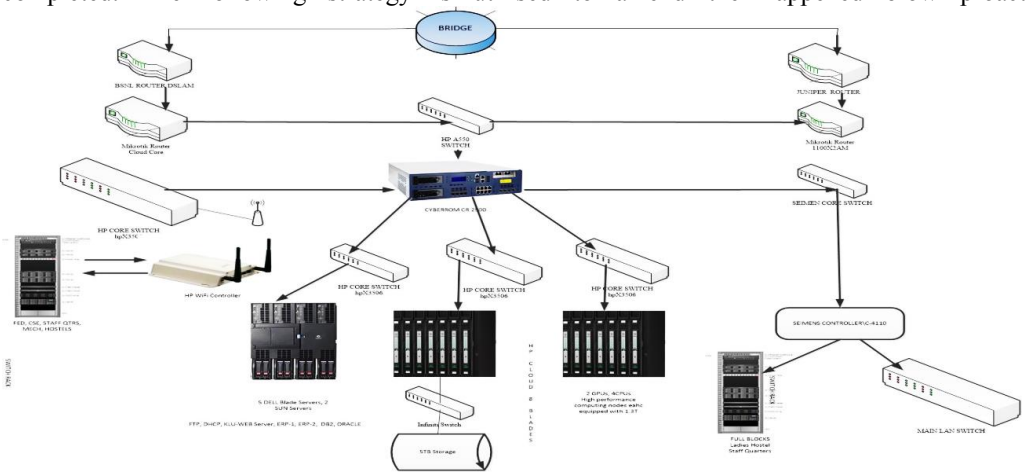

Figure1: Typical university University cloud Network**.**

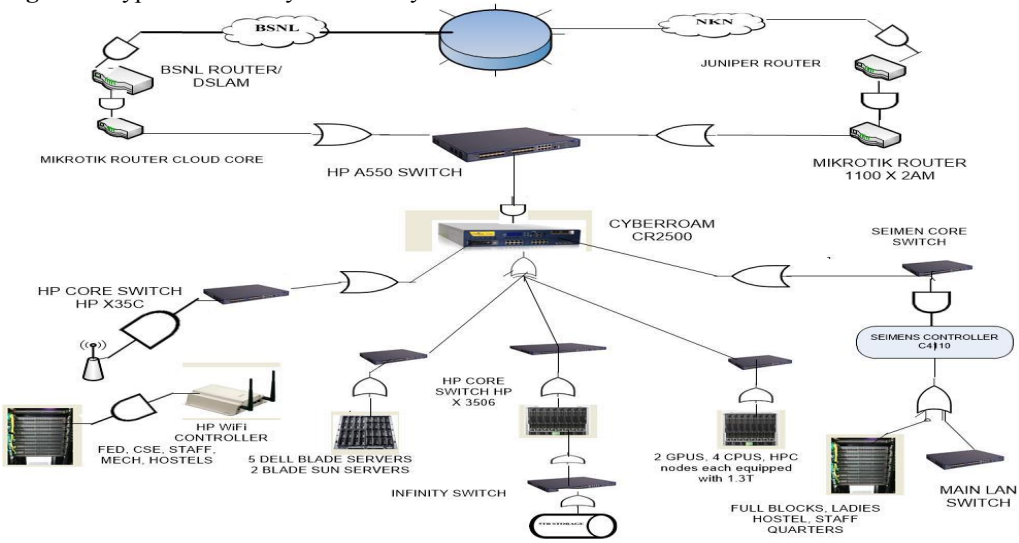

Figure 2: Fault tree diagram for the University Network

2. Literature survey

adaptation to non-critical failure as a fundamental issue in Cloud Computing and created a calculation that will reallocate the errand of a flawed worker to the worker with least burden around then and creator analysed the MPI furthermore, MPIL calculations. [1]. Lately, disappointment expectation utilising AI procedures has increased colossal consideration in a vast scope dispersed elite cloud condition, and a ton of exploration has been completed in this field. Regardless, next to no investigation has endeavoured to investigate thoroughly and observationally estimate superior cloud framework information utilising continuous information disappointment being developed. The authors in [10] had a useful endeavour has been made to analyse the disappointment information of a vast scope cloud creation condition comprising of more than 12,500 workers, including an examination of disappointment and fix times and highlights for both cloud outstanding tasks at hand and workers. In any case, they have never taken a gander at the disappointment affiliation Strength of remaining burden and gadget scale, separately, The creator in[11] set up an AI technique that recorded it as substantially more precise than the customary MTBF strategy for foreseeing only part times before disappointment. Their calculation was intended to follow the soundness of 14 equipment tests and alarm them of a fast-approaching blow well ahead of time of genuine misfortune, giving adequate opportunity to address the issue before absolute trouble happened the main drawback, in any case, was that their model had not been prepared on a continuous disappointment module. Like this, there is

no arrangement that this model would dependably anticipate disappointment and that the information they utilised was not made accessible to people in general. Even though the creators in [12] introduced another contraption dissatisfaction estimate approach By methods for help vector machines (SVM) considering the information found in the log reports, where their extended technique exploits the back to back the thought of log messages and makes sense of which progression of notes are trailblazers to frustration

The Authors in [13] explored disillusionment data that has been assembled as of late at Los Alamos National Laboratory and fuses 23,000 Failures have been represented on more than 20 unmistakable structures, for the most part, immense SMP what's more, NUMA centre point gatherings. The information insights, including the underlying driver of disappointments, the interim among disappointments and the interim for a fix, were examined., yet they never applied any forecast methods. Creators in [14] The experimental and factual properties of gadget mistakes and disappointments were assessed from an organisation of almost 400 heterogeneous workers longer than a year running an assortment of significant burdens. Their discoveries demonstrate that time-differing movement with long fixed periods comprises of machine mistake and disappointment designs. These static stretches show different concrete connection structures, and ordinary practices, which sway execution yet also, can be used to address such execution issues. Creators in [15] portray Cloud datacentres' equipment dependability from an assortment of information sources eventually fail to assess the remaining task at hand disappointments and didn't utilise a freely available dataset in their trials.

The Authors in [22, 23], focused on programming dependability demonstrating and programming defect forecast utilising neural organisation classifier pulls near. While the author in [24] proposed a financially savvy and blamed versatile reusability forecast model by using hereditary calculation, the creators in [25] proposed a top to bottom neural organisation based half breed approach for programming imperfection expectation utilising programming measurements. Our system is to use openly accessible equipment dataset utilising time arrangement and AI (ML) calculations to anticipate required disappointment of all the framework part and applications. Despite the vast majority of the cutting edge research, we select to use a university cloud dataset so different features in the area can compare the result with our proposed system results.

Cloud computing is a significantly fast advancement to deal with the massive proportion of moving toward data adequately. These may encourage lead to the vast number of inadequacies relating the system. Therefore, it is fundamental to address this issue; it is essential to give capable transformation to non-basic disappointment techniques. The technique used by our structure is just a gainful strategy for industry development and try to show resources handle specific weaknesses like worker mishap and System blockage. Furthermore, simple obstacle control techniques are never really stopped up control. Our proposed scheme is ready.

3.Methodology

The complete procedure that would be expressed in this review is portrayed in this section. As the point of this is to build up a model that can predict segments and deployment of conceivable disappointment process in an elite cloud environment. We start by using the time-arrangement to illustrate the solution since five years of dissatisfaction has occurred. To evaluate the device and network failures of the aggravated dissatisfaction dataset extracted from the PC, we collect the data set from the KL university cloud data centre to regret the data from the university cloud dataset[39]. This is a collection of different failures of the framework components reported over a given time. We had the option from the information collected to imagine the timestamps of the specific system section that fizzled (yield), without the disappointment (input) wellsprings. In this way, as every blow was registered at average spans at an alternate point after some time, we were absent with no choice but to apply time arrangement.

Once again, by modifying the data and applying AI, we went above and beyond. They followed the accompanying developments. We defined and acknowledged our concern as a multi-arrangement

problem (multi-ostensible) that needs some expectation that helps us to discern particular components that will come up shortly afterwards. We organised and modified our information and applied some estimates of guided learning and played out a connexion between them. By selecting the best analysis based on execution and accuracy, we tested our analyses and improved our outcome. The care bundle in R was sent because it provides a steady interface to many AI calculations and provides information representation, information resampling, model tuning and model correlation with helpful comfort techniques. Be that as it may, by transmitting specific ML measurement, which involves upholding vector machines (SVM) and arbitrary woods (RF), Classification and Regression Trees (CART), we chose to boost the methodology.

3.1 Data collection Phase

An original dataset on framework segments disappointment for a time of five years beginning from 2015–2019 was gathered [40]. The information was collected to give disappointment particulars to I/O connected frameworks; however, considerable detail as could be expected so examination may deliver some valuable discoveries. Information was gathered for capacity, organising, computational machines, and record frameworks underway use at K college cloud. The data was removed from an information base utilised for global positioning framework inconveniences, called Remedy, and is right now put away in a MySQL information base and accessible for the fare to Top design.

3.2 Data Pre-Processing Phase

A dataset [40] set up a yield variable addressing the bombarded system parts. To use managed machines learning figurings, we want to mix the knowledge parts to the dataset. As earlier referred to, we tend to get the information factors from the examination in [13] wherever the information used was isolated from a comparable house [39]. In Table 1, we tend to gift 5 (5) wellsprings of structure components disillusionment, for instance, Hardware; programming; human screw up; association and subverted [13]. For the duration of this assessment, we'd use the going with shortenings HW, SW, HE, NW and UD, severally to mean the wellsprings of structure portion dissatisfaction. Within the entire dataset, the undercut bounties of hardship appeared solely a solitary time within the amount beneath assessment. We, this way, discard its possessions within the examination in light-weight of its less chance of an occasion.

We passed on combinatorics assessment [41, 42] and designated the quality blends of wellsprings of framework items feebleness to the yield factors. Table two shows, however, the yield factors are named to varied mixes of knowledge factors. This half is union as follows:

Accepted, we have n different achievable dissatisfaction of discontent with a machine variable and we seem to be excited about taking clearly k varied mixes in a very steady progression. During this section, we tend to apply the combinatorics to avoid a repetition of Disappointment prediction using AI, we tend to thoroughly investigate and analyse some notable AI methods that are often used to predict disappointment in a very superior cloud-based process. We prefer to fit the technique into our model, considering and selecting the most successful out of each of them at that stage.

Table 1 The sources of failure of cloud-based systems measured in this study.

S.NO	SOURCE OF FAILURE
1	Hardware failure
2	Software failure
3	Human Error
4	Network failure
5	Unterminated

The AI procedures handle the issues of how to create and schedule PC programmes that enhance their exhibition and accuracy based on past occasions or expectations for some unique errand. The methods we considered are straight discriminant inquiry, order and classification regression trees and SVM, as previously expressed.

3.3.Classification and regression trees

The estimate of the classification and regression tree depends on the plan and Backslide Trees. A classification and regression tree is an equal decision tree which is developed by reliably dividing a centre into two child centre points, starting with the root centre containing the entire learning test. The Decision Tree is a recursive distribution approach, and all data centre points are divided into two adolescent centre points by classification and regression tree, thus the Binary Decision Tree is the classification and regression tree decision tree. The calculation recognises a condition at each level of a decision tree, which variable and status should be used to separate the input centre (data test) into two points of the youth centre. Decision Tree Building Computation explicitly integrates many.

Steps according to the corresponding steps:

Step-1 Take named input data with a goal variable and an overview of components that are self-governing.

Step-2 Best split: For all the independent variables, find the best split.

Step-3 Best factor: for the split, choose the best component.

Step-4 Split the data into centres on the left and right.

Step-5 On all of the centre points, proceed step 2-4 until it meets the final rules.

Step-6 Decision cutting tree: steps created to prune the decision tree.

3.4.Random forest (RF)

Another type of organised learning estimation in information mining is Random Forest. During this review, we appear to propose to fabricate a model for predicting the mistreatment of structure fragments disillusionment to communicate with differentiating and SVMs. Subjective forest areas have representational or drop-off teams of trees. This technique makes the use of bootstrap testing during tree selection on the readiness dataset and arbitrary step call.

Expect the subjective forest tests m > > M to half at any tree centre point development for a given variety of options M. The estimates are obtained by averaging for this scenario. The effects are the speed increase in mean square bumbles from zero to 100 per cent in erratic wood mistreatment drop off trees, with a lot in imperative features showing a lot of critical components.*3.5.Support vector machines (SVM)*

Support vector machines (SVMs) are controlled learning methodology used for backsliding assessment, portrayal issue and peculiarity acknowledgement. The critical idea behind SVMs is to pick the hyperplane that in a perfect world isolates two classes with the most noteworthy edge. For instance, given a readiness data D, described a ton of n centres and addressed in the structure:

$$\mathbf{D} = \{(x_i, y_i) | x_i \epsilon \mathbf{R}^p, y_i \epsilon \{-1, -1\}\}_{i=1,2,\ldots,n}$$

where yi suggests the two classes either +1 or - 1, to show the level for the point xi has a place.

In d-measurements and elements the primary area in 2 halfspaces, the hyperplane job g(x) provides an immediate discriminant: maybe a d-dimensional weight vector, and b is scalar inclination. The Associate in Nursing uninflected hyperplane is always located on the off probability that the dataset is

directly detachable with the tip objective that

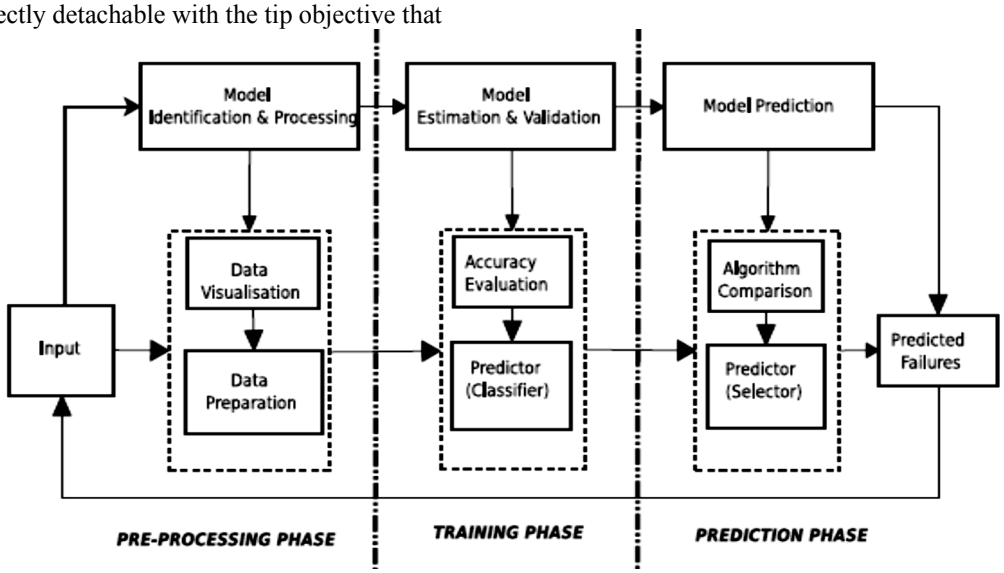

Figure 3: Architecture of Proposed system model

for all focuses with name-1, g(x) < 0>0.0. By designing the primary d-dimensional region in d*—dimensional space, SVMs are designed to take care of problems with non-straight selection limits. That the d*>d focal points are possibly directly free. Mistreatment of the alteration work/, another dataset is obtained as a changing area necessary for this operation to change area in the internal item, which is the portion work (K)between xi and xj.

3.4 Architecture of the system

In Figure. 1, we have a tendency to present the planned schematic diagram of disenchantment need model of this examination. It's contained three (3) organises, The pre-dealing with steps, the readiness stage and therefore the estimate stage, independently.

a) Pre-getting prepared stage (unmistakable model proof and taking care of)

The final distinctive check is the vital sum of the action model construction time course when stationarity is exercised. With the autocorrelation work guide (ACF) and short autocorrelation work (PACF), as shown in Figs, we can understand the most efficient achievable model subject to the model and solicitation showed by the correlogram. 4 and 5 in a straightforward way.

b)The arrangement stage (model analysis and endorsement)

After identifying the correct model, the next step is to examine the limits of victimisation of specific conventional techniques, such as least-squares technique, most noteworthy opportunity evaluation and set up for a second, and so on. The model is then tested for consistency and endorsement, although the suggestion has been made that all models are not correct, some are better than others. For Example, considering the properties of the residuals and testing whether or not the AN ARMA residuals may be a standard or subjective dispersion.

c)*The model need stage*

The perceived model will be used at this point to determine what's to come. To adopt a base commotion the surveyed residuals of the model will be meticulously investigated.

4. Results Discussion

In this segment, we partitioned off the oral communication of results into two: The principal presents and talks concerning the time arrangement approach and also the noninheritable outcomes throughout the conversation Figure. Three projected framework model offers the 5-millilitre calculation, and its examination hooked into our model. It's primer investigation to select up understanding into the instance of the frustration of the half and to check for the normality of the frustration information.

4.1 System failure model

In Example. 5, to understand the case of its occasion, we appear to plot the repetition of time-subordinate device efficiency. The arrangement of the discontented system indicates that it is not fastened and once it slows, the mean and differential of the setup remain dynamic. We want to die some technique of knowledge adjustments to determine this situation, for Example, log amendment and distinction procedure similarly to address their properties. In Figure, we gift the plots of machine dissatisfaction repeat amendment. Half a dozen mistreatment and log discrepancies, separately. As a result of some dubious outcomes due to zero reported structure dissatisfaction, the log-change will not be affordable for this case. Wherever the methods and comparisons of the course of action are seen as low, the issue of systemic disenchantment is seen. During this analysis, we appear to prefer the method of differentiation over the log. Since the model shown by the differentiation shows

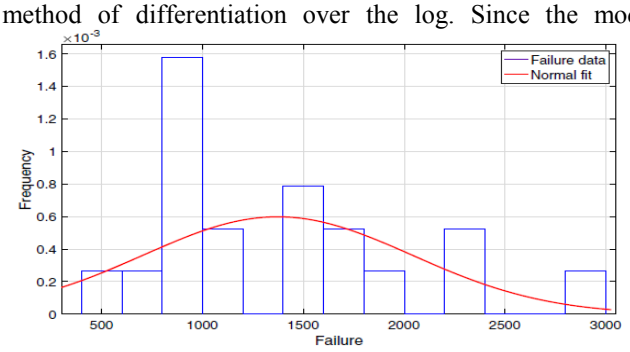

Figure 4: failure data routine distribution test

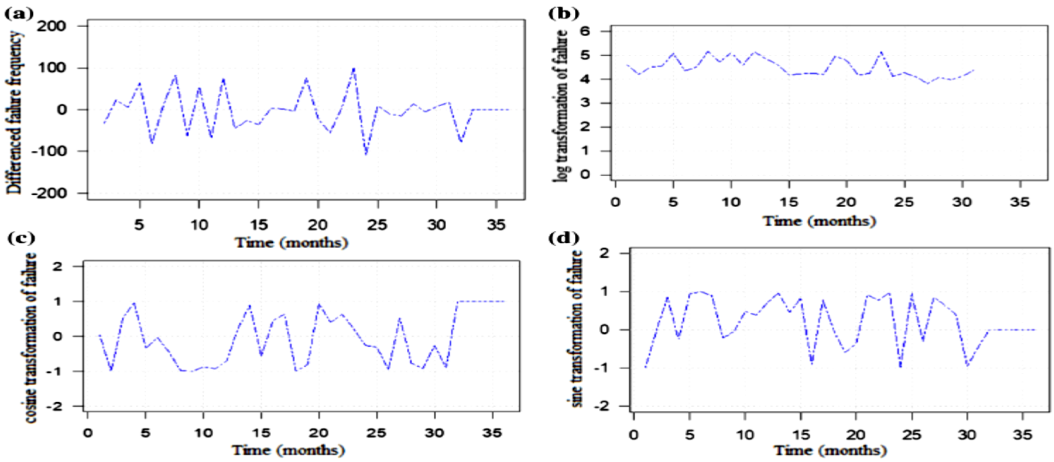

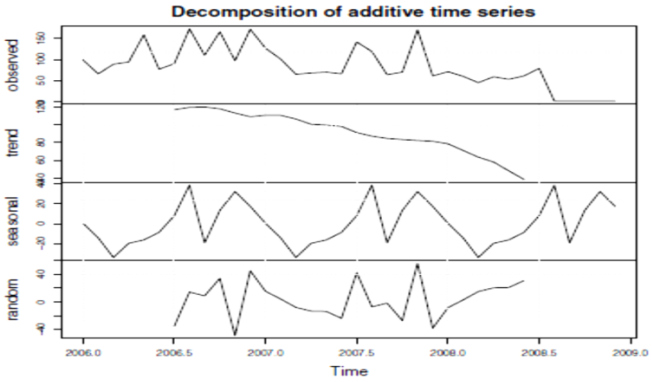

Figure 5: Differenced and log failure frequency transition plots that mean and variance of system failure series are relatively constant.

4.2. Prototypical Model Identification

Figure 6: Decomposition of additive time series plot of the failure

We plot a correlogram of the structure discontent game arrangement showing auto-association work and fractional autocorrelation work (see Figures 4 and 5). We tend to have the option to consider the usual moving model of solicitation one, victimisation of the ACF correlogram, whereas the auto-in reverse model is another, AR, of solicitation one (1). The ARIMA (1,1,1) model offers the combination of the 2 models wherever one at the middle is that the model's events are separated. As a consequence of stationary practises, the machine edification repeat of the arrangement was distinguished only once. All the autocorrelation evaluations that fall within the 2 blue dotted lines indicate non-immense at ninety-five. 95 per cent. All the while, those features that fall beyond the ninety-five.5 per cent guarantee stretch mean that they are enormous.

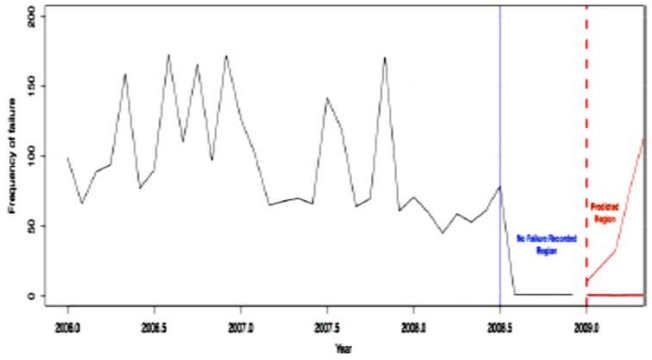

Figure 7: prediction region of the failure data

5.Conclusoin

This paper offers a rational technique to manage discontent estimate, exploitation time game arrange and AI. Our planned models are exemplified with the dataset accumulated from the K L University cloud centre to present discontent specifics to I/O connected systems and sections. The info was gathered for limit, arranging, machine machines, and record structures ongoing use at K L University cloud networks from the 2015–2019 timeframe [40].

Via aid vector machine, subjective forest, appeal, and lapse trees, the experimental results for discontent conjecture models have what is more evaluated. Because the truth was to build a model that can reliably predict achievable structure and disillusionment with the application, we prefer to use a quantity of game arrangement that demonstrates an approach recently. We appear to recognise an associated ARIMA (1,1,1) model for the information set of irritated anger extracted from the computer disillusionment data vault (CFDR)[39]. At that point, at taking a goose at and tweaking our model before selecting the most successful investigation, we appear to apply cubic centimetre computation on our dataset. Because of the best model, the degree of affectability, followed by LDA and RF, the analysis of our findings demonstrates SVM. This was achieved with SVM by differentiating half the dissatisfactions of the whole system and hence the anticipated disappointments.

Finally, once diverged from RF, CART and LDA, the failure estimate model exploitation of the assist vector with machining has absolute sufficiency with a standard accuracy of (90 per cent). Later on, we prefer to recommend choosing the best-performed model-related additional model-tuning framework with a 100 per cent accuracy for predicting frustrations in an incomparable cloud structure of the Brobdingnagian degree. In the same way, we can demonstrate even more the primary use of the outcomes obtained in a very cloud.

Malla Reddy Engineering College (Autonomous), India

ABSTRACT

Blockchain and artificial intelligence are two disruptive technologies in the today's world; Blockchain can connect data storage and data users from multiple domains, and different kinds of analytics applications run on top of the data in artificial intelligence techniques. So that Blockchain technology provide the excellent backbone for the development of artificial intelligence algorithms, it is useful to secure the data input from multiple data storage locations and to have whatever applications running on top of the data in a Blockchain visible to everyone. The concept of Blockchain technology and artificial intelligence techniques together develop interesting uses cases and nice applications. When paired with Blockchains, AI is better understood by humans, operates more efficiently, and the blockchains in general more efficiently. AI and Blockchain together support B2B environment and getting better outcomes.

INTRODUCTION

Blockchain is a digitized and decentralized system for facilitating secured transactions. These transactions are stored in ledgers similar to the traditional ledger. This ledger can store and manage transactions. Once transactions are completed, these completed transactions are stored in blocks and recorded chronologically in a transparent setup. (Rohitha, 2018). The Blockchain technology has been made popular by cryptocurrencies. Cyrptocurrencies such as Bitcoin use Blockchain to maintain a public

DOI: 10.4018/978-1-7998-3632-2.ch004

Copyright © 2020, IGI Global. Copying or distributing in print or electronic forms without written permission of IGI Global is prohibited.

ledger for every single transaction (Chikara, 2019). Hence, Blockchain technology is the foundation of Cryptocurrency technique. Therefore, Blockchain is a concept and bitcoin is the implementation of that concept. Nevertheless, Blockchain is equipped with digital signatures, which enables secure transactions. Security in Blockchains is enabled by the utilization of public &private keys inorder to solve puzzles on cryptographic hash functions (Yaga, Mell, Roby & Scarfone, 2018).

Blockchain technology is the next generation of the internet (Rohitha, 2018). It is not a centralized data systems. Rather this is a system of decentralized distributed database systems. Hence, the ledger can be distributed all around the world (ibid). Bitcoin demonstrates how the decentralization is implemented using Blockchain. Bitcoin is a peer-to-peer digital currency developed using Blockchain, The peer-to-peer network consists of nodes. Each node verifies and validates the legitimacy of payments before a transaction is completed. Hence, there is no need for intermediaries (such as banks) in the Bitcoin payment process (Agrawal, 2019).

Although Blockchain has been used for Cryptocurrencies, it has value for enhancing the performance of other technologies. An example of such a technology is Artificial Intelligence. Artificial Intelligence (AI) enables the implementation of computer systems that can solve independently and intelligently. It influences operational processes in workplaces. These processes are enabled via the building of machines capable of performing intelligent tasks. (Yessi Bello Perez, 2019). The machines operate by receiving and executing commands generated from data gathered, analyzed, interpreted and reinterpreted by algorithms powering the machines. This enables the machine to act independently and efficiently with limited human supervision (Budko, 2018). AI uses different techniques to enable machine intelligence. These techniques include the use of neural networks, support vector machines, natural language processing, fuzzy logic, robotics and machine learning etc., (Marwala & Xing, 2018). These techniques are data driven, and the security and encryption of such data is important. The compromise of such data will have consequence on the intelligent operation of the machine. This is where Blockchain comes into play.

Blockchains will enable the storage of encrypted AI data in a distributed, decentralized, & immutable ledger format. The data collected and stored in Blockchain can be used to facilitate the decision-making ability of the machine within the AI engine or system. The synergy between Blockchain and AI will ensure the availability of data storage and power resources to the overall network. This synergy will reflect a combination of two network approaches, which are the centralized (for AI), and Decentralized (Blockchain) network approaches (Gonfalonieri, 2018). Industries that have utilized both technologies in their production processes have realized that they synergy presents a unique and powerful pair which further contributes to the growth within that industry (Daley, 2019). Therefore, this chapter provides very basic explanations of both technologies and how they can work together.

BACKGROUND

In this section, an overview of Blockchain technology and artificial intelligence, with its concepts, applications and its use cases will be discussed. Blockchain technology, as mentioned earlier, is a digitized, decentralized, distributed ledger that can be used for different kinds of transactions. These transactions occur in a decentralized on peer-to-peer (P2P) network. The structure of Blockchain technology is represented by data structure concepts of pointers (information of the variable pointing to one another) and linked lists (with help of pointer each block points to specific data and link, that contains the sequence of blocks) (Lastovetska, 2019).

A Heuristic Model for Predicting Human Fall Detection using Machine Learning Techniques

Mohammed Inayathulla, PA Hima Kiran, M Chandana Sri, M Deepika

Abstract*: *It is very obvious that human fall due to unconsciousness is a very common health problem in every human being. With the evolution of many smart health devices, we should contribute the technological advancement of machine learning into it. Different techniques are already used in order to detect human fall detection in human beings. In this paper we have studied the patterns of falling of human through the fall detection dataset while this human was performing various motions. By understanding all these we have generated the prediction protocol which estimates the fall of a person using fall detection dataset. Machine Learning classifiers were used to predict the human fall and a comparative study of various algorithms used was developed to find out the best classifier.

Keywords*: *Classification, Fall Prediction, Machine Learning, Random Forest.

I. INTRODUCTION

The term fall can be defined as an unintentional event in which the body moves from its initial position to a lower level. This would cause some serious injuries also in adverse conditions. Hence a fall prediction system would be really useful in such conditions where it can predict the human fall prior to falling so that required remedies can be carried out. A fall detection system can be defined as a usable device whose main motive is to alert when a fall action has occurred. The fall alert detectors can estimate when the user was about to fall by detecting the sudden changes of body movements. Old age people have high degree of risk of death or injury resulting from falls. As the density of population is increasing human fall prediction system can be very handy. The aim of this paper is to implement a fall detection model by using different machine learning techniques. Human fall prediction can be considered as a typical classification problem of machine learning. To carry out this work data is collected from publicly available datasets. Supervised classifiers are then implemented on the collected data. All the features available in the dataset are used to build the classifier. After the classifier was built its accuracy was built on the unseen data. Several researchers have been working in this field to expose the importance of machine learning. As the current work is based on supervised schematic studies this also can be extended in computer vision where the data is collected by using visual sensors and based upon the data collected machine learning can be applied to identify the human fall detection. The structure of the paper is as follows in the next section related work is discussed then implementation details are discussed followed by results and conclusions.

II. LITERATURE SURVEY

In [1] the authors worked on visual surveillance for detecting the fall detection. Their approach was a two step process ellipse approximation and motion history image. In [2] the authors used an embedded camera in human body to identify the joint movements and there by classifying whether the person will classify or not. SVM classifier was used by the authors. In [3] the authors proposed a step by step process for identifying the fall detection. The critical steps were feature extraction human identification and fall detection. Histograms of Oriented Gradients and Local Binary pattern were used in combination of deep learning techniques to expose the human fall detection by authors in [4]. In [5] the authors worked on mobifall dataset with five different classifiers and proved that KNN classifier outperformed the other classifiers used. In [6] the authors used a smartphone based approach to identify the fall detection and thereby generating an alarm to the responsible of the victim. Three point based technique was employed to identify the fall detection in indoor video surveillance[7]. CHLAC features with skeletal image sequences were extracted using a mobile robot and KNN algorithm was used as a classifier for fall detection [8]. Deep Learning LSTM neural network method was used [9] with a smart phone as a sensor for fall detection. Convolutional Neural Networks was used in [10] in order to identify the fall detection with respect to the furniture and human characteristic relationships.

III. PROPOSED METHODOLOGY

The aim of this paper is to implement the classification scheme to identify the fall detection of a person. The algorithms used are Random Forest, K-Nearest Neighbor, Decision Tree and Naive Bayes. Fall detection prediction system can be categorized into four stages: Data Collection, Data Cleaning, Implementation, Prediction.

The main recognition of this paper is to identify the sophisticated among those mentioned classification algorithms. The methodology is described in figure 1.

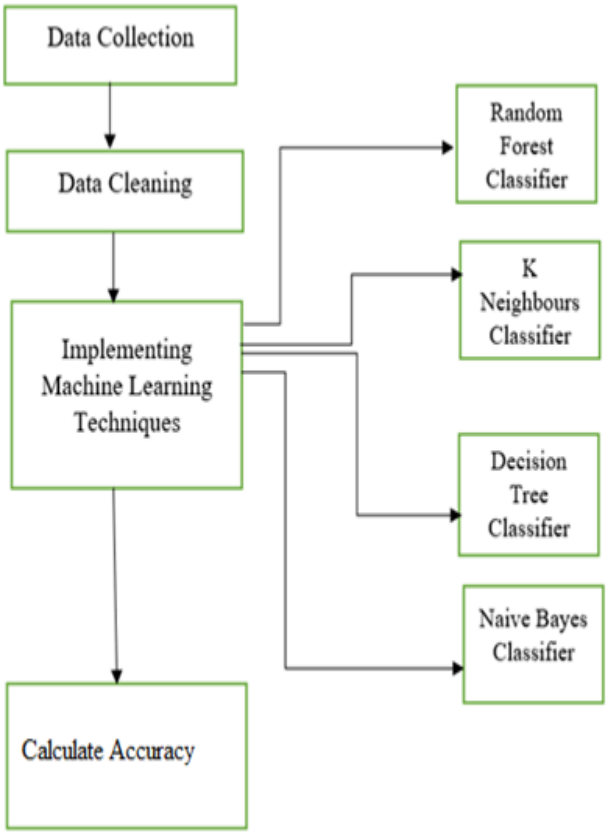

Fig 1: Fall Detection Prediction Model

Data Collection:

The "fall detection" dataset[11]is used for fall detection prediction which is used has the China Activity of elderly patients along with their medical information". The dataset consists of following features: Time, Sugar level, EEG monitoring rate, Blood pressure, Heart beat rate, Blood circulation.

Data Cleaning:

Data cleaning is the important phase as the erroneous data would significantly impact the overall performance of the system. In this phase data is thoroughly inspected to find out any missing values null values and standard statistical measures are used to deal with the null values and missing values.

Implementation and Accuracy:

Fall Prediction Model was implemented in python. After loading the dataset split the data into training and testing data. Using the training dataset train the model using the machine learning classifiers. Confusion matrix is used to test the model. All the features were used to built the classifier. The data split was performed in the ratio of 80 and 20 were 80% was used to training and 20% for testing. For decision tree entropy was used as the splitting criteria. In KNN 7 neighbours were worked for each unseen instance. When building random forest 500 trees were grown. Accuracy was computed based on the confusion matrix which is the familiar metric to evaluate the classifier and the accuracy values of each classifier are shown in the table 1.

IV. RESULTS

Table: 1 Accuracy scores of various classifiers used.

Classifiers	Accuracy
Naive Bayes Classifier	0.83
Decision Tree Classifier	0.89
K NN Classifier	0.7
Random Forest Classifier	0.92

The above table shows the accuracy values of each classifier and Random Forest has outperformed the other classifiers used with an accuracy of 92%. For every classifier the train test split ratio was 80 and 20 respectively as mentioned above.

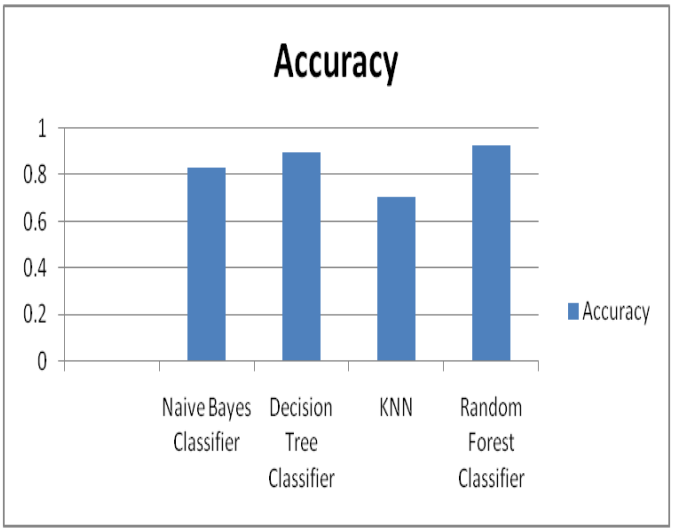

Fig 2: Comparision Chart of accuracy of classifiers

V. CONCLUSION

Out of the four learning algorithms used Decision tree and Random Forest have shown the better results. In future fall detection prediction system can be used to work in real time with regularly modernized datasets from distinct devices in various conditions. Deep Learning Techniques can be used to explore the surveillance data collected of various patients thereby predicting the human fall detection in real time.

Abstract

Due to the technological provoke in the digital era, there is an inevitable exponential growth in the video content generation and utilization for various applications. Browsing the complete video contents is tedious and time-consuming work. Hence, the summary of the video enables the user to browse the video content and proceed further (into the original video content), if interested. Henceforth, this paper aims to propose a video summarization method to extract keyframes from the input video based on the absolute frame difference method. When evaluated on the publicly available video, the examined results stated that the proposed method has improved performance regarding the keyframe extraction.

Keywords *– Video Summarization, Frames, Key Frames, Absolute Difference, RGB Channels*

1. INTRODUCTION

Segmentation, a contemporary technique, plays a significant role in processing the data acquired and making it simpler, meaningful and understandable for the user. In terms of research study, data may include digital media or patterns that aid in the analysis and understanding of video or interpretation of images or video summarization for detailed study. Irrespective of the field of study, interpretation or analysis of information needs to be in place [9]. As a matter of interest, Video Segmentation in digital media processing is practiced in medical imaging, image interpretation, surveillance, computer-guided surgery, motion object recognition, video summarization and many more.

Video segmentation is the method of segregating a video into multiple sets in subsequent frames that are homogeneous to specific criteria. The homogeneity in video segmentation is mostly in terms of pixels. Instances include segmentation of moving objects, object and background identification and so on. The following depicts the applications of video segmentation summarized from [10].

- Video monitoring to improve and track moving objects
- Object recognition to extract the features of the region of interest.
- Data compression to improve quality and reduce visual artifacts
- Computer vision
- Videophone applications to improve the foreground visually
- Digital entertainment to add effects and use for virtual scenes.

2. EXISING METHODS

The following section deals with few of the existing video segmentation methods.

Gopal, Kalpana and Bhose [1] proposed the detection and segmentation of objects in motion from an input video based on frames through Differencing and Summing Technique (DST). Initially, 8 successive frames from a video sequence are read and converted into greyscale for further processing. Consequently, each of the frames is subtracted from the background image and averaged. Further, averaged image is converted into a binary image and the noises in the resultant image are removed by morphological operation. Finally, the object with maximum displacement identified is covered with a bounding box for thorough labeling and scanning of pixels. As the samples for the study included indoor and outdoor videos, DST is robust and efficient in segmenting the object with displacement.

Onur, Ugur, Ozgur [2] claim content-based segmentation from videos by the Fuzzy Color Histogram method. The features of the input frame are computed by linear regression in the opening frame dropping detector step. The noises in the frame are pulled out through the median filter. Further, the mask is generated for the pattern or logos and the boundary is clipped out for the frame. Finally, the Fuzzy color histogram is applied where precision and recall values of other trending algorithms such as Color Histogram, Probabilistic Block intensity, Edge tracking, and Local Keypoint Matching are computed and compared. The technique revealed a 93.67% superior precision rate for color frames but reduced to 75.8% when the frames were transformed to greyscale.

Long and Wu [3] used the Canny Edge Detection technique for frame segmentation and pattern recognition-based technique to extricate the background from the segmented frame. The edge mask obtained in the Canny operator act as input for the pattern recognition technique. The edges are distinguished in either way. The pixel motion is decided based on the presence of an edge in the background or to the moving object. The other way is based on the pixel movement the edges belonging to background and object are decided. The edges that belong only to the object remain to discard the background. Techniques like Histogram, Threshold value help reduce the complexity.

Shigang, Xuegen and Hexin [4] put forth an algorithm fusing Disparity map with frame difference to fragment the object from the input video. The foremost step is to segment based on Disparity map to acquire the initial segmentation object. Then the objects are extracted by the Stereo Vision object Segmentation algorithm where the acquisition of an accurate motion picture is possible. As the disparity maps are of size, 160 X 120, the vision is clear. Less complexity is one of the vital features of this technique.

Chun Yu and Ming Yue [5] segmented the video by combining Kirsch edge operator and three frame difference. Three consecutive frames from a video and its greyscale conversion act as input. The moving object's border is identified obviously by the Three Frame Difference algorithm without noise or light or a shadow or background reappearance. Further, an adaptive Kirsch edge operator detects the edges with discontinuity which is eliminated using mathematical morphology.

Zhongkun, Yonping and Dechun [6] proved the LBP descriptor coding method segmented the video in ease without background construction and uncomplicated computation. The LBP method put forth by the authors is based on 3D spatial-temporal neighborhood value. Further, iterative threshold and morphological filter in binarization of frame ensure noise-free frame. The supremacy of the 3D LBP technique is proved by comparing the result with the difference algorithm.

Kavitha and Shanmugam [7] demonstrate a robust and proficient Edge Detection Technique by comparing Model matching and change detection of edges in Video object Extraction techniques. The comparison proved VOP extraction based on Model matching segmented even overlapped complex motion objects with partial occlusion. When combined with the motion vector and Haunsdroff measure improved segmentation results. The major pitfall, boundary inaccuracy in Change Detection Method was partially overcome by the Model Matching method and segmentation was amazing even in muddle background.

3. PROPOSED METHOD

The proposed video segmentation and key frame extraction method has two phases, namely, Phase-I and Phase-II. The Phase-I comprises the decomposition of video, i.e., the segmentation of input video into frames and write the corresponding frames into a specific directory, whereas the phase-II deals with the extraction of key frames from the generated frames using absolute difference parameter between the consecutive frames. Figures 1 and 2 depict the pseudo code for phase-I and II of the proposed method, respectively.

Input : *Video with ".avi" or ".mp4" format*
Output : *Frames*
Step 1: Read the video and store it in a variable 'v'.
Step 2: Create a destination directory 'd'.
Step 3: Extract the frames 'f' (i.e. the images) from the video 'v' and store it in the directory 'd'

Figure 1 Pseudo code for Phase-I

Input : *Frames from video*
Output : *Keyframes*
Step 1: Start reading the frames 'f' from the directory 'd'
Step 2: Number of available frames is stored in 'n'
Step3: Repeat the following for 'n' frames
Step 3 (a): Read the first frame and store it in 'f'
Step 3 (b): Euclidean norm or Euclidean length is determined for successive frames i.e. 'f1' and 'f2' regarding red, green and blue components and stored in '*eudiff*'.
Step 4: Threshold 't' is determined by calculating the mean value for '*eudiff*' parameter
Step 5: Repeat the following from the second frame to (n-2)
Step 5 (a): if the 'eudiff' of the current frame (j) is greater than the previous frame (j-1), next frame (j+1) and 't', then mark as "Keyframe"

Figure 2 Pseudo code for Phase-II

Initially, loading of input video followed by extracting the frames from it is carried out in the Phase-I. Later, Phase-II deals with the keyframes extraction from the resultant frames of Phase-I. Here, the Euclidean norm or Euclidean length of the successive frames for Red(R), Green (G), and Blue (B) components are determined regarding all the frames. Then, the threshold 't' is determined by the mean value of Euclidean norm values. Whenever the Euclidean norm values of RGB components of the current frame is greater than the previous frame, subsequent frame and determined threshold value 't', then the corresponding prevailing frame is identified as a "Keyframe". The procedure is repeated iteratively until all the frames are processed.

Later, the phase-II procedure is repeated with a frame difference of three; that is, the k^{th} frame is compared with $(k+3)^{th}$ frame.

4. EXPERIMENTAL RESULTS

The proposed work is implemented on MATLAB version 2018(b) installed on the Intel Core I3 2100 CPU @ 3.10 GHz machine with 4GB RAM. A 'Tom and Jerry' video is downloaded from the World Wide Web (WWW) [8], which plays for two minutes and fifty-nine seconds. In phase-I, the input video is divided into 5378 number of frames. The phase-II is made to execute twice with the frame difference one and three and extracted the keyframes from the input video. Table 1 shows the number of keyframes extracted for one and three frame difference methods.

ISSN: 2005-4262 IJGDC

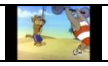
Table 1 Keyframes extracted in the proposed method

Sl. No	Name of the input video	Duration of the Video	Extracted keyframes with a frame difference of	
			One	Three
1	Tom and Jerry Show – Beach Bully (1975).mp4	2 minutes and 59 seconds	143	47

Further, the efficiency of the proposed keyframe extraction method is assessed by Compression Ratio (CR) [11]. CR is defined as the ration of total frames in the input video to the extracted keyframes as represented in Equation 1.

$$CR = \frac{\text{total frames in the input video}}{\text{extrated keyframes}} \quad (1)$$

CR of keyframes extraction method based on single frame difference= $\frac{5378}{143} = 37.608$ and CR of keyframes extraction method based on three frame difference = $\frac{5378}{47} = 114.425$



Observing Table 1 and extracted frames (manually), extraction based on the absolute difference of three subsequent frames method resulted in better performance than the single frame difference method. Table 2 shows the comparison of extracted keyframes with one and three frame differences. With respect to frame difference of one and three, the number of extracted frames is 143 and 47, respectively. Table 3 depicts the resultant 22 extracted common frames between the frame difference of one and three with their frame numbers.

5. CONCLUSION

The proposed method aimed to extract the keyframes from the input video using an absolute keyframe difference method. There are two phases, namely, (1) the first phase extracted the frames from the input video and (2) the second phase extracted the keyframes from the generated frames. The keyframes were determined using the absolute keyframe difference method with the frame difference of one and three frames. Experimental results concluded that the three frame difference method outperformed the one frame difference method regarding the extracted frames. Since the major pitfall of this approach is the execution time (the execution time grows exponentially with respect to the number of frames) Clustering-based technique and dimensionality reduction technique would be the choice for future enhancements in the keyframe extraction methods.

Abstract

The Internet of Things (IoT) is that the capability to produce regular dailyproductsby the approach of reorganization and otherwise by communicating with other devices. The main element of IoT application stream is extremely massive together with sensible homes, sensible cities, wearable, e-health etc. Therefore tens plus many billions of productsis going to be associated. Such product has sensible abilities to gather, investigate and create selections with non-human collaboration. Safety may be anabsolute demand for these conditions, associated specially verificationis given main importance given by malicious unauthenticated product in IoT system. Fingerprint based mostly biometry authentication approaches can enhance the protection in several industries and endless applications reminiscent of police work, automotive business, sensible town development, sensible home etc. This paper presents the fingerprint {basedmostly primarily based mostly} identification for breakdown the protection challenges in IoT based applications.

The abstract is to be in fully-justified italicized text as it is here, below the author information. Use the word "Abstract" as the title, in 12-point Times New Roman, boldface type, centered relative to the column, initially capitalized. The abstract is to be in 11-point, single-spaced type, and may be up to 3 in. (18 picas or 7.62 cm) long. Leave two blank lines after the abstract, and then begin the main text. All manuscripts must be in English.

1. Introduction

Technological revolution in info and communication Technology sector is being increased to facilitate the users of advanced and intelligent services. It integrates the event of sensible devices and IoT services. IoT predictsanupcomingnetworkmodel and repair orientating set-up within by spatially scattered physical substances are going to be arranged to make info networks to enableinnovative and intellectualfacilities [1]. The devices cited as "things" could embrace numerous types of sensors, actuators, RFID, mobile devices and sensible appliances. Researchers estimate that IoT can encompass fifty billion objects by 2020[2]. Maximum IoT devices are often examined and control by sensible productpresentations. IoT devices and applications are

interfaced and accessed solely by genuine users. Authentication systems are also physical devices or logical model. The best implementations of physical authentication devices are sensible cards and secret tokens. Compared to those ancient ways of authentication, biometry based mostly authentication is a lot of convenient and quicker. It's safer to use biometric based mostly authentication to access our personal devices.

2. IoT Generic design

Same time ancient administration net associate persons to an network, IoT holds totally distinctive method inside where that gives Machine-to-Machine (M2M) furthermore Human-to-Machine (H2M) property, for mixed manifestations of machine with the goal Similarly as on help type about provisions (e. G. , distinguishing, discovering, tracing, observing, also supervising) [8]. Interfacing an expansive mixed bag for heterogeneous machines [9] brings about an enormous traffic, In this way the need will wrist bindings the capacity from claiming tremendous majority of the information [10,11].

Thus, the TCP/IP design, utilizes an extended phase for network property, doesn't ensemble wants of IoT relating to numerous features together with isolationplussafety (e.g., info secrecy, machine's safety, information privacy, encoding, and network safety) [12], measurability, dependableness, ability, and quality of service [13].

Though various designsare planned for IoT even though there is a necessity for demo design [14,15], the fundamental design ideal planned within the works may be a three-layer design [13,16–18],here fig 1a having application layer, network and perception

Discernment layer: its those physical layer that faculties setting to see all those physical belongings (e. G. , heat, moistness, rapidity, position, and so forth throughout this way, observing and stock arrangement of all instrumentation may be enha.) exploitation end-nodes, but livelihood for dissimilardetecting innovations (e. G. , RFID, GPS, NFC, and so on.).

Network Layer: it's the layer guilty of obtaining information from presentation layer and transmission it to the appliance layer over numerous network technologies it's conjointly accountable of information managingas ofloading to process by assistance of middle-wares reminiscent of cloud computing.

Another planned superimposed design is that the five-layer design (Figure 1b) [13,16–18]. Here 5 layers are business layer, processing layer, application layer, presentation layer and finally transport layer.

Those capacities about presentation, transport (i. E. , organize layer) and application layers are An comparable Similarly as inside the 3 layer plan. The remaining layers are given as:

Processing layer: conjointly referred to as the middle-ware layer, it's accountable of given that numerous forms of facilities, principally loading, investigating, and process information by relation to machine consequences.

Benefits of the business layer: Its fill in blankets those IoT framework activities Also practicality. The machine layer sends the data of the benefits of the business layer whose part will be to make business models;graphs and flowcharts will research information, thereabouts as should assume an errand for choosing in regards to benefits of the business routes Furthermore road-maps.

Other architectures might additionally make known inside the expositive expression. On [20,21], the creators utilized An five-layer plan upheld administration orientating outline (SOA) that serves those blending from claiming IoT to endeavor administrations. Done [22], those creators considered perfect an non-layered approach for the outline. (e. G. , cloud design, haze design, social IoT, Also configuration underpinned human mind processing).

ISSN: 2005-4262 IJGDC

For the leftover portion about this paper, we bring a inclination to consider those three-layer outline.

3.1. Security Services

Likewise prior stated, the employment about interfacing Questions for regular people exists will make security issues extreme. The brilliance incorporated under homes, cars, Also electrical grids are frequently interested under hurtful eventualities when misused by hackers. Totally distinctive hacking eventualities provided for inside the secret word a long time delineate the degree for harm that may come about from An security breach, especially for those occasion Furthermore gigantic reception of IoT provisions taking care of delicate data (personal, industrial, governmental, and so forth).
The fundamental IoT safety considerations are: verification, permission, honesty, privacy, nonrepudiation, availableness and security.
Authentication: the system for affirming and insuring that personality of Questions. In IoT context, each item ought on need the force to spot and confirm constantly on elective Questions inside the framework (or clinched alongside an exceedingly provided for only those framework with that it relates).
The approval: the system for providing reasonably with connects substance with attempt to alternately need person relic. Integrity: the methodology by givingsteadiness, preciseness Also dependableness of dataabove its entire life cycle. For IoT, the modification about fundamental data alternately Perhaps those implantation about invalid illumination might prompt significant problems, e. G. , in sensible wellbeing frameworks utilization situations it might prompt those demise of the tolerant.
Confidentiality: the method of making certain that the data is just accessed by approved folks. 2 main problems ought to be thought of relating to privacy in IoT: first to safeguard that the thing getting {the information theinfo the information} isn't planning to move the information alternative itemsandby thinking about management.
Non-repudiation: the approach to promising those energy on exhibit that an undertaking or occasion need happened (and toward whom), for the objective that this can't be precluded after the fact. On elective words, that relic can't deny that tenability for chosen majority of the data exchanged. Availability: That system for making sure that the administration needed is advertised anywhere Furthermore anytime to those implied clients. This incorporates clinched alongside IoT, that supply of the Questions to them.

Confidentiality, the method of making certain non-accessibility to non-public info by public or malicious objects.

3. 2. Security tests over IoT Layers

In this section, we bring a inclination with consider the first essential configuration about IoT (three-layer architecture), and examine the insurance considerations, strike And security necessities toward each layer of the outline.
3. 2. 1. Discernment layer security issues And necessities: The observation layer comprises about sensors that arecharacterized by confined procedure control Furthermore stockpiling proficience. A number security issues Also ambush dangers Ascent due to such restrictions. Huge numbers strike on the observation layer need aid noticed:. Hub Capture: hubs (base hub or gateway) would often essentially controlled Toward the attackers. Getting An hub empowers copartner someone not singularly will actuate firmly from claiming science keys and protocol states, Notwithstanding conjointly on clone Also circulate pernicious hubs inside the network, that influences the security of the entirety system.
Denial of service (DoS) Attack: An sort strike that shuts down those framework or organize And keeps affirmed clients from gaining entrance to it. This might make attained by overpowering the framework or organize for great bargain about spam solicitations the greater

ISSN: 2005-4262 IJGDC
Copyright ⓒ2020 SERSC

part at a comparative time, subsequently overloading the framework And keeping it starting with delivering those customary administration [34].

Denial of sleep attack: you quit offering on that one On the whole those vital objective for associate IoT system is that the ability for sensing through a escalated consideration mixture of dispersed nodes, each giving work to minimal information, reminiscent of temperature, humidity, vibration, and so on. , at an assembly interim with the goal arranging should rest for you quit offering on that one All the more amount thus Concerning illustration with tolerance the hubs will control to long administration life. Those refusal of rest strike meets expectations on the office the table of the hub with An huge objective should augment those office utilization something like that as on scale once again the administration time period of the hub Toward keeping those hub from setting off sleeping When causation the worthy recognized majority of the data.

Distrubuted denial of service (DDoS) Attack: an oversized gagevariation for dos strike. Those principal troublesome issue may be that the capacity to utilize the enormous amount from claiming IoT hubs with pasquinade movement gathered at those victimized person server. There would signs that those DDoS strike eluded should Similarly as "Mirai" occurring on oct 2016 aidedsincean oversized assortment about IoT hubs.

Fake Node/Sybil Attack: a sort strike wherever the assaulter will convey blunder personalities exploitation blunder hubs. With the vicinity of a Sybil node, those finish framework might produce bad majority of the data alternately possibly those neighbor hubs might accept spam majority of the data Also might lay their security. Those blunder hubs might make acclimated transmit data should "legitimate" hubs heading them to expend their energy,.Which may lead the complete service to travel down?

Replay Attack: during this attack, info is hold on and re-transmitted later while not having the authority to try to to that. Such attacks are normally used against authentication protocols.

Routing threats: this sort of strike may be that those the majority essential strike during the system layer notwithstanding it might happen during the observation layer On majority of the data sending technique. Co partner assaulter will generate a directing circle inflicting the deficiency or development of the directing path, expanding that end-to-end delay, and expanding those slip messages.

Side-Channel Attack: This sort of strike happens for cryptography gadgets by taking advantage of the equipment data wherever the crypto-system will be connected with respect to (chips), reminiscent of those execution time, control consumption, force dissipation, Also attractive energy impedance constructed By electronic units All around those cryptography technique. Such illumination might be investigated to get mystery keys utilized all around the cryptography strategy [44–47].

Mass Node Authentication: the system for authenticating extraordinary arrangement of units to connect IoT system, which needs enormous amount of organize correspondence to the Confirmation Some piece will complete Also this could bring an impact on the execution of the finish framework.

Bringing under thought the first risks, there's a need to hub Confirmation to hinder blunder hub Furthermore dark access, Moreover of the need to encoding will watchman those secrecy about majority of the data while continuously transmitted the middle of hubs (end node, entrance or server). Due to the properties of the hubs with connection to the deficiency of force And thusly the confined capacity capability, there's a need for develop light-weight security schemes that grasp each light-weight science calculations and security conventions.

3. 2. 2. Organize layer security issues And necessities: Those system layer is liable of the dissemination about majority of the data starting with the observation layer of the machine layer. This might make wherever majority of the data directing happens Also on account of the essential majority of the data Investigation. Throughout this layer, a significant number system advances would utilized reminiscent of those Different innovations for portable correspondence generations (2G, 3G, 4G and 5G) Furthermore remote networks (Bluetooth, WiMAX, WI-Fi, Lora WAN, and so forth.). Huge numbers strike Furthermore dangers on the system layer are identified:. Man-in-the-Middle (MITM): for every McAfee [6], those first lasting strike need aid

ISSN: 2005-4262 IJGDC
Copyright ⓒ2020 SERSC

refusal about. Administration (Dos) and mamoncillo inside the program (MITB) strike. This latter, nearby those secure attachment layer (SSL) attack, that permits attackers will concentrate will traffic, block attempt it, and parody each finishes of the info, speak to the MITM ambush [48,49].

Refusal of administration (DoS): this sort of strike happens conjointly In those system layer Toward electronic countermeasures the transmission for radio signals, utilizing a blunder node, poignant the transmission or directing for majority of the data the middle of hubs [50,51].

Eavesdropping/sniffing: this sort of indifferent strike offers those intruder the force should think of the non-public correspondence In those correspondence join [52]. The intruder might great make prepared to extricate supportive illumination reminiscent of usernames Furthermore passwords, hub ID number or hub configuration,. Which might prompt elective types of attacks, e. G. , fake node, recharge attack, etc?. Directing attacks: this sort of strike influences then again the messages alternately data ar routed. The intruder spoofs, redirects, misdirects alternately possibly drops packets In the system layer. Those resulting particular strike might a chance to be considered:. Dark Hole: it might additionally be considered perfect Likewise a dos attack, inside which the intruder utilization An blunder hub that welcomes all movement By definitive that its those briefest way. Likewise An result, every one movement is setting off with a chance to be disclosed of the blunder hub that need the force should redirect them will a proxy server alternately possibly drop them [53].

Gray Hole: this sort of strike may be tantamount to the district strike then again as opposed dropping every last one of packets, it exclusively drops designated ones [54, 55].

Worm Hole: Throughout this sort attacks, those intruder makes a companionship between 2 focuses inside the system By Possibly prevailing a base of 2 hubs of the organize alternately including new blunder hubs of the organize. Once framing those link, those intruder collects data from particular case complete And replays them of the inverse complete [56, 57].

Greetings Flood: those point of the assaulter Throughout this sort strike will be with devour the office for hubs inside the framework Toward television howdy solicitation packets Toward a blunder hub on impact every last one of hubs inside the framework that they're inside the same vary, In this manner inflicting every will send packets. Will its neighbor inflicting an expansive movement inside the organize [58–60]. (hello messages would illustrated On exactly directing protocols, with the goal hubs declare themselves will their neighbors.). Sybil: Throughout this attack, An blunder hub displays different identities, In it will management a significant An and only those skeleton By being done a few puts inside the organize at a comparable duration of the time. When l a few sybil hubs need aid inside An comparative network, they're setting off on then send an oversized amount for information denying those customary hubs starting with exploitation those organize [61].

These possibility strike at the organize layer (wired or wireless) result in the meaning of the resulting security requirements: hop-to-hop cryptography, point-to-point authentication, magic understanding Furthermore management, security directing and interruption identification [62].

3. 2. 3. Requisition layer security issues And necessities: The requisition layer is chargeable for giving benefits. It hosts an aggregation from claiming conventions for message death [19,63], e. G. , unnatural requisition Protocol (COAP), message Queuing estimation transport (MQTT), protractile electronic correspondence and vicinity Protocol (XMPP), propelled message Queuing Protocol (AMQP), and so forth. This layer specifically interacts for the client. Once condition that those “traditional” application-layer conventions don't perform great inside IoT, Furthermore since those IoT doesn't have its identity or worldwide standards, a number security issues emerge toward the machine layer [27].

Information approachability Furthermore Authentication: each requisition might need a few clients [64]. Blunder or bootleg clients might have a great sway on the supply of the finish framework. Such decent mixed bag about clients prescribes that totally distinctive consent Also entry administration.

Information protection Furthermore identity: those exceptionally way that IoT associate {different completely totally distinctive totally different} units from different makers brings

ISSN: 2005-4262 IJGDC
Copyright ⓒ2020 SERSC

about those machine for Different verification schemes. The blending for the individuals schemes might be An troublesome issue on affirm data security Also personality card.

Managing the supply for immense data: IoT associate an extensive assortment of complete devices, the individuals brings about an extensive amount about majority of the data on be figured out how. This reasons cohort overhead on the machine to explore this data that holds an enormous effect on the supply of the administration given By those machine.

Viewing those security necessities to the machine layer, Confirmation may be required inasmuch as protective the protection of clients (respectively, information). Additionally, there ought to be connect information security oversaw economy topic that features asset administration Also physical security illumination oversaw economy. Table you quit offering on that one offers an framework of the insurance necessities of the three-layers inside the. IoT plan.

Majority of the data security management. On table 1, its reasonable that Confirmation might be a center security component that ought should apply at totally distinctive layers. Connect IoT utilize situation might might want cohort Confirmation the middle of those tip gadgets connected a intermediate gadget (gateway). Those entrance ought on confirm itself while causation majority of the data of the cloud, And Along these lines those requisition (mobile alternately web) ought with be certified of the cloud thus Similarly as to assemble majority of the data to dissection.

4. Taxophytina of IoT verification Schemes

This area displays scientific categorization about IoT Confirmation schemes exploitation various criteria designated backed those likenesses and accordingly the fundamental qualities from claiming the individuals schemes. Likewise prior mentioned, those Confirmation need aid regularly connected In each of the 3 layers of the IoT design, that makes those mixture of the verification systems. These criteria are illustrated clinched alongside figure An couple of Also summarized Likewise takes after.

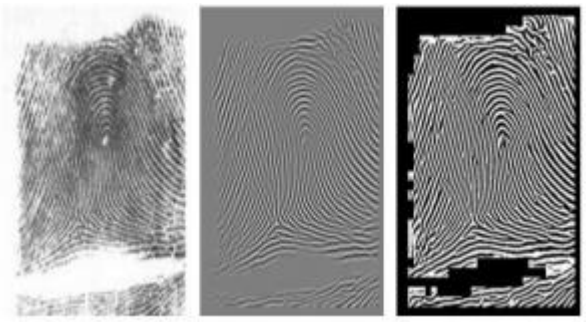

Figure 1.Taxophytina for IoT verification schemes.

1. Confirmation issue. Identity: connect information provided for By one get-together to an alternate to confirm itself. Identity-based Confirmation schemes will utilize you quit offering on that one (or a combination) about hash, interchangeableness alternately uneven science calculations.

Context: which might be:. Physical: Biometric illumination backed physical aspects of a private, e. G. , fingerprints, hand immaculate mathematics, retinal scans, and so forth.

Behavioral: Biometric underpinned behavioral qualities of a private, e. G. , keystroke Progress (pattern from claiming musicality Also transient game plan made When somebody types), walk examination (method acclimated assess the approach we bring An inclination with stroll or run), voice id al-adha (voice Confirmation that employments voice-print), and so on.

2. Utilization of tokens. Token-based Authentication: Authenticates An user/device upheld connect ID number token (piece from claiming information) made By a server reminiscent of OAuth2 protocol or open id al-adha.

ISSN: 2005-4262 IJGDC
Copyright ⓒ2020 SERSC

Non-Token based mostaccioli authentication: includes those occupation of the accreditations (username/password) each run through there's An need should trade data (e. G. , TLS/DTLS).
3. Confirmation technique. One-way authentication: over a exceedingly state of undertakings for 2 gatherings wish to talk for one another; only person party could confirm itself of the opposite, while those inverse one remains unauthenticated.
Two-way authentication: its conjointly alluded on as common authentication, inside which each substances confirm each other.
Three-way authentication: wherever An focal power attests those 2 gatherings And serves them to proportionally validate themselves.
4. Verification configuration. Distributed: utilizing a dispersed straight verification procedure between the human activity gatherings.
Centralized: utilizing An incorporated server or a indeed outsider on circulate and wrist bindings those accreditations utilized to Confirmation.
If unified alternately distributed, the verification subject plan will be:. Hierarchical: using a multi-level outline will handle those verification methodology.
Flat: no hierarchal plan may be utilized to oversee the Confirmation technique.
Particle layer: demonstrates the layer In that those Confirmation methodology will be connected.
Observation layer: chargeable for grouping, processing, And digitizing information recognized data Toward the tip hubs in IoT stage.
System layer: chargeable to getting the recognized data from discernment layer And methodology it.
Provision layer: chargeable to accepting majority of the data from the system layer, In this way giving work to benefits asked for Toward clients.
Hardware-based: the Confirmation system might compelling reason those job for physical qualities of the fittings or those fittings itself.
Understood hardware-based: employments the physical qualities of the equipment with support the Confirmation reminiscent of physical Unclonable perform (PUF) or accurate irregular assortment generator (TRNG).
Unequivocal hardware-based: A percentage verification schemes need aid underpinned those livelihood of a indeed stage module (TPM), a chip (hardware) that saves Also forms the keys utilized for fittings verification.

5. Security Challenges In Iot

IoT setting is enabled by open wireless technologies reminiscent of Bluetooth, frequency Identification (RFID), embedded sensors, actuators, moreover as Wi-Fi for dominant the connected devices. IoT setting is collaboration of assorted technologies and distributed and distributed devices. Because the numbers of connected devices will increase, new challenges may also be accrued. Security necessities can differed by the employment of applications and methods. If any of sensible devices are lost or purloined, it's simple for the hacker to retrieve all the sensitive info from the devices. There are many potential attacks which can be masquerading, spoofing, Middleman attack, do's attack, and secret changes. it's necessary to think about of these attacks and things within the IoT setting. Moreover, existing ways aren't enough to beat the challenges. Security challenges within the setting of little embedded devices should be simple to implement and value effective. Mechanisms for enhancing the protection in Iota setting should provide by well unnatural authentication.
Biometric Based Mostly Authentication And Iot Domain: Biometrics based mostly authentication has been receiving in depth attention within the Iota network society due to its dependableness and growing would like of security. It offers higher security and fewer likelihood of spoofing associated is tried to be an economical and correct answer to the matter [6]. Many surveys and studies are conducted by many researchers targeted on imposing the protection by biometry in Iota setting [7]. As unauthorized users aren't ready to show a similar distinctive physical properties to possess a positive authentication, dependableness are going to be ensured.

ISSN: 2005-4262 IJGDC
Copyright ⓒ2020 SERSC

This can be far better than the standard ways of victimization passwords, tokens or personal positive identification (PINs) at a similar time provides a price effective convenience approach of getting nothing to hold or keep in mind [8]. Most of the schemes target the key institution between the user and entry node. identification need not been considered perfect for particle provisions to 2 fundamental reasons; 1) particle architectures point toward automatization with no human intercessions 2) mixture from claiming particle gadgets need confined registering capabilities, inasmuch as burdensome And delicate biometric confirmation routes grasp a considerable measure of convoluted calculations to deciding, personality card prediction classifiers, meta-biometric prediction classifiers.

6. Implementation

Finger impression ID number Fingerprints would made of a arrangement about edges And furrows on the surface of the finger Furthermore bring An center around which examples like swirls, loops, or arches would bended to guarantee that each print will be exceptional [13]. A curve will be a design the place the ridges enter starting with person side of the finger, Ascent in the focus shaping an arc, et cetera retreat the opposite side of the finger. The circle is An design the place the ridges enter from one side of a finger, manifestation aarc, And need An propensity from claiming to passageway starting with the same side they enter. In the whorl pattern, ridges type circularly around An essential issue on the finger. The ridges And furrows would portrayed By irregularities known as minutiae, the different characteristic whereupon whatever remains of finger checking innovations are built. Minutiae focuses are neighborhood edge aspects that happen In whichever An edge bifurcation or An edge finishing. The edge completion will be those side of the point at which An edge terminates. Bifurcations would focuses at which An absolute edge parts under two ridges. Minutiae Also designs would extremely critical in the Investigation of fingerprints since no two fingers bring been indicated with be indistinguishable twin. There are five phases included in finger-scan confirmation Also identification:

1. Finger impression picture securing
2. Image transforming strategy
3.Placing dissimilar aspects
4.Format production technique
5. Format matching technique

A sensor takes a scientific preview of the user's interesting pattern, which will be At that point spared to An finger impression database. An finger impression upgrade algorithm (that employments gabor filters Likewise band-pass filters will uproot those clamor and preserve genuine inconsistency ridge/valley structures) is included in the minutiae extraction module to guarantee that those execution of the framework is not influenced by varieties for personal satisfaction from claiming finger impression pictures.

Proposed Technique For Fingerprint Based Mostly Identification :A well-performed biometric modality ought to contain the traits reminiscent of individuality, accuracy, richness, easy acquisition, dependableness and user acceptance. Among numerous biometric based mostly authentication methodologies, Fingerprint based mostly authentication is thought to be associate effectual technique for distinguishing persons with high confidence. The planned model of framework for IoT setting by biometric based mostly authentication by fingerprints victimization Star IoT Network is meant.

Illustrates the model involves associate IoT entry node through that the users are connected to perform many activities. The advantage of star IoT network is that every one the quality within the style of the network is managed by a central node or Iota entry Node '$\boldsymbol{GN}$'. As shown within the figure, the planned technique includes a group of entities representing the set of users connected with the help of a relationship set 'SIG'. the link set is mathematically developed as given below.

$SIG \rightarrow (U, R, C)$ ----------(1)

ISSN: 2005-4262 IJGDC
Copyright ⓒ2020 SERSC

From (1), the star IoT graph 'SIG' within the planned technique includes the set of users 'U', with the link set denoted as 'RS' and relative constant denoted as 'C' severally. every user 'U' is outlined as below.

$U \in Ui$----------(2)

$Ui \rightarrow Ui \cup fp1, 2, \ldots, fpn$---------- (3)

'Ui ' represent the set of users, where, 'FPi ' represent a fingerprint attribute of the user with finger print feature sets '$fp1$ ', '$fp2$ ' and then on extracted at completely different time settings '$t1$ ', '$t2$ ' severally. the link set within the technique is drawn as 'RS' within the IoT setting, wherever 'U' represents the nodes or users and 'I' corresponds to the link or interactions that connect between the users and IoT devices. Here, the nodes or users are drawn as points whereas the interactions between the users and IoT devices are given as lines. Besides, the constant worth 'C' symbolizes ' $*U \rightarrow r, wherer \in RS$' corresponds to a perform that assigns a relationship kind 'r' between a given user, 'Ui ' and IoT services. The network is associate extended integration of sensible applications, things and open wireless technologies for storing and forwarding a lot of important info. 2 stages within the planned framework ar registration and authentication.Throughout registration stage victimization multifactor fingerprint identities, the user registers their personal digital assistants and devices with the entry. The entry node provides on demand IoT services to the registered user once authentication. Nothing management maintains a register of devices, sensors and actuators which might be accustomed briefly disables or isolates the affected devices till they'll be patched. This feature is especially necessary for key devices reminiscent of entry devices so as to limit their potential to cause hurt or disruption, as an instance, by flooding the system with faux information if they need been compromised. At any time, the user access the Iota devices through network, the system authorizes and validates the user through fingerprint module (i.e. fingerprint images) that are hold on as templates. In alternative words, if the user fails to authorize himself through fingerprint recognition as hold on in templates, he cannot access the IoT devices. This fingerprint module has the aptitude to be integrated with differing kinds of sensors like machine-driven door lock, completely different electronic devices, security devices and then on. In system implementation, a biometric fingerprint security model is developed for sensible home observation. Actions are often applied mechanically employing a rules engine with rules supported vulnerability management policies.

Feature extraction is the greater part characteristic extraction calculations work on the taking after four steps determine a reference point to the finger impression image, decorate the district around the reference point, channel the locale of enthusiasm toward different directions, and, characterize the characteristic vector.

Finger print matching finger print matching alludes all the should discovering the similitude between two provided for finger impression pictures. Because of clamor furthermore twisting presented throughout finger impression catch and the estimated way from claiming characteristic extraction, the finger print representational frequently need missing, spurious, or loud offers. Therefore, the matching calculation ought to further bolstering a chance to be safe with these errors. Those matching algorithm outputs a comparability esteem that demonstrates its certainty in the choice that the two pictures come from those same finger. The existing well known finger print matching systems might a chance to be comprehensively arranged under three classifications contingent upon the sorts of features utilized [8].

A standout amongst the primary challenges in the minutiae-based approach may be that it is exceptionally troublesome on dependably extricate minutiae on a poor personal satisfaction finger impression picture. That simplest correlation-based procedure may be with adjusting those two finger impression pictures also subtract that information picture from the format picture with check whether those ridges relate. For that third approach, matching will be dependent upon a basic calculation of the euclidean separation between those two comparing characteristic vectors, and more consequently is greatly quick.

Algorithm for Preprocessing:-

Step 1: Acquire I/P fingerprint

ISSN: 2005-4262 IJGDC
Copyright ⓒ2020 SERSC

Step 2: Perform Normalization on input finger, to adjust the intensity value by adjusting the range of gray level values.
Step 3: Perform Segmentation, to separate the foreground regions in the image from the background regions. The foreground regions consist of fingerprint area containing the ridges and valley and background consist of regions outside the borders of the fingerprint area. If we do not remove background regions from the fingerprint then the extraction algorithm extracts noisy and false Minutiae.
Step 4: Perform Image Enhancement through Fingerprint image was rotated with the difference of 10 degree by selecting arbitrary image rotation option from the image menu till the core of both the images become uniform with respect to each other.(4)The core of fingerprint was kept at 90 degree which was adjusted by selecting image > image rotation > arbitrary image rotation.(5)The core aligning 90 degree was checked with the help of grid option. The straight line of the grid should run parallel to the core line.
Step 5: Converts Enhanced Image into Binary Image through Binarization. It is the process that converts a grey level image into a binary image.

Conclusion And Future Work

IoT technology enhances the prevailing life vogue by desegregation all the devices to a digital level within the in depth directions. The appliance areas of IoT infrastructure are going to be extended from sensible devices to sensible homes, sensible industries, and educational activity establishment's aid organizations, Scientific and analysis industries and sensible town development. Digital users have their own sensible devices with custom-made authentication procedures and completely different security standards for various functions. All told these applications and technologies, usually associate identification of many challenges, many security attacks in IoT setting were analyzed during this article. The planned model of framework for IoT setting by biometric based mostly authentication by fingerprints victimization Star IoT Network is meant. The advantage of star IoT network is that every one the quality within the style of the network is managed by a central IoT entry Node. The planned framework is going to be developed additional and its security analysis and performance measures to be analyzed on IoT context in future.

Deep Learning CNN Architecture for Automatic Grading of Brain Tumor

Yarava Rokesh Kumar[1], Margani Harinadha[2]
[1,2]*Assistant Professor, Department of CSE*
[1,2]*Malla Reddy Engineering College, Hyderabad, Telangana, India*

ABSTRACT

Deep Learning is the newest and the current trend of the machine learning field that paid a lot of the researchers' attention in the recent few years. As a proven powerful machine learning tool, deep learning was widely used in several applications for solving various complex problems that require extremely high accuracy and sensitivity, particularly in the medical field. In general, the brain tumor is one of the most common and aggressive malignant tumor diseases which is leading to a noticeably short expected life if it is diagnosed at a higher grade. Based on that, brain tumor classification is an overly critical step after detecting the tumor in order to achieve an effective treating plan. In this paper, we used Convolutional Neural Network (CNN) which is one of the most widely used deep learning architectures for classifying a dataset of 3064 T1 weighted contrast-enhanced brain MR images for grading (classifying) the brain tumors into three classes (Glioma, Meningioma, and Pituitary Tumor). The proposed CNN classifier is a powerful tool and its overall performance with an accuracy of 98.93% and sensitivity of 98.18% for the cropped lesions, while the results for the uncropped lesions are 99% accuracy and 98.52% sensitivity and the results for segmented lesion images are 97.62% for accuracy and 97.40% sensitivity.

Index terms: Convolutional neural networks, medical image analysis, machine learning and deep learning.

1. INTRODUCTION

Machine learning algorithms have the potential to be invested deeply in all fields of medicine, from drug discovery to clinical decision making, significantly altering the way medicine is practiced. The success of machine learning algorithms at computer vision tasks in recent years comes at an opportune time when medical records are increasingly digitalized. The use of electronic health records (EHR) quadrupled from 11.8% to 39.6% amongst office-based physicians in the US from 2007 to 2012 [1]. Medical images are an integral part of a patient's EHR and are currently analyzed by human radiologists, who are limited by speed, fatigue, and experience. It takes years and great financial cost to train a qualified radiologist, and some health-care systems outsource radiology reporting to lower-cost countries such as India via tele radiology. A delayed or erroneous diagnosis causes harm to the patient. Therefore, it is ideal for medical image analysis to be carried out by an automated, accurate and efficient machine learning algorithm. There is a myriad of imaging modalities, and the frequency of their use is increasing. Smith-Bindman *et al.* [2] looked at imaging use from 1996 to 2010 across six large integrated healthcare systems in the United States, involving 30.9 million imaging examinations. The authors found that over the study period, CT, MRI and PET usage increased 7.8%, 10% and 57% respectively. The symbolic AI paradigm of the 1970s led to the development of rule-based, expert systems. One early implementation in medicine was the MYCIN system by Shortliffe [3], which suggested different regimes of antibiotic therapies

for patients. Parallel to these developments, AI algorithms moved from heuristics-based techniques to manual, handcrafted feature extraction techniques. and then to supervised learning techniques. Unsupervised machine learning methods are also being researched, but most of the algorithms from 2015-2017 in the published literature have employed supervised learning methods,

2. RELATED WORK

Recently, Machine learning (ML) and Deep Learning (DL) methods are widely been used for detection and grading brain tumors using different imaging modalities, especially those acquired using MRI. In this section, the most recent and related research works on the paper topic are presented. Mohsen, Heba, et al. [8] propose a system that combines discrete wavelet transform (DWT) features and deep learning (DL) techniques. They have used fuzzy c-mean method for segmenting the brain tumor, and for each detected lesion the DWT was applied to extract the features, where these features are fed into the principal component analysis (PCA) for feature dimension reduction and finally the selected features are then fed to deep neural networks (DNN). The results show that they achieve an accuracy rate of 96.97% and a sensitivity of 97.0 %. Widhiarso, Wijang, Yohannes Yohannes, and Cendy Prakarsah [10] presented a brain tumor classification system using a convolutional neural network (CNN) and Gray Level Co-occurrence Matrix (GLCM) based features. They extracted four features (Energy, Correlation, Contrast, and Homogeneity) from four angles (0°, 45°, 90°, and 135°) for each image and then these features are fed into CNN, they tested their methodology on four different datasets (Mg-Gl, Mg-Pt, Gl-Pt, and Mg-Gl-Pt) and the best accuracy achieved was82.27% for Gl-Pt dataset using two sets of features; contrast with homogeneity and contrast with correlation. Seetha, J., and S. S. Raja [12] proposed a deep CNN based system for automated brain tumor detection and grading. The system is based on Fuzzy C-Means (FCM) for brain segmentation and based on these segmented regions a texture and shape features were extracted then these features were fed into SVM and DNN classifiers. The results showed that the system achieved a rate of 97.5% accuracy. On the other hand, Cheng, Jun, et al. [13] enhanced the performance of the brain tumor classification process using region of interest (ROI) augmentation and fine ring-form partition. They applied these enhancements to different feature extractions methods which are intensity histogram, GLCM, and the bag-of-words (BoW) where these features vectors are fed into a classifier. The experimental results showed that the accuracy enhanced from 71.39% to 78.18%, and 83.54% to 87.54%, and 89.72% to 91.28% for intensity histogram, GLCM, and BoW respectively.

3. PROPOSED SYSTEM

Currently, CNNs are the most researched machine learning algorithms in medical image analysis [4]. The reason for this is that CNNs preserve spatial relationships when altering input images. As mentioned, spatial relationships are of crucial importance in radiology, for example, in how the edge of a bone joins with muscle, or where normal lung tissue interfaces with cancerous tissue. As shown in Fig. 2., a CNN takes an input image of raw pixels, and transforms it via Convolutional Layers, Rectified Linear Unit (RELU) Layers and Pooling Layers. This feeds into a final Fully Connected Layer which assigns class scores or probabilities, thus classifying the input into the class with the highest probability. CNNs are currently the most widely used deep-feed forward neural networks that can treat different types of data inputs either 2D images or 1D signals. In general, CNN consists of many layers namely, input layer, convolution layer, RELU layer, fully connected layer, classification layer, and output layer. CNN is basically based on two processes; convolution using a trainable filter which has a pre-specified size, and weights that adjusted during the down sampling process in the training phase to achieve a high accuracy. In this research, the

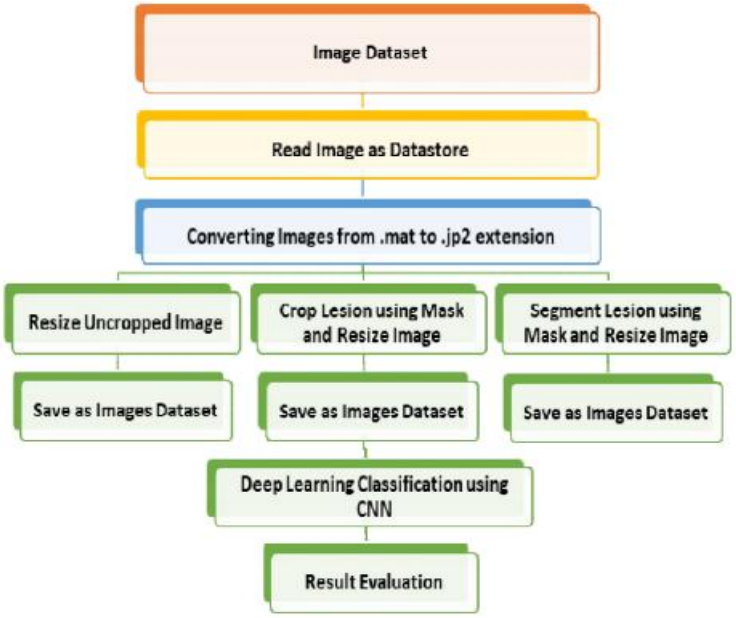
cropped and uncropped brain tumors images are stored as a database and three folders are created, each one consists of the images for specific class glioma, meningioma, and pituitary tumor. The database is partitioned into training and testing data, where 70% of the data is utilized in the training stage and the rest is used in the test stage. A new CNN architecture is employed in this paper. The next sections will explain the structure of the proposed CNN architecture. In this paper, we have proposed and used a newly designed CNN architecture. The architecture consists of 18 layers to enable the classifier to grade the brain tumor effectively. In this paper the architecture is modified and transferred to be applied on three different images dataset; cropped, uncropped, and segmented and the performance of the architecture was evaluated. Figure 2 illustrates the structure of the used CNN architecture.



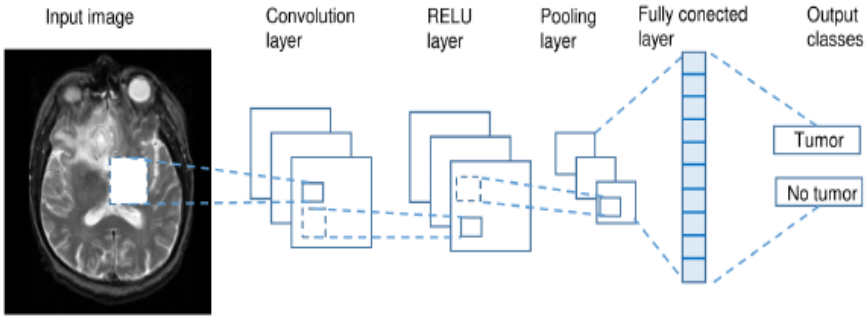


Figure 1: Block Diagram of the Proposed Methodology

The main aim and motivation behind this research paper are to provide a new CNN architecture for grading (classifying) brain tumors using T1-weighted contrast-enhanced brain MR images. Figure 2 Shows the Block diagram of the proposed methodology. In this section, the following sub-sections are discussed in detail, the used dataset, and the proposed methodology. To evaluate the performance of the proposed CNN architecture in grading the brain tumor in both cases; cropped and uncropped image, the confusion matrix for all cases (cropped, uncropped, and segmented) were generated, and a comparison between the CNN architecture outputs with its corresponding original image label was carried out based on these generated confusion matrices. In general, using these generated confusion matrices we can calculate the accuracy, sensitivity, precision, and specificity, to measure how precisely the brain tumor being graded.

Figure 3: CNN approach

Convolution Layer: A convolution is defined as an operation on two functions. In image analysis, one function consists of input values (e.g. pixel values) at a position in the image, and the second function is a filter (or kernel); each can be represented as array of numbers. Computing the dot product between the two functions gives an output. The filter is then shifted to the next position in the image as defined by the stride length. The computation is repeated until the entire image is covered, producing a feature (or activation) map. This is a map of where the filter is strongly activated and 'sees' a feature such as a straight line, a dot, or a curved edge. Unlike some neural networks where every input neuron is connected to every output neuron in the subsequent layer, CNN neurons have sparse connections, meaning that only some inputs are connected to the next layer. By having a small, local receptive field (i.e., the area covered by the filter per stride), meaningful features can be gradually learnt, and the number of weights to be calculated can be drastically reduced, increasing the algorithm's efficiency.

ReLU Layer: The ReLU layer is an activation function that sets negative input values to zero. This simplifies and accelerates calculations and training and helps to avoid the vanishing gradient problem. Mathematically it is defined as: f (x) = max(0, x). where x is the input to the neuron. Other activation functions include the sigmoid, tanh, leaky ReLUs, Randomized ReLUs and parametric ReLUs.

Pooling Layer: The Pooling layer is inserted between the Convolution and RELU layers to reduce the number of parameters to be calculated, as well as the size of the image (width and height, but not depth). Max-pooling is most used; other pooling layers include Average pooling and L2-normalization pooling. Max-pooling simply takes the largest input value within a filter and discards the other values; effectively it summarizes the strongest activations over a neighborhood. The rationale is that the relative location of a strongly activated feature to another is more important than its exact location.

Fully Connected Layer: The final layer in a CNN is the fully connected layer, meaning that every neuron in the preceding layer is connected to every neuron in the fully connected layer. Like the convolution, RELU and pooling layers, there can be 1 or more fully connected layers depending on the level of feature abstraction desired. This layer takes the output from the preceding layer (Convolutional, RELU or Pooling) as its input, and computes a probability score for classification into the different available classes. strongly activated features that would indicate the image belongs to a class. For example, on histology glass slides, cancer cells have a high DNA to cytoplasm ratio compared to normal cells. If features of DNA were strongly detected from the preceding layer, the CNN would be more likely to predict the presence of cancer cells. Standard neural network training methods with backpropagation and stochastic gradient descent help the CNN learn important associations from training images.

4. EXPERMENTAL RESULTS

All experiments were executed using a desktop computer with Intel Core-I7 processor and 16 Gb RAM. Both image dataset cropped and uncropped were run with a minibatch size of 64, ADAM optimizer as optimizing method, and with learning initial rate of 10-3 which results in 1600 iterations. The dataset was divided into three subsets: training, validation, and testing with a percentage of 70%, 15%, and 15% respectively. The following sections report the results of the proposed two image datasets using the designed CNN architecture. Figure 4 shows the accuracy variation overtraining and validation process during the CNN training and Training and.

Figure 6: CNN properties

The dataset that has been used in this paper contains three types of brain tumors; benign and Meningioma. In this work, an efficient automatic brain tumor classification is performed by using the proposed convolution neural network. Various manners have been applied to the dataset, such as segmented, cropped and uncropped tumors.

5. CONCLUSION

In this paper, we have presented a new convolutional neural network (CNN) architecture for automated grading (classification) of a brain tumor in three brain datasets: uncropped, cropped, and segmented region of interest (ROI). Our architecture succeeded in grading the brain tumor three classes with high performance in accuracy and sensitivity in all dataset cases: uncropped, cropped, and segmented. The system can significantly grade the tumor into three levels: meningioma, and benign tumor using T1 weight contrast-enhanced brain MR images. This architecture grading efficiency may even be further improved by including more brain MR images with different weights and with various contrast enhancement techniques to allow the architecture to be potentially more generalized and robust application for larger image databases.

ABSTRACT

Data is a valued asset especially when data moving to the cloud. Cloud computing model attracts different users because of its various benefits such as scalability, simplicity, expense reduction, and high resource resistance. Cloud computing is a wide-ranging architecture based on different models for providing different software services and hardware services. There may be different types of data and the degree of protection needed for all the data is also may vary. Data privacy and data security is the major area of research and development in the cloud computing. Privacy protection and data leakage became essential thing for so many organizations moving on to cloud. Several classification methods that are expressed various parameters based on different dimensions for providing the data security can be based on the level and are required protection. But, the latest approaches introduced by the cloud, related to distributed resources, multi-tenancy idea, computation outsourcing, high dynamism of the model, data warehousing and the non-transparent style of cloud increase the security and privacy concerns and makes building and maintaining trust among cloud service providers and consumers is a serious security issue. In this paper, we proposes a new approach to improve security of data in cloud computing. It proposes a classification model to classify data before being presented into a suitable encryption system based on the category. Because data in cloud has not the same sensitivity level, encrypting these different types of data with the same algorithms can lead to a lack of security or resources. By this scheme, we can achieve high security for our data, and can optimize the computation cost and resource consumption while ensuring data confidentiality.The efficiency of the proposed classification scheme is analysed with the sample dataset collected.

Key words: Cloud computing, Cloud storage, Data security, Data privacy, Data classification, Data sensitivity.

1. INTRODUCTION

In general data can be represented as set of raw facts. Data is a big asset of any organization. Data could be in any of the forms like numbers, letters, words, images, audio, video etc. Data privacyand security is a key issue for any organization. Data can be structured or unstructured. Majority of organizations maintain their data as structured manner, so that very easy to classify, manage, and access. Usually classification process of structured data found in spreadsheets and databases are less complex and time consuming to manage than those of unstructured data such as source code, documents, and email. Irrespective of whether structured data or unstructured data, it is very important for organizations to manage the data sensitivity. When data classification properly implemented, it ensure that sensitive or confidential data assets are managed with greater mistake than data assets that are considered public or free to distribute.

The cloud computing refers to a model for supportingflexible and convenient, global, on-demand network access to a sharable group of configurable computing resources (e.g., servers, storage, networks, applications, and services) that can be quickly provisioned and released with minimal efforts to manage or service provider interaction [1].It lessens the need of user involvement by complicating technical details such as licenses, software upgrades, and maintenance from their clients [2]. We can understand clearly about the cloud and its environment through the figure1 shown in below.

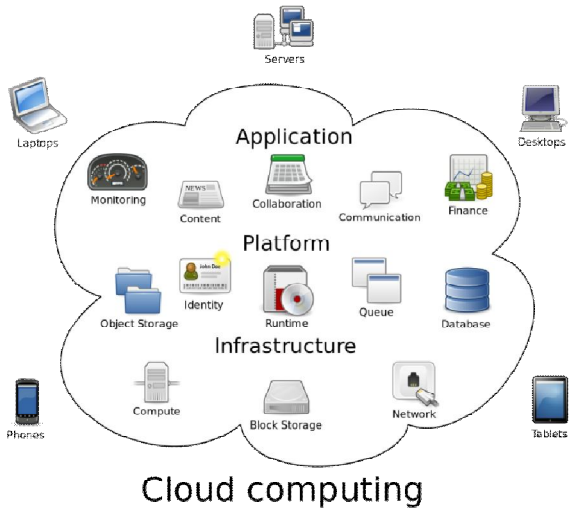

Figure 1: Cloud Computing Environment

Though, the innovative methods presented by the clouds, related to outsourcing computation, multi-tenancy concept, distributed resources, high dynamism, data warehousing and the non-transparent model of cloud maximize the security and privacy issues and makes a critical security challenge [3] forconstructing and hold trust among cloud service providers and cloud consumers.

When a user stored his data in cloud or to use a cloud service whereever his data is involved, majority times, he cannot pay attention to know the details of the security risks faced there; attacks, vulnerabilities, malware information and security policies established in the cloud. For instance, an attacker can introduce a piece of code into web application to ignore access control mechanisms, to gain free access to all customer's data, authorized data, tokens and also plaintext passwords by cross locate scripting attack. Also, attacks such as denial of service(DoS) attack, flooding attack, Wrapping attacks, XML Signature and others lead to taking the administrative rights of the cloud user or to making data unavailable [4]. In these scenarios the user loses the control of his data and especially the cloud service provider or an external party can read and use it for their benefit. To touch a high privacy and security goals associated to data and cloud services, cloud service provider(CSP) establish a Service Level Agreement (SLA) to the cloud consumers, but unfortunately no standard procedure provided to conceive an SLA. SLA reports associated to the approved services, which is very helpful for both consumers and provider. However, these SLA reports do not fully conform to the consumer needs in terms of security. Several cloud providers does not provide sufficient SLA to assure that user data is fully secure [5]. If cloud computing is feasible alternative to the traditional systems and gain user's trust, cloud's infrastructure must implement and provide a security at a level that ensure the data protection and guarantee to its confidentiality,data integrity and availability. Consequently, a more awareness is required about tools and measures to take in order to avoid malicious activities that target data.

In [15], Frank Simorjay et al. given some clarification on the different parameters or factors from which we should know how to achieve the data security and confidentiality,such as data access control, Authentication, Authorization ,etc. They described about them as follows:

Data access Control

To control the data accessing from the user, we use Authentication and authorization. Sometimes Authentication and authorization are confused with each other and their roles misinterpreted. In reality they are quite different, as shown in figure below:

Figure 2: Difference between Authentication and Authorization.

Authentication usually consists of at least two things: a user ID or username to identify a user and another is a token such as a password, to confirm that the username credential given is valid or not. it verifies that the user is a valid user or not. Authorization is a process of providing the ability to access data set, data file, an application, or some other object to an authenticated user. Assigning the rights for use, modify, or delete items to authenticated users that they can access, needs care to data classification. The difference between Authentication and Authorization is described in the figure2 very well. The validity of data in the sense, data which is recorded and used with respect to related requirements that should be valid over a given period of time. Relevance means, the data captured should be used with respect to relevant requirements. Completeness of data means data should be complete or fulfilled with respect to its usage. Data accessibility deals with the access of data with respect to time, scope and cost. Data consistency deals with the uniformity of the content which is stored with respect to changes made by transactions that used data.

Basic security issues of data comprise confidentiality, availability and integrity. Data confidentiality deals with the privacy of data that comprises authentic and authorized accessibility of sensitive data. Data integrity deals with data consistency and data accuracy which are required to achieve integrity. Data availability issues relating to fool proof storage, storage type, requirements for disaster recovery and also backup plan.Data availability is most important issue to any organization moving to the cloud. Security issues concerning data increases when moving to the cloud. User controls about data, data protection technique and data availability are some of the issues that user requires to know before using the cloud for data storage. The data stored on the cloud should be protected from unwanted malicious disaster that may be man-made or natural. A cloud provider should know and accordingly need to provide measures to achieve data availability.

Data Classification Process

Many organizations understand the need of data classification and want to implement it is a basic challenge. One effective and simple implement of data classification is by using the PLAN, DO, CHECK, ACT model from MOF. The figure3 below shows the tasks that are needed to implement successfully in data classification model.

Select a suitable model that addresses your needs

Many types of processes are present for classifying the data, like manual processes, location-based processes that classify data based on a system's or a user's location, application-based processes such as database-specific classification, and automated processes used by various technologies.They introduced two generalized terminology models based on well-used and industry-respected models. Both of these terminology models, provide three levels of classification sensitivity, which are shown in the table1 below.

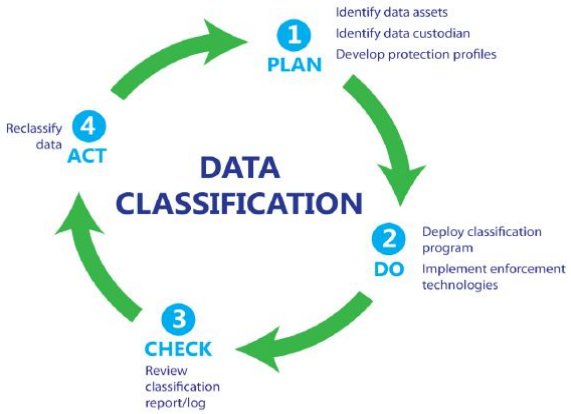

Figure 3: Steps in classification process

Table1: Levels of classification sensitivity

Sensitivity	TerminologyModel 1	TerminologyModel2
High	Confidential	Restricted
Medium	For internal use only	Sensitive
Low	Public	Unrestricted

Data Ownership

To provide the security for the data it's important to launch a clear chain of ownership for all the data assets. The table2 given below identifies different data ownership roles in data classification and their relevant rights.

Table 2: Data ownership roles and their relevant rights

Role	Create	Modify/delete	Delegate	Read	Archive/restore
Owner	X	X	X	X	X
Custodian			X		
Administrator					X
User*		X		X	

The data owner is the original creator of the data file, who can give ownership and assign a guardian (called custodian) . When a file is created, the owner should assign a classification, they have a responsibility to understand what needs to be classified as confidential data based on their organization's policies. Data of all owners can be auto-classified for internal use only (sensitive) unless creating or owning confidential (restricted) data types. Frequently, the owner's role will change after the data is classified.An **administrator** is a user who is responsible for ensuring the data integrity, but they are not a data owner, custodian, or user. The administrator role includes backup, restoration, maintaining records of the data,, and choosing, obtaining, and operating the devices and storage that stores the data assets. The **asset user** is anyone who is granted access to data or a file, access assignment is often given by the owner to the custodian.

To implement these classification process, we need to consider details about who, where, when, what, and why a data asset would be used, changed, deleted or accessed. Sometimes reclassifications also need to be done. Reclassifying is a changing of classification state of a data when a user or system defines that the data risk profile or importance has changed. This reclassification is very important for ensuring the classification status continues to be current and valid. Reclassification can be done either manually or automatically.

The classification of data process has been used for decades by large organizations such as Microsoft, governments, private organizations, and military entities to manage the integrity of their data. Organizations which are assessing cloud computing for future use or organizations that are presently using cloud services and looking for ways to optimize data management will benefit from this paper. Data Classification is a method of defining different data levels and determining a level of sensitivity to it. It is a crucial activity at different stages as data is being created, stored, modified, or transmitted. The classifications of the data determine up to what extent the data needs to be secured and its value in terms of Business Resources. Data classification can be done based on the different aspects. Some based on the risk related with the disclosure are public, internal, confidential (or highly confidential), restricted, regulatory, or top secret. And some based on its way of creation are user personal data, their usage patterns etc.

To provide the access control and authorization, classifying data based on security levels, many organizations felt it as area of interest by using or providing cloud services. In this paper, we have studied a set of classifications procedures given in the literature survey and recognized a set of parameters based on the security needs for cloud data. We have analysed some sample data sets that provide the security based on their usage and access control with respect to cloud computing environment.In the literature, we mentioned several mechanisms implemented in the cloud infrastructure to protect data. Moreover manymethods were proposed to secure the data at various levels, on different platforms and different domains such as network, hardware, software, hypervisors, storage, access control, classification model to classify the data before being presented into an applicable encryption system. Because data in the cloud has not same sensitivity level, encrypting it using same algorithms can lead to lack of resources or of security. Hence,it is needed to optimize computation cost and the resources consumption while ensuring the data confidentiality.

2.PROPOSED SYSTEM MODEL

The system model of our proposed scheme is given in below figure4. In the cloud virtual environment, the data can be taken from the different local servers to store into the cloud. Before storing that data into the cloud,it is classified based on the application areas belonging that data, then reclassifying it deeply based on its sensitivity and its properties. Finally, the fully classified data can be store into the cloud environment as different type of clusters in such a way that, it is possible to apply security algorithms on a specific data set , so that it can be high protected.

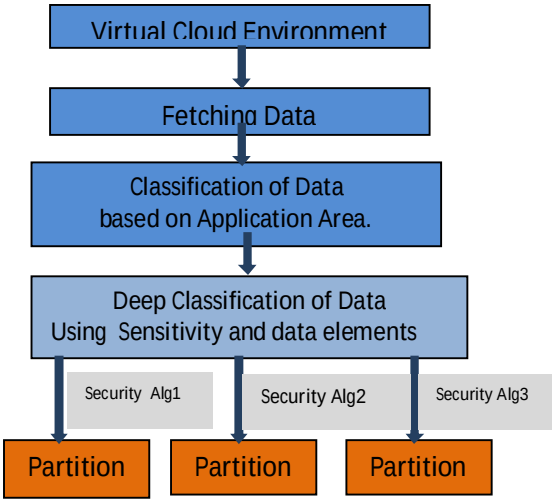

Figure 4: Cloud simulation Environment

Data security is the key issue in cloud computing. Though, several experimentations had been done to solve this issue,still different data leakage problems are facing in the cloud. In this paper we concentrate on the data stored in the cloud and to secure it by adopting a classification method. Weobserved that different types of data are loading through the cloud infrastructure. Some customers need more security and some needs more confidentiality and protection than other for their data. But reality exist in the in cloud environment is different; a cloud provider accomplishes the same models or mechanisms for security for different types of data, or sometimes simply they uses same security procedures for allclient's needs. Itleads to waste of time, a loss of cost; and a misuse of resources. We identified some of the research work existing in the literature related to this paper.The main idea is the classification of data before applying to any security technique that optimize its security.

Barker et al. proposed a new privacy data model based on data classification. They recommendto build a system that should have the capability of protecting user privacy by using the three fundamental aspects such as purpose, visibility and granularity. They spited granularity into the four sub-aspects (None, Existential, Partial, and Specific). The visibility is also divided into the five sub-aspects (None, Owner, House, Third party, All/Work). And for the Purpose, they proposed five alternatives aspects (Single, Reuse same, Reuse selected, Reuse any, and Any) [6].

3.LITERATURE SURVEY

In [1], the sensitive data is outsourced to a cloud service provider with the authorisation of block level modifications. Unplanned mutual belief is established between data owner and user by using third party. Pearson discussed policies and assessment procedures in [2] for privacy enhancement methods and tools. Privacy is provided in terms of legal obedience and user belief, data leakage for sensitive data. Ji Hu and Klein A, in [3] gave a benchmark to secure the data-in-transit in the cloud. And also protecting the data during migration is discussed via benchmark for the encryption overhead and security. Additional encryption is needed for high security but it needs more computation. So a benchmark provides balance for the security and also encryption overhead.Tetsuya M, Kazuhiro S and Hirotsugu, K. provided a large scale search system for the information exchange between the internet communities that leads to formation of hidden Channels [4]. An agent based security model used to control data from hidden channel is presented. It may solve the problem of data leakage in the cloud.In [5] discussed aboutthe privacy issue by holding data control to user to increase confidence, also discussed cloud computing attacks and some provisions to overcome from the same.

In [6], aninnovative patient-centric framework is presented for data access control of Patient Health Records,where data is stored in semi-trusted servers. Attribute based encryption techniques used to encrypt each patient's Health Record file to achieve fine-grained and scalable data access control.In [7], data characteristics are studied with respect to the online social networks.They have identified the information and its leakage at the time of data sharing in the network. For this purpose they also used third party check.

Data protection organisation is proposed in [8] by considering several aspects. A case study is inspected by providing the solution for data protection in terms of questionaries' like who needs protection, what has to be protected etc. A restriction to data accessibility by the third party applications is proposed in the form of framework in [9]. Policies are applied for restricted access and therefore the privacy of user confidential data is achieved from the third party applications.Data privacy is achieved to the user that makes use of the hotspots for the internet access in [10].

In [11],a three dimensional vision for data taxonomy is proposed. This classifies the data as per visibility, and Granularity. Various levels of data are defined along these dimensions to achieve the data privacy. Taxonomy for social data is presented in [12], which classifies the data based on the way data is generated in the social network, and hence the privacy and access rights have to be applied. Data classification at various phases in a social network is presentedin [13], which classifies the data based on security parameter confidentiality in a network. This classification applies in several phases of data like collection, processing, dissemination and invasion.

In [14], data security andvarious security issues areanalysed, and a trust based solution is proposed for the same. Here data security concerns have identified and attempted to provide security by classifying the data. Many dimensions are identified along which security and protection level can beapplied to different data. Sometimes security need to check in the different levels like PaaS,SaaS and IaaS,Dr.N.Srinivasu et al. in[20] found threats at all these levels and resolved them by using the security mechanisms..

In [16], RasmeetKour et al. proposed a classification mechanism to classify thedata depending upon the security elements of the data.Thiswill divide data into two parts-sensitive and non-sensitiveby improved bagging and boosting technique.In [17], Kumar Pal Singh et al. proposed a mechanism for data classification based the data

sensitivity. Depends on the sensitive rating of the data in terms of confidentiality, integrity and availability, data can be classified into three categories:low impact, moderate and high impact. Hence the security algorithms can be applied on to the data based on suitability. It is also giving good results.In[15], RizwanaShaikh et al. given the data classification mechanism through that they classified the date based on the three properties: Access control, Content and Storage. Each property again divided into sub-properties as given in figure5.This method given detailed classification up tosome level. The value of data is identified based on their usage and access control restrictions.

Data Classification Properties		
Access Control	**Content**	**Storage**
Frequency of Access Frequency of Update Visibility and Accessibility Retention	Precision Accuracy Reliability/Validity Degree of Completeness Consistency and Auditability	Storage-encryption Communicationencryption Integrity Access Control Backup and recovery plan Data Quality Standards

Figure.5: Data Classification Properties

Content of data have several properties with respect to its modification such as Precision/ Accuracy, Reliability/ Validity, Degree of Completeness, Consistency, Auditability,
Data storage policies can be applied based on the norms and constrictions applied to the different types such as Storage-encryption, Communication-encryption, Integrity, Access Control, Backup and recovery plan, Data Quality Standards. Access Control category defines the access restrictions we can applied on data. That includes Frequency of access, Frequency of update, Visibility and Accessibility, Retention etc.

They Simulated the classification of data based on personal data set elements like name, addresses etc. is taken as sample data and analysed. They have used the subjective criteria to classify them and based on that, security requirements for the storage and communications can be incorporated. These criteria can be transformed to values and threshold can be set for objective evaluation.

Garigipati,N.et al. presented a study on the data security and the query privacy in cloud in [27], thru that we can get some security issues. In [28] Keerthi,G et al. presented the source based privacy for the confidential data in the cloud based e-healthcare systems. In [29], Mane,P.M et al. presented a method to achieve confidentiality and efficient access control of data in cloud using CP_ABE.

After classifying the data, we need to apply the security mechanisms to obtain the high security for our data. For instance, in [21], N.Srinivasu et al. proposed a security algorithm named Honey Encryption which is a different technique that solve the brute force problems also.Some techniques are used to enforce the security mechanisms like used in [24].Babukarthik et al.proposed a mechanism for data owners to execute their security policies to confirm data confidentiality and integrity, which also enable trusted data sharing through untrusted cloud providers.In[25],different decisional learning parity with noise (DLPN) named as key-Ordered DLPN based security algorithm is proposed, here DLPN is extended to an even-odd-order mechanism for the encryption, in this, odd and even bits are input integer values for the key generation algorithm in that security method.

In centralized controlling cloud, the Host Controller(HC) manages the resources such as virtual machine (VM) and physical hosts across hosts in the Data Center (DC).If HC is down,the services hosting by several hosts in DC also will down. Hence, decentralized VM management used to avoid by taking one of the hosts from DC as HC to keep DC in running.The host's in DC does VM migration across various hosts incorporate the security mechanism on hosts to protectdata in migration[22]. It is mandatory to allocate the resources and using good and suitable scheduling algorithm to complete the given task in the cloud in minimal amount of time. In [23], S.Phani Praveenet. al, proposed a method with two phases as resource allocation and tasks scheduling. Efficient resource allocation is done using social group optimization scheme and tasks scheduling using shortest-job-first scheduling algorithm. In [30],Naresh et al. presented the method to optimize the resourceschedule in the cloud.Sometimes we need to prevent the data attacks like, In [26], Chaitanya,G.K., et al. proposed a method to prevent data theft attacks inIaaS cloud through the trusted computing

4.PROPOSED CLASSIFICATION METHOD

From the above literature, we can understand that data classification is very essential method to enhance the data security in the cloud both at storage level as well as access level. So, in this paper we proposed a mechanism for achieving the security to the next level, by classifying the data into some more deep.
Data can be classified into different categories based on its sensitive level or rating as low sensitivity, moderate sensitivity and high sensitivity. The data should be stored and maintained based on its context. The sensitivity level can be defined to the different type of data whether it is public, private, personal, official, health related data, criminal issues data etc.For example, some sample data is shown in the table3 and table4 with their sensitive levels.

Table 3: Different Type of data and its Sensitivity (For sample)

Type of data & its Sensitive level	
Type of data content	**Sensitivity level**
Public data	Low
Private data	Moderate
Personal data	High(Restricted)
Official data	Moderate
Health related data	High
Criminal issues data	High
Hospital Data	High
Research Data	High

In addition to the sensitive level, we described some properties of data in terms of security, integrity, availability of data as said in [15]. If the data classification is applied according these properties and based on the above specified

sensitive level at the storage level of cloud, then very easy to maintain and access it. After the data classification is done with these properties and sensitivity, we can apply the suitable security algorithms to achieve optimal security of the out sourced data. Instead of applying the security mechanisms on the entire data blindly without concentrating on the type and sensitivity of the data, if we apply based on the specific type and sensitivity of the data, we can achieve the optimized security. Once the data is outsourced to the cloud, in general auditing can be done to verify the data integrity as done in [18].

5. ANALYSIS

By observing the literature survey, we can say that, some mechanisms are providing security only based on the security algorithms on the entire data, some are providing only based on classification, some are providing based on both classification and security mechanisms. Though they are providing security, which may not give as optimal, since they are doing only basic level classification The classification process given in this proposed method will definitely will give optimal level security for our data which is outsourced to the cloud, since here classification is doing deeply and then applying the security algorithms on the sensitized and classified data. To perform the data classification automation, we should use any data classification algorithms. If we apply the data classification algorithm and data security algorithm, definitely we can reduce the execution cost of both secure data storage as well as retrieval.

6. CONCLUSION

Data security and privacy is one of the major issues facing while data out sourcing to the cloud storage. Even though somany classification methods exist in the literature survey, they cannot reach to the optimal level security for our data. We proposed amethod, in which we can identify the different type of data with their sensitivity, and we can divide the data into smaller to identify their sensitivity clearly, so that we can store the data into the cloud as clusters and sub-clusters, hence it is possible to access very easily with the proper access rights. Moreover,we identified a set of parameters based on these and data sensitivity, classification can be done deeply and then suitable security algorithm can be applied on a specific data set, not on the entire data. And then data can be stored intothe cloud.So, here we providing security levels based on type of content and accessibility, and in cloud storage as per the required confidentiality and accessrestrictionsforthedataspecified.Wehaveanalyzedfewdataelements andclassifiedthembasedonthe proposed parameters. The classification provisions can be given for storage and communication encryption, integrity and access control mechanisms. Also a regularized backup plan can be decided for disaster and recovery.

ABSTRACT

To investigate the effect of deep neural networks with transfer learning on MR images for tumor classification and improve the classification metrics by building image-level, stratified image-level, and patient-level models. Three thousand sixty-four T1-weighted magnetic resonance (MR) imaging from two hundred thirty-three patient cases of three brain tumors types (meningioma, glioma, and pituitary) were collected and it includes coronal, sagittal and axial views. The average number of brain images of each patient in three views is fourteen in the collected dataset. The classification is performed in a model of cross-trained with a pre-trained InceptionV3 model. Three image-level and one patient-level models are built on the MR imaging dataset. The models are evaluated in classification metrics such as accuracy, loss, precision, recall, kappa, and AUC. The proposed models are validated using four approaches: holdout validation, 10-fold cross-validation, stratified 10-fold cross-validation, and group 10-fold cross-validation. The generalization capability and improvement of the network are tested by using cropped and uncropped images of the dataset. The best results for group 10-fold cross-validation (patient-level) are obtained on the used dataset (ACC=99.82). A deep neural network with transfer learning can be used to classify brain tumors from MR images. Our patient-level network model noted the best results in classification to improve accuracy.

1. INTRODUCTION

The effective decision-support system is very much essential for radiologists in medical diagnostics. According to the World Health Organization (WHO) [1] cancer is the second leading cause of death. Globally, 9.6 million deaths in 2018 due to the cancer disease and about 1 in 6 deaths in the global population. Death from cancer can be prevented with early detection. Brain cancer is much critical than other types of cancer and clinical diagnostic of brain cancer is difficult. In general, unlike cancer, tumor could be benign, pre-carcinoma, or malign. Benign can be removed surgically and it does not affect other organs and tissues. However, brain tumors are meningiomas, gliomas, and pituitary. Meningiomas tumor occurs from membranes (the area that protects the brain and spinal cord), gliomas arise from brain tissues and pituitary tumors are lumps that sit inside the skull at the pituitary gland area. In fact, benign tumors do not spread to other tissues, cells, and organs of the body [2]. The difference between these three types of tumors is that meningioma and pituitary are benign, and glioma is malignant. One of the ways to detect the brain tumor is to examine the MRI images. An experienced radiologist can examine the MRI images and decide the type of brain tumor. This decision depends on the experience of the radiologist and the available data of the patient. Since the identification of tumor depends on the experience of the radiologist and a large amount of data observation is difficult for radiologists or humans. Brain tumor biopsy must require brain surgery. Therefore, it is to develop a computer-based decision-making tool for tumor classification and segmentation from MR imaging [3].

Advanced Machine Learning models based on deep learning and neural networks will be optimized to perform at the edge [4-7]. These models provide useful assistance for many medical applications and medical imaging. Several deep learning methods for classifying images and detecting regions in MR images. The advanced decision support system for machine learning can serve as a second opinion for radiologists before going for biopsy of the tumor.

Many researchers have been implemented tumor segmentation and classification on various datasets, which are publicly available in internet. Most of the datasets are very small in size. In addition, implemented models are concluded in small datasets. But advanced machine learning models based on deep learning and neural networks demands large volume of data to perform optimally. Since, researchers are claiming that better results with small number of input observations. In the literature, image classification, segmentation, and image analysis are implemented in various advanced deep learning techniques and modified pre-trained networks. Different approached are developed in MR imaging datasets of brain tumors. These approaches are discussed in the Literature Review section of this paper. This paper focuses mainly on the deep learning networks. In particularly, convolutional neural networks (CNN) with transfer learning with the same dataset, which is used in this paper.

Convolutional Neural Network based models need large volume of data to note the optimal results in the taken application area. For MR imaging, it is required to have different planes (views) of same patient to increase the size of

dataset. Further, data augmentation and pre-processing are used on the images before feeding into CNN models [8-11]. The main advantage of the deep convolutional neural network (DCNN) is that data augmentation and pre-processing do not required. DCNN can be able to extract the specific to subject feature from the images without pre-processing techniques. Pre-processing procedures may take extra resource to perform the segmentation and classification. This paper proposed DCNN with transfer learning. The advantage with transfer learning is that pre-trained model provides the generalized features and these features are combined with specific features of MRI images.

The objective of this research is to investigate the effect of deep neural networks with transfer learning on MRI images for tumor classification and improve the classification metrics by building image-level, stratified image-level, and patient-level models. In addition, our results are compared with other works which are carried out on same database of images and in same approaches. We have tested the designed model on pre-processed and original image database. In addition, we examined the performance of network to show how the various validation strategies yield the performance metrics results.

In this paper, we proposed DCNN based transfer learning (InceptionV3 pre-trained model from imagenet) architecture for brain tumor classification of three kinds (meingioma, glioma and pituitary) from T1-weighted MRI images. The performance of the architecture is tested using hold out, 10-fold cross validation, stratified 10-fold cross validation and group 10-fold cross validation in the combination of cropped image dataset and uncropped image dataset. The performance evaluation is done using the classification metrics such as accuracy, loss (error), precision, recall, kappa and AUC. Finally, we made a comparison study with state-of-the-art methods to discuss our results.

2. LITERATURE REVIEW

Several approaches to the classification of brain tumors using MRI images have been developed in recent years. Unlike basic machine learning architectures, we have used transfer learning to concentrate on DCNN-related literature. Cheng et al. [12] implemented tumor classification using augmented tumor region of interest. He is first person presented the image database, which is used in our research work. He also presented the work in the augmented tumor region is split into increasingly fine ring-form subregions. Finally, he was made the accuracy of 91.28% for MRI image tumor classification. Badza et al. [13] present a new CNN based model for brain tumor classification of three tumor types. The performance of the network is evaluated in four approaches in the combination of two 10-fold cross validations and two databases (original database and augmented database). This work presented the accuracy of 96.56% in tumor classification from MRI images. Hossain et al. [14] proposed a method to extract brain tumor from MRI images using Fuzzy C-mean clustering algorithm followed by CNN model. This work was implemented in keras & tensor flow and gained an accuracy of 97.87%. Özyurt et al. [15] presented a hybrid method using Neutrosophy and Convolutional Neural Network (NS-CNN). In this proposal, features of brain tumor are extracted using CNN and classified using KNN and SVM. The network was evaluated in 5-fold cross validation and gained the classification accuracy of 95.62%. Kaur et al. [16] presented explored the capabilities of various pre-trained models with transfer learning for brain tumor images. This work was evaluated using holdout validation (in the ratio of 60:40, training, and testing). The networks were tested on three types of databases and gained the results of 100%, 94% and 95.92% using pre-trained Alexnet. Phaye et al. [17] propose Dense Cap- sule Networks (DCNet) and Diverse Capsule Networks (DCNet++) by replacing CNN, which leads to learning of discriminative feature maps. DCNet achieves state-of-the-art performance an accuracy of 99.75% on MNIST dataset and DCNet++ performs better than CapsNet on SVHN dataset an accuracy of 96.90%. Balasooriya et al. [18] proposed CNN based model for brain tumor type identification. This work is claimed an accuracy of 99.68% for tumor recognition. Sobhaninia et al. [19] developed tumor segmentation using CNN and gained dice score of 0.79. Seetha and Raja [20] proposed an automatic brain tumor detection using convolutional neural networks and achieved an accuracy of 97.5%. Sultan et al. [21] presented brain tumor classification using deep learning based CNN network on two databases of MRI images. For two databases, they achieved overall accuracy of 96.13% and 98.7%. Afshar et al. [3] presented modified CapsNet for brain tumor classification with access to the tumor surrounding tissues, without distracting it from the main target. In this mode, they used tumor coarse boundaries as extra inputs to achieve the outperformance. Gumaei et al. [22] proposed an accurate brain tumor classification with hybrid feature extraction method and regularized extreme learning. They evaluated the model using holdout validation and achieved an accuracy of 94.23%. Kurup et al. [23] analysed the effect of pre-processing in disease classification. Hence, they proved that data pre-processing improves the brain tumor classification from MRI images in capsulenet architectures.

In this research, we proposed brain tumor classification using deep neural network with convolutional neural network and achieved an accuracy of 99.82% from MRI image database. We developed multi class classification, which is more challenging and complex task than binary classification. We have adopted the T1-weighted MRI image database from figshare and used by Cheng et al. in 2017. This database of MRI images is publicly available to everyone and it is very small in size compared to general image datasets. Therefore, working with small image datasets in deep learning is more challenging and leads to overfitting when the networks are trained from scratch. To overcome these issues from the deep learning models, we have adopted transfer learning pre-trained models, which are trained from natural images (ImageNet). Finally, based on the generalisation capabilities to extract the features of images of InceptionV3 pre-trained model. We used InceptionV3 for taking general image features and combined with specific features of MRI image features by adding last layers in the network. The full-length details of the network are discussed in 3.2.3 proposed CNN architecture model.

3. PROPOSED METHODOLOGY

3.1 Dataset

The T1-weighted MRI brain tumor dataset is publicly available for research community at https://figshare.com/articles/brain_tumor_dataset/151242. This image data was initially used by Cheng. et al. in 2017 [12]

for tumor type classification. The MRI image dataset contains 2-D images of three brain tumor types (1. menigioma, 2. glioma, and 3. Pituitary). In addition, the database consists three plane views (i.e. axial view, coronal view, and sagittal view) of three types of brain tumors, which are shown in the Figure 1). As shown in the Table 1, the dataset contains 3064 MRI images from 233 patients over all three views and three tumor types. The dimensions of each MRI image are 512x512 pixels. All the statistical details of the MRI image dataset are given in the Table 1.

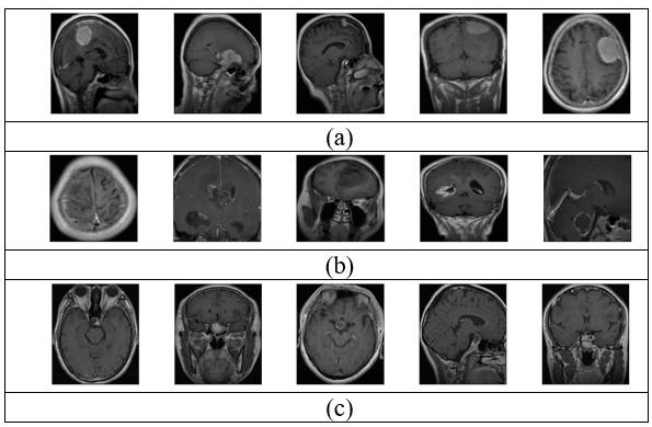

Figure 3. Cropped images for tumor (a) meningioma (b) glioma (c) pituitary

Table 1. The details of dataset (T1-weighted MRI Images)

Type of Tumor	MRI View	Number of MR images	Number of patients
Meningioma	Axial	209	82
	Coronal	268	
	Sagittal	231	
Glioma	Axial	494	89
	Coronal	437	
	sagittal	495	
Pituitary	axial	291	62
	coronal	319	
	sagittal	320	
Total		2064	233

3.2 Methodology

3.2.1 Pre-processing

We have generated two datasets from the original image dataset. One dataset with cropping operation around the brain view in the MRI image and another one without cropping operation. The variation between two datasets shown in the Figures 2 and 3. Two datasets are normalized and resized to 256x256 pixels. The original size of the image is 512x512 pixels. We have used two size of images for input layer of the network. We did not identify any noted improvement in the accuracy rate of classification and consumed more resources in terms of memory and processing time for the dataset of 512x512 pixels compared to the dataset of 256x256 pixels.

3.2.2 Convolutional Neural Networks

CNNs or ConvNets are widely used to do image classification, image recognition and object detection. Deep learning CNN (DCNN) models contain series of layers with filters to perform feature extraction and dimensional reduction. Technically, DCNN passes an input through series of convolution layers with kernels (filters) to classify an object. Models make a probabilistic value between 0 and 1 for given input. In general, DCNN architectures contain a series of convolution layers with filters, pooling, DropOut, ReLu and fully connected layers and finally softmax or sigmoid function to do classification. Sigmoid function is used for binary classification. Softmax function used in multi class classification problems. The CNN models perform automatic feature detection and extraction with high performance.

In this research, we used DCNN with transfer learning with pre-trained InceptionV3. The mechanism of transfer learning is briefly illustration in Figure 4. IncpetionV3 model contains 311 layers and 1,60,36,416 trained weights. The model needs large dataset for training and result optimization. But getting big datasets in the medical applications is very difficult and usually, small datasets will suffer from overfitting. Hence, weights for the model are initialized from IncpetionV3 pre-trained model. Therefore, weights will be transferred from pre-trained model for fine tune.

There are three versions of inception deep convolutional architectures are developed by Szegedy et al. [24]. InceptionV1 is also galled GoogLeNet. InceptionV1 was refined using batch normalization to decrease the computational time and error rate (by Szegedy et al. [24]) and it is named as InceptionV2. Later, they added factorization with second version and named as IncpetionV3. The architecture of InceptionV3 shown in the Figure 5. InceptionV3 focuses on to use less computational power compared to previous versions. This version of deep

convolutional architecture adopted various convolutions to burn less computational resources such as factorized convolutions, smaller convolutions, asymmetric convolutions, auxiliary classifier and grid size reduction [24].

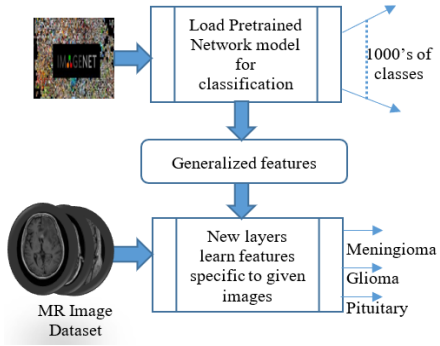

Figure 4. Deep Neural Network with transfer learning

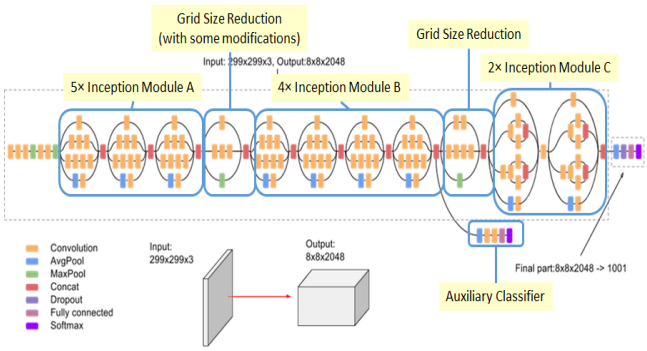

Figure 5. InceptionV3 architecture

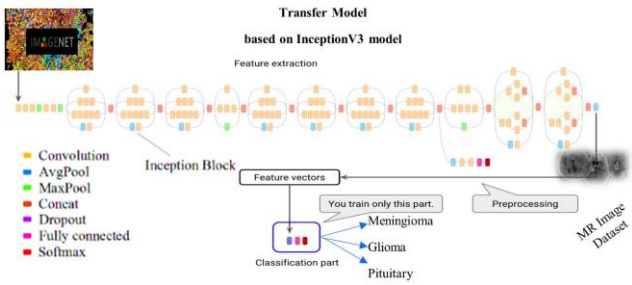

Figure 6. Illustration of transfer learning-based model

3.2.3 Proposed CNN Architecture Model

The proposed CNN architecture was developed in Keras and Tensorflow. The network architecture consists of pre-trained InceptionV3 model trained from ImageNet (311 layers), Fully connected layer with 256 neurons (ReLu activation function), Dropout layer with 20%, softmax classification layer and ouput. From pre-trained model general image features extracted to the fully connected layer. This extraction gives good discriminative representation for trained images. These general image features combined with MRI image features from the fully connected layer. Later, 20% dropout will be applied on the values of ReLu activation of previous layer. In last layer, the number of hidden units is equal to the number of the classes of brain tumor. The schematic representation of proposed CNN architecture shown in the Figure 6. The last layer of InceptionV3 is composed of 1000 hidden units corresponds to classes in the ImageNet dataset. Therefore, the last layer of InceptionV3 replaced with a layer with 3 hidden units according to classes in the MRI image dataset.

Transfer Learning has become increasingly popular, as it greatly decreases training time and needs much less data to train in order to improve efficiency. We used all the layers in the pre-trained model except the last fully connected layer as it is specific to the ImageNet contest. Staring layers of pre-trained models contain the generic feature and last layers contain domain specific features. We made all the layers of pre-trained model frozen to learn MRI tumor image specific features. The loss metric and optimizer in the model are categorical_crossentropy and RMSprop with a learning rate of 0.0001 respectively. While passing the input to the model, images were resized to 256x256 pixels form original size (512x512 pixels). we have fine-tuned the network with above said hyperparameters and achieved an accuracy of 98.82% from selected dataset.

3.2.4 Performance evaluation

Classification is one of the most used machine learning problems for various industrial applications, face recognition, YouTube video categorization, content alteration, medical diagnosis, text classification, hate speech detection on twitter. Some of the most popular classification models such as logistic regression, decision trees, support vector machine (SVM), random forest, convolutional neural network, recurrent neural network. There are various ways to evaluate a classification model. The classification accuracy is interrelated with sensitivity and specificity which utilize the terms: true positive (TP), true negative (TN), false negative (FN), and false positive (FP). One of the important concepts in classification performance is confusion matrix. It is tabular visualization of the model predictions and truth labels. In confusion matrix, rows represented with predicated class and columns represented with actual class. The diagonal elements of confusion matrix denote correct predictions of classification and non-diagonal elements denote the misclassification. The dimension of confusion matrix is number of classes x number of classes in an application for classification. All the terms such as true positive (TP), true negative (TN), false negative (FN) and false positive (FP) are derived from the elements of confusion matrix. These terms are used to calculate accuracy, precision, recall, sensitivity, and specificity to estimate classification performance.

Classification accuracy: The primary performance evaluation metric for classification is accuracy. It is the number of correct predictions divided by the total number of predictions and multiplied with 100.

$$Accuracy = \frac{(TP) + (TN)}{(TP) + (FP) + (TN) + (FN)} \quad (1)$$

Precision: If the data set contains imbalanced observation points then the accuracy of the classification is not a good indicator of model performance. In this case, even if you predict all samples as the most top class, you 'd get a high accuracy rate which makes no sense at all. The model, therefore, does not know anything, so it only forecasts anything as the highest level. Hence, class specific performance metric must require for validation. Precision is one of such metrics, which is defined as:

$$Precision = \frac{True\ Positive\ (TP)}{True\ Positive\ (TP) + False\ Positive\ (FP)} \quad (2)$$

The above mathematical formula applied for each class of the model and validate the performance. When the precisions of all classes are almost the same then it can be inferred that model has trained equally for all classes.

Recall: It is another essential metric, defining as the fraction of observation points from a class that the model correctly predicts.

$$Recall = \frac{True\ Positive\ (TP)}{True\ positive\ (TP) + False\ Negative\ (FN)} \quad (3)$$

F1-Score: Combining precision and recall into a single metric is another important measure. It is the harmonic mean of precision and recall. Mathematical definition of F1-Score is defined as:

$$\mathrm{F1-Score} = \frac{2 * \mathrm{precision} * \mathrm{recall}}{\mathrm{precision} + \mathrm{recall}} \quad (4)$$

Kappa: Cohen Kappa tells you how much better your model is than the random classifier that predicts class frequencies based on it.

$$\mathrm{Kappa} = \frac{\mathrm{Accuracy} - \mathrm{randomAccuracy}}{1 - \mathrm{randomAccuracy}} \quad (5)$$

$$\mathrm{randomAccuracy} = \frac{(\mathrm{TN} + \mathrm{FP}) \times (\mathrm{TN} + \mathrm{FN}) + (\mathrm{FN} + \mathrm{TP}) \times (\mathrm{FP} + \mathrm{TP})}{\mathrm{Total} \times \mathrm{Total}} \quad (6)$$

The area under the curve (AUC): It is an aggregate measure of a binary classifier 's performance over all possible threshold values. AUC calculate the area under the ROC (recursive operating characteristic curve). ROC is a plot which shows the performance of a binary classifier of tis cut-off threshold. AUC is as the probability that the model ranks a random positive observation more highly than a random negative observation. The higher AUC value of a model can give better results.

4. RESULTS ANALYSIS

Brief information about the experimental setup and the results obtained is presented in this section. The experimental setup includes the details used in the present work about the model training and the software platform.

4.1 Experimental setup

We made four types of validation on two datasets (cropped and uncropped) of the proposed pre-trained model with transfer learning. Validation types are list in the Table 1 and 2. The data set was partitioned into a ratio of 70:30, in holdout validation. 70 percent of the dataset is used for training, and the remaining 30 percent are used for testing. 10-fold validation was done in three variations such as image level only, stratified image level and patient level. Further, the comparison study with the current state-of-the-art research is made in the discussion section.

The proposed model was developed with tensorflow platform in keras and implemented in colab pro environment. Google Colab is a valuable resource for the online sharing of work for data scientists and AI researchers. Users can write and execute Python on the web with zero configuration, free GPU access, and easy sharing using the very same Google Drive interface, within the collaborative environment of a Colaboratory. The transferred models were trained using loss metric and optimizer in the model are categorical_crossentropy and RMSprop with a learning rate of 0.0001 respectively. The mini-batch size was taken as 20 and the maximum number of epochs was 25. We validated the design model with same hyperparameters on two datasets in four validation types.

4.2 Results

The results of our model are summarized in Table 2, Table 3, graphical Figure 6, and graphical Figure 7. Four validation type performance metrics on cropped dataset of designed transfer model are illustrated in Table 2. Similarly, Table 3 illustrates metrics on uncropped dataset. These results indicate that uncropped dataset with group10-fold patient level cross validation achieves the best results over all other combinations. The attained values of accuracy, precision, recall, f1 score, kappa, and AUC are 99.82, 97.57, 99.47, 98.40, 94.60, and 99.50 respectively. The second-best combination over other is uncropped stratified 10-fold image level cross validation. The attained values are shown in the Table 3 3rd row. In our case of research on Figshare dataset, precision and recall values are little better in uncropped image level 10-fold cross validation and stratified 10-fold cross validation. The performance metrics value indicates the benefit of transfer learning in reducing overfitting and increasing the convergence speed. We can state that DCNN-based transfer learning models may not require the cropping of images to have classification of tumors.

The graphical Figure 7 and 8 show performance metrics of four types of validations on cropped and uncropped datasets. Figure 7 (a1, a2, a3) presents the holdout validation confusion matrix, training accuracy vs validation accuracy and training loss vs validation accuracy for cropped dataset. Similarly, Figure 7(b1, b2, b2), 7(c1, c2, c3), and 7(d1, d2, d3) presents the graphical representation for 10-fold, stratified 10-fold, and group 10-fold cross validation training progress curves on cropped dataset. All the training and validation progress curves in accuracy and loss clearly shows that there is no overfitting in the model. In four types of validations, our classification model does not suffer from overfitting. Figure 8(a1, a2, a3), 8(b1, b2, b3), 8(c1, c2, c3) and 8(d1, d2, d3) present the training and validation progress curves for classification performance metrics on uncropped MRI images dataset.

Table 2. Performance metrics from 4 types of validations on cropped images dataset

Validation Type	Accuracy	Precision	Recall	F1- Score	Kappa	AUC
Hold out	95.07	91.53	92.05	91.77	88.38	98.89
10-fold (Image Level)	99.10	98.85	98.38	98.57	97.92	99.88
Stratified 10-fold (Image Level)	99.23	98.60	98.82	98.68	98.20	99.84
Group 10-fold (Patient Level)	99.27	98.67	99.53	99.07	99.70	99.70

Table 3. Performance metrics from 4 types of validations on uncropped images dataset

Validation Type	Accuracy	Precision	Recall	F1- Score	Kappa	AUC
Hold out	96.7	95.70	93.98	94.69	92.43	99.55
10-fold (Image Level)	99.10	98.11	98.71	98.33	97.85	99.82
Stratified 10-fold (Image Level)	99.32	98.95	98.87	98.88	98.42	99.85
Group 10-fold (Patient Level)	99.82	97.57	99.47	98.40	94.60	99.50

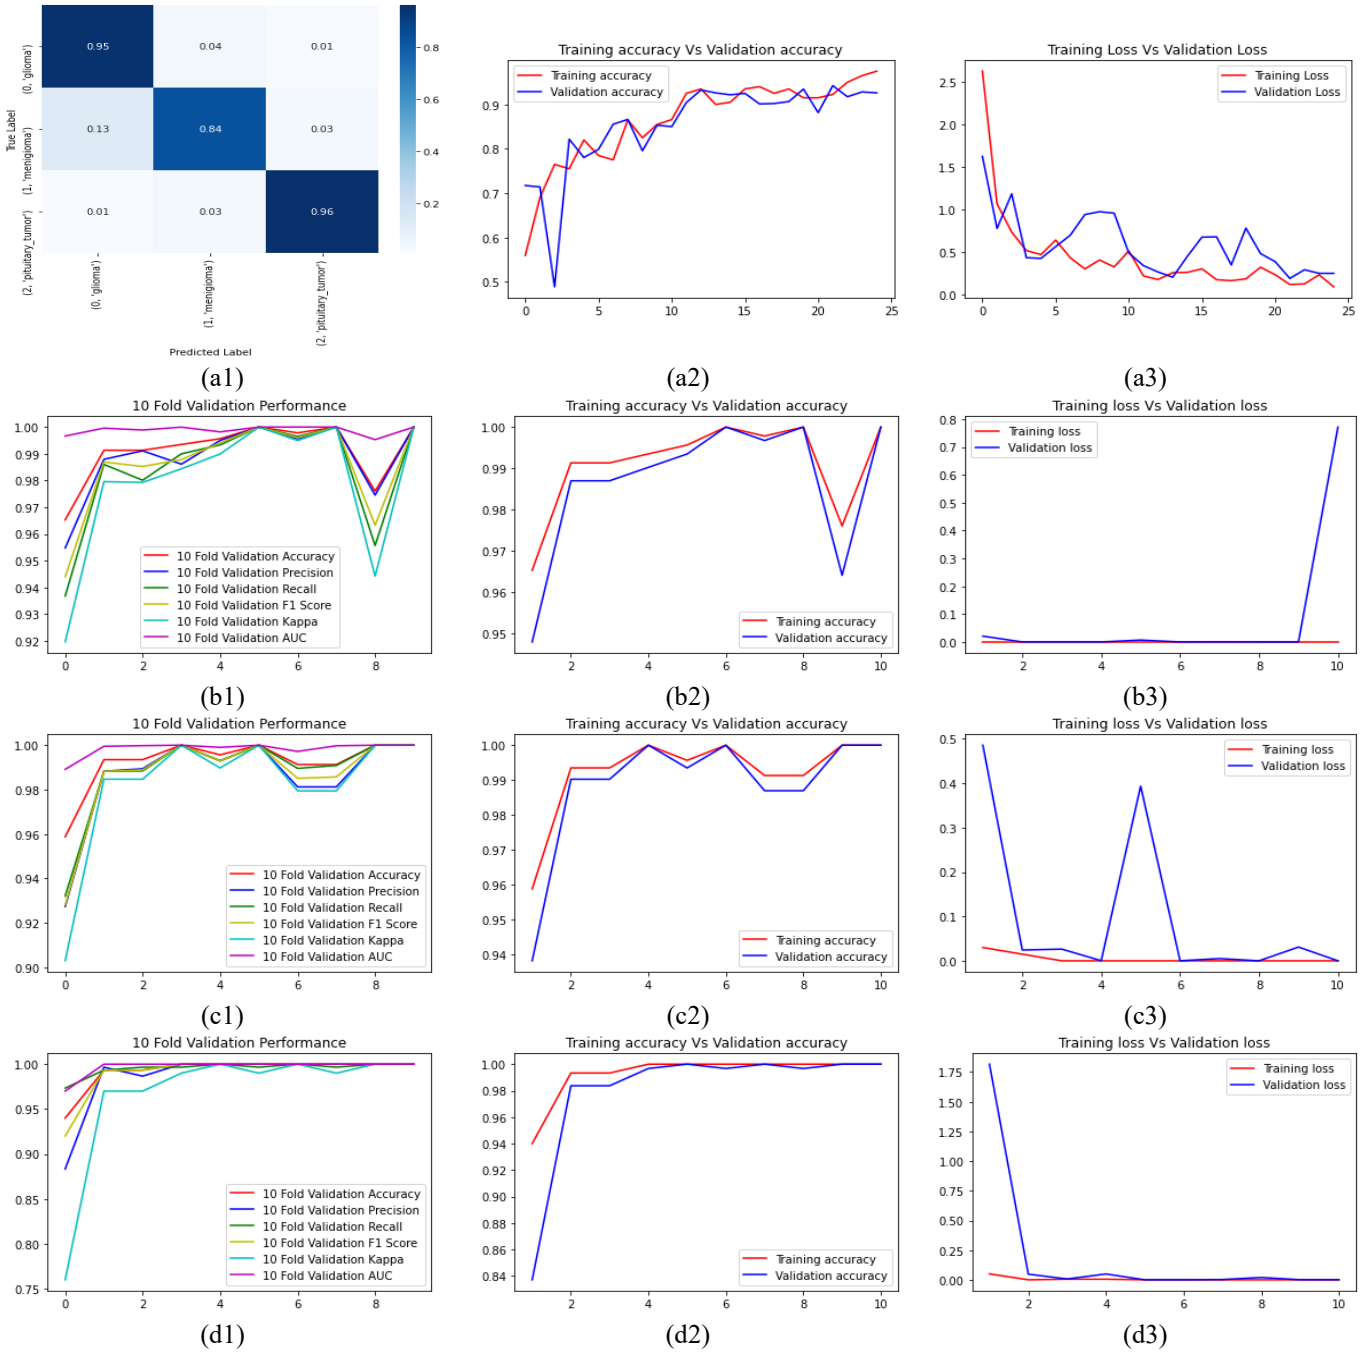

Figure 7. Proposed model performance metrics, accuracy and loss history of cropped images (a1,a2,a3) holdout validation (b1,b2,b3) 10-fold cross validation(image-level) (c1,c2,c3) stratified 10-fold cross validation (image-level) (d1,d2,d3) group 10-fold cross validation (patient-level)

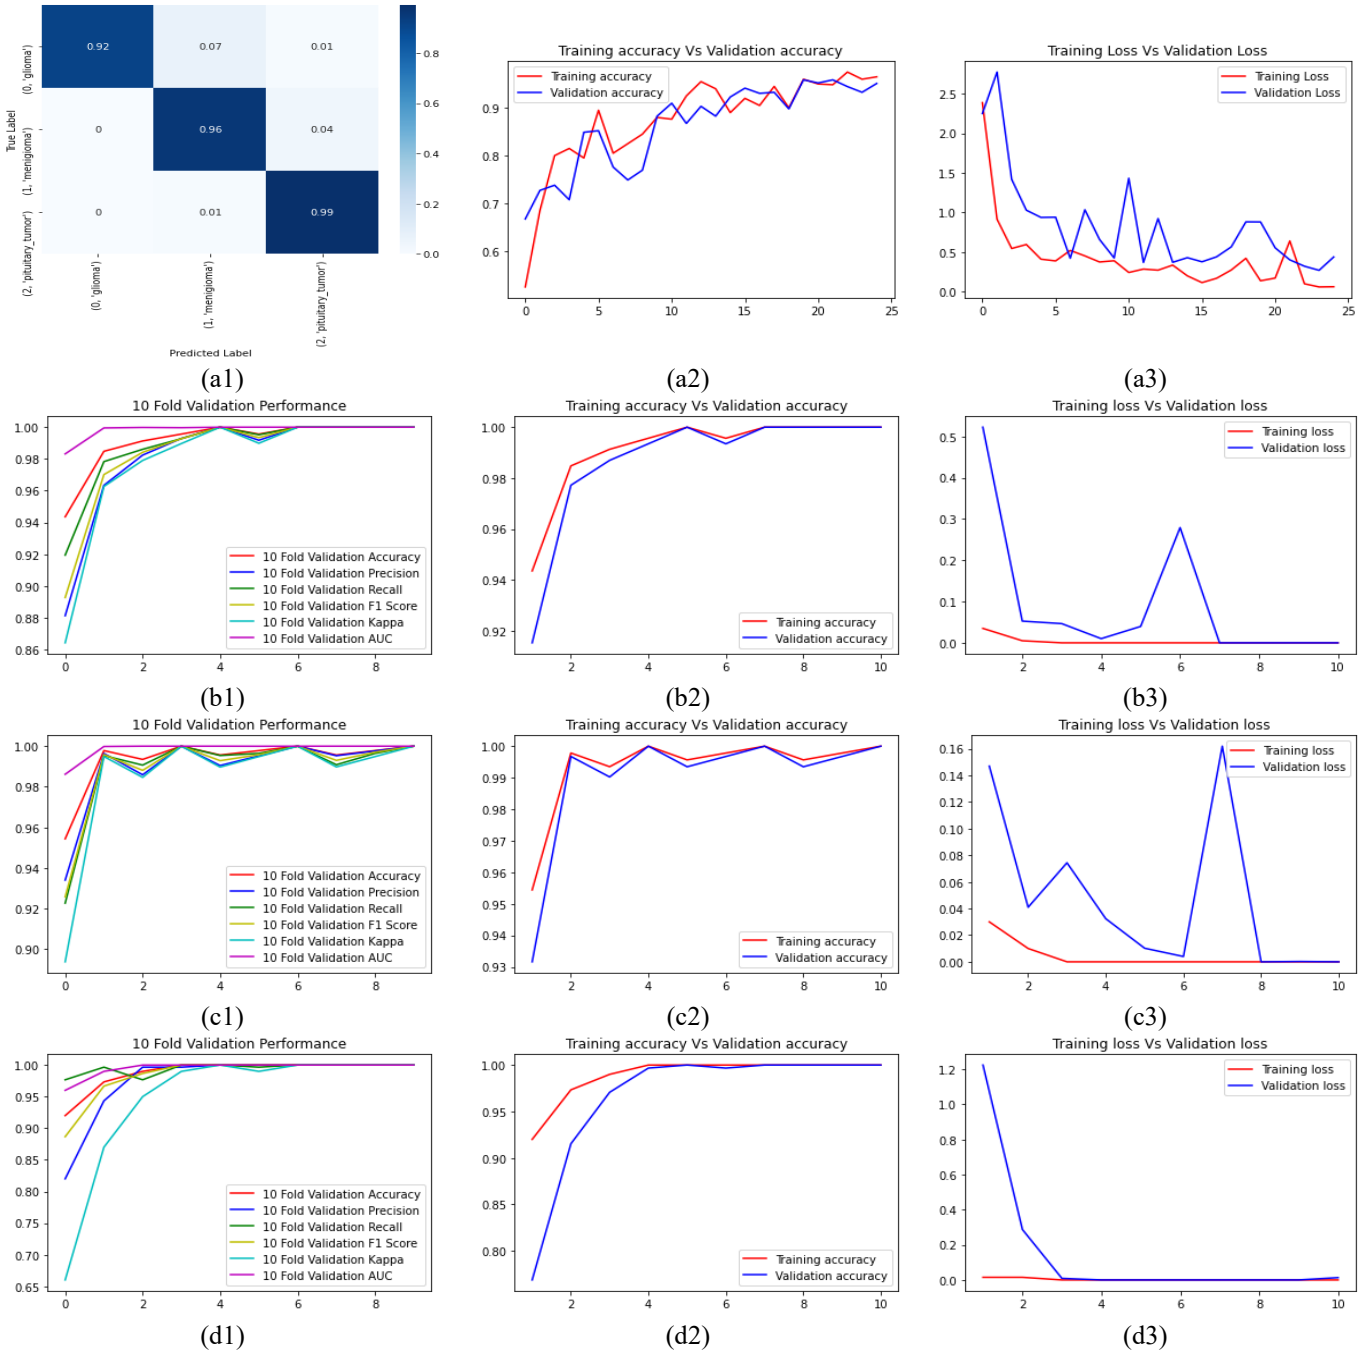

Figure 8. Proposed model performance metrics, accuracy and loss history of uncropped images (a1,a2,a3) holdout validation (b1,b2,b3) 10-fold cross validation(image-level) (c1,c2,c3) stratified 10-fold cross validation (image-level) (d1,d2,d3) group 10-fold cross validation (patient-level)

5. DISCUSSION

Table 4. Comparison of results with existing state-of-the-art works using Figshare dataset

Existing Reference	Accuracy	Precision	Recall	F1-Score	AUC
Afshar et al. [3]	86.56	-	-	-	-
Phaye et al. [17]	95.03	-	-	-	-
Sultan et al. [21]	96.13	96.06	94.43	-	-
Gumaei et al. [22]	92.16	-	-	-	-
Pashaei et al. [25]	93.68	94.60	91.43	93.00	-
Proposed (cropped dataset)	99.27	98.67	99.53	99.07	99.70
Proposed (uncropped dataset)	99.82	97.57	99.47	98.40	99.50

This section presents the comparison of the best performed transferred DCNN models with existing state-of-the-art works on the same dataset for brain tumor classification. To compare our findings with those of previous studies, we selected only

those papers that built a neural network based on DCNN, used whole images as classification inputs and checked their networks using holdout and k-fold cross validation methods, as shown in Table 4. Unlike previous studies which recorded the performance in terms of overall accuracy, the best performing transferred model achieves the higher accuracy value under the fixed partition and the cross-validation scenario. This obtained an accuracy value of 96.70% and 99.82% higher than current state-of-the-art systems for holdout and 10-fold cross validations.

6. CONCLUSION

We compared our model with various DCNN models that focused on the classification of MR brain images. A ceiling classification standard was reached in our approach of using pre-trained InceptionV3 DCNN model. We have shown that no pre-processing or classification segmentation of the tumors was needed. In addition, the network has a very good execution speed of 15s per epoch. To check the network, we used both cropped and uncropped data sets with holdout (70:30 ratio) and 10-fold cross validation at the image level & patient level. The patient-level models increased the classification accuracy dramatically from the four evaluated models. Through making a 99.82% classification accuracy for figshare MRI data set, our model has proven to be the finest.

Future works will be focused on other approaches to database augmentation and other ways to perform pre-processing of data to improve the more generalization capability of the network. We want to work on the best turning hyperparameters of network architecture for tumor classification. Further, it could be used during brain operation, classifying, and accurately locating the tumor. Hence, Tumor detection in the operating room will be performed in real-time and in real-world conditions. In the future, we want to apply our designed DCNN architecture model on various medical images and find the adaptability of the model in the real-world scenarios.

A New Cross Layer Design for Efficient Routing Protocol using Ant Colony Optimization

Gudepu Sai Krishna[1], P. Swapna[2]

[1,2]*Assistant Professor, Department of IT*
[1,2]*Malla Reddy Engineering College (A), Hyderabad, Telangana, India.*

Abstract

In military applications mobile ad-hoc network plays very important role because it is specifically designed network for on demand requirement and in situations where set up of physical network is not possible. This special type of network which takes control in infrastructure less communication handles serious challenges tactfully such as highly robust and dynamic military workstations, devices and smaller sub-networks in the battlefield. Therefore, there is a high demand of designing efficient routing protocols ensuring security and reliability for successful transmission of highly sensitive and confidential military information in defence networks. With this objective, a power efficient network layer routing protocol in the network for military application is designed and simulated using a new cross layer approach of design to increase reliability and network lifetime up. But here PDO-AODV approach does not support to optimal path selection. So, we propose a new ACO-DAEE (Ant colony optimization with delay aware energy efficient) for optimal path selection and mitigating the delay time in network system. The main goal is to maintain the optimal routes in network, during data transmission in an efficient manner. Our simulation results indicate that ACO-ADEE performs extremely well in terms of packet delivery ratio, end to end delay, and throughput. Simulation results through NS2 software to verify the effectiveness of our method.

Keywords: *Mobile Ad-Hoc Network, Cross layer design, ant colony optimization*

1. Introduction

The gigantic technological rejuvenation of wireless communiqué [1] has been emerged in the system of mobile ad hoc networks (MANETs) in current decade. MANETs are excellent networking structure that is based with no settled framework. Because of the highly dynamic, extremely mobile and self-configurable nature of its autonomous nodes, performance of this network is outstanding in terms of transmission, throughput and reliability. Mobile ad hoc networks [1] have very important application and operations in battle fields and in disaster situations such as deployment of networks, high security measures in the network, any end to end transmission, mobile connectivity without failure, anti jamming mechanism, etc. All network activity must be done spontaneously without any link failure even in microsecond level. The soldiers during online battle should be able to remain continuously connected with each other to get any latest information, or command from their chief or to discuss before any action. Sometimes penetration of the satellite signals is not desirable to caves or dense forest or under sea places where it is again challenging to sustain connectivity. Many research works have focused on the security of MANETs. Most of them deal with prevention and detection

 Copyright © 2020 Authors

approaches to combat individual misbehaving nodes. In this regard, the effectiveness of these approaches becomes weak when multiple malicious nodes collude together to initiate a collaborative attack, which may result to more devastating damages to the network.

2. Related Work

In previous works [2], power delay optimized AODV protocol is a routing engine that is the controller of all functions in the mobile workstation. Sequentially it performs three important tasks during static or mobile position of a node and after a packet arrives to a node such as the channel sensing, the mini database handling module and the intelligent decision taking sub module. In the first sub module of channel sensing, status messages are transmitted periodically with formal interruption of time by the node to broadcast presence of that node in the channel. In the next sub module, a small database is maintained to reserve and recall routing information's regarding a path, which can be referred next time data transmission takes place between same sender and receiver. A threshold value is calculated procedure to select the next hop station as per the algorithm as given below, which will be used in the routing decision module to finally select a suitable station. We existed a cross layer mechanism between the data link layer and the system layer by introducing a friendly packet between the two layers. To reduce the overhead of route finding in terms of delay and power consumption we suggest that this friendly packet provides necessary information from the data-access link layer to its upper network layer. Developed an improved channel access technique at the MAC layer make it compatible to work with PDO-AODV.

3. Proposed Framework

In this section, we present our model, **ACO B**ased **E**fficient **R**outing protocol for MANET with **D**istance, **E**nergy, and **L**ink quality. The model is shown in figure 1 which consists of three main components -Trust Model, Optimal Forwarder Selection Function and Improved Pheromone Update Model.

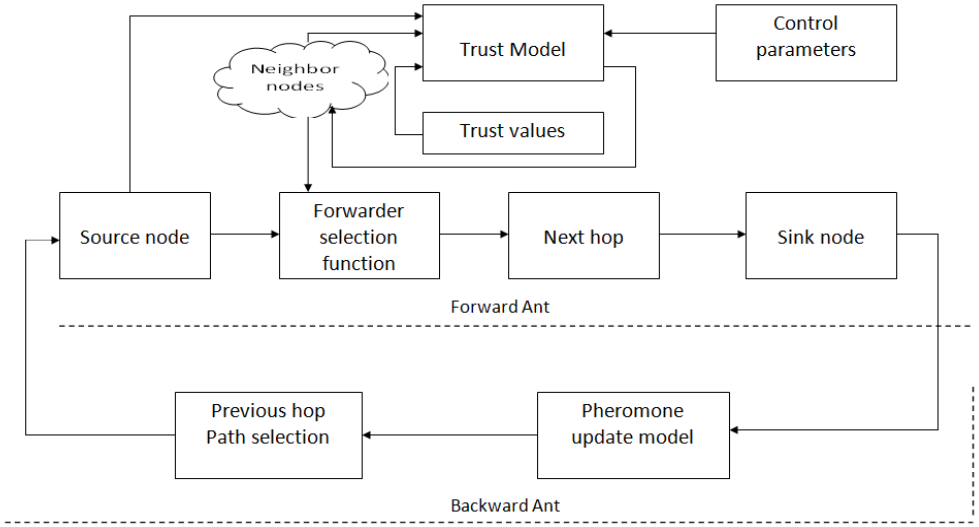

Figure 1. ACO based efficient routing framework

 Copyright © 2020 Authors

3.1. Trust model

In Trust Model, nodes rate each other by using the information of their own direct interactions with their neighbors. This is termed in the literature as First-Hand Information (FHI). To make the rating unbiased, the nodes also collect their neighbors' interactions with that node being rated considered as indirect interaction. This rating information collected from the neighbors is also known as Secondhand Information (SHI). The simulation period is now divided into 'n' slots where each slot consists of two sub-periods -Forwarding and Monitoring Interval, TFMI followed by Update Interval TUPI.

3.2. Forwarder selection function

Forwarder Selection Function is a probability function that is used at every node along the path from source to sink node in the network to select the best next neighbor to forward the packet to the sink node. The Forwarder Selection Function must always choose an optimal path from source to the sink to forward the packets with the sole objective to improve the Network Lifetime by balancing the energy among the nodes in the network to ensure that some nodes along the path do not get depleted fast and at the same time selecting good quality links along the path to guarantee that node energy is not wasted due to too frequent retransmissions.

With these objectives in mind, we have used the Forwarder Selection Function, FSF, a probability function to select the best forwarder node among the neighboring nodes of the current node, which is based on Pheromone Trail (PT) and heuristic function involving two parts representing Node Energy level (EN) and node link quality (LP) functions. Pheromone Trail (PT) represents the concentration of pheromone deposited on the path between the nodes considering Energy, distance and link quality along the path (containing the link between current and neighboring nodes) from source to destination. In other words, higher PT represents the better good quality path from source node to the destination in terms of energy, distance and link quality. Node Energy (EN) function represents energy level of the neighbor node and Link quality (LP) function represents the quality of the link between the current node and the neighbor node under consideration.

The Forwarder Selection Function is a probability function which must always choose an optimal path from source to the sink to forward the packets with multiple objectives:

- To provide a secure trustworthy path from source to sink by avoiding insider attacks,
- To improve the Network Lifetime by balancing the energy among the nodes in the network to ensure that some nodes along the path do not get depleted fast (resulting in Network disconnections or partitioning)
- At the same time selecting good quality links along the path to guarantee that node energy is not wasted due to too frequent retransmissions.
- Further, selection of shorter paths involving less number of nodes resulting in further saving of energy due to less number of nodes participating in packet forwarding.

Forwarder Selection Function, FSF (n_i, n_j) to select the best forwarder node n_j among the neighboring nodes of the current node n_i can be defined as

 Copyright © 2020 Authors

FSF (n_i, n_j) =

$$\begin{Bmatrix} \frac{[PT(n_i,n_j)]^{\alpha}[EN(n_j)]^{\beta}[LP(n_i,n_j)]^{\gamma}[TR(n_i,n_j)]^{\delta}}{\sum n_j \in NBS(n_i)[PT(n_i,n_j)]^{\alpha}[EN(n_j)]^{\beta}[LP(n_i,n_j)]^{\gamma}[TR(n_i,n_j)]^{\delta}} & if\ n_j \in NBS(n_i) \\ 0 & otherwise \end{Bmatrix} \quad (1)$$

Where NBS (n_i) represents the set of neighboring nodes of n_i, PT (n_i,n_j) represents the concentration of pheromone deposited onthe path between the nodes n_i and n_j, EN (n_j) represents the energy level of the neighbor node n_i. TR (n_i,n_i) represents the Trust rating of the neighbor node n_j as given by node n_i.

LP (n_i, n_j) represents the quality of the link between nodes n_i and n_j, i.e., link probability. The Expected Transmission Count, ETX is a measurement of the transmission link which is calculated based on the past events occurred on that link.

Then the link probability LP (n_i, n_j) between nodes n_i and n_j is given by the expression:

$$\text{LP}(n_i, n_j) = \frac{1}{\text{ETX}(n_i,n_j)} \quad (2)$$

α, β, γ, δ are the parameters to control the significance or importance of pheromone trail of the path, node energy level, link quality between nodes and node trust rating.

When α= β =γ = δ =1, all four parameters PT, EN, LP, TR are given equal importance in the selection of the forwarder node. If one is interested in giving higher importance to TR, node trust rating, then one could make α=β =γ =2,δ =1, similarly α=2, β =1,γ =δ =2 to raise importance of EN, Node Energy Level, α=2, β =δ=2,γ =1 to make importance of link quality more significant in the selection of forwarder node.

Let EI (n_j) be the initial energy of node n_j and ER (n_j) be the Remaining (Actual) Energy of node n_j, then the Node Energy level, EN (n_j) is defined as

$$EN(n_j) = \frac{ER(n_j)}{EI(n_j} \ Where\ ER(n_j) > E_{th} \quad (3)$$

3.3. Pheromone Model

It has been observed that the amount of pheromone computed to be placed on the path during return journey is not proper to reflect that path as the optimal during the simulation period. Strongest path should have largest amount of pheromone whereas weakest path should have least amount of pheromone or almost zero. Among the competing stronger paths for selection, the variations in pheromone concentration should be such that always strongest path is selected. Keeping these in mind, pheromone update model has been designed considering the parameters the forward ant has collected during its travel from source to the destination. Once the forward ant reaches the destination, the following parameters collected by the forward ant are analyzed.

4. Result and Discussion

Our experiments are conducted using the NS-2.34 simulator. We conduct the experiments in two steps. The initial step is to check the viability of our plan, and then deeper study is investigation is done to assess the delay and throughput in more detail. In

Copyright © 2020 Authors

the first step, there are 40 mobile nodes in the network, and communication starts from source to destination. Here hop to hop communication occurs and we can calculate the distance based on position of an individual node. The individual communication between user to user, numbers of data flows measured. Here we can know the transmission rate of every node based on pheromone values. In our work, we can maintain power and delay for individual nodes and finding the optimal path for selection of a routing. The connections among mobile nodes are UDP connections, and we send CBR (Constant Bit Rate) traffic in each communication channel. The CBR rate of the connections is 512Kb/s. The size of the scenario field is 1500m x 1500m. The routing protocol we use is a revised AODV routing protocol that integrates our ACO-DAEE, PDO-AODV methods.

Table II. Simulation parameters

PARAMETER	VALUE
Application traffic	CBR
Transmission rate	5 packets/sec
Radio range	250m
Packet size	1000 bytes
Channel data rate	2Mbps
Maximum speed	20m/s
Simulation time	10secs
Number of nodes	40
Area	1500x1500
Routing protocol	AODV
Routing methods	PDO-AODV, ACO-DAEE

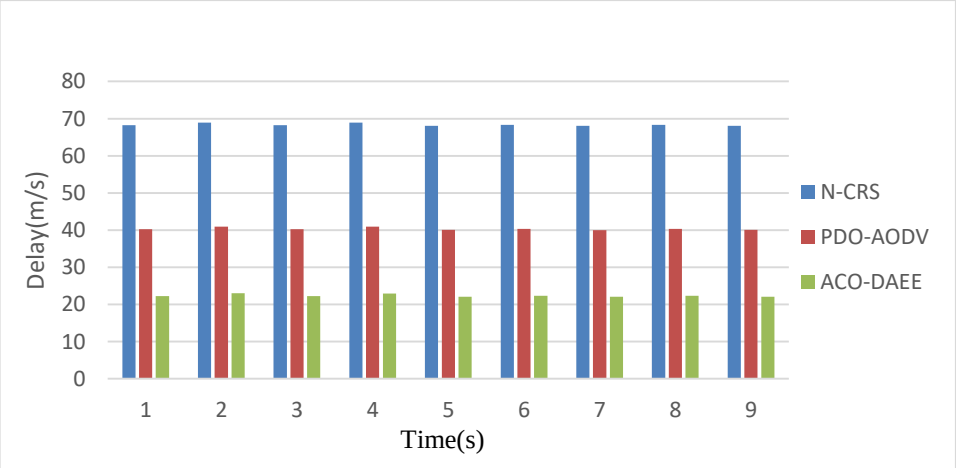

Figure 2. Network Routing delay

 Copyright © 2020 Authors

The above graph represents the delay time in network, and it depends on time to vary the output. It depends on number of packets travelling and delivered as per process. Here each packet travelling time based on that delay time measured. The performance of the ACO-DAEE decrease the delay time in network compare to PDO-AODV method and Cross Layer Power Control method.

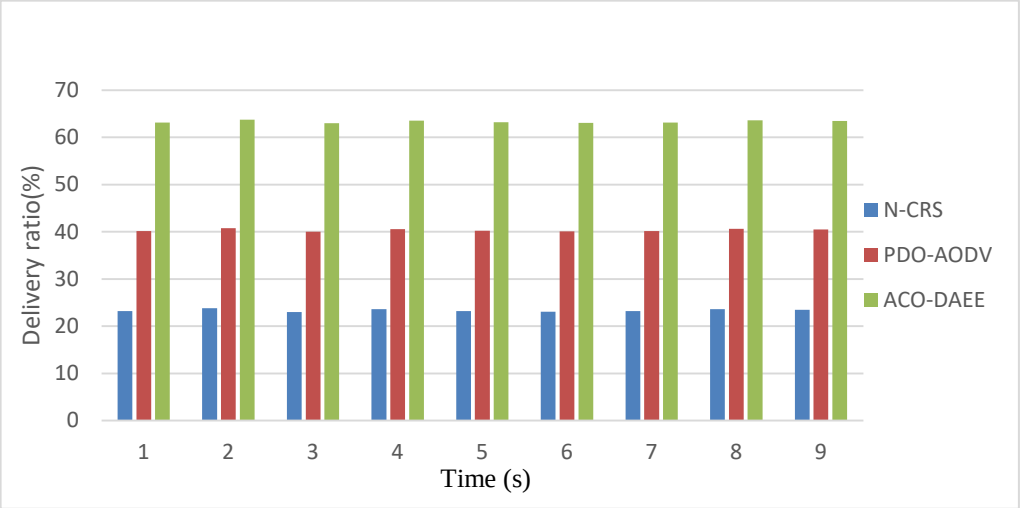

Figure 3. Packet delivery ratio

Figure 3 represents packet delivery ratio performance, which depends on time to vary the output also depends on number of packets travelling and delivered as per process. The performance of the ACO-DAEE improves the delivery ratio compare to PDO-AODV method and Cross Layer Power Control method.

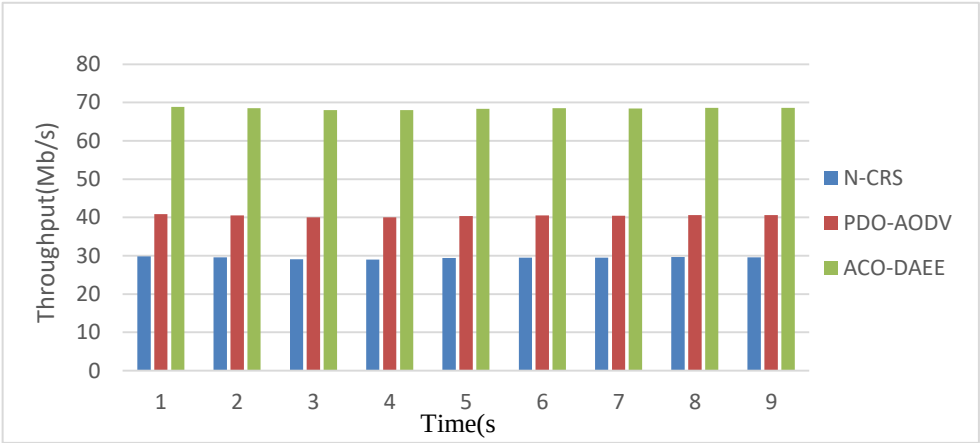

Figure 4. Network performance

Performance of throughput is demonstrated in Figure 4, where it depends on time to vary the output. The performance of the ACO-DAEE improves the throughput compare to PDO-AODV with DDOS attack algorithm and Cross Layer Power Control method.

5. Conclusion

This article inspected the issue of power efficiency, node selection and unfair load balancing for mobile ad-hoc networks using an interaction based cross layer mechanism. They focused on optimizing link cost based on power and delay metric to mitigate this severe issue restoring precious network resources. In addition to this we have used a

 Copyright © 2020 Authors

friendship-based handshaking utility as a cross layer approach between data link layer and network layer to accelerate the routing layer process. Here collection of data and delay on routing more so we proposed ACO (ant colony optimization) with delay aware energy efficient method. This protocol solves the resource constraint problem of ad-hoc network and the simulation study shows that it shows better performance than other leading MANET protocols based on similar cross layer approach. We also conducted simulation by using NS2 and exploratory outcomes demonstrate that our ACO-DAEE is practical for the discriminate delay aware nodes and improve the performance ratio in network.

A Novel, Distributed, and Reliable Search Policy for Unstructured Peer-to-Peer Networks

Dr. Shanmugam Kannan[1], Goski Sathish[2]

[1]*Associate Professor,* [2]*Assistant Professor, Department of IT*
[1,2]*Malla Reddy Engineering College (A), Hyderabad, Telangana, India.*

Abstract

Finding a document or resource in an unstructured peer-to-peer network can be an exceedingly difficult problem. In this paper we propose a query routing approach that accounts for arbitrary overlay topologies, nodes with heterogeneous processing capacity, e.g., reflecting their degree of altruism, and heterogenous class-based likelihoods of query resolution at nodes which may reflect query loads and the manner in which files/resources are distributed across the network. The approach is shown to be stabilize the query load subject to a grade of service constraint, i.e., a guarantee that queries' routes meet pre-specified class-based bounds on their associated a priori probability of query resolution. An explicit characterization of the capacity region for such systems is given and numerically compared to that associated with random walk-based searches. Simulation results further show the performance benefits, in terms of mean delay, of the proposed approach. Additional aspects associated with reducing complexity, estimating parameters, and adaptation to class-based query resolution probabilities and traffic loads are studied.

Keywords: *P2P network, Query routing and Capacity region*

1. Introduction

Peer-to-Peer (P2P) systems continue to find increasing and diverse uses as a distributed, scalable and robust framework to deliver services, e.g., file sharing, video streaming, expert/advice sharing, sensor networks, databases, etc. One of the basic functions of such systems is that of efficiently resolving queries or discovering files/resources. This is the problem addressed in this paper. There is a considerable body of work exploring the design of efficient search/routing mechanisms in structured and unstructured P2P networks, see e.g.,[1]–[10]. In structured networks, peers/files/resources are organized to form overlays with specific topologies and properties. Search mechanisms that perform name resolution based on distributed hash table (DHT) coordinate systems can be devised to achieve good forwarding-delay properties, see e.g.,[2]. In such systems, the query traffic may depend on how keys are assigned. So, load balancing requires proactive/reactive assignments of keys to peers and data/service objects, e.g., [11], and possibly exploiting network hierarchies [10]. Fundamentally, in such networks the difficulty of search/discovery is shifted to that of maintaining the structural invariants required to achieve efficient query resolution particularly in dynamic settings with peer/content churn or when reactive load balancing is required. Unstructured networks, by contrast, are easier to setup and maintain, but their mostly *ad hoc* overlay topologies make realizing efficient searches challenging. In a purely unstructured P2P network, a node only knows its overlay neighbors. With such limited information, search techniques for unstructured networks have mostly been based on limited-scope flooding, simulated random walks, and their variants [3]–[5]. Much research in this area has focused on evaluating these search techniques based on the contact time, i.e., number of hops required to find the target, using the spectral theory of Markov chains on (random) graphs, see e.g., [4]–[6].

 Copyright © 2020 Authors

Unfortunately, in heterogenous settings where service capacity or resolution likelihoods vary across peers, such search techniques perform poorly under high query loads. The inefficiencies of purely unstructured networks can be partially addressed by hybrid P2P systems, e.g., Fast Track and Gnutella2. Such systems use a simple two-level hierarchy where some peers serve as 'super-peers.' These are high degree nodes which are well connected to other super-peers and to a set of subordinate nodes in a hub-and-spoke manner [12]. Though such systems have advantages in terms of scalability, proposed search techniques are still based on variants of flooding and random walks. The work of [7] proposes an approach where peers cache the outcomes of past queries as informed by reverse-path forwarding. The idea is to learn, from past experience, the best way to forward certain classes of queries, i.e., to intelligently "bias" their forwarding decisions by correlating classes of queries with neighbors who can best resolve them. This approach involves considerable overhead, is not load sensitive, and has not yet given guarantees on performance. Although, as will be clear in the sequel, our results are not exclusive to hybrid P2P networks, these will serve as the focus of the paper. We assume that each super-peer contributes a possibly heterogenous amount of processing resource for resolving queries for the network—incentives for doing so are outside of the scope of this paper, see e.g., [8], [9]. Super-peers serve their subordinates by resolving queries or forwarding them to other super-peers. Super-peers can resolve queries by checking the files/resources they have, as well as those of their subordinate community. In our approach we also introduce a notion of query classes. These might, for example, represent types of content, such as music, films, animations, documents, or some other classification of files/resources relevant to the application at hand. The idea is that such a grouping of queries into classes can be used as a low overhead approach to make useful inferences on how to relay queries. Given a hybrid P2P topology and query classification, we propose a novel query resolution mechanism which stabilizes the system for all query loads within a 'capacity region', i.e., the set of loads for which stability is feasible. Essentially, our policy is a biased random walk where forwarding decision for each query is based on instantaneous query loads at super-peers. To balance the load across heterogeneous super-peers, the policy aims at reducing the differential backlog at neighboring super-peers, while taking into account the class and history information to improve the query's resolvability. Our policy draws upon standard backpressure routing algorithm, which is used to achieve stability in packet switching networks, e.g., see [13], [14].

In previously studied backpressure-based systems, the goal is to deliver packets to the corresponding destinations. By contrast, our aim is to provide a grade of service in resolving queries with no fixed destinations. The random nature of the location of query resolution in the network leads us to deal with expected queue backlog instead of current queue backlog. Further, in P2P systems, the probability of resolution of a query at a given node depends on the query's history, i.e., the path that led it to the current node. These characteristics of P2P systems are not captured in previous works on backpressure by Tassiulas and Ephremides [13] and the subsequent enhancements, see e.g., [14]–[21]. To summarize, our approach differs from standard work on backpressure in that we incorporate the following different issues that arise in P2P search: (a) we model the uncertainty in the locations where a query may be resolved depending upon where the file/object of interest are placed, (b) we guarantee a grade of service to each query under such uncertainties, (c) we incorporate the information about a query's resolvability available through the knowledge of its history

2. Existing System

- In a purely unstructured P2P network, a node only knows its overlay neighbors. With such limited information, search techniques for unstructured networks have

 Copyright © 2020 Authors

mostly been based on limited-scope flooding, simulated random walks, and their variants.

- Much research in this area has focused on evaluating these search techniques based on the contact time, i.e., number of hops required to find the target, using the spectral theory of Markov chains on (random) graphs, see e.g., Unfortunately in heterogenous settings where service capacity or resolution likelihoods vary across peers, such search techniques perform poorly under high query loads.
- The inefficiencies of purely unstructured networks can be partially addressed by hybrid P2P systems, e.g., FastTrack and Gnutella2.

Disadvantages

- In structured networks the difficulty of search/discovery is shifted to that of maintaining the structural invariants required to achieve efficiency.
- In query resolution particularly in dynamic settings with peer/content churn or when reactive load balancing is required.
- Standard backpressure-based routing our policies suffer from a major drawback: each node needs to share the state of its potentially large number of non-empty queues with its neighbors.
- Complexity problem will be also raised.

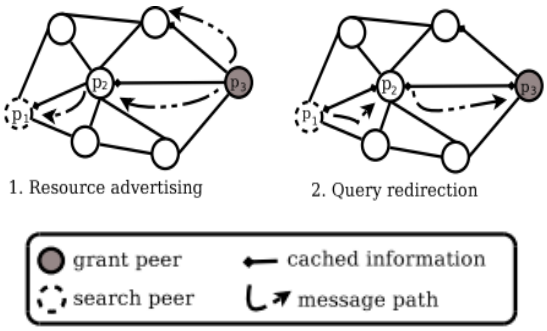
3. Proposed System

Given a hybrid P2P topology and query classification, we propose a novel query resolution mechanism which stabilizes the system for all query loads within a 'capacity region', i.e., the set of loads for which stability is feasible. Essentially, our policy is a biased random walk where forwarding decision for each query is based on instantaneous query loads at super-peers. To balance the load across heterogeneous super-peers, the policy aims at reducing the differential backlog at neighboring super-peers, while taking into account the class and history information to improve the query's resolvability. Our policy draws upon standard backpressure routing algorithm, which is used to achieve stability in packet switching networks. Further, proposed a query forwarding mechanism for unstructured (hybrid) P2P networks with the following properties. It dynamically accounts for heterogeneity in super-peer's 'service rate,' reflecting their altruism, and query loads across the network. To the best of our knowledge, this is the first work to rigorously account for such heterogeneity in devising a search mechanism for P2P networks. It is based on classifying queries into classes. This classification serves as a type of name aggregation, which enables nodes to infer the likelihoods of resolving class queries, which, in turn, are used in learning how to forward queries. Our approach is fully distributed in that it involves information sharing only amongst neighbors, and achieves stability subject to a Grade of Service (GoS) constraint on query resolution. The GoS constraint corresponds to guaranteeing that each query class follows a route over which it has a reasonable 'chance' of being resolved. We provide and evaluate several interesting variations on our stable mechanism that help significantly improve the delay performance, and further reduce the complexity making it amenable to implementation.

Resource discovery is a challenging issue in unstructured peer-to-peer networks. Blind search methods including flooding and random walks, are the two typical algorithms used in such systems. Blind flooding is not scalable because of its high communication cost. On the other hand, the performance of random walks approaches largely depends on the random choice of walks. Some informed mechanisms use additional information, usually obtained from exciting queries, for routing. Such approaches can reduce the traffic overhead, but they limit the query coverage. We propose a simple index scheme to enhance search in unstructured P2P network. The index scheme uses a data structure

 Copyright © 2020 Authors

"Bloom Filters" to index files shared at each node, arid then gossip to one another to change their Bloom filters. In effect, each node indexes a random set of files in the network, thereby lowing every query to have a constant to be successfully resolved within search space. We propose two schemes which can be used to improve the search performance in unstructured peer-to-peer networks. The first one is a simple caching mechanism based on resource descriptions. Peers that offer resources send periodic advertisement messages. These messages are stored into a cache and are used for routing requests. The second scheme is a dynamic Time-To-Live (TTL) enabling messages to break their horizon. Additional aspects associated with reducing complexity, estimating parameters, and adaptation to class-based query resolution probabilities and traffic loads are studied.



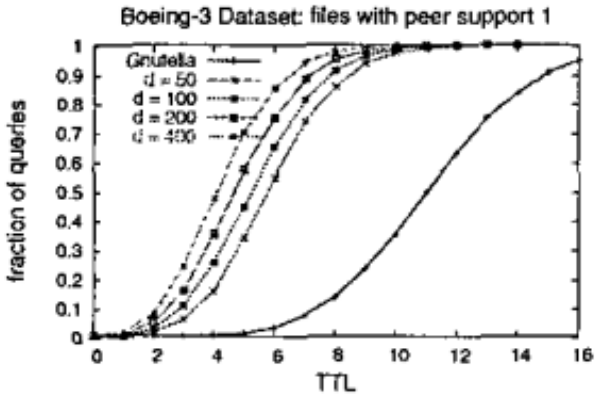


Figure 1. The basic operations of routing approach

Advantages

1. A simple but efficient cache system based on resource description.
2. A cache-based routing scheme aiming at forwarding messages towards resource location.
3. A dynamic TTL which enables messages to break their horizon when necessary while still maintaining a low overhead.
4. A set of schemes which can be used to improve the performance of existing search protocols based on caching and TTL.

Performance of Surrogate Queries to study how many queries should he reissued in the "Surrogate Queries" algorithm. The setting is similar to the previous one. Note that security is treated as a separate issue in the paper. Because peers are quite autonomous, all peer-to-peer networks are vulnerable to various security attacks, e.g., a peer responds with a 'poisoned' file, or blocks queries and fakes search results.

4. Conclusion

 Copyright © 2020 Authors

To summarize, we provided a novel, distributed, and reliable search policy for unstructured peer-to-peer networks with super-peers. Our backpressure-based policy can provide capacity gains of as large as 68% over traditional random walk techniques. We also provided modifications to the algorithm that make it amenable to implementation.

Abstract

Internet of Things (IoT) is a fairly disruptivetechnology with inconceivable growth,impact, and capability.We present the role of REST API in the IoT Systems and someinitial concepts of IoT, whose technology is able to record andcount everything. We as well highlight the concept ofmiddleware that connects these devices and cloud. Theappearance of new IoT applications in the cloud has broughtnew threats to security and privacy of data. Therefore it isrequired to introduce a secure IoT system which doesn't allowattackers infiltration in the network through IoT devices andalso to secure data in transit from IoT devices to cloud. Weprovide the details on how Representational State Transfer(REST) API allows to securely expose connected devices toapplications on cloud and users. In the proposed model,middleware is primarily used to expose device data throughREST and to hide details and act as an interface to the user tointeract with sensor data.

I. INTRODUCTION

The Internet of Things interconnects computer devicesintegrated in everyday objects through the Internet, allowingthem to send and receive data.There are two-fold advantages,we can empower our computers to gather information aboutsurroundings without depending on humans and by processing the information collected we can reduceextravagance, loss, and cost.The Internet of Things allowsfor interaction between the physical world and the digitalworld.The digital world interacts with the physical world viasensors and actuators. These sensors collect information that must be stored and processed. Data processing can take placeat the edge of the network or at a remote server or cloud.The storage and processing capabilities of an IoT objectare restricted by the resources available, which areconstrained due to size limitation, energy, power, andcomputational capability. So thesesystems rely on IoTmiddleware to provide needed capabilities.

A. REST for machine-to-machine connectivity and IoTAPIs allow to expose the connected device to users in asecure manner. RESTful APIs are widely being used in theodern web. Data transfer is

International Journal For Recent Developments in Science & Technology
2581-4575
Crossref
A Peer Reviewed Research Journal

usually done using JSON orXML over HTTP. It is a good model for the heterogeneoussystems. REST API makes the device information easilyavailable. They can standardize on a way to create, read,update, and delete this data. All these operations will be
input to the REST query calls. REST APIs allow to delegateand manage authorization. The API can authenticate on theserver and the server can authenticate to the API to preventtheman-in-the-middle attacks.

B. IoT Middleware architecture

One way to handle such heterogeneous applications isthat we can have a middleware platform that will become thebridge between things and applications in the cloud.Middleware packages and abstractshardware, and providesapplication programming interfaces (APIs) forcommunication, data processing, computing, privacy andsecurity.Figure 1 gives the overall picture of the role ofmiddleware in I oT.In the broad category, there are fourmain components of an IoT System – things itself, the localnetwork which can include a gateway, middleware, loud(for user access control, Business Data Analysis etc.).

II. SECURITY CHALLENGES IN IOT

IoT applications are becoming part of personal lives anddata collected is rather sensitive and private to an individual.Privacy and Security issues must be addressed in all of theseenvironments. As in the health sector, health data is highlyritical for personal privacy, therefore it should not beaccessed by an unauthorized entity.The recent voluminousDDoS attacks (October 2016) on DYN's servers thatbrought down many popular online services in the US,
letting us know what can happen when attackers are able toleverage up to 150,000 unsecure IoT devices as maliciousterminals [1]. To understand the overall approach to datasecurity, there is a need to know about the securityrequirements for all key components of IoT system i.e. IoT
devices, IoT users, Middleware/ IoT gateway,communication channel, and cloud applications.

A. Security Challenges in Constrained IoT DevicesIoT systems are made of resource-constrained devices.

• Public key infrastructure is not suitable for IoTenvironments as it becomes a computationallyexpensive task to calculate cipher text because of thelarge key size.

• Once the system is compromised, it is difficult toupdate it. In addition, shutting down a potentiallycompromised systems, reinstalling or restartingsoftware, or replacing components or subsystems isnot suitable for multiple IoT systems, as this can alsoresult in severe business loss and disruption. It isalso impractical and infeasible to use a securefirewall for IoT devices. [2].

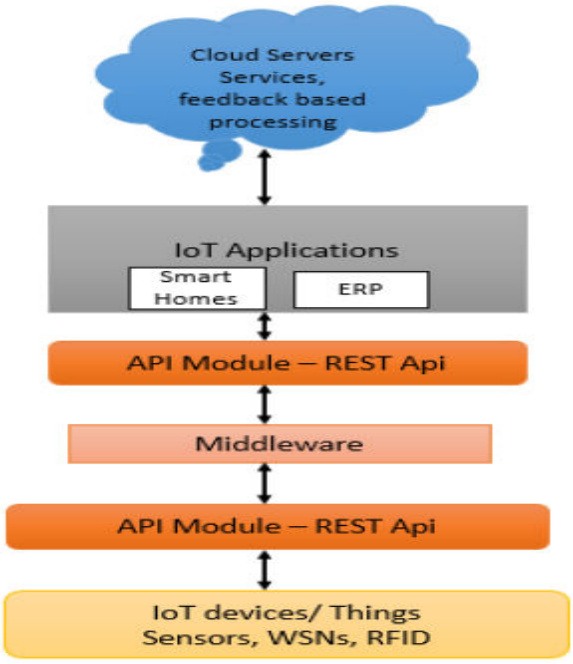

Figure 1: IoT Middleware Architecture

B. Need for Trusted Devices

IoT middleware needs to manage a trust relationship withdevices so that these devices can be authenticated andauthorized to share data. It needs to enforce authenticationprior to communication with any device enabling proof ofthe origin of data. These devices are assigned uniqueidentitiesthat disallow the reuse of security credentials acrossdevices.

C. Connecting IoT devices to Middleware.

There is a requirement to connect a large number ofheterogeneous smart devices like connected cars, connectedwearable, smart cities etc. IoT devices are typicallyconnected to the Internet through an IP stack. This stack nowhas its own complexity and requires a lot of power and
memory from connected devices.

D. Security of Communication channel.

IoT Data needs to be secured while at rest as well aswhile in transit to ensure data integrity. Security solutionsare implemented in a way to detect unwanted intrusions andprevent malicious attacks on the communication layer. Alsosecuring against attacks like Replay attacks, offline id
guessing attacks, unauthorized login, user anonymity, andsensor node anonymity.Figure 2 gives an overview ofsecurity requirements for different pillars of IoT system.

III. RELATED WORK

There are multiple solutions available to cater to differentsecurity requirements of an IoT System. The first andforemost requirement is mutual authentication between theIoT device and gateway within the resource-constrainedenvironment of IoT System.Recently, many authentication schemes for IoT havebeen proposed. In [3], the author suggested arobustanonymity preserving authentication protocol for IoTdevicesthat provides mutual authentication between tag andreader through the server. This scheme uses Elliptic CurveCryptography (ECC) to implement authentication.It is already established that ECC based cryptographicalgorithms are secure. The security of ECC relies on thedifficulty of solving these two problems:-

• Elliptic Curve Discrete Logarithm (ECDL)problem: Let E be an Elliptic curve over a finite
field. Let P and Q be the points in Zq (modulo q). Its difficult to compute the special integer α belongstoZq satisfying Q = α P.

International Journal For Recent Developments in Science & Technology
2581-4575
Crossref
A Peer Reviewed Research Journal

• Elliptic Curve DecisionalDiffie-Hellman (ECDDH)problem: aP, bP, and cP are three points in G. It ishard to verify if abP = cP.As a method to provide the user the access of sensor or
sensor data, the user is usually authenticated through thegateway. There will be mainly three parties: the user,gateway, and sensor. In [4] the authors proposes a verifiable,provable and privacy preserving user authentication schemefor wireless sensor networks (WSN). Authors point out thattheHsieh and Leu's scheme [13] is not secure because of itsseveral security shortcomings including Insider attack, offlinepassword guessing attack, user forgery attack, and
sensor capture attack. For WSN, a new two-factorauthentication scheme also based on ECC is presented. Thisscheme meets the authorization, confidentiality and integrityproperty for IoT security.Different multi-factor authentication schemes aresuggested for user authentication. Different factors likepasswords, biometrics, and smartcards are used together foridentity authentication mechanism. Like in [5], a three factorauthentication scheme for WSN was proposed (2018). Thethree factors are password, smartcards and fingerprintdentification. Here Gateway is supposed to be a trustedparticipant and bridge between user and sensor. This scheme
successfully register a user and sensor on the gateway,authenticate the user to access sensor andprovides passwordchanging facility tothe user.

Researchers have also proposed some ultra-lightweightauthentication schemes which only involve simple bit-wiseoperations (like XOR, AND, OR, etc.) on tags. Therefore, itis very efficient in terms of storage and communication cost[6].
Razouket. al. suggested a new Security MiddlewareArchitecture based on Fog Computing and Cloud to supportresource constrained devicesfor authentication [7]. IoTconstrained devices communicate through proposedmiddleware which provides access to more computing power
and enhanced capability to perform secure communications.This model is based on usual technologies like the"Constrained Application Protocol (CoAP)" and REST APIfor easy implementation.

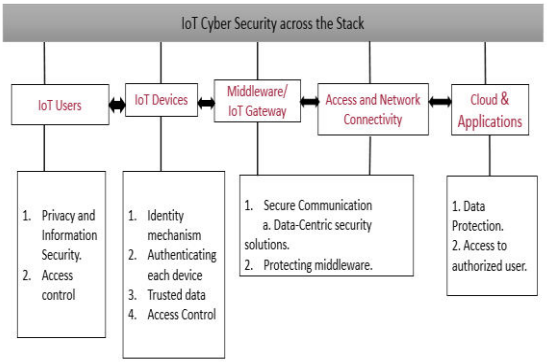

Figure 2: Security Model for IoT System.

IV. PROPOSED MODEL

IoT devices typically connect to the Internet via anInternet Protocol (IP) stack. This stack is very complex andrequires a lot of power and memory from the connecting IoTdevices.In the proposed model IoT devices are connectedlocally through non-IP networks and are connected to theInternet through anintelligentgateway. This gateway

International Journal For Recent Developments in Science & Technology
2581-4575
Crossref
A Peer Reviewed Research Journal

act as aninterface to the internet for the IoT devices. Because of thesmart gateway devices can be hidden in enterprise behindmultiple firewalls and will not require any inbound ports.The proposed solution provides a middlewarearchitecture that is able to adapt according to applicationrequirements. Middleware is responsible for deviceregistration, identification and database management. It alsoensures the privacy and security of data. The stored data isexposed after authentication and authorization via RESTAPI. Figure 5 summarizes the overall scenario.There are many authorization protocols available. Forexample, OAuth is an open authorization protocol which canallow accessing the resource at middleware using username,password, and tokens. Figure 3 and 4 explainthe architectureto achieve this onboard flow.

Step 1:- Device Registration requires an Authorized userho already has created an online account throughmiddleware.

Step 2:- Whenever an authentication request comes from theIoT device, gateway validates the devices request includingthe device payload by accessing the exposed REST API.Now the gateway will in turn request access to exposed APIwith its own credentials. The request will contain gateway idand secret key as input parameters. The API will bothauthenticate and authorize the gateway and will validate therequest. All methods in REST API requires authentication.

Once the gateway is authorized, a response in an encryptedform containing device details is sent back to the gateway.Now after verifying, gateway gives the access token to thedevice and device can now send real-time data to thegateway.

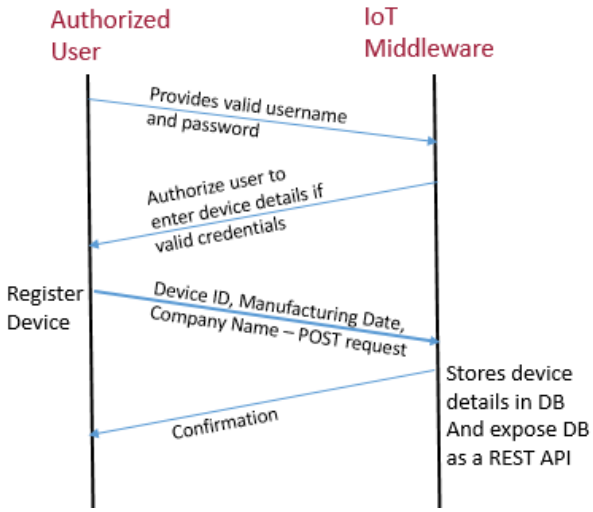

Figure 3: Device Registration

ANALYSIS OF PROPOSED MODEL

In this paper, we proposed a secure IoT framework thatensures end-to-end security from IoT application to IoTDevices. We can evaluate the security of the system byanalyzing the integrity of each component.

• IoT devices are isolated and have no interactionwith the outside world. They are connected to agateway and this gateway act as an interface to theinternet for the IoT devices. Because of the smartgateway devices can be hidden in enterprise behindmultiple firewalls and will not require any inboundports. Therefore there are no chances ofcompromising these devices by an attacker.

• IoT gateway acts an intermediate between IoTdevices and middleware. Gateways are

International Journal For Recent Developments in Science & Technology
2581-4575
Crossref
A Peer Reviewed Research Journal

enabled tocall REST API and exchange all informationsecurely.

• Communication between IoT gateway andmiddleware is secure with traditional cryptographic
algorithms. There is no need to use lightweightalgorithms because the two parties involved are notresource constrained.

• Authentication and Authorization is taken care byREST APIs which makes the whole process lesscomplex and compatible with industry standards.

```
$.ajax({
        type: "POST",
    url:  "http://localhost:8080/test/webresources
/com.mycompany.test.devicedetails",
    data: JSON.stringify({
    deviceidentifier : self.newDeviceId(),
    devicemanufacturingdate : self.newMDate(),
    uid : self.newUid()
          }),
    headers: {
    'Content-Type': 'application/json'
          },
    success: function() {
              console.log(data);
          },
    error: function(err) {
              console.log("AJAX Error: " + err);
          }
        });
```

CONCLUSION

We proposeda middleware architecture which providesan end-to-end security solution for contributors who uploadsensing data. This approach allows an end to end encryptionof data to secure data in transit. In the proposed middlewaresolution all IoT system constraints are taken intoconsideration. REST API is used for communication anddata exchange. Middleware successfully assists IoTdevelopment by exposing REST API and providing aninterface to the user to register their IoT devices and thensecurely accessing data collected by the device.

FUTURE SCOPE

Our future plan is to provide a multi-factor userauthentication scheme at middleware to provide secureaccess to sensory data to an authorized user. Also to providea privacy solution to prevent any data leakage and databreaches at middleware.

Abstract

Detecting node failures in mobile wireless networks is incredibly challenging because the network topology can be highly dynamic, the network may not be always connected, and the resources are limited. In this paper, we take a probabilistic approach and propose two node failure detection schemes that systematically combine localized monitoring, location estimation and node collaboration. Extensive simulation results in both connected and disconnected networks demonstrate that our schemes achieve high failure detection rates (close to an upper bound) and low false positive rates and incur low communication overhead. Compared to approaches that use centralized monitoring, our approach has up to 80 percent lower communication overhead, and only slightly lower detection rates and slightly higher false positive rates. In addition, our approach has the advantage that it is applicable to both connected and disconnected networks while centralized monitoring is only applicable to connected networks. Compared to other approaches that use localized monitoring, our approach has similar failure detection rates, up to 57 percent lower communication overhead and much lower false positive rates (e.g., 0.01 versus 0.27 in some settings).

Keywords: *Wireless sensor networks, node estimation, two-node failure detection*

1. Introduction

Mobile wireless networks have been used for many mission critical applications, including search and rescue [17], environment monitoring [11], [20], disaster relief [25], and military operations [18]. Such mobile networks are typically formed in an ad-hoc manner, with either persistent or intermittent network connectivity. Nodes in such networks are vulnerable to failures due to battery drainage, hardware defects or a harsh environment. Detecting node failures is important for keeping tabs on the network. It is even more important when the mobile devices are carried by humans and are used as the main/only communication mechanism (see discussion in Section III). Node failure detection in mobile wireless networks is very challenging because the network topology can be highly dynamic due to node movements. Therefore, techniques that are designed for static networks are not applicable. Secondly, the network may not always be connected. Therefore, approaches that rely on network connectivity have limited applicability. Thirdly, the limited resources (computation, communication, and battery life) demand that node failure detection must be performed in a resource conserving manner. One approach adopted by many existing studies is based on centralized monitoring. It requires that each node send periodic “heartbeat” messages to a central monitor, which uses the lack of heartbeat messages from a node (after a certain timeout) as an indicator of node failure [5], [12], [19]. This approach assumes that there always

 Copyright © 2020 Authors

exists a path from a node to the central monitor, and hence is only applicable to networks with persistent connectivity. In addition, since a node can be multiple hops away from the central monitor, this approach can lead to a large amount of network-wide traffic, in conflict with the constrained resources in mobile wireless networks. Another approach is based on localized monitoring, where nodes broadcast heartbeat messages to their one-hop neighbors and nodes in a neighborhood monitor each other through heartbeat messages. Localized monitoring only generates localized traffic and has been used successfully for node failure detection in static networks [15].

However, when being applied to mobile networks, this approach suffers from inherent ambiguities—when a node A stops hearing heartbeat messages from another node B, A cannot conclude that B has failed because the lack of heartbeat messages might be caused by node B having moved out of range instead of node failure. In this paper, we propose a novel probabilistic approach that judiciously combines localized monitoring, location estimation and node collaboration to detect node failures in mobile wireless networks. Specifically, we propose two schemes. In the first scheme, when a node A cannot hear from a neighboring node B, it uses its own information about B and binary feedback from its neighbors to decide whether B has failed or not. In the second scheme, A gathers information from its neighbors, and uses the information jointly to make the decision (see Section V for details). The first scheme incurs lower communication overhead than the second scheme. On the other hand, the second scheme fully utilizes information from the neighbors and can achieve better performance in failure detection and false positive rates. We have evaluated our schemes using extensive simulation in both connected and disconnected networks (i.e., networks that lack contemporaneous end-to-end paths). Simulation results demonstrate that both schemes achieve high failure detection rates, low false positive rates, and incur low centralized monitoring, while our approach may have slightly lower detection rates and slightly higher false positive rates, it has significantly lower communication overhead (up to 80% mlower). In addition, our approach has the advantage that it is applicable to both connected and disconnected networks. Compared to other approaches that use localized monitoring, our approach has similar failure detection rates, lower communication overhead (up to 57% lower) and much lower false positive rate (e.g., 0.01 versus 0.27 in some setting).

2. Existing System

Mobile wireless networks have been used for many mission critical applications, including search and rescue, environment monitoring, disaster relief, and military operations. Such mobile networks are typically formed in an ad-hoc manner, with either persistent or intermittent network connectivity. Nodes in such networks are vulnerable to failures due to battery drainage, hardware defects or a harsh environment. Detecting node failures is important for keeping tabs on the network. It is even more important when the mobile devices are carried by humans and are used as the main/only communication mechanism.

2.1. Disadvantages

1. Node failure detection in mobile wireless networks is very challenging because the network topology can be highly dynamic due to node movements. Therefore, techniques that are designed for static networks are not applicable.

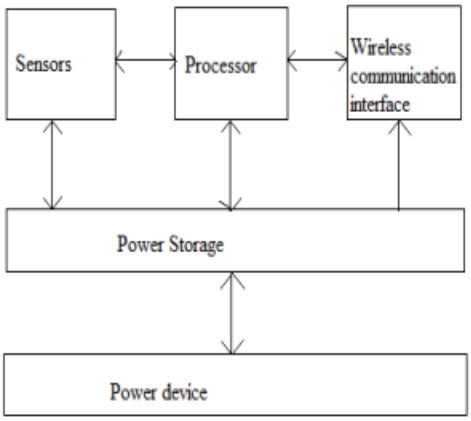
 Copyright © 2020 Authors

2. The network may not always be connected. Therefore, approaches that rely on network connectivity have limited applicability.
3. The limited resources (computation, communication, and battery life) demand that node failure detection must be performed in a resource conserving manner.

3. Proposed System

Our network model consists of a set of low-power radio frequency (RF) transceivers which move relative to each other across an irregular terrain subject to RF propagation impairments. The low transmitter power defines a radio coverage which limits the probability of intercept and the number of neighbors but optimizes frequency reuse. The combination of low power and propagation environment produces a network characterized by stochastic link failures.

We propose a novel scheme Link Scanner (LS) for monitoring wireless links at real time. LS issues one probe message in the network and collects hop counts of the received probe messages at sensor nodes. Based on the observation that faulty links can result in mismatch between the received hop counts and the network topology, we are able to deduce all links' status with a probabilistic model. A few distributed solutions have been proposed. In this paper for the detection of node replication attacks, We first analyze the desirable properties of a distributed mechanism. After that we show the solutions for the problem and later for detection of node replication attacks, we propose a self-healing RED protocol. Randomized, Efficient, and Distributed protocol and we see that it meets the requirements. Finally, it shows that our protocol is highly efficient in memory, communication and computation.



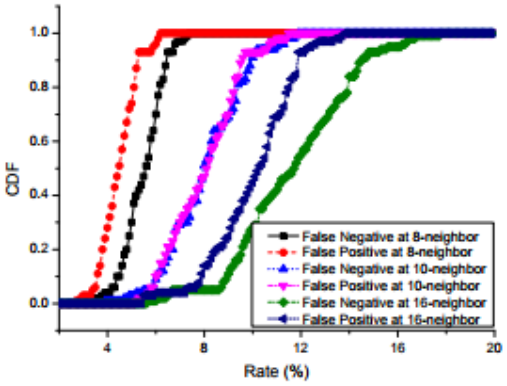


Figure. 1 Proposed network model.

3.1. Advantages

- We proposed a novel and low-cost link scanning scheme LS for faulty link detection. LS infers all links statuses on the basis of data collection from a prior probe flooding process in which we leverage hop count to reflect node in (or) out-going link performances.
- A distributed mechanism and shown the solution and later for detection of node replication attacks, to detect node replication attacks, a self-healing, efficient, and distributed protocol are proposed.

 Copyright © 2020 Authors

- We are investigating the efficiency and performance characteristics of survivable and adaptive network protocols with computer simulation techniques. Preliminary results will be reported on the evaluation of the algorithm in terms of message delay and acknowledgment overhead for different network sizes and routing restrictions.

Impact of network density: Network density can also significantly change the network topology. What is more, a dense network should suffer more channel collision and packet lost due to hidden terminal, thus may impact the probe flooding process and cover the real link performance. Here we define a network density in terms of average neighbor number. We show three densities in a 60-node network. Clearly, when the network is sparse LS can achieve a false negative rate about 5%, which means there is only one out of 20 normal links reported by LS is faulty in fact, while the false positive rate is only 4.8%. Following the network density increases, each node is expected to receive more probes with the same hop count number, since its neighbors are more centralized around itself. In DLV its corresponding group has a larger size, hence produces more possibilities once the number of probes mismatches the group size

4. Conclusion and Future Work

In this paper, we presented a probabilistic approach and designed two node failure detection schemes that combine localized monitoring, location estimation and node collaboration for mobile wireless networks. Extensive simulation results demonstrate that our schemes achieve high failure detection rates, low false positive rates, and low communication overhead. We further demonstrated the tradeoffs of the binary and non-binary feedback schemes.

As future work, we plan to evaluate our schemes using real world mobility traces and in scenarios with irregular transmission ranges. Our approach relies on location estimation and the usage of heartbeat messages for nodes to monitor each other. Therefore, it does not work when location information is not available or there is communication blackouts (e.g., due to weather conditions). Developing effective approaches for those scenarios is left as future work.

A Study on Knowledge based Propagation for Query Facets

P. Swapna[1], T. Swapna[2]
[1,2]*Assistant Professor, Department of IT*
[1,2]*Malla Reddy Engineering College, Hyderabad, Telangana, India*

Abstract

Important features of a query are generally presented and repeated in the top retrieved documents in the style of lists. Query facets can be extracted by collecting these significant lists. Query facets may provide direct information or instant answers that users are seeking i.e. user can select a particular facet item which he found relevant to his search need. So, the list format style is much more user friendly than displaying searches sentence wise. The scope of this survey is limited to get search results of a query in list format i.e. facets. Previously there has been lot of work done for retrieving more relevant data to users in order to meet their information needs thus improving performance of search engines. Search engine provide the platform for users to describe their information need more clearly by using query facets mining. Different approaches for extraction of query facets from web search results to assist information finding for queries are discussed along with similar techniques used earlier for information retrieval of queries. Query facets represents interesting facets of a query using groups of semantically related terms extracted from search results. This paper reviews techniques that represents interesting facets of a query using groups of semantically related terms extracted from search results along with approaches that are similar to query facets mining.

Keywords: *Query facets, Text mining, Multi- faceted queries, Knowledgebase.*

1. Introduction

Query facet is a collection of items which summarized the content of a query. In conventional method the user can browse a webpage user can view many documents for the information they are seeking, this takes a lot of time and confused the user [6]. Here use an automatic summarization of search result will produce it will help the user to know about the query they are searching without browsing many web pages. Mining query facets is an approach to solve the above-explained problem using text mining algorithms to mine the query facet. Table 1 shows an example of query facet the query is ―Beijing subway is a place in a European country. Its query facets cover aspects of related country lines temple, important city etc. These query facets help users learn about the topic―Beijing subway without browsing so many web pages. Query facets are good summaries of a query and are useful for users to understand the query and help them explore information [1]. Existing algorithm like QD Miner, QF-I, QF-J has used automatically mine query facets by aggregating frequent lists contained in the results. The facet item is extracted as a top search result from a search engine. One problem can arise by using this kind of methods the coverage of facet mined can be limited [6].

To solve this problem, use a knowledge base as a data source to improve the quality of query facet. Knowledgebase contains structured information such as entities and

Copyright © 2020 Authors

ISSN: 2278-4632
Vol-10 Issue-3 No. 1 March 2020

properties of the related query [6]. A text mining algorithm can be used to mine the query facet. Text mining is also known as text analytics, is the process of deriving high-quality information from text. Text mining is a process to extract interesting and significant patterns to explore knowledge from textual data sources [4]. Text mining is a multi-disciplinary field based on information retrieval, data mining, machine learning, statistics, and computational linguistics [4]. The user can search for a keyword by using the system.

Table 1. Example of query facet

Query	Beijing subway
1	Line 1, line 2, line 4, line 5, line 10, line 13, batong line
2	xizhimen, jianguomen, dongzhimen chongwenmen
3	Forbidden city, the temple of heaven, Tiananmen square

Then the URL of the search result is retrieved from the web and finally view the summarised search result and the user can download the search result. There are two methods are used to construct the final facet namely Facet Generation and Facet Expansion.

2. Query Facets Mining

2.1. Query Reformulation

The reformulation process is an iterative attempt between users and search engines in getting a satisfactory set of results [4]. Query reformulation is the process of iteratively modifying a query to improve the quality of a search engine results. Reformulations are close to the previous query both syntactically, as sequences of characters or terms, and semantically, regularly involving clear naming conventions [5]. Herdagdelen. et. al. [5] proposed an approach to query reformulation that provide a principled framework for the combination of string similarity and corpus-based semantic association measures using generalized Levenshtein distance algorithms. An exploration of class of models viz. unsupervised, compact and efficient for query reformulation which combines the syntactic and semantic aspects are given. Huang et.al. [4] studied users reformulation strategies in the context of the AOL query logs and describes the human side of query reformulation. A taxonomy of query reformulation strategies is created and built a high precision rule-based classifier to detect each type of reformulation.

2.2. Entity Search

Entity retrieval is the task of finding objects related to an information need [10]. Balog et. al. [10] explore the potential of combining Information Retrieval (IR) with Semantic Web (SW) technologies to improve the end-to- end performance on a specific entity search task. To get the best of both worlds, Balog et. al. [10] proposed to combine text- based entity models with semantic information from the Linked Open Data (LOD) cloud. Approaches to the REF task are described using IR and SW techniques and aim to find a set of entities for each topic. Semantic class construction tries to discover the peer or sibling relationship among terms or phrases by organizing them into semantic classes. Zhang et.al. [11] presented an approach that employs topic modelling for semantic class construction. Given a query q, all raw semantic classes (RASCs) are

Copyright © 2020 Authors

ISSN: 2278-4632
Vol-10 Issue-3 No. 1 March 2020

retrieved containing the item to form a collection CR (q) where CR is collection of RASCs. Latent Dirichlet Allocation (LDA) model and probabilistic Latent Semantic Indexing Model (pLSI) are used to generate semantic classes. Offline processing is performed for CR (q) that contains RASCs and store the results on disk, in order to reduce the online query processing time.

2.3. Search Results Diversification

It has been studied as a method that deals with ambiguous or multi-faceted queries while a ranked list of documents remains the primary output feature of web search engine today. Search result diversification tries to diversify the ranked list to account for different search target or query subtopics. A weakness of search result diversification is that the query subtopics are hidden from the user, leaving him or her to guess at how the results are organized. Query facet extraction addresses this problem by explicitly presenting different facets of a queries using groups of coordinate terms. T. Sakai et.al. [15] compare the properties of existing metrics related to the points viz. queries may have multiple intents, the likelihood of each intent given a query is available and graded relevance assessments are available for each intent. Also compared a wide range of traditional and diversified IR metrics for search results diversification after adding graded relevance assessments.

2.4. Facets Extraction according to Data Types

Existing automatic facets extraction methods can be divided into three categories corresponding to the different data types: unstructured, semi- structured and structured. They are explained below.

2.4.1. Facet Extraction of Unstructured Data

Unstructured data refers to information that either does not have a pre-defined data model or is not organized in a predefined manner. Unstructured information is typically text heavy, but may contain data such as dates, numbers, and facts as well. In facet term extraction, the most common form of unstructured data is the natural language text, which is always ambiguous and ill-formed.

2.4.2. Facet Extraction of Semi-structured Data

Semi-structured data is a form of structured data that does not match with the formal structure of data models associated with relational databases or other forms of data tables i.e. does not conform to an explicit data schema but on the other hand contains tags or other markers to separate semantically related elements. Semi-structured data lies somewhere between the structured and unstructured data. Examples of the semi-structured data include HTML pages, XML pages, JSON or JavaScript Object Notation. E.g. A Word document is generally considered to be unstructured data. It is possible to can add metadata tags in the form of keywords and other metadata that represent the document content and make it easier for that document to be found when people search for those terms , the data is now semi-structured. Semi-structured data has an implicit formal structure, which can be exploited to improve the quality of facet term extraction. For example, the hyperlinks of web pages can be used to evaluate the importance of facet terms.

3. System Analysis

3.1. Existing System

Query facets summarize a query in different aspects. They may help users quickly understand important aspects of the query and help them explore information. Dou et al. first introduced this problem and addressed QDMiner algorithm, which first extracts frequent lists in top search results using predefined patterns, and then weights each list and group them into final facets. Like QDMiner, Kong and Allan developed supervised approaches, namely QF-I and QF-J, to mine query facets. Facet item candidates are extracted from frequent lists which are obtained in a similar way as QDMiner. Then two Bayesian models are learned to estimate how likely a candidate is a facet item and how likely two candidates belong to the same facet. All the existing works are based on top search results; hence the quality of final facets might be limited. If some words or phrases don't appear in a list within top search results, they have no opportunity to be facet items.

3.1.1. Disadvantages

- There are no efficient techniques to generate Query facets like Query Based Summarization.
- There is no option to Provide Protection on User Query facets data.

3.2. Proposed System

In the proposed system, the system proposes leveraging a knowledge base as a complementary data source to improve the quality of query facets. Knowledge bases contain high quality structured information such as entities and their properties and are especially useful when the query is related to an entity. The system also proposes using both knowledge bases and search results to mine query facets in this paper. The reason why we don't abandon search results is that search results reflect user intent and provide abundant context for facet generation and expansion. The system's target is to improve the recall of facet and facet items by utilizing entities and their properties contained in knowledge bases, and at the same time, make sure that the accuracy of facet items is not harmed too much.

3.2.1. Advantages

- Automatic Query Recommendation.
- The system is more efficient due to Query.
- Based Summarization.

3.3. Implementation

3.3.1. Admin

In this module, admin server has to login with valid username and password. After login successful he can do some operations such as View all users and authorize, View all Researchers and authorize and Add category and subcategory, View all all products details based on clusters with rank, rating, reviews and View all products details with rank, rating, reviews, View all users search transaction based on Search type and View

Copyright © 2020 Authors

all user purchased products, View all Keyword Facet by rank and give link to show in chart, View product's rank in Chart

3.3.2. User

In this module, User should register before searching the Website contents. After registration successful the user can login by using valid username and password. After Login successful the user will do some operations Manage Accounts and Query Facet Mining and Faceted Search.

1. Single Facet Query Search

Enter your keyword or keyword+cat, or keyword+cat+Sub Cat, each based on pdesc_Cat+Sub cat and display products Facet details and view details(inc rank), review, Rate, view similar products facets, purchase

2. Multiple Facet Query Search

Select Category and Subcategory and display products Facet details and view facet details(inc rank), review, Rate, view similar products facets, purchase

3.Question Type Query Search

Type some question and match any one word with cat or sub cat or pdesc and diplay products. Facet details and view details (inc rank), review, Rate, view similar products facets, purchase View all search transaction based on Search type and Enter top k value and view searched Keyword facets.

3.3.3. Researcher

In this module, Researcher should register before searching the Website contents. After registration successful the user can login by using valid username and password. After Login successful the researcher will do some operations Select category and sub category and Add products according to category and sub cat with pname, Pdesc(enc), Manufacturer name, Price, Nodel no ,Color, Add image, View all your products details with rank, rating, reviews, View all purchased your products with total bill and View all Keyword Facet by rank.

4. Conclusions

Existing query facet mining algorithms, including QDMiner, QF-I, and QF-J mainly rely on the top search results from the search engines. The coverage of facets mined using this kind of methods might be limited, because usually only a small number of results are used. We propose leveraging knowledge bases as complementary data sources. We use two methods, namely facet generation and facet expansion, to mine query facets. Facet generation directly uses properties in Freebase as candidates, while facet expansion intends to expand initial facets mined by QDMiner in property based and type-based manners. Experimental results show that our approach is effective, especially for improving the recall of facet items.

Abstract

Today expanding cloud computing services take great opportunities for consumers to take better service and security conveniently new challenges to select the best service reporter out of the huge pool. In the proposed system the trust value is finding with the interaction between the users and the reporter. With the help of the ratings reporter to the cloud service providers by the users trust worthiness is estimated at different level, which is determined by the present interaction and the interaction. Oriented by requirement of trust management in number of cloud environment this paper presents T-broker a trust total service brokering method for efficient matching cloud services to satisfy different user requests. Trustworthiness is computed from personal work gained in direct interactions. Competence is assessed based on transparency in provider's SLA guarantees. We proposed secured proxy-based multi-cloud computing composition take dynamic, on the- fly collaborations and resource sharing many cloud-based services, addressing trust, policy, and security models. We integrate cloud with data confidentiality and the possibility of executing concurrent operations on encrypted data The prototype is implements the proposed cloud scheduler. The trusted Scheduler component it is important to analysis clouds is managed. The Scheduler trusted input trust status of the cloud infrastructure and provides cover new properties the foundation for planned future work. Cloud Trust Management, which provides the scheduler entry in the trust status of the cloud infrastructure

1. Introduction

Many of today's Information Technology (IT) applications rely on access to state-of-the-art computing facilities. In response to the resulting demand for flexible computing resources, cloud computing has taken the IT industry by storm over the past few years [2]. Cloud computing emerges as a paradigm to deliver on-demand service to customers, much akin to electricity or cable television [3], [4]. The paradigm shift from IT as a product to IT as a service and the accompanying flexibility proliferate the cloud applications [5], [6]. According to [7], [8], the public cloud services market is expected to expand from $109 billion in 2012 to $207 billion by 2016. The same physical resource among several tenants Customer does not have to manage and maintain servers, and in turn, uses the resources of cloud provider as services, and is charged according to pay-as-

 Copyright © 2020 Authors

you-use model. Similar to other on-line distributed systems, like e-commerce, p2p networks, product reviews, and discussion forums, a cloud provides its services over the Internet [1]. Cloud service provider provides [9] users the immediate access of a large range of resources. Cloud consumers have a wide range of choice of cloud service providers. Cloud Service Level Agreements (Cloud SLAs) are an important one for the relationship between a cloud service, customer and a cloud service provider [10] of a cloud service. The service provider must have the property like availability, response time and performance. The services and the storage space specified in the SLA are not satisfied and the trust and transparency are not maintained.

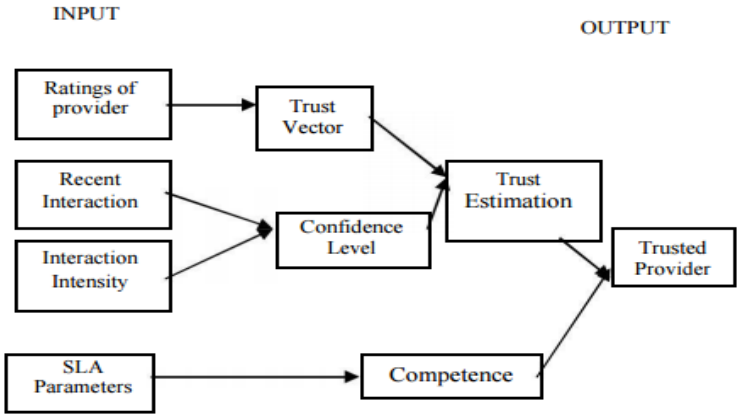

Figure 1. Trust Based System Architecture

Topical progressions in reckoning, storage service-oriented architecture, and network admission have simplified rapid growth in cloud marketplace. For any service a cloud customer may have many service providers to choose from. Major challenge lies in choosing an "ideal" service provider among them. By the term ideal, we suggest that a service provider is trustworthy as well as competent. Range of an ideal service provider is non-trivial because a customer practices third-party cloud services to serve its clients in cost-effective and efficient manner. In this situation from the cloud customer's perspective, persevering to a guaranteed level of service, as negotiated through starting service level agreement (SLA), is crucial Data loss owing to provider's incompetence or malicious intent can never be replaced by service credits.

- Support for customer-driven service management based on customer profiles and QoS requirements.
- Definition of computational risk management tactics to identify, assess and manage risks involved in the execution of applications with regards to service requirements and customer needs.
- Derivation of appropriate market-based resource management strategies that encompass both customer-driven service management and computational risk management to sustain SLA-oriented resource allocation;

2. Related Work

Decision trust is the extent to which one party is willing to depend on another even though negative consequences are possible. In cloud scenario, both notions are prevalent as customer depends on third-party provider, believing that it is reliable enough to

 Copyright © 2020 Authors

produce positive utility. Some works [11], [12] have proposed computation models for trust by incorporating the concept of risk. Like trust, reputation has also been studied extensively. From the perspective of social network researchers [13], reputation is perceived as an entity which is globally visible to all members of a social network community. Trust in cloud systems is often subjective and may be calculated using a centralized or distributed approach. When using a centralized approach, a single authority or trust broker collects all ratings from consumers, computes a reputation score for every participant, and makes all scores publicly available. When using a distributed approach, there can be distributed storages where ratings can be submitted, requiring interaction between storages to compute a single trust value for a given provider. A broker-based trust model was proposed in [1] based on SLA violation and user experience where the authors exploited SLA and cloud characteristic parameters such as CPU, number of virtual machines (VMs), and service down time, for evaluating the trustworthiness of providers. This approach is also robust against malicious group of entities performing reputation-based attacks. Recently, Ghosh [14] proposed SelCSP, a risk model which enables clients to select the most reliable CSP by using trustworthiness and competence of each CSP to estimate the provider reliability. SelCSP focuses on metrics such as number of CPUs and VMs, down time and interaction. This is a review paper based on the research work done by the researcher in the field of a new environment in cloud computing i.e. the collaboration of multi-cloud. This will give an overview of the techniques which will be helpful for shifting from the single cloud architecture to multi-cloud architecture, a security model and cost effectiveness of multi-cloud compared to a cloud. This section reviews literature that has been available on cloud computing security issues and other related topics. There were many researches that focused on cloud computing security issues. For instance, in [15] multi-shares were proposed that makes use of secret sharing algorithm Single cloud environment issued in [16] to solve service availability problem. The main issue in implementing multi-cloud is its working in a distributed environment as the services are to be collaborated with different cloud service providers to make it possible a framework is laid in the research work of “Collaboration Framework for Multi-cloud Systems” which specify the use of proxies at different level of collaboration. Trust plays an important role in all commercial grid and cloud environments. It is the estimation of competence of a resource provider in completing a task based on reliability, security, capability and availability in the context of distributed environment. It enables users to select the best resources in the heterogeneous grid and cloud infrastructure. This paper introduces. A novel trust model to evaluate the grid and cloud resources by means of resource broker. The resource broker chooses appropriate grid/cloud resource in heterogeneous environment based on the requirements of user. Our proposed trust management system is implemented with Kerberos authentication and PERMIS authorization to enhance the trust of the broker itself. The proposed trust enhanced resource broker evaluates the trust value of the resources based on the identity as well as behavioral trust. The proposed model considers metrics suitable for both grid and cloud resources. The results of the experiments show that the proposed model selects the dependable and reliable resources in grid and cloud environment.

 Copyright © 2020 Authors

3. System Design

User requirements are both hardware and software requirement. Infrastructure properties are availability, reliability, security, privacy concern. Users enter the cloud environment a chain of trust made consisting of username, password and provide some unique ID to enter the cloud. Scheduling perform as committing resource between possible task. Trust management implemented information security, in particular access control policies. Resource allocation are the virtual machine managed by the cloudlet length of resource management. This middleware uses a confidence conscious brokering architecture, in which the broker itself as the TTP acts for the trust management and resource planning. Cloud dispatchers do not consider the entire cloud infrastructure not look at them the entire user and infrastructure characteristics. Virtual resources are hosted using physical resources that meet their needs without getting users to understand the details of the cloud infrastructure involved. The prototype made available implements the proposed cloud scheduler. The trusted Scheduler component, it is important to understand how to have clouds, are managed. The Scheduler trusted input via the trust status of the cloud infrastructure and provides cover other properties the foundation for planned future work. Cloud Trust Management which provides the scheduler entry via the trust status of the cloud infrastructure

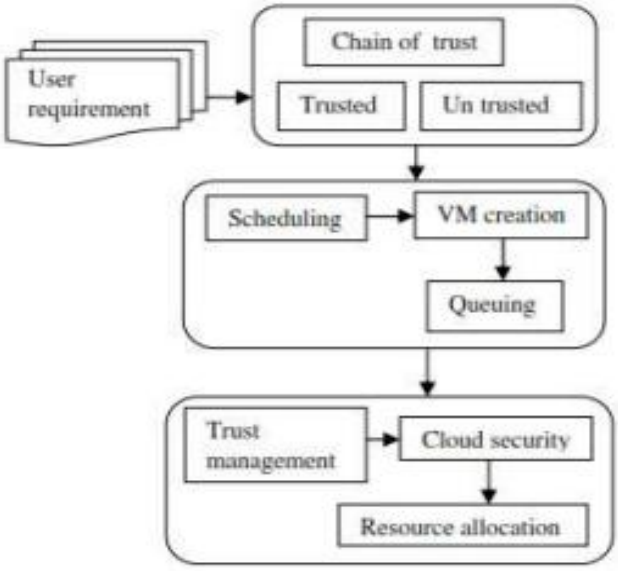

Figure 2.System Design

4. Proposed System

Independent systems dynamically come together to share information for a period of time. No global policy is maintained as interoperation requests are “on-demand” to facilitate dynamic data sharing. In a cloud environment, both tight and loose coupling may take place depending on the nature of collaboration. For example, if different departments of an organization collaborate using cloud services, it is an instance of tightly coupled collaboration. However, if autonomous domains mash-up “on demand” for a limited period of time, it is an example of loosely coupled collaboration. For both collaborations, if multiple collaboration requests are generated within the same period of time or particular session. propose a trust-aware framework to verify the security controls

Copyright © 2020 Authors

considering consumers' requirements [15]. The authors model the security controls in the form of trust properties. Then, they introduce taxonomy of these properties based on their semantics and identify the authorities who can validate the properties. The taxonomy of these properties is the basis of trust formalization in their proposed framework. Furthermore, a decision model is proposed as an integral part of the framework in order to empower consumers to determine trustworthiness of cloud providers. A trust enhanced secure model for trusted computing platforms [11]. The authors argue that given the nature of both binary and property-based attestation mechanisms, an attestation requester cannot be absolutely certain if an attesting platform will behave as it is expected to behave.

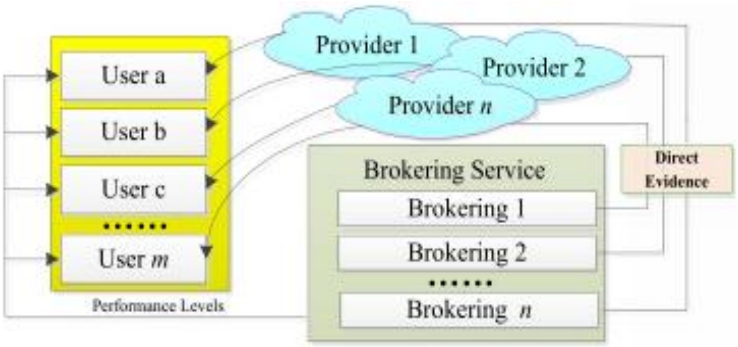

Figure 3. Scenario without user feedback

4.1. Sensor-Based Service Monitoring (SSM)

This module is used to monitor the real-time service data of allocated resources in order to guarantee the SLA (Service Level Agreement) with the users. In the interactive process, this module dynamically monitors the service parameters and is responsible for getting run-time service data. The monitored data is stored in the evidence base, which is maintained by the broker. To calculating QoS-based trustworthiness of a resource [7], [10], we mainly focus on five kinds of trusted attributes of cloud services, which consists of node spec profile, average resource usage information, average response time, average task success ratio, and the number of malicious access. The node spec profile includes four trusted evidences: CPU frequency, memory size, hard disk capacity and network bandwidth. The average resource usage information consists of the current CPU utilization rate, current memory utilization rate, current hard disk utilization rate and current bandwidth utilization rate. The number of malicious access includes the number of illegal connections and the times of scanning sensitive ports.

4.2. Virtual Infrastructure Manager (VIM)

Each cloud provider offers several VM configurations, often referred to as instance types. An instance type is defined in terms of hardware metrics such as CPU frequency, memory size, hard disk capacity, etc. In this work, the VIM component is based on the OpenNebula virtual infrastructure manager [12], [13], this module is used to collect and index all these resources information from multiple cloud providers.

 Copyright © 2020 Authors

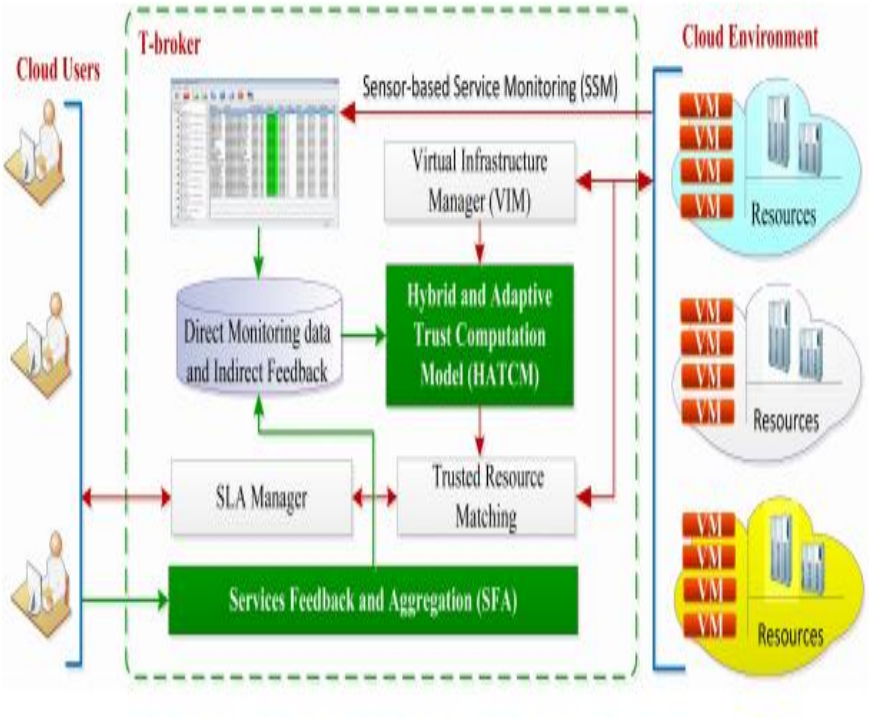

Figure 4. T-broker's Architecture and main function modules

It obtains the information from each cloud provider and acts as a resource management interface for monitoring system. Cloud providers register their resource information through the VIM module to be able to act as sellers in a multi-cloud marketplace. This component is also responsible for the deployment of each VM in the selected cloud as specified by the VM template, as well as for the management of the VM lifecycle. The VIM caters for user interaction with the virtual infrastructure by making the respective IP addresses of the infrastructure components available to the user once it has deployed all VMs.

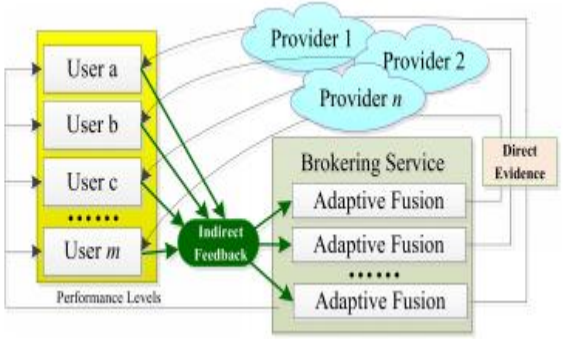

Figure 5. Scenario with adaptive fusion mechanism

4.3. Methods

1) Create Cloud Environment: We provide cloud users and cloud data centers and virtual machines as per our requirement. Job Manager, Cloud Controller also created. The Job Manager is replaced by the customer's orders, which is responsible for planning them responsible and coordinates their execution. It is capable of the cloud server provides the

Copyright © 2020 Authors

interface communicates the instantiation of VMs to control. We call this interface, the Cloud Controller. Using the Cloud Controller Job Manager can configure or deallocate VMs after the current job execution phase.

2) Chain of Trust: A chain of trust is designed to allow multiple users and use the system to create software that would be more difficult if all the keys were stored directly in the hardware. The signing authority will sign only boot programs to enforce the security as they run only programs that are registered, or only allow signed code access to certain features of the machine to have. The final software can be trusted to have certain characteristics, because if it has been changed illegally his signature would be invalid and the previous software would not run it.

3) Scheduling: It is the process of deciding how to commit the resources between the varieties of possible tasks. Shared resources are available at certain times and events are planned at this time. The schedule keeps separation between the users of the resources. Scheduler, often as workload automation, usually offers a single point of control for the definition and monitoring. Scheduling is the method given by the threads, processes or data streams access to system resources. This is done to load normally, a system balance effectively or reach a target quality of service. The need for a scheduling algorithm results from the requirement for most modern systems multitasking and performs multiplexing. Job Scheduling is the most important task in cloud computing environment because the user used to pay for resources, based on time. Thus, an efficient use of resources must be important, and because of this scheduling plays an important role maximum advantage of the resource base.

4) Trust Management: The trust management is an abstract system that processes symbolic representations of social trust, usually automated decision-making support. The automated verification of measures against security policies In this concept, actions are allowed if they show sufficient credentials, regardless of their actual identity, to separate symbolic representation of the confidence of the actual person. Trust management can be used as an icon-based automation of social decisions be seen in connection with trust, where social actors instruct their technical presentations on how to act to make technical presentations while other agents. Further automation of this process can lead to automated trust negotiation in which technical devices negotiate confidence by selective disclosure Credential, defined according to the rules of social agents that represent them.

5) Resource Allocation: Resource allocation is used to allocate the available resources in an economical manner. Resource allocation is the planning of activities and the necessary resources from these activities, while taking into account both the availability of resources. could Resource access to a section of the store computer data in a device interface buffers, one or more files or the required amount of processing power. A single processor can perform only one process at a time, charged regardless of the number of programs by the user.

5. Experimental Results

The Trust Based Cloud Service Provider Selection involves the procedure of finding the cloud service provider for the effective use of their resources by the cloud consumers. The trustworthiness and the competence are said to be determined with the interaction of providers with consumers that are provided as in the form of ratings. The Extended

 Copyright © 2020 Authors

Opinion dataset is used in order to find the trust, it contains 5000 user feedbacks in it. The dataset file contains the item id, rating, user ID, date. Trust Based Cloud Service Provider helps to efficiently find the cloud service provider it uses trustworthiness and competence estimating technique in finding the effective cloud service provider. The trustworthiness and competence are said to be determined, calculating the evaluation of the ratings that are provided by the users to the cloud service providers by the interaction with the providers. The trust estimation is determined by calculating the various parameters. The competence is determined by the interaction with the providers and SLA parameters. By comparing the value of the trustworthiness, the trust estimation is said to be calculated. This experimental result shows efficient results by using this trustworthiness and competence estimation.

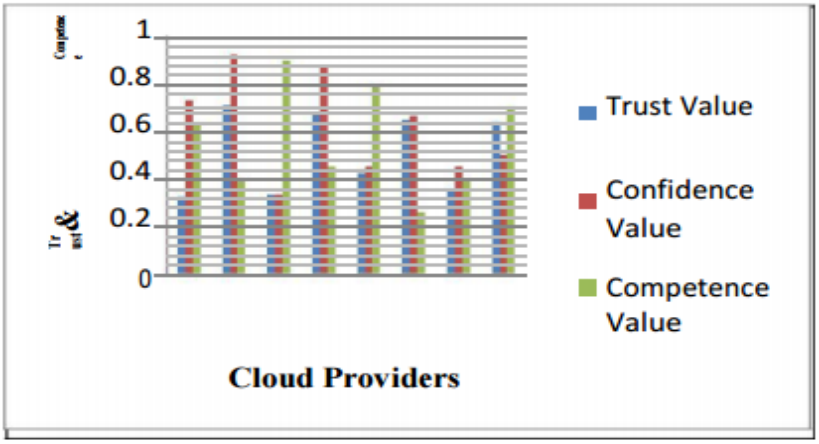

Figure 6. Comparison between Trust and Competence

6. Conclusion

We propose a risk model to characterize data breach for cloud service providers, enabling users to identify parameters of most concern to them and provide a weighting function to priorities them. Multi-attribute utility theory is used to aggregate risk probabilities across the measured parameter. The cloud service providers are determined based on the interaction of the providers and the users. It also considers various parameters like security and availability. The trustworthiness and competence are said to be estimated with the interactions with the users with the cloud service providers and the recent interaction of the providers. The confidence level is established by considering the recent interaction and interaction intensity of the providers with the users. Later the trust network has to be formed, that contains the indirect interaction can also be formed by the users and providers. Then the trust has to be estimated from the social network like Twitter, from that the direct communication and feedback of the users to the providers can be determined. The framework estimates trust worthiness in terms of context specific, dynamic trust and reputation feedbacks. It also computes competence of a service provider in terms of transparency of SLAs. Both these entities are combined to model interaction risk, which gives an estimate of risk level involved in an interaction we implemented a multi-cloud environment where users can store data in multiple clouds. The advantages of this kind of environment include high service availability, low security risks and the insider theft is eliminated to a greater extent.

 Copyright © 2020 Authors

In the future it is important for the adoption of public cloud systems, consumers and citizens are reassured that the privacy and security is not compromised. It will be necessary to address concerns expressed the problems of privacy and security in this chapter to provide trustworthy and innovative cloud computing services available and support that are useful for a number of different situations.

Abstract

Content based image retrieval (CBIR) is an imperative and testing errand in numerous fields, for example, military, common, restorative and even in web applications. Here, we introduced novel content based medical image retrieval with decimated bi-orthogonal spline wavelet filter banks. Proposed algorithm is an extension for the existing low-level feature extraction method done by using spline wavelet filters, also utilized iterative partitioning (IP) for extracting the similar patterns of query and database images. Simulation results shows that the proposed method has performed superior to the existing scheme in terms of precision and recall.

Key words: *CBIR, Bi-orthogonal spline wavelets, DWT, segmentation, iterative partitioning and precision*

1. Introduction

Content based image retrieval (CBIR) is an imperative and testing errand in numerous fields, for example, military, common, restorative and even in web applications. Late years there is a fast development in seeking motors, for example, Bing image hunt: Microsoft's CBIR motor (Public Company), Google's CBIR framework, note: does not take a shot at all images (Public Company), CBIR web crawler, by Gazopa (Private Company), Imense Image Search Portal (Private Company) and Like.com (Private Company), image retrieval has turned into a testing undertaking. The interest in CBIR has developed in view of the retrieval issues, constraints and time utilization in metadata-based systems. We can seek the literary information effectively by the current innovation, yet this looking techniques obliges people to portray every images physically in the database, which is unrealistic for all intents and purposes for extremely gigantic databases or for the images which will be generated naturally, e.g. images generated from reconnaissance cameras. It has more disadvantages that there is an opportunity to miss images that utilization distinctive proportional word in the portrayal of images. The systems based on arranging images in semantic classes like "tiger" as a subclass of "creature" can suspend the miss-order issue, yet it will requires more exertion by an utilization to recognize the images that may be "tigers" , however every one of them are sorted just as a "creature". Content-based image retrieval (CBIR) is a utilization of techniques for securing, pre-handling, examining, representation furthermore understanding images to the image retrieval issue, that is the issue of investigating for digital images from extensive databases. The CBIR framework is against customary methodologies, which is known on concept-based methodologies i.e., concept-based image indexing (CBII) [1].

2. Related Work

In the previous decades a few CBIR systems have been proposed, and still the specialists are concentrating on creating augmented CBIR systems with more powerful results. The letter proposed in [4] gives a correlation of various methodologies of CBIR based on comparability measures and image features to recognize the closeness between the images, which gives accurate information to recovering the pertinent images from vast

 Copyright © 2020 Authors

database. Wan Siti et.al proposed in [5] thinks about the few medicinal image retrieval systems based on the feature extraction and to enhance the viability of the CBIR framework for restorative images, for example, attractive reverberation (MR) images and computed tomography (CT) images [10]. The significant concept proposed in [5] is to help in the determination, for example, to locate the comparative ailment and observing of patient s advance persistently. B. S. Manjunath et.al displayed in [6] is the combination of shading, surface with consideration of edge minimization for Motion Picture Expert Group (MPEG)- 7 guidelines. Another methodology proposed in [7] utilized diverse shading spaces, for example, HSV and YCbCr clarifies a comparative methodology based on shading and surface analysis. The work proposed in [8] presents another retrieval framework which has done by utilizing wavelet transformation with both shading and surface features together and will perform superior to anything existed condition of craftsmanship algorithms. As of late, retinal image retrieval framework called CBIR for retinal and veins extraction [9] has been broke down by the histogram features of RGB shading components. The multi resolution analysis has connected to the image to gain the surface information. Notwithstanding enhance the execution, morphological operations are connected to concentrate on the state of article. Swati Agarwal has proposed another CBIR framework in [11], which is by utilizing discrete wavelet transform and edge histogram descriptor (EHD). Here the retrieval is based on shading and surface features not by utilizing shading information as a part of the image, input image first deteriorates the info question image into a few sub bands i.e., estimation coefficients and point of interest coefficients, where subtle element coefficients comprises of even (LH), vertical (HL) furthermore the askew information (HH) of the image. A short time later, EHD is utilized to assemble the information of prevailing edge introductions. This blend of 3D-DWT and EHD will enhance the productivity of the CBIR framework.

3. Proposed Methodology

For image retrieval, grouping and indexing both shading and surface have been utilized generally as a part of different applications. Histogram of an image is a graphical analysis of an image, which speaks to the shading information of image. It is a first request factual measure. The significant downside of this histogram-based methodologies is that the spatial conveyance and nearby varieties will be disregarded. Nearby spatial variety of pixel power is regularly used to catch surface information in an image. Wavelet transform is a one of the best ways to deal with locate the low-level features of image which is an expansion for both fourier (FT) and short time fourier transforms (STFT). It utilizes an adaptive window to ensure that the all aspects of the sign or image information will be separated by utilizing the scaling property. Here, we utilized a discrete wavelet (DW) transform with bi-orthogonal spline channels to get the example arrangement of restorative x-beam images.

3.1. Discrete Wavelet Transform (DWT)

Discrete Wavelet Transform (DWT) is an adjusted variant of Continuous Wavelet Transform (CWT). DWT principles are fundamentally the same as the CWT however the wavelet scales and positions are heaps of two.

The fundamental principle of DWT is to pass the info signal through a gathering of channels i.e., low pass and high pass channels to get the low frequency (LF) and high frequency (HF) of source sign. Low frequency substance incorporates LL and these coefficients are known as the estimation coefficients. This means the approximations are gotten by utilizing the high scale wavelets which relates to the low frequency. The high frequency components which are known as LH, HL and HH of the sign are known as the points of interest which will be gotten by utilizing the low scale wavelets which relates to the high frequency.

 Copyright © 2020 Authors

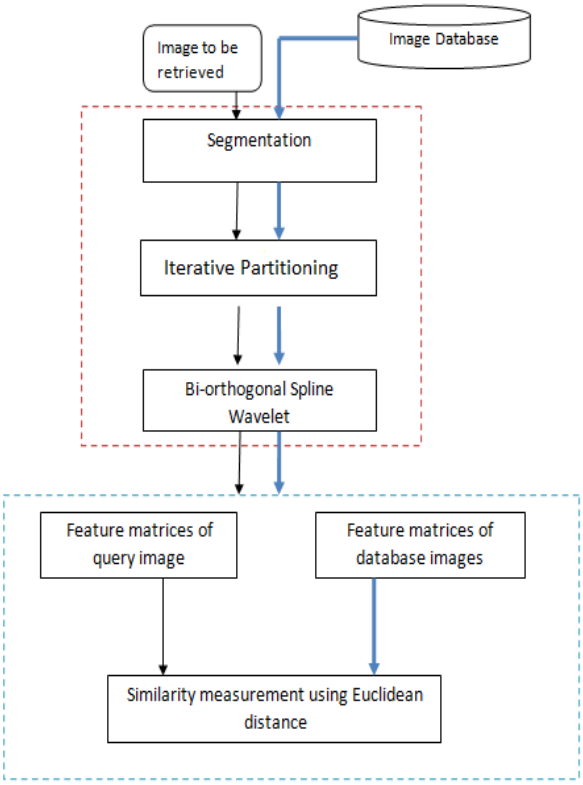

Figure 1. Proposed CBIR flow chart

The procedure of DWT filtering incorporates; first the sign is bolstered into the wavelet channels. These wavelet channels contain both the high-pass and low-pass channel. At that point, these channels will separate the high frequency substance and low frequency substance of the sign. Be that as it may, with DWT the numbers of tests are lessened by scale. This procedure is known as the sub-testing. Sub-inspecting means decreasing the specimens by given element. Because of the detriments forced by CWT which requires high preparing power [11] the DWT is picked due its straightforwardness and simplicity of operation in taking care of complex signs.

3.2. Iterative Partitioning

Step 1: First we will choose the quantity of centroids arbitrarily i.e., relies on upon number of groups

Step 2: Now, allotment the items inside every group

Step 3: It discovers parcels to such an extent that pixels inside every group are as near each different as could be allowed, and as a long way from articles in different bunches as could reasonably be expected.

Step 4: The items are in the group or not will be computed by measuring the separation between the bunch pixels. At the point when the figured Euclidean separation has minima esteem then the pixels will be assembled with the individual group

Step 5: Do the above procedure for outstanding bunches too. At that point, we will get three groups with their comparative pixels.

Step 6: Now, compute the mean of every group and supplant the mean qualities with the centroids

Step 7: Repeat the same procedure with these new centroids by giving the quantity of cycles until unless the joining event i.e., the mean estimation of bunches = group centroid esteem.

Copyright © 2020 Authors

3.3. Proposed Algorithm

The steps involved in proposed scheme are as follows:

Step1: Select and read the inquiry image from the database.

Step2: Apply division with iterative partitioned clustering to the query image.

Step3: Now, select the bi-orthogonal spline wavelet channels and apply decimated wavelet to remove the low-level features.

Step4: Make feature vector by utilizing the above three stages.

Step5: Read all the database images and apply all the three stages which have been connected to the inquiry image to discover the feature vectors.

Step7: Combine all the feature vectors and make it into a solitary feature vector for question image features and database images too.

Step8: Calculate the Euclidean separation for the closeness check, when the likeness between the inquiry and database images will be more than 85%.

4. Simulation Results

In this section we discussed the simulation results of CBIR system for bio-medical images. The proposed algorithm has been tested with few databases and displayed the outputs in the below figures. Fig3 shows that the initial GUI model for retrieving images using proposed CBIR schemes. Proposed retrieval system has been shown in fig4 and 5. As a measure of performance we have used two widely used metrics of Precision and Recall.

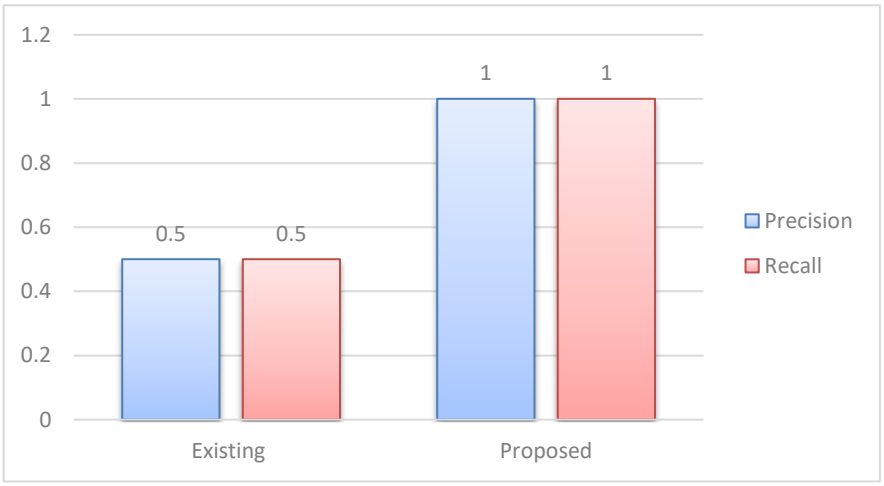

Figure 2. Performance of Proposed and conventional CBIR schemes

Precision is a measure of ability of CBIR algorithm to retrieve only relevant images, while Recall decides the ability of CBIR algorithm to retrieve all relevant images as defined by below equations respectively.

$$P = \frac{Total\ numebr\ of\ relevant\ images\ retrieved}{Total\ numebr\ of\ retrieved\ images}$$

$$R = \frac{numebr\ of\ relevant\ images\ retrieved}{numebr\ of\ relevant\ images\ in\ database}$$

5. Conclusion

Copyright © 2020 Authors

We had proposed an adaptive CBIR scheme for large database systems. Feature vectors have been generated by considering multiple features of images with decimated bi-orthogonal spline wavelet filter banks and iterative partitioning. Euclidean distance is used to measure the similarity between the query and database feature vectors to retrieve the relevant images. By using low level feature extraction and IP, the performance of the proposed CBIR system had improved in terms of the accuracy and computational complexity while improving the system efficiency. The proposed system has proven that this approach has got superior performance than the existing CBIR schemes.

Design and Analysis of Autonomous Anomaly Detection Models

Racharla Ramya[1], Gudepu Sai Krishna[2]
[1,2]*Assistant Professor, Department of IT*
[1,2]*Malla Reddy Engineering College, Hyderabad, Telangana, India*

Abstract

Recent data mining deviation to recognition data point the expected system to sufficient dataset or is incomparably many data exhibits that as dimensionality increases there exists hubs and anti hubs the points that frequently occur in k nearest neighbor (kNN) lists. Ant hubs are points that uncommonly model in kNN lists. This proposed system to developing and comparing to autonomous anomaly detection models. This proposed method to details about the development and analysis of outlier (anomaly) detection methods is Local Outlier Factor (LOF), and Local Distance Based Outlier Factor (LDOF). Outliers outperforms the results of the previous systems to reference to speed, complexity and efficiency. The classification algorithms are used to finding the corresponding features and classify the criteria in data mining methods. These techniques deteriorate to increasing difficulty, size and variety of data sets. The proposed incremental LOF algorithm takes equivalent finding performance as the iterated static LOF algorithm while requiring less computational time. In addition to this, the incremental LOF algorithm is dynamically change the data of data points. This is a very important application, change data profiles to change over time.

Index Terms: Clustering-based, Density-based and Model-based techniques, Nearest Neighbours, Outlier Detection, Discrimination, Outliers, data mining, Clustering, Neural Network.

1. Introduction

Outlier detection or anomaly detection means identifying the data patterns that do not comply or far from other observations.[5] Outliers can have many anomalous causes. To normal behavior Outliers occur due to changes in system behavior, fraudulent behavior, human error and instrument error or simply through natural deviations in populations. Outliers may contain demanding and actionable information in fraud detection, intrusion detection and medical diagnosis. Data Mining is a non-trivial method of identifying valid, novel, potentially useful and finally understandable patterns [1]. Now, data mining is becoming an important area to convert the data into information. It is basically used in fraud detection, marketing and scientific discovery. Data mining actually refers to extracting the hidden interesting patterns from the huge number of datasets and databases [2]. Mining is basically used to show the patterns of the data, but this can be carried out on the sample of data. The mining process will be completely useless if the samples are not the good representation of the large body of the data. Automated identification of suspicious behavior and objects [3] based on information extracted from video streams is currently an active research area. Other important applications include traffic control, surveillance of commercial and residential buildings. These tasks are characterized by the need for real time processing and by variable, non-stationary and usually noisy environment. Hence, there is necessity for incremental outlier detection that can adapt to

Copyright @ 2020 Authors

novel behavior and provide timely identification of unusual events.[4] The errand of distinguishing anomalies can be classified as administered, semi-regulated, and autonomous, contingent upon the presence of marks for exceptions and/or general occurrences. Regulated anomaly discovery procedures have an unequivocal thought of the typical and exception conduct and thus accurate models can be assembled. The downside here is that precisely marked preparing. Among these categories, autonomous methods are more widely applied, because the other categories require precise and representative labels that are usually prohibitively expensive to obtain [5].

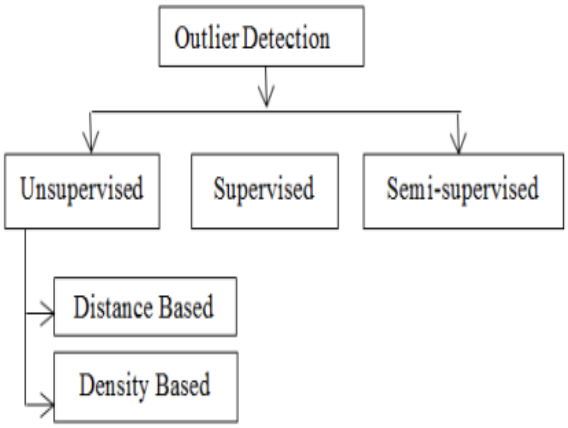

Fig. 1 Modes of operation of outlier detection techniques

Autonomous methods include distance-based methods that mainly depend on a measure of distance or similarity in order to detect anomalies. Formulation of outlier detection relies upon the various factors such as input data sample type and distribution, availability of data and resource conditions introduced by application domain. Detecting unexpected entries in databases which ultimately detect anomalies for data mining, frauds or valid but unexpected entries,[6] Due to so many applications accurate detection of anomalies becomes must. Many outlier detection methods were suggested till date. In this paper, we will categorize and review some of the existing methods in the following sections. The overview of the techniques which will be discussed is given in the figure below:

2. Related Work

The classification and recognition of individual characteristics and behaviors create a preliminary step and is an important aspect in the behavioral sciences. Current statistical approaches do not always give satisfactory results [3]. To improve performance in this area, we present a methodology based on one of the principles of artificial neural networks, the back-propagation gradient. In classification tasks, data set that comply to a certain representation or a classification model was considered. If one were to confuse a few data samples by making small changes to some of their attribute values, the original classification model which represents the data set was modified. Also, if one were to delete those data instances, the original model could change significantly [7], The magnitude of modifications to the original model provided clues to the criticality of such data instances, as more critical data instances tend to impact the model more significantly than data instances that are comparatively noncritical. The hub marvel has been as of late seen in a few application territories including sound and picture Data quickly say hubness

 Copyright @ 2020 Authors

in the setting of chart development for semi-directed learning. Also, there have been endeavors to dodge the impact of center points in 1-NN time-arrangement order, obviously without clear knowledge about the presence of the wonder (Islam et al.) and to represent conceivable imbalance of the circulation of N1 in converse [8] nearest neighbor look where Nk(x) indicates the quantity of times point x happens among the k closest neighbors of every other point in the Data set. None of the said papers, be that as it may, effectively break down the reasons for hub or sum it up to different applications. Initially proposed outlier detection methodologies determine outliers once all the data records (samples) are present in the dataset. We refer to these algorithms as static outlier detection algorithms. In contrast, incremental outlier detection techniques identify outliers as soon as new data record appears in the dataset. Incremental outlier detection was also used within more generic framework of activity monitoring [18]. In addition, [19] proposed broad requirements that incremental algorithms need to satisfy, [21] used online discounting distributional learning of Gaussian mixture model and scoring based on the estimated probability density function. In [8] propose a outlier ranking depending upon the objects anomaly in a set of relevant subspace projections. It do not include irrelevant projections showing no clear difference between outliers and the relevant objects and find objects which deviates in multiple relevant subspaces. The study in [9] distinguishes three problems occurred by the "curse of dimensionality" in the context of data mining, searching and indexing applications like poor inequity of distances caused by concentration, presence of irrelevant and duplicate attributes, all of which make difficult the usability of traditional similarity and distance measures. Parameter free outlier detection algorithm [10] to compute Ordered Distance Difference Outlier Factor Formulate a new outlier score for each instance by considering the difference of ordered distances. Then use this value to calculate an outlier score.

3. Density Based Approaches

Distance-based approaches are very known to face the local density problems created by the various degrees of cluster density that exist in a dataset. In order to solve the problem, density-based approaches have been proposed. The basic idea of density-based methodology is that the density around an outlier remarkably varies from that around its neighbors [14]. The density of an object's neighborhood is correlated with that of its neighbor's neighborhood. If there is a significant anomaly between the densities, the object can be considered as an outlier. To implement this idea [11], several outlier detection methodologies have been developed in recent past. The detection methods estimate the density around an object in different ways [15], implemented the local outlier factor (LOF), which is amongst the most commonly a used method in outlier detection methodology. LOF is influenced by different variations like local correlation integral (LOCI) [16]. Local distance-based outlier factor (LDOF) [17], and local outlier probabilities (LOP) [18]. Now we will look into some density-based outlier detection methodologies. Many outlier methods are proposed till date, these existing methodologies can be broadly classified as: distribution (statistical) based, clustering based, density based and model-based methodologies [13]. Statistical methodologies [12] assume that the data follows some standard or predetermined distributions, and this type of approach aims to find the outliers which doesn't follow such distributions. The methods in this class always assume the typical example follow a particular data distribution. Nevertheless, we

 Copyright @ 2020 Authors

ISSN: 2278-4632
Vol-10 Issue-5 No. 20 May 2020

cannot always have this kind of priority data distribution information in practice, mainly for high volumes of multidimensional real data sets [13].

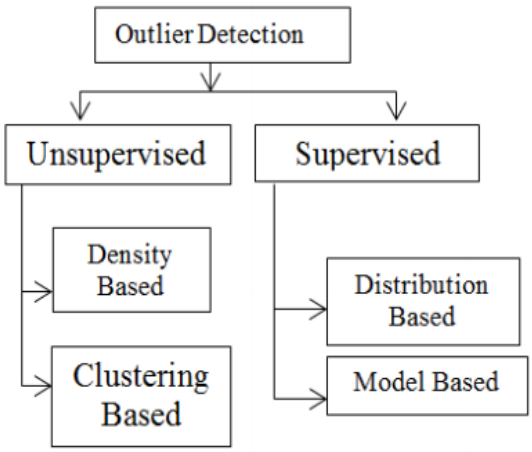

Fig. 2 Classification of Outlier Detection

4. Neural Network Methods

Neural Network methodologies are usually non parametric and model based and suits well to the hidden patterns and are capable of learning complex class boundaries .The entire data set has to be traversed multiple times to allow the network to settle and model the data correctly .Neural Networks are comparatively less vulnerable to the jinx of dimensionality as compared to the statistical methods, the neural networks are further classified into two types – Supervised Neural Methods and Unsupervised Neural Methods[16]. Supervised Neural Networks uses the classification of the data to drive the learning process. If this classification of the data is not available, then it is known as unsupervised neural network.

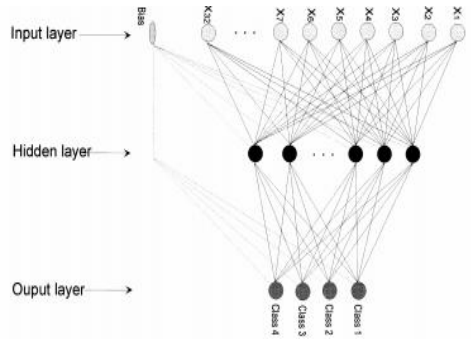

Fig. 3 Structure of a Neural Network

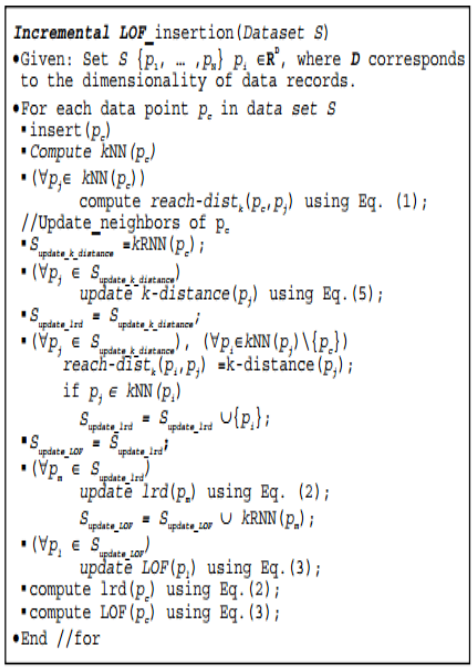
Unsupervised neural networks contain nodes which compete to represent parts of the data set. As with Perceptron based neural networks, decision trees or k-means, they require a training dataset to allow the network to learn. They individually cluster the input vectors through node placement to allow the underlying data distribution to be modeled and the normal/abnormal classes differentiated [18]. They assume that related vectors have common feature values and depend upon identifying these features and their values to topologically model the data distribution. The neural network uses the class to adjust the weights and thresholds to make sure the network that can correctly classify the overall

Copyright @ 2020 Authors

ISSN: 2278-4632
Vol-10 Issue-5 No. 20 May 2020



network. These methods are also used to detect the noise and novel data [19]. Neural Network is a very crucial methodology that plays a crucial role in the outlier detection.

5. Outlier Detection Algorithms

Clustering and outlier identification is one of the important tasks in high dimensional data. Clustering methodologies are supported by outlier detections for new optimistic methodologies. The thrust of the new optimistic approach applies nearest neighbor-based clustering method and detect outliers in high dimensional data.

A. Local outlier factor (LOF)

In LOF, compare the local density of a instances with the densities of its neighborhood instances and then assign anomaly score to given data instance. For any data instance to be normal not as an outlier, LOF score equal to ratio of average local density of k nearest neighbor of instance and local density of data instance itself.

Incremental LOF insertion(*Dataset S*)

- Given: Set S $\{p_1, \ldots, p_n\}$ $p_i \in \mathbf{R}^D$, where D corresponds to the dimensionality of data records.
- For each data point p_e in data set S
  - insert(p_e)
  - Compute $kNN(p_e)$
  - ($\forall p_j \in kNN(p_e)$)
    compute $reach\text{-}dist_k(p_e, p_j)$ using Eq. (1);

  //Update neighbors of p_e

  - $S_{update_k_distance} = kRNN(p_e)$;
  - ($\forall p_j \in S_{update_k_distance}$)
    update $k\text{-}distance(p_j)$ using Eq. (5);
  - $S_{update_lrd} = S_{update_k_distance}$;
  - ($\forall p_j \in S_{update_k_distance}$), ($\forall p_i \in kNN(p_j) \setminus \{p_e\}$)
    $reach\text{-}dist_k(p_i, p_j) = k\text{-}distance(p_j)$;
    if $p_j \in kNN(p_i)$
    $S_{update_lrd} = S_{update_lrd} \cup \{p_i\}$;
  - $S_{update_LOF} = S_{update_lrd}$;
  - ($\forall p_n \in S_{update_lrd}$)
    update $lrd(p_n)$ using Eq. (2);
    $S_{update_LOF} = S_{update_LOF} \cup kRNN(p_n)$;
  - ($\forall p_i \in S_{update_LOF}$)
    update $LOF(p_i)$ using Eq. (3);
  - compute $lrd(p_e)$ using Eq. (2);
  - compute $LOF(p_e)$ using Eq. (3);
- End //for

To find local density for data instance, find radius of small hyper sphere centered at the data instance. The local density for instances is computed by dividing volume of k, i.e. k nearest neighbor and volume of hyper sphere. In this assign a degree to each object to be an outlier known as local outlier factor. Depends on the degree it determines how the object is isolated with respect to surrounding neighborhood [20]. The instances lying in substantial region are normal instances, if their local density is similar to their neighbors, the instances are outlier if their local density lower than its nearest neighbor. LOF is steadier with top-n manner. Hence it is called as top-n LOF means instances with highest LOF values considered as outliers.

B. Local distance-based outlier factor (LDOF)

Local distance-based outlier factor Measure the objects outlierness in distributed datasets. In this uses the relevant location of an object to its neighbors to obtain the object deviation degree from its neighborhood instances. In this distributed neighborhood is considered. Higher deviation [21] in degree data instance has, more likely data instance as

Vol-10 Issue-5 No. 20 May 2020

an outlier. In this algorithm evaluate the local distance-based anomaly factor for each object and then sort and ranks the n objects having highest LDOF value. The first n objects with highest LDOF values are consider as an outlier

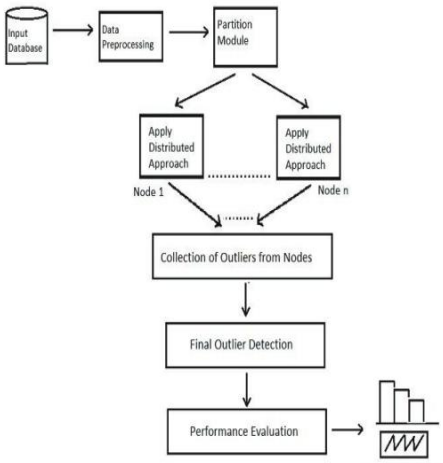

Fig. 4 Proposed System Architecture

6. Novel Boundary Based Classification Approach (NBBC)

The proposed Novel Boundary based categorization including the imputation methods and ordinal classification methods are explained in this section. The detailed description of WDBC dataset as follows. WDBC dataset: The Wisconsin Diagnostic Breast Cancer (WDBC) contains various attributes namely, diagnosis, ID number and real valued features. There are ten real valued features namely, radius, area, perimeter, smoothness, texture, compactness, concave points, concavity, symmetry and fractal dimension computed from digitized image of breast mass.[8] For each class, an added classification representation is built or trained by first deriving data set, which is a separation of the innovative training data set. The new data set was derived by relating a subset of the original data records into two new classes

A. The Greedy Algorithm

Overview

Our greedy algorithm takes the number of desired outliers (supposed to be –k) as input and selects points as outliers in a greedy manner, Initially the set of outliers (denoted by OS) is specified to be null and all points are marked as non-outlier we need k scans over the dataset to select k points as outliers[3]. In each scan, for each point labeled as non-

Copyright @ 2020 Authors

ISSN: 2278-4632
Vol-10 Issue-5 No. 20 May 2020

outlier, it is temporally removed from the dataset as outlier and the entropy object is recalculated. A point that achieves maximal entropy impact the maximal decrease in entropy experienced by removing this point, is selected as outlier in current scan and added to OS.The algorithm terminates when the size of OS reaches k. In the initialization phase of the greedy Algorithm each record is labeled as non-outlier and hash tables for attributes are also constructed and updated (step 01- 04). In the greedy procedure, we need to scan over dataset, we read each record t that is labeled as nonoutlier,its label is changed to outlier and the changed entropy value is computed. A record that achieves maximal entropy impact is selected as outlier in current scan and added to the set of outliers (step 05-13).In this algorithm, the key step is computing the changed value of entropy. With the use of hashing technique, I o(1) expected time ,we can determine the frequency of an attribute value in corresponding hash table. Hence, we can determine the decreased entropy value in o(m) expected time since the changed values is only dependent on the attribute values of the record to be temporally removed [17].

One of the simplest methods for showing that a greedy algorithm is correct is to use a "greedy stays ahead" argument. This style of proof works by showing that, according to some measure, the greedy algorithm always is at least as far ahead as the optimal solution during each iteration of the algorithm. Once you have established this, you can then use this fact to show that the greedy algorithm must be optimal.

12                  label t as a outlier with flag "1
13      Until counter = k
14      End
```

For the comparable fractional problem, however, the greedy strategy, which takes item 1 first, does yield an optimal solution. Taking item 1 doesn't work in the 0-1 problem because the thief is unable to fill his knapsack to capacity, and the empty space lowers the effective value per pound of his load. In the 0-1 problem, when we consider an item for inclusion in the knapsack, we must compare the solution to the sub problem in which the item is included with the solution to the sub problem in which the item is excluded before we can make the choice. The problem formulated in this way gives rise to many overlapping sub problems--a hallmark of dynamic programming, and indeed, dynamic programming.

7. Experimental Setup and Results

System Requirement Our algorithms have performed on high dimensional dataset that is Cover Type dataset from UCI machine learning Repository The experiment was performed on an Intel core i5 CPU at 2.53 GHz and RAM 4 GB , having a Windows 7 as its operating system. The algorithms were implemented in Java to process data instances in high dimensional data. Results The figure 6 shows the data insertion time required in five datasets and figure 7 shows the comparative study of outlier detection rate with existing and proposed algorithms for outlier detection.

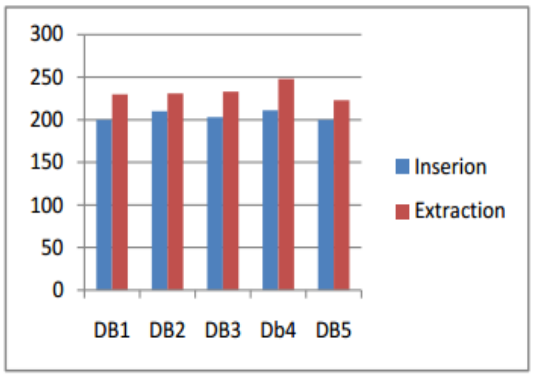

Fig. 6 Data insertion time required

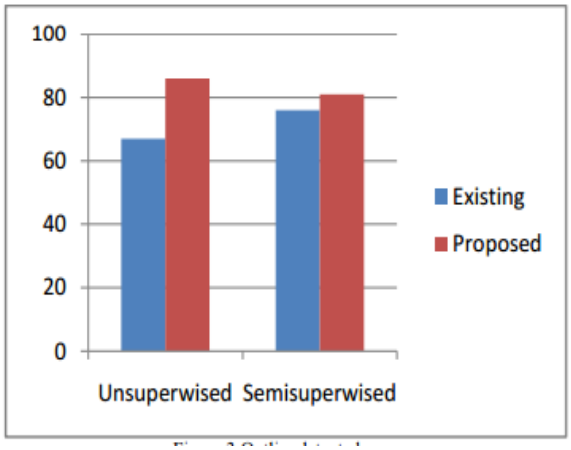

Fig. 7 Outlier detected

Outlier-Detection Methods and the hubness phenomenon, extending the previous examinations of (anti) hubness to large values of k, and exploring the relationship between hubness and data sparsity Based on the analysis, we formulated the IQR, Greedy, AntiHub method for semi-supervised and unsupervised outlier detection, discussed its properties and proposed a derived method which improves in terms of speed and accuracy, reducing the false positive and false negative rate and improve the efficiency of density based outlier detection.

8. Conclusions

Outlier detection is very important and has applications in wide variety of fields. So it becomes important to learn how to detect outliers. The main objective of this paper is to review various outlier detection techniques and to study how the techniques are categorized. So we can conclude that, methods used for outlier detection are application specific. The training algorithm and testing algorithm are used for training and testing the class. Reducing the search close to the class boundaries saves computation time in identifying such nuggets. Results from the evaluation on the real-time WDBC data sets revealed that the proposed approach achieves better performance than the existing classification algorithm. Proposed a derived method which improves in terms of speed and accuracy, reducing the false positive and false negative rate and improve the efficiency of density-based outlier detection. The future implementation is in machine learning techniques such as supervised and semi-supervised methods.

9. Future Work

Future work on deleting data records from database is needed. More specifically, it would be interesting to design an algorithm with exponential decay of weights, where the most recent data records will have the highest influence on the local density estimation. In addition, an extension of the proposed methodology to create incremental versions of other emerging outlier detection algorithms Connectivity Outlier Factor (COF) is also worth considering. Additional real-life data sets will be used to evaluate the proposed algorithm and ROC curves will be applied to quantify the algorithm performance.

Detection and Removal of Wormhole Attacks in Mobile Ad-Hoc Networks

Kunduru Saidi Reddy[1], Ailuri Venkatrami Reddy[2]

[1,2]*Assistant Professor, Department of IT*
[1,2]*Malla Reddy Engineering College (A), Hyderabad, Telangana, India.*

Abstract

In real time environment, the nodes in a mobile ad-hoc network (MANET) moves actively. There will be many attacks in network layer which lead to the performance degradation of the wireless network. Among them wormhole attack causes serious problems which will affect the owl MANET system. Wormhole attack can be defined as a created tunnel from more than one malicious node. Here, we proposed a new approach for preventing the wormhole attack by utilizing the threshold algorithm (NWATP-TA). Our proposed algorithm notices these sorts of attack effectively in MANET systems. Experimental analysis shows that the robustness of the proposed approach over the conventional wormhole attack prevention schemes in terms of throughput, end-to-end delay and energy consumption. We also compared our results with the Trusted AODV protocol.

Keywords: *Mobile ad-hoc networks, wormhole attack, AODV routing protocol, trusted AODV routing protocol,*

1. Introduction

A mobile ad-hoc network (MANET) is wireless network that means it's not recurred infrastructure. In MANET nodes are move energetically nature. The dynamic natures of MANET make it more vulnerable. In network layer many attacks possible but we focus only wormhole attack. When more than one malicious node creates tunnel is called wormhole attack. In ad-hoc network, routing is a vital challenge because of node's high mobility. Trust-based routing is being defined in our proposed approach, which calculates the value of trust based on the hyperbolic function of tangent that computes the trust value of their adjacent nodes promiscuously. In MANET, there is no fixed infrastructure therefore the mobile nodes communicate over multi-hop wireless links. These are often cited as infrastructure-less network model because the mobile hosts in the network establish route between themselves. Caching has been proved to be a very important method for improving data recovery and performance in mobile communication area. Caching, data or information process delay is minimized since queries or requests are served from the local cache there by clearing the need for data transmission. There are several attacks in an unexpected network. referable to their open nature, mobile ad hoc networks system nonresistant to most of the attacks such as gray hole, denial of service, wormhole, black hole, Sybil etc. Among these attacks, wormhole attack detection is a challenging and difficult task since this attack detection doesn't need any skill violation by the user. In a network location, one venomous node register traffic and then that traffic will be tunneled to a various venomous node that is found far in other location which is

 Copyright © 2020 Authors

known to be distribution of routing. It's very crucial and important to detect such attacks in MANET systems. Various routing protocols in [1-5] presented in the literature, which provides the transmission of data from the source to destination with a best effort. These protocols work proactively or reactively and find a minimum hop path from source to destination. Route discovery and route maintenance procedures incorporate node mobility and are kept simple to impose minimal routing overhead on the network. Nodes in an ad hoc network are equipped with batteries and are usually mobile with varying node speeds. Inefficient utilization of battery energy via increased load (i.e. data transmission) on nodes may disrupt communication as nodes may die sooner due to energy depletion. Also, traditional routing protocols quickly discover a single route towards destination and source forwards data via this route. In case of abrupt link failures due to mobility or errors in wireless transmission on the discovered path a new route discovery is initiated leading to increased delays. The above-mentioned issues can be facilitated by disclosing the multiple directions to the destination, which can be stored at the source node or at the in between nodes and can be utilized immediately in case of any failure happens in the nodes link.

2. Related Work

In [6], proposed a CTPKM with no central trust entity with the goal of maximize presentation, at the same time as justifying security liability. Each node provides a trust threshold to determine whether or not to trust another node. Each node's choice creation using the known trust threshold affects presentation and security of CTPKM. Author take three different parameters competence, integrity, and social contact on the basis of this parameter set the trust level. In [7] author proposed a method based on route redundancy, route aggregation and round-trip time There are three phases on which proposed algorithm works in first phase, create a multipath to authenticate RREQ, second phase is used to aggregate which help to know the all possible paths of the source and destination. In last phase there is calculation of average time of all routes based on the number of hopes. In [8] author proposed a technique called PAWAODV (Power-Aware AODV) these techniques help to enhance the performance of device which has limited power resources and with help PAW-AODV devices can perform better as compare the normal AODV, Hop-Count limit is also a factor which helps to choose the efficient path.

2.1. Trusted AODV routing method

Trusted AODV is a trusted routing protocol based on trust model for mobile Ad-hoc network. Trusted AODV has many relevant features like Nodes perform trusted routing behaviors mainly according to the trust relations between them. A node that performs malicious behaviors will finally be detected and denied to the entire network. System routine is improved at every routing hop. Here the AODV routing protocol is embedded along with the trust function. The communication between the nodes in the mobile Ad-hoc network depends on the cooperation and the trust level with its neighbors. Based on the trust on neighbor and appropriate threshold values the nodes be capable of be categorize in to the subsequent. The conditions of node level:

Unreliable: it's having trust value between 0 to 0.5.

Reliable: it's having trust value between 0.4 to 0.7.

Most Reliable: it's having trust value between 0.7 to 1.

3. Proposed System

In this paper, we propose a new method named as Wormhole attack prevention-threshold algorithm and it is described as Wormhole nodes and are announced to all other nodes. All nodes remove wormhole node id from its neighbor table and routing table. If any forwarding node receives the wormhole announcement node, it will send RERR message to source. It will reinitiate route discovery process and find the new path to the destination without wormhole node.

3.1. Algorithm

Step1: whenever a source node needs a route to destination the protocol starts route discovery. During route discovery, source node broadcasts RREQ packets through neighboring nodes. RREQ packet contains destination address and sequence number along with source address. Sequence number provides the freshness of the route.

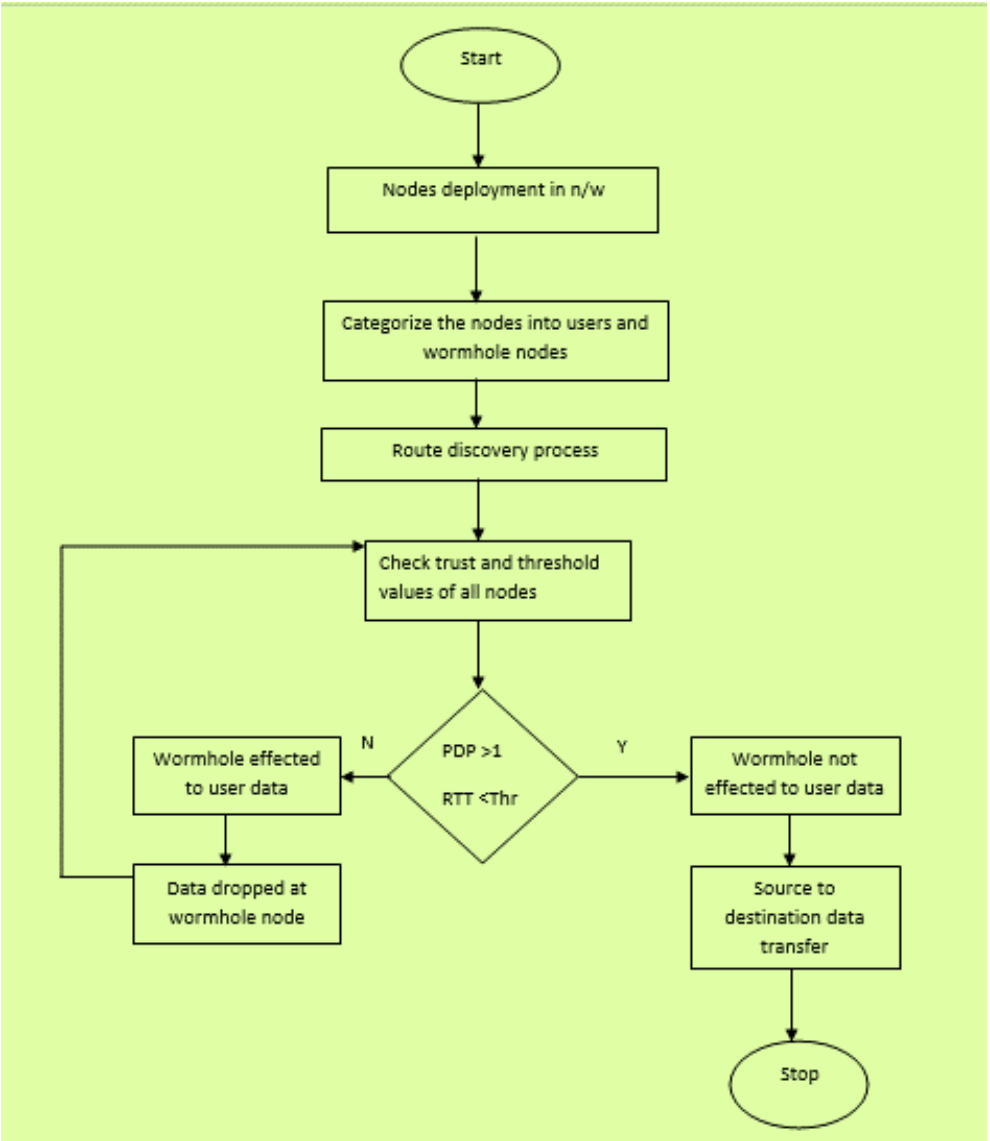

Figure 1. Flowchart of proposed algorithm

Copyright © 2020 Authors

Step2: once an RREQ packet is received by an intermediate node and verifies destination address. If the destination address not matches with the RREQ packet, then forwards it to its next hop. This process is repeated until it reaches the destination.

Step3: route path nodes are saved in routing table.

Step4: when source node starts sending packets, it sends to next node and that node sends to next until it reaches destination. The traversed path nodes are checked with the path nodes in routing table.

Step5: if the traversed path nodes are not in the routing table, wormhole is detected, and it is out band wormhole.

Step6: while sending packets to next neighbor node, PDR is calculated for each node. the ratio of sent packets to received packets is calculated for each node.

Step7: Hello packets also sending to each node along with packets until it reaches destination. Roundtrip time is calculated for each consecutive node. if the roundtrip time is less than threshold, that link is high speed link and the two nodes are malicious and detected as wormhole. And, if the PDR is less than 1, that node is wormhole node. the wormhole detected is active wormhole as it affects the packets.

Step8: If PDR less than 1 and RTT is not less than threshold means the loss may be due to traffic.

Step9: If PDR not less than 1, check for RTT less than threshold or not. If it is less passive wormhole is detected as the packets are not affected. If it is not less than the threshold, there is no wormhole.

Step10: Wormhole nodes are announced to all other nodes. All nodes remove wormhole node id from its neighbor table and routing table. If any forwarding node receives the wormhole announcement node, it will send RREP message to source. It will reinitiate route discovery process and find the new path to the destination without wormhole node.

4. Simulation Results

This section describes the simulation analysis of our proposed approach with comparison to the existing wormhole attack nodes prevention such as trusted AODV and normal AODV routing algorithms. We performed our test results in network simulator 2 (NS2) under the specifications provided in simulation table 1. The figure 2 shows that the analysis of throughput in which the simulation time has considered as X-axis and in Y-axis we took throughput values. We can observe that the performance of our proposed algorithm enhances the value of throughput when we compare with the Trusted AODV routing algorithm and normal AODV method. Figure 3 and 4 shows that the performance analysis of end-2-end delay and energy consumption, which provides that the superiority of our proposed wormhole attack nodes prevention algorithm.

5. Conclusion

In this paper, we focused on detection and removal of wormhole attack during data transmission. The proposed algorithm provides more security to ad hoc networks and also prevent from such kind of attacks. It helps to increases the packet delivery ratio and reduces the control overhead by improving the performance of the routing protocol. Here we are discovery following conclusion on NS-2simulation. Like End to end delay of new fresh algorithm is better compare to TAODV. In future, we also plan to improve the table entries at destination node to get the detection of wormhole nodes faster. And also improve the security of wireless ad hoc networks. By deploying such efficient methods to prevent DoS attacks and hybrid attacks with the help of Wormhole attack prevention threshold algorithm.

Detection of Malicious Apps in Online Social Network: Application of Facebook

Gudepu Sai Krishna[1], P. Swapna[2]
[1,2]*Assistant Professor, Department of IT*
[1,2]*Malla Reddy Engineering College, Hyderabad, Telangana, India*

Abstract

The owners also resort and fraudulent model to deployment the ranking of the apps in the popularity list. There is limited understanding in the evolvement though the prevention of fraud has been widely is finding. We implement Firefox users to the number of installed applications on their Facebook profiles. We present the temporal analysis of the Facebook applications' stating and removal dataset take user requirements. Online social networks (OSNs) are new vectors for cybercrime and hackers are finding new ways. We present results in the perspective of over 12K users to install. Our purpose system is creating a Facebook application and user goal is to develop a FRAppE Face book's Rigorous Application. Online Social Networks (OSN) takes third party apps to changes the user experience on the platforms. Such modifications are interesting communicating number of online friends and new models such as playing games. We take facebook provides to developers an API that facilities app applied into Facebook user experience. Present Ackers to started taking advantage of the resource of this third-party apps platform and deploying small applications and small apps will give a profitable business for hackers given the recognition of OSNs. It is safe and secure data is added in our wall. Thus, the Offensive words and posts are blocked with the help of dictionary using filters and it is not publicly posted to user wall.

1. Introduction

One of the most popular application to comes with own advantages and disadvantages is Facebook. Today we can see that there are 500k apps is available on Facebook within that 40M apps [2] is stating everyday by the Facebook users. Such changes is consist of interesting even enjoyable way associated with communicating number of online good friends in addition to different things to do like since getting referrals even enjoying tunes. One example is Myspace supplies developers the API [3] in which facilitates software integration in to the Myspace user-experience. In [4] the data detection system for mobile apps has been studied and it is provided a holistic view. The leading sessions and the leading events of the app were studied using the mining leading session's algorithm. In [5], it proposed Facebook's Rigorous Application Evaluator (FRAppE). It failed to recommend to the website the hackers. Online social networks (OSN) are third party apps to enhance the user experience on the platforms. In our previous study [6] we presented preliminary statistics on this dataset We finding that within the first week after the add-on's stating use the user's number of applications decreased by 12.1% on average. The application removal rate continued to grow up to 27.7% by an average of 63 days after the

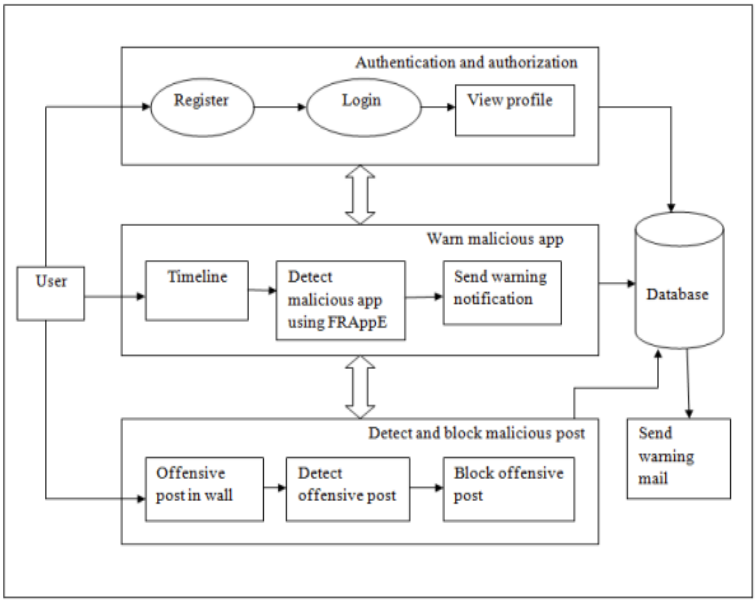

Fig. 2 System Architecture for Proposed System

We found any installation of the malicious app user wall gives total notification that the app found is small whether to install it or not. Offensive words or posts which are related and detected and blocked using the FRAppE tool. These words are posts will not display in the public wall. Instead of that such post will be migrated to the blocked post list a tool stands for Face book's Rigorous Application Evaluator which is helpful in modify the entire system. In Authentication and Authorization module the user in register the data and login into the pages to view their profile to see all the contacts the user.

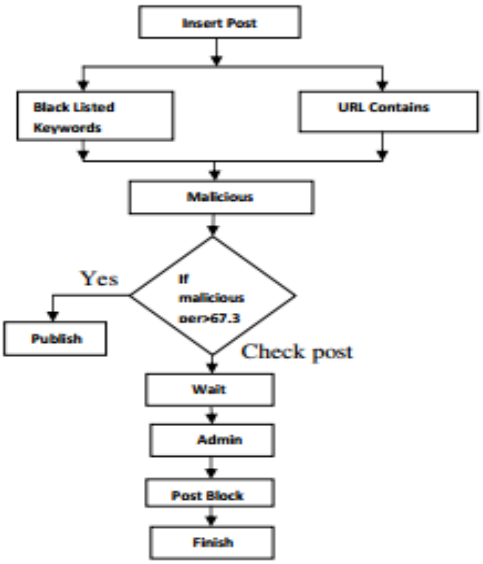

Fig. 3 Proposed Methodology

A. Detecting Spam on OSNs

We analyzed posts on the walls of small Social networking app users 10% of links posted on Social networking app walls in spam. We develop efficient models for online spam filtering on OSNs such as Social networking app is used only by the OSN provider; develop a third-party application for spam detection on Social networking app. Others

Copyright © 2020 Authors

present model find the spam URLs on Social networking app and contrast to all of these efforts rather than classifying individual URLs or posts as spam we aim on identifying small applications is main source of spam on Social networking app.

4. Implementing Mypagekeeper

We provide some details on MyPageKeeper's implementation.

A. Facebook application

First, we implement the MyPageKeeper Facebook application using FBML [12]. We implement our application server using Apache (web server), Django (web framework), and Postgres (database). Once a user installs the MyPageKeeper app in her profile, Facebook generates a secret access token and forwards the token to our application server, which we then save in a database. This token is used by the crawler to crawl the walls and news feeds of subscribed users using the Facebook open-graph API

B. Crawler instances and frequency

We run a set of crawlers in Amazon EC2 instances to periodically crawl the walls and news feeds of MyPageKeeper's users. The set of users are partitioned across the crawlers. In our current instantiation, we run one crawler process for every 1,000 users. Thus, as more users subscribe to MyPageKeeper, we can easily scale the task of crawling their walls and news feeds by instantiating more EC2 instances for the task. Our Python-based crawlers use the open graph API, incorporating users' secret access tokens, to crawl posts from Facebook. Once the data is received in JSON format, the crawlers parse the data and save it in a local Postgres database.

C. Checker instances

Checker modules are used to classify every post as socware or benign. Every two hours, the central scheduler forks an appropriate number of checker modules determined by the number of new URLs crawled since the last round of checking. Thus, the identification of socware is also scalable since each checker module runs on a subset of the pool of URLs. Each checker evaluates the URLs it receives as input—using a combination of whitelists, blacklists, and a classifier— and saves the results in a database

5. Social Malware Ecosystem

We discover the harmful apps , after that we check the several ways how the social malware support each other. From our observation we find the interesting thing that malicious apps do not operate in segregation they share the same name and their work must collaboratively in encouraging each other.

- The emergent‘s of AppNets We observed that more than 6,330 malicious apps in our dataset that emerge in collaborative promotion. In that 2.5% are promoters,58.8% are promotes, and the remaining 16.2%play both roles.
- Piggybacking The app piggybacking is a approach in which hackers are using this. The facebook‘s API and their post are harmful post by using popular apps. There are several ways that hackers are benefited by this. The hackers make the user to share the harmful post by offering rewards. They crawl the API from Facebook by hacking the users account; they again post the harmful app in the user‘s wall. By the app in the

 Copyright © 2020 Authors

ISSN: 2278-4632
Vol-10 Issue-3 No. 1 March 2020

request to post the harmful post. The Facebook could not recognize this because the app ID is already included in the appID.

6. Session Tracking Algorithm

This session tracking concept [13] is used in the proposed system to identify the users that are trying to misuse the particular App. There are three typical solutions to this problem: cookies, URL rewriting, and hidden form fields. You can use cookies to store an ID for a downloading session; with each subsequent connection, you can look up the current session ID and then use that ID to extract information about that session from a lookup table on the server machine. URL rewriting is a moderately good solution for session tracking and even has the advantage that it works when browsers don't support cookies or when the user has disabled them. The users that are using the App and downloading it are provided with a session each and they are continuously been tracked by the admin with the help of a session tracking algorithm. A cookie is assigned to each user as a session starts and it is been tracked as the user is continuously using the App. When a number of users are using the system by downloading and uploading the Apps, even when a particular user is found to be misusing the Apps among all other users, he is blocked with the help of a session tracking algorithm and all the user details are sent to the Admin immediately and the user is blocked from accessing the apps. The user is notified of the block and is permitted to access other apps. The number of times or the hits a particular user is using the App is being recorded with which the overall misusing of the App is calculated.

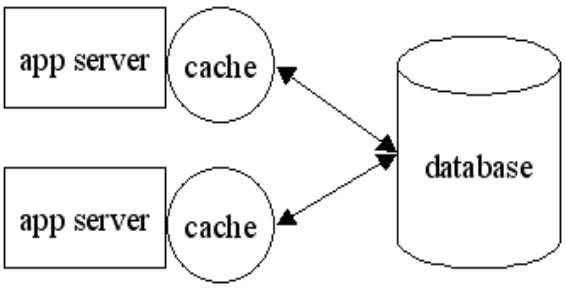

Fig. 4 Session Tracking Flow

7. EXPECTED RESULTS

The study presented in this paper is a work in progress with many available future directions. By gathering additional information about what kind of applications users tend to restrict, we can develop an algorithm for application removal recommendations. Moreover, when the same applications are restricted by many users, we can conclude with high likelihood that these applications are fake applications and recommend to Facebook and our users to remove these applications from the social network and their accounts.

Another possible future direction is discovering the point in time when the Add-on Users' application numbers start increasing again, and at that point, to give the user a special warning regarding his or her number of applications.

- FacebookNets form large and densely connected groups
- Posting direct links to other Facebooks
- Indirect Facebook promotion
- Facebooks with the same name often are part of the same FacebookNet.
- Amazon hosts a third of these indirection websites.

8. Conclusions

In this study, we presented our initial methods and results in studying online social network applications with an aim of improving user's safety and awareness. According to our results, it is possible to predict the number of applications a casual user has with high accuracy. we presented the design and implementation of MyPageKeeper a Facebook application that can accurately and efficiently identify socware at scale. Using data from over 12K Facebook users, we found that the reach of socware is widespread and that a significant fraction of socware is hosted on Facebook itself. Applications present a convenient means for hackers to spread malicious content on Social networks. However, little is understood about the characteristics of malicious apps and how they operate. And finally, we explore the ecosystem of malicious Facebook apps and identify mechanism that these apps use to propagate. We will continue to investigate on hacker's platform dig deep into their ecosystem to reduce the malicious app on Facebook.

9. Future Enhancement

We undergone the concept is all about posting and detecting applications on the Wall and the project has been designed keeping in mind the future scopes. A lot of tools can be used to shape many things in the future; thus this project will give rise to many future modifications focusing in all t he directions. The near future scope of this project is to block the images with offensive form of text and messages from the user wall Leveraging our observations, we developed FRAppE, an accurate classifier for detecting malicious Face-book applications. Most interestingly, we highlighted the emergence of AppNets large groups of tightly connected applications that promote each other. The application which are malicious their review, ranking and reporting will be done.

Distributed File Replication Algorithm for Content based File Sharing System using Dynamic Peer-to-Peer Networks

Kunduru Saidi Reddy[1], Ailuri Venkatrami Reddy[2]
[1,2]*Assistant Professor, Department of IT*
[1,2]*Malla Reddy Engineering College, Hyderabad, Telangana, India*

Abstract

The main aim of the research work is to develop the data replication algorithm based on data security, data processing and load balancing in order to take the minimum energy consumption and high data availability rate in the network. Mobile Ad hoc Networks (MANET) take collection of wireless mobile system dynamically forming new network without the use of any backend infrastructure or centralized administration. Based on Peer-to-Peer (P2P) network file destitute is mainly implementing in MANET. Several data replication protocol is proposed to minimize results degradation. These selfish nodes could data is reduce total data in the network. We introduce a new concept of Distributed File Replication algorithm which considers file dynamics network such as file addition and deletion in dynamic manner. Content-based file sharing scheme using dynamic network is proposed user interest is determined by the proposed scheme before searching and sharing the files in the peer-to-peer network. The locations in the network are utilized as per the contents of the files to be shared. It provides security to decentralized p2p network by the implementation of key server and Intrusion Detection System (IDS) with new P2PHBA algorithm is used for the prediction modify path in the network by the scout is implementation to the efficient file sharing. The present replication protocol drawbacks, they are node storage and the allocation of resources in the replications. Future wireless communications are heading many all-Internet Protocol (all-IP) design and will rely on the Session Initiation Protocol (SIP) to manage services such as voice over IP (VoIP).

Index Terms: *Content-based file sharing; interest extraction, interest-oriented file sharing; peer-to-peer network, Mobile Ad hoc Network (MANET), file Replication, Query Delay.*

1. Introduction

In a mobile ad hoc network (MANET), mobile hosts can communicate directly with one another using direct pair wireless links. Because it requires no fixed infrastructure and most of the time no explicit administration a MANET can extremely useful to support communication in challenging situations, such as in rural, remote disaster-struck areas. P2P computing refers to technology that enables two or more peers to collaborate spontaneously in a network of equals (peers) by using appropriate information and communication systems without the necessity for central coordination.[1] Content inserted into the network is stored and forwarded by cooperating nodes. Metadata and queries are also inserted to represent essential attributes of content and to retrieve appropriate content from the network. Routing

ISSN: 2278-4632
Vol-10 Issue-5 No. 20 May 2020

and caching perform in-network matching between metadata and queries. Content and metadata/queries must be protected by a decentralized security framework to enable access control of content. Optimization of the content management strategy under constraints can be seen like many other problems in networking as a utility maximization problem. Generally, optimizations at each layer require situation- and resource-aware cross-layer adaptation that is cognizant of features, limitations, and dynamicity at each layer to maintain content accessibility with reasonable trade s between availability and bandwidth. [2].

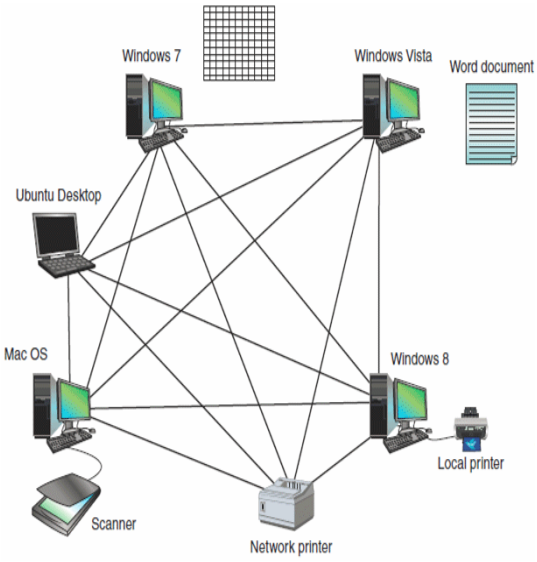

Fig. 1. MANET Peer-to-Peer Networks

For instance, the degree of redundancy for caching of content in a cluster of nodes should take into account the cluster density and stability (lower layer), and at the same time the type and importance of the content (higher layer). MANET (Mobile ad hoc network) is dynamic networks populated by mobile stations. Stations in MANETs are usually laptops or mobile phones. These devices feature Bluetooth or Wi-Fi network interfaces and communicate in a decentralized manner. Mobile ad hoc networks are composed of a set of communicating devices able to spontaneously interconnect without any pre-existing infrastructure for it. Devices in specific range can communicate in a point-to-point fashion. More and more people are interested in mobile ad hoc networks.

Peer-to-peer (P2P) networks and Virtual Private Networks (VPNs) are two typical overlay networks in constructing large scale distributed applications over large networks. Peer-to-peer networks run on top of the Internet. Peer-to-peer networks are distributed systems where the software running on each node provides equivalent functions. A definition of P2P networking is a set of technologies that enable the direct exchange of services or data between computers. Implicit in this definition are the fundamental principles that peers are equals. P2P systems emphasize sharing among these equals. A pure peer-to-peer system runs without any centralized control or hierarchical organization. A hybrid system uses some centralized or hierarchical resources. Peers can represent clients, servers, routers, or even networks [3].

2. Related Work

With the everyday increasing importance of privacy, security, and wise use of computational resources, the corresponding technologies are increasingly being faced with the problem of file type detection. True identification of computer file types is a difficult task especially when dealing with suspicious goals. Computers are dealing with the huge number of file formats that are transmitting between the insider and outsider networks. Without the true file type detection, the security will not be achievable. File type detection has the most usage and importance in the proper functionality of operating systems, firewalls, intrusion detection systems, anti-viruses, filters, Steganalysis, computer forensics, and applications dealing with the file type classification [4].

Although there are many applications dealing with file type detection, they have very limited methods for determining the true type of files. The newest method of file type detection is based on the file contents. McDaniel and Heydari published the first paper on content-based file type detection [5, 6]. In mobile environment, data is distributed across the network majorly in the form of pushing (data dissemination) and pulling (data hosting) techniques. Few of the possible techniques based on push/pull mechanism have been surveyed in [7]. This includes data dissemination over limited bandwidth channels, location-dependent data querying and advanced interfaces for mobile computers. Moreover, these approaches have few issues to be addressed such as how to store information on database, how to effectively and optimally design database for mobile network, low bandwidth in network; and frequent network partitioning caused by mobility and energy constrained of peers.

The works in [8-10] show the several approaches to address these research issues in mobile networks. Content-based routing and caching solutions for disruption tolerant networking (DTN) require resource provisioning to determine storing or forwarding of a particular piece of content to maximize its availability. Quantifying the benefit and cost of such operations can be formulated as a utility maximization problem Our compositional optimization improves content-based utility by treating individual layers as modules, which makes it easier for further generalization to incorporate various local optimizers, such as deferent routing or caching schemes. Cross-layer optimization under constraints has been studied in networking previously. The work proposes Conquer, a broker-based economic incentive model for

mobile peer-to-peer networks. Although the work considers free riders to host data in mobile peer-to-peer networks, it assumes that all peers are trusted and they do not cheat. some strategies for handling selfish behavior have been proposed in the research field of distributed databases. However, these works cannot be directly applied to a MANET, since they did not consider the constraints such as the bandwidth limitation for the detection of selfish nodes and system failures due to frequent node disconnections of a MANET.

3. System Design

Architectural diagram deals with cluster of mobile nodes. In this architecture each cluster contains cluster head. Each cluster head of each cluster is communicated with centralized node. Cluster head is also elected by centralized node. Each member in the cluster is identical in some features. Each member in the cluster requests the cluster head for files and data. Cluster head includes all information about cluster members. Cluster head one group must communicate to cluster head of another cluster in order to get information of cluster member of that particular cluster.

Fig. 3. MANET Architecture

4. Proposed Solution

The content-based file sharing in peer-to-peer networks using threshold. File sharing client allows a number of people to use the same file or files by some combination of being able to read or view it, write to or modify it, copy it, or print it. Typically, a file sharing system has one or more administrators. File sharing clients may all have the same or may have different levels of access privilege. we propose a new distributed file replication protocol to minimize the average querying delay.

Priority Based Dynamic Replication (PBDR) technique is used adding and deleting the replica files based on the priority. The file has been succeeded in the priority competition then adding the replica files, otherwise deletes the replicas. The proposed algorithm well considers the caching overhead and adapts the cache node selection strategy to maximize the caching benefit on different MAC layers. Results show that the asymmetric approach outperforms the symmetric approach in traditional 802.11 based ad hoc networks due to removal of most of the processing overhead. This file sharing client generated request to share file. In request

analysis, the request is analyzed to see whether it is authorized or not. If it is authorized then process will be continued otherwise it is stop there. The sample files are collected from different sources to ensure that the sample files of a file type are not generated by one source.

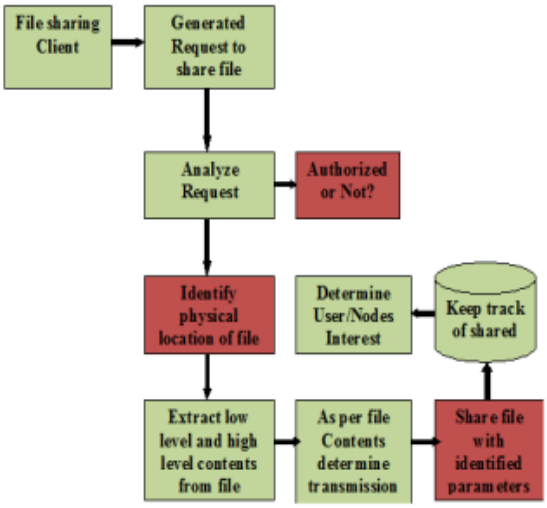

Fig. 4. Content-Based File Sharing using Threshold

A. Replica Allocation

The SCF-tree based replica allocation techniques are inspired by human friendship management in the real world, where each person makes his/her own friends forming a web and manages friendship by himself/herself. He/she does not have to discuss these with others to maintain the friendship. The decision is solely at his/her discretion. After building the SCF-tree, a node allocates replica at every relocation period.

Algorithm:

1. Initialize :
    a. Initialize node memory(in pkt)
    b. Initialize the update timer
2. Send request for allocate replica
3. If node selfish
    a. Give wrong reply or no response
4. If not
    a. Send correct reply
5. If reply is received by originator
    a. Process the reply
    b. And make the route
6. If timer is triggered

a. Send the query for checking

7. If node is correspond node then sends the query reply

8. Originator checks the query reply

a. And forms the SCF tree

b. And allocates priority and replica according to the tree

B. The P2PSIP Protocol

P2PSIP implements traditional proxy and registrar SIP functions in a distributed way. Resource information is distributed among all the peers in the overlay, and requests are also handled by the overlay infrastructure. The main advantages of P2PSIP are cost reduction and the elimination of single failure points. Using P2PSIP, any DHT-based P2P network can locate resources in a decentralized way. The clients only use resources from the overlay. They do not participate in its maintenance. The information stored in the P2PSIP overlay consists of registers of the peer nodes and the resources available at these nodes. Kademlia's distributed resource tables (DRTs) are similar to DHTs employed for peer registration A P2PSIP deployment has an overlay name, and the participants can be peers SIP clients. The peers are identified by a peer-ID, and they collectively serve as a directory service for locating resources using the defined DHT structure. The same procedures as those described based on unique resource-IDs and a XOR metric, are employed. In order to keep registers up-to-date. Protocol dSIP [11] uses SIP messages to implement P2PSIP, while preserving the semantics of conventional SIP messages as much as possible. Although there are newer P2PSIP implementations, dSIP has several advantages:

- Simplicity of implementation (still text-based)
- Minimization of the number of protocols required for a P2P UA.
- Easy integration into existing UAs and reuse of available SIP stack implementations.
- Widespread support.

The message to add, remove and query bindings in DHT and resource tables is SIP REGISTER [12]. dSIP supports:

- Peer and resource registration.
- Session establishment.
- DHT maintenance (dSIP is modular, so it allows multiple DHTs).

dSIP peers are active members of the overlay and provide operations to enable self-organization (SIP server-like functions) in addition to the basic functionality of any SIP endpoint. The dSIP overlay serves as a directory service for locating resources.

C. Vehicular Network (VANET)

VANET is one type of mobile ad hoc network where each vehicle act as a router either V2V i.e., Vehicle to Vehicle communication, Vehicle to Infrastructure communication take place. This simply means, Network on wheels. To perform agent migration and mobility

Copyright @ 2020 Authors

among nodes (handover) in an infrastructure less vehicular ad hoc network (VANET) the concept of opportunistic communication is evaluated and by considering this, [13] looks at location awareness to support agent mobility. One of the interesting applications of this idea is "virtual sensor network" composed of software agents that done the task in form of sensing services with the help of available resources provided by physical nodes like computer platforms, communication devices or physical sensor devices. Exchanging events in vehicular ad hoc network (VANET) helps drivers to receive information about relevant places or to avoid undesirable situations. The work in [14] presents data management as a solution for event exchange in vehicular networks and comparison of two different approaches. From that the first approach is helpful to estimate the relevance of events by calculating of geographic vectors; and second approach exploits digital road maps. For the testing of proposals in a real environment, a prototype is described here. The usefulness of utilizing the information stored in digital road maps for data management and sharing in vehicular networks as well as the first approach is useful in cars where maps are not available has been proved by an exhaustive simulation-based experimental evaluation[15].

D. Dynamic Source Routing Protocol

DSR is a reactive routing protocol with no periodic update messages like table-driven routing protocols to manage a MANET. It is specifically designed for use in multi-hop wireless ad hoc networks where the protocol allows the network to be completely self-configuring self-organizing where there is no need for an existing network infrastructure or administration. Only at the time routing a path is required by a node (On-Demand Routing) the process to find a path is get executed to restrict the excessive use of bandwidth. In DSR the source node (sender, initiator) first determines the communication path to reach the destination node (Source-Routing) and then deposits the intermediate node addresses in the packets. Compared with other reactive routing protocols like SSA or ABR DSR will be beacon less that is there is a no need of hello-messages by the nodes to notify their neighbors about their presence. DSR was developed for MANETs with a moderate speed at small diameter of 5 to 10 hops. DSR uses the Link-State-Algorithms that is each node can be able to save the best way to a destination. Whatever may be changes were made in the network topology will be broadcasted to the whole network by flooding. DSR contains 2 phases Route Discovery (find a path), Route Maintenance (maintain a path).

5. Performance

The output of each technique in the simulation test on NS-2 the hit rates and average delays of the four protocols. We used the following metrics in the experiments:

Hit Rate: It is the number of requests successfully handled by either original files or replica files.

Average delay: This is the average time of all requests that finish execution. The delay that calculate using the throughput and the performance of the requests.

A. Hit Rate

 Copyright @ 2020 Authors

ISSN: 2278-4632
Vol-10 Issue-5 No. 20 May 2020

The hit rates of the four methods with the simulations results. The hit rates continue SAF>DAFN> DCG >PBDR. The PBDR achieve higher hit rate than other methods. since PBDR realizes distributed way, it presents slightly differ from performance compared to others. PBDR considers the intermediate connection properties of disconnected MANETs and replications. DCG only considers temporarily connected group for file replication.

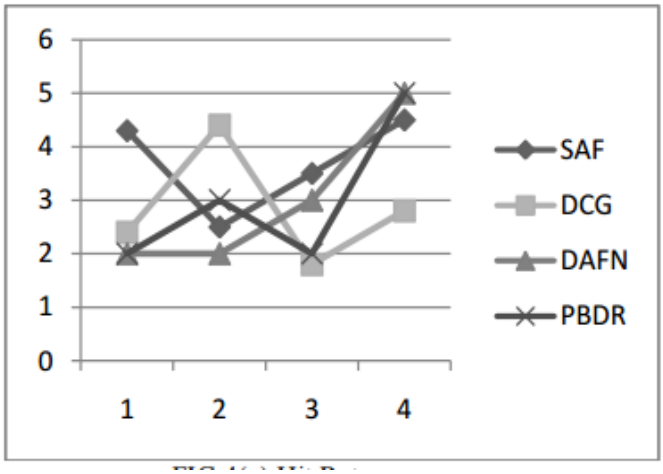

Fig. 5. Hit Rate

B. Average Delay

Demonstrate the average delays of the four methods with simulation results. The average delays show PBDR<SAF<DAFN which is in reverse order of the relationship between the four methods on hit rate as shown in Fig5 . This is because the average delay is related to the overall file availability in descending order. The PBDR have high file availability .SAF distributes every file to different Nodes while DCG only shares data among simultaneously identify neighbor nodes, and DAFN has a low file availability since all files receive equal amount of memory resources for replicas. The PBDR has the minimum average delay in the simulation results.

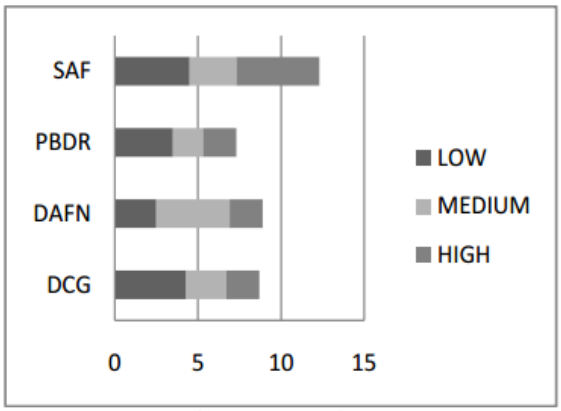

Fig. 6. Average Delay

6. Conclusion

Copyright @ 2020 Authors

We also plan to improve the current leveling technique by considering the frequency of disconnections and/or the weighted ratio of total number of items and average of shared memory space we will discuss the important research issues in more detail related to mobile databases. This survey presents various mobile applications, including facility of data sharing and data storing for easy and handy access to the static and dynamic information in the mobile databases. It also discussed the various communication strategies in mobile ad hoc networks. The proposed mechanism can be used in any network environment having limited number of resources and maximum number of transmissions. This cluster form of monitoring will also decrease the overhead which may be happened while cluster head has maintaining the routes. IDS will identify the nodes as trusted and untrusted based on some threshold values and also inform about entrusted to all nodes in the network to transfer data in a secured manner. For the dynamic routing purpose nodes outside the network coverage need to get authenticated by IDS. We are currently working on the impact of data updates and different moving patterns on our scheme. In future the proposed scheme can be extended for identifying the requirements of the network for best effort network services

7. Future Work

Future work consists in enhancing protocol with quality of service mechanisms and providing measurement studies of the protocol performance. Considering the problem of overlay topology design, future work could also focus on studying the overlay topology creation and adaptation in case of unknown traffic demands. A hybrid network with a mix of selfish and cooperative nodes is an additional interesting scenario. Heterogeneous values of the overlay cost coefficient could be proposed for each node in the network, and its effect on the overlay topology creation could be studied. Otherwise, there can be an interesting joint between overlay networks and Pocket Switched Networks which could be studied in depth to make solid proposals.

Fuzzy-based Efficacious Routing Protocol for Large-scale Mobile Networks

T. Swapna[1], Dr. Shanmugam Kanna[2]

[1]*Assistant Professor,* [2]*Associate Professor, Department of IT*
[1,2]*Malla Reddy Engineering College, Hyderabad, Telangana, India*

Abstract

An efficient detection and recovery algorithm to identify clone node efficiently to recover the Wireless Sensor Networks by replacing only few sensor nodes along with often used alternative routes. Wireless sensor networks are exposed to different types of security threats is reduce the performance of the total network. Defensive mechanisms like key management protocols, authentication protocols and secure routing is providing security to WSN. We first analyze the desirable properties of a distributed model. After that we show the solutions for the problem and later for detection of node replication attacks. We propose a self-healing RED protocol Randomized, Efficient, and Distributed protocol. We propose a technique to improve routing protocols by considering both energy and failure constraints and managing the proposed protocol, the routing protocols dynamically modify to node's failure. We propose a fuzzy based efficient routing protocol (FBERP) for large scale mobile networks that aims to minimize the packet loss rate. Every node in the network is characterized by its communication parameters. We develop a fuzzy logic controller that combines these parameters, Packet Loss Rate, Communication Rate, Energy and Delay Parameters.

Index Terms*: Distributed Solutions, Physical Capture Attacks, Wireless Sensor Networks, Security, Intrusion Detection System, Fuzzy Logic, Route Recovery, Route Discovery.*

1. Introduction

A wireless sensor network consists of spatially tribute autonomous sensors to monitor physical conditions in wireless sensor networks is deployed in harsh environments to fulfill both military and civil applications [1]. A Wireless Sensor Network (WSN) is a highly distributed network of resource constrained and wireless devices are called sensor nodes. Each sensor node modifies some physical phenomenon inside the area of deployment [2]. The collected measurement is sent to a base station. The communication range of sensor nodes is limited to tens of meters and directly communicates with the base station [3]. The Wireless sensor network is a collection of sensors is spread over large geographic area. Since sensors is widely spread and large in number the occurrences of faults in the network.

Hence to detect the fault node and to replace the fault node an efficient algorithm is proposed [4]. Fuzzy logic implements human experiences and preferences via membership functions and fuzzy rules. A membership function is a mathematical formation of representing a fuzzy set [5]. A fuzzy number is a quantity total value is imprecise rather than exact as is the case with "ordinary" numbers [6].

Vol-10 Issue-3 No. 1 March 2020

2. Related Work

Failures are unavoidable in Wireless Sensor Networks due to the lack of updating and unattended deployment. There are many methods related to energy, memory and computational ability of a sensor node. The occurrences of faults are mostly due the presence of faulty sensor nodes [7]. To identify a fault node and to replace it many techniques is proposed [8]. Most of the sensor network applications used reliable data delivery to sink instead of point-to-point reliability. It is vital to provide fault tolerant techniques for distributed sensor network applications [9]. The metrics find Link Expiration Time (LET), Received Signal Strength (RSS), Available Bandwidth (ABW) and Residual Energy (RE) and based on these metrics' node is classified as weak, normal or strong using fuzzy set[10]. Proposed distributed routing protocol TORA is provides functions, Creation of routes, Maintenance of routes and Erasing of routes. The protocol uses different packets for these functions [11]. The same results show that the proposed RED protocol meets the desirable properties. We find the feasibility of the RED protocol. The set of simulations result shows the RED protocol is implemented in sensor network is analyzed [12]. And, as a self-healing model it used continuously iterated over the same network without significantly affecting the detection protocol and network performance itself. We consider the influence of an attacker intervening on message routing both for RED and LSM [13].

Figure 1. Mobile network

3. Threat Model

It replicates one or more clones into multiple copies by compromising a certain fixed number of nodes. In general, it is possible to cope with threat to assume that nodes are tamper-proof. We will assume that the nodes do not have tamperproof components consistently with a large part of the tamper-proof hardware is expensive and energy demanding [14]. To prevent clones from being detected by the detection protocol used in the mobile network is the adversary goal. The sensors choosing from the total network is compromised by adversary. Intuitively an adversary that needs some time to move from one point to another of the network area is described by the localized adversary, while the ubiquitous adversary security nodes regardless of their position during the same time interval [15].

4. Proposed System

Our mobile network model takes set of low-power radio frequency (RF) transceivers which move relative to each other across an irregular terrain subject to RF propagation impairments. The combination of low power and propagation environment produces a network characterized by stochastic link failures. We propose a novel scheme Link Scanner (LS) for updating wireless links at real time [16] We propose a self-healing RED protocol. Randomized, Efficient. Distributed protocol and it meets the requirements. Finally, it shows that our protocol is highly efficient in memory, communication and computation. The mobile robots check the group of sensor functions and exchange secret keys and verify their identities. Upon new inclusion, a node is collecting enough authorizations from its neighbors and privilege is accepted by the sink [17] . The presence of unauthorized node is detected by Bootstrapping algorithm. Bootstrapping the sensor network refers to the discovery of deployed sensors and finding direct communication links between each gateway and sensors that are reachable to it. We propose a fuzzy based efficient routing protocol (FBERP) for large scale mobile networks that aims to minimize the packet loss rate. Each node in the network is characterized by its communication functions develop based on fuzzy logic [18].

4.1. Grade Diffusion Algorithm

The Grade Diffusion algorithm not only creates the routing for each sensor node is also identifies a set of neighbor nodes to reduce the transmission loading. Each sensor node is select a sensor node from the set of neighbor nodes relay. The number of sensor nodes is functioning exceeds the threshold [19]. Genetic algorithm is used for replacement [20]. There are 5 steps in the genetic algorithm: Initialization, Evaluation, Selection, Crossover, and Mutation

Copyright © 2020 Authors

ISSN: 2278-4632
Vol-10 Issue-3 No. 1 March 2020

Initialization: Here chromosomes is generated. Each Chromosome is an expected solution. The number of chromosomes depends on number of sensors is replaced.

Evaluation: The Number of routing path available some nonfunctioning sensors is replaced evaluated based on fitness value. This fitness value is calculated with number of sensor nodes grade values, number of reusable routing paths.

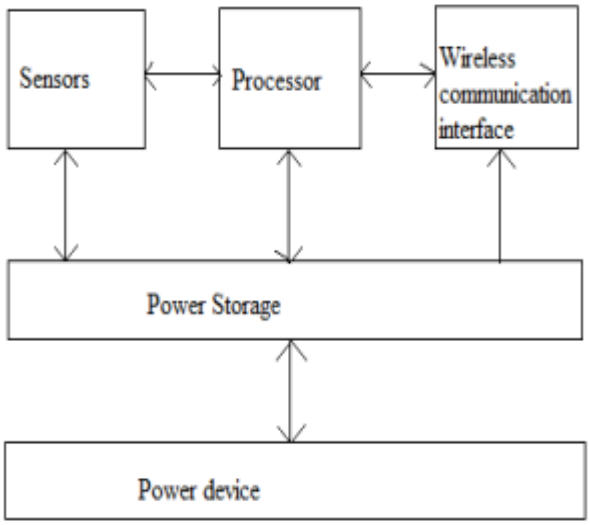

Figure 3. Block Diagram of Mobile Network

Selection: Here chromosomes with lowest fitness values are eliminated.

Cross over: Two individual chromosomes is selected and compared and a part of it is replaced with the other to produce new offspring.

Mutation: Here a single gene is replaced after comparison.

4.2. Fuzzy Based Efficient Routing Protocol

We propose new fuzzy based efficient routing protocol (FBERP) for large scale mobile networks that aims to minimize the packet loss rate. Every node in the network is characterized communication parameters [21]. We develop a fuzzy logic controller that combines these functional Packet Loss Rate, Communication Rate, Energy and Delay Parameters. The value obtained, indicates the priority of a node with maximum throughput is selected and it is used in route formation. Our simulation of proposed protocol outperforms the standard AOMDV routing protocol as the packet loss rate is minimized in our proposed work. In future work can be done to lower down the packet delay and any other communication parameters may be used to further improve the protocol [22].

4.3. Algorithm

Step 1: N nodes is distributed in network.

Step 2: Initially all nodes conserve same energy.

Step 3: Each packet sensed by a node is assigned a unique number id & broadcast it to all nodes in the network.

Step 4: Each node that receives the id checks if it is already stored in its memory.

Copyright © 2020 Authors

ISSN: 2278-4632
Vol-10 Issue-3 No. 1 March 2020

Step 5: If yes, the data will be discarded.

Step 6: Else, select the higher residual energy node with the shortest distance path.

Step 7: Else if node with same residual energy and distance then packets is transmitted with higher timestamp value.

Step 8: Maintain the location information of node and continue the same process till destination found.

Step 8: If packets collision occurs then reduce the contention window by giving the priority to node with higher residual energy.

Step 9: check whether the data reach to the destination

Step 10: If yes, broadcast the packet id to all nodes

5. Results

Network density is significantly changing the network topology. A dense network should suffer more channel collision and packet lost due to hidden terminal, thus may impact the probe flooding process and cover the real link results. We used NS2 to simulate our proposed protocol. In our simulation the packet interval is set to be 0.0008sec. We use IEEE 802.11 for wireless LANs as the MAC layer protocol. It has the functionality to notify the network layer in link breakage. In our simulation, 25 mobile nodes move in a 500×500 m region for 10 seconds simulation time. We assume each node moves independently with the same average speed. In our simulation, the simulated traffic is TCP (ftp).Our simulation settings and parameters are summarized.

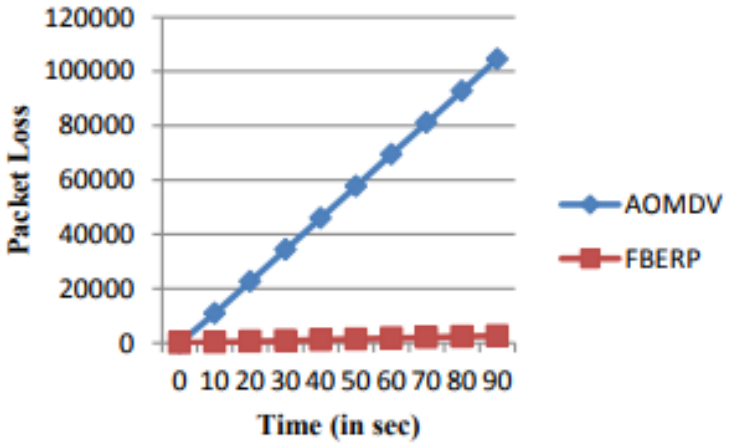

Figure 4. Packet delay

6. Conclusion

The detection of node replication attacks We first analyzed the desirable properties of a distributed mechanism. The Efficient fault detection and recovery algorithm is identifying a fault node when some of the sensor nodes shut down, either because they no longer have battery energy or they have reached their operational threshold but also when an unauthorized sensor got included in the network. We develop a fuzzy logic controller that combines functions, Packet Loss Rate, Communication Rate, Energy and Delay Parameters. The value obtained, indicates the priority of a node; a node with maximum

throughput is selected and it is used in route formation. Also try to further reduction of load in the network by increasing the lifetime of the network.

Hybrid Cloud Model for Data Integrity and Replication

Ailuri Venkatrami Reddy[1], Racharla Ramya[2]
[1,2]*Assistant Professor, Department of IT*
[1,2]*Malla Reddy Engineering College, Hyderabad, Telangana, India*

Abstract

The cloud computing is popular for the virtually storing data because it provides the big storage space and provides the portability and mobility functions. Even if data de duplication is main advantages in security and privacy concern occur as user's confidential data are liable to both attacks insider and outsider. A convergent encryption method imposes data security while making de duplication possible. Traditional de duplication systems based on convergent encryption even though offer confidentiality but do not maintain the duplicate check on basis of differential rights. The cloud storage service (CSS) reuses total storage traction and maintenance. Hybrid cloud model is new deduplication constructions supporting authorized duplicate check. The proposed security models contain the illustration of security analysis model. as a proof of data contains the implementation framework of proposed authorized duplicate check scheme and conduct experiments using these prototypes the many de duplication methods are implemented in Hybrid Cloud system. Our proposed model is implemented for text file, pdf file, book, and image and video, it also verifies the confidentiality of private cloud.

Index Terms: *Deduplication, authorized duplicate check, hybrid cloud, confidentiality, Secure auditing, Reliability, Cloud computing, Third Party Auditor.*

1. Introduction

Cloud computing provides biggest virtualized recourse to user as services across the total internet while hiding the platform and implementing details. Cloud data service is the management of evergreen increasing mass of data [1]. To make data management security in cloud computing, deduplication is conventional technique. Data compression technique is used for eliminating the duplicate copies of among data in cloud storage to reduce the data duplication [2]. Integrity is simply defined as consistency. Integrity is one of the security factors which influence the cloud performance. Data integrity defines rules for writing data in a reliable manner to keep persistent data storages. There are number of models is recommended [3] and [4] to preserve integrity of data. Integrity is most important security for cloud data storages because it ensures about completeness of data also provide detail data that available data is correct easily accessible to authorized users only data is consistent and of high quality. Data security is most model in present organizations not fully take up this technology. The users do not use the data is being residing after uploading to cloud and even is handling his data. We consider those challenges that the users must deal when they use cloud computing [5].

2. Related Work

The main goal of this work is to acquire data integrity as well as the secure data deduplication. In existing system, there was only the one server is used but in proposed

system Cloud uses the multiple servers in order to load balance as well better uploading downloading speed [6]. Probabilistic queries and periodic verification as well as an optimization method of parameters of cloud audit services are implemented to provide secure access. The third-party auditor (TPA) [7] verifies the integrity of the dynamic data stored in the cloud. The TPA reduces the involvement of the client through the auditing of whether his data stored in the cloud storage. The data is stored temporarily while being authorization process. Store and forward transactions processed after completing the authorization. POR [9] protocol is designed to protect a static archived file in cloud storage. Critical information stored as storage-as-service in encrypted format. It is more flexible and cost-effective storage environments. PORs lead to several possible researches in the future. The classic merles hash tree constructed for block tag authentication to achieve secure cloud storage and data dynamics. Should clients conventionally encrypt their files their savings are lost. Message locked encryption resolves this all the tension [10]. It is inherently subject to the brute force attack is recover files falling into some known set. It enables the client for storing encrypted data with an existing service that have the service perform de duplication on their behalf and yet achieves strong confidentiality guarantees [9]. Showing that encryption for the de-duplicated storage can achieve the performance and the space savings close to that of using all the storage service with plaintext data.

To develop authorized data de-duplication for privacy the data security differential privileges of users in the duplicate check and conduct test bed experiments to evaluate the overhead of the prototype. De-duplication is one of most important data compression model for eliminating duplicate copies of repeating data [14].

Cloud User: A cloud user is one who needs to outsource data on public storage which acts as a public cloud in cloud computing [11].

Public Storage: Public Storage is a storage disk which permit to store the users data which contains authorization and not permit to upload the duplicate data [12].

Private Cloud: A private cloud acts as a proxy to allow both data owner and user to strongly perform duplicate check along with disparity permissions.

Auditor: Auditor is a TPA work as proficiency and capabilities where cloud users to faith assess the cloud storage service reliability on behalf of the user upon request. The user registers into the system, permissions are assigned to user according to identity given by the user at registration time means on basis of situation which access by the user [13].

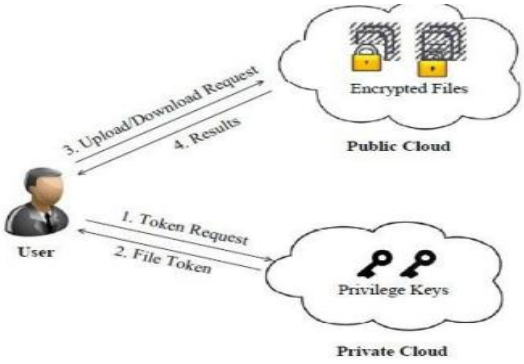

Fig. 3 Architecture of Authorized Deduplication System

4. Proposed System

User easily access the secure cloud storage model is constructed with administrator, third party auditor and cloud servers auditing model is verifying the integrity verification of cloud data storage. Administrator controls the user access of unauthorized party [15].

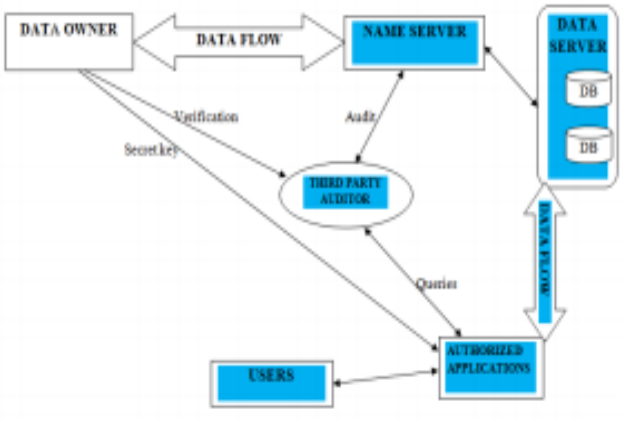

Fig. 4 System architecture of the proposed system

ISSN: 2278-4632
Vol-10 Issue-5 No. 20 May 2020

Key Generation: The owner generates the public/secret key pair (pk, sk) by system manager. The secret key is not visible and then sends the public key (pk) to TPA. Data owner provides the access to authorized users and shares the public key [16].

Tag Generation: The user's/clients use the secret key (sk) to pre-process a file in cloud storage. It takes access of n blocks and generates a set of public verification parameters and index hash table. User data is stored in TPA (Third party auditor) and transmits the file with some verification tags to Cloud Service Provider

Periodic Sampling Audit: TPA (Third party auditor) challenges to audit the integrity and change outsourced data stored in TPA. Audit model detects some errors in secure storage of unauthorized modification. Administrator collects all the user details within the cloud server. Verification process is constructed with insufficient proof protocol of cloud storage [17].

Audit for Dynamic Operations: Authorized application holds the secret key (sk) and it can modify the index hash table stored in TPA. User inserts the files in cloud storage with authorized access from administrator.

A. Dynamic Data Operations

Insert operation: User inserts the file in cloud storage and file is stored in Encrypted data format. Audit process audits the file in secure methods 18]

Update operation: It is an algorithm find the applications update the block of a file. It updates the data's only trusted parties.

Delete operation: After verifying the user is authorized the TPA gives the access to delete the file in cloud storage.

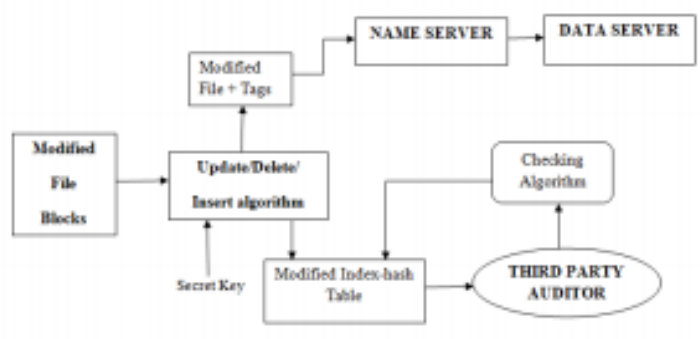

Fig. 5 Flow of dynamic data operation

Checking algorithm to tests the audit model is controlled by Administrator. The User data application takes and Update, Delete, and Insert algorithms, and then sends to TPA and CSP, respectively. It is important to security and audit process of TPA [17]. Finally, Admin gives the permission to change audit records after the confirmation message from CSP is received.

5. Algorithm

1. Take any one of the following user information. Username, password, mobile number, uploaded document name, document size.
2. Convert bit to byte conversion.
3. Byte conversion answer placed in 64*64 cells.

Vol-10 Issue-5 No. 20 May 2020

4. Insertion order is not unique.
5. Reorders the element and placed in outside the cell
6. Finally add the mobile number or document size to reorder element

A. Hash Table Lookup

A hash table is a data structure that is used to implement an associative array. A hash table uses hash function that computes an index into an array of slots [20]. In a well-dimensioned hash table and average cost for lookup is independent of the number of elements. Many hash tables designs access arbitrary insertions and deletions of key-value pairs which are performed at constant average cost per operation.

B. Merkle Hash Tree

A hash tree is every non-leaf node is labeled with the hash of the labels of its children nodes. Hash trees is used to verify any security data stored. Currently the main use of hash trees is to make sure that data blocks received from other peers in a peer-to-peer network is received unaltered and undamaged [21] and even to check that the other peers do not send fake blocks.

6. Result

The authorizes deduplication model used is removed duplicate copies of data in the given cloud. Proposed system implemented by using block level duplication which compare the given blocks with database, the data will be store security format and maintain security each block contain their own token, cipher text and private key. The database size will be reduced by using this technique. The prototype of proposed system is implemented use new technology. The server machine has configuration of Intel Core Duo CPU 2.4 GHz with 4GB of RAM. Heidisql used for the database storage. When user upload file, it divides into the blocks then another same file is uploaded at that time it compare with given database

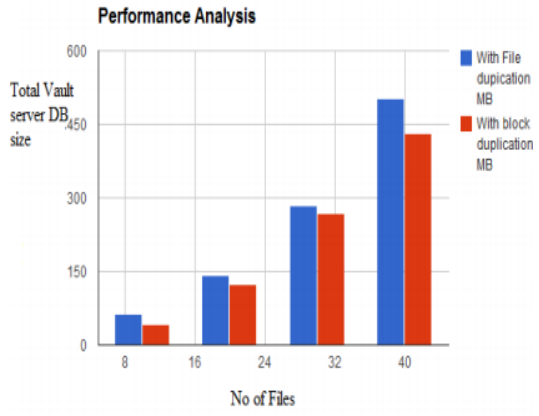

Fig. 6 Comparison between file level deduplication

7. CONCLUSION

Secure upload we can assure the user about high data security and are move data deduplication. Security analysis finding our schemes is secure in terms of insider as well as outsider attacks the proposed security model. It increased the data integrity of the cloud storage and remove the hackers to access the storage process. File insertion, File updating, File deletion is possibly used to authorized users. Cloud service users offered an audit

Copyright @ 2020 Authors

service to audit the integrity and availability of Secure Storage Pool. Additional this will enable secure block level deduplication through introducing a Proof of Ownership protocol and preventing all the leakage of side information in data deduplication. In future, the methodology is proposed to resolve the security related model is used to endeavor on numerous security model that has been mentioned, in order to cater translucent services that can be trusted by all users.

8. FUTURE WORK

It introduces the proof of ownership protocol for element the leakage of side channel information. As compare to previous work computation time is decreased here. SecCloud+ uses the security mechanism for stored file. In simple words, it stores all files in encrypted format. Future work includes introduction of concept parallel computing, to support it multi-threading environment is useful it helps in improving the overall auditing performance

Multiple Sink Placement Algorithm in Wireless Sensor Networks using PSO Approach

P. Swapna[1], T. Swapna[2]

[1,2]*Assistant Professor, Department of IT*
[1,2]*Malla Reddy Engineering College (A), Hyderabad, Telangana, India.*

Abstract

Minimizing energy consumption and maximizing network lifetime are two important challenges in battery operated Wireless Sensor Networks (WSNs). Sensor nodes sense the environment periodically and forward the collected data to a sink. In a single sink WSNs, nodes closer to the sink become overburdened for relaying excessive data. This may incur faster energy consumption by nodes and lead an energy hole around the sink. As a result, the network lifetime is shortened. Multiple sinks mitigate this problem, reduce energy consumption at nodes and prolong the network lifetime by distributing the traffic over multiple sinks. Two multiple sink placement strategies in WSNs which select the potential sink locations with an iterative manner is presented in the literature. Here, we introduce a lifetime-oriented approach (LOA) to maximize the average network lifetime and an energy-oriented approach (EOA) to minimize the average energy consumption of sensor network. Our existing algorithm proceeds iteratively and after a finite number of iterations, it produces the result which maximizes the average network lifetime (in lifetime-oriented approach) and minimizes the average energy consumption (in energy-oriented approach). In this paper, we propose a particle swarm optimization (PSO) based algorithm for placement of multiple sinks in WSNs. The performances of proposed system is evaluated and compared with previous approaches as LOA and EOA with the random sink placement (RSP) policy under various network scenarios. The experimental results show that the proposed algorithms prolong the average network lifetime and minimize the average energy consumption than LOA, EOA, and RSP.

1. Introduction

Wireless sensor networks (WSNs) consist of hundreds to thousands number of resource constraint sensors which have the capability to sense and monitor the region where they are deployed [1]. WSNs have drawn a significant attention in recent years in many applications, e.g., health care monitoring, disaster management, environment monitoring, object tracking, etc. One of the primary concerns of the sensor network is to minimize the energy usage of sensor nodes since sensors are often batteries operated. In [2], the authors introduced a dynamic routing technique for multi-hop wireless networks to minimize the energy burden at wireless node. In the cited approach, the authors focused on the wireless networks with a single sink. Here, the sink is responsible for gathering, analyzing, and forwarding the processed data to the cloud storage [9]. In [3], the authors proposed a single sink placement strategy, both in single and multi-hop WSNs to enhance the network lifetime. In a single sink WSNs, nodes nearer to the sink forward high-volume data traffic, deplete energy faster than the nodes which are away from the sink. This may lead uneven energy depletion among the nodes, and the network becomes disconnected

 Copyright © 2020 Authors

soon. The unbalanced energy consumption does not only shorten the network lifetime, but also increases the network latency, number of retransmissions simultaneously. Under this paradigm, it is sensible to place multiple sinks to improve the network performance. In multiple sink WSNs, energy consumption is reduced, latency is minimized, and the lifetime of the network is prolonged [6]. However, the optimal sink placement is NP hard problem [8]. Several heuristics [4, 5] and meta heuristics [7, 8] approaches have been developed in the literature to address this problem.

2. Related work

In previous works [10], many people working on energy efficient sink placement strategies. So, they are specially two strategies taken named as Lifetime oriented approach (LOA) and Energy oriented approach (EOA) to maximize the average network lifetime and to minimize the average energy consumption of network, respectively. The algorithm has four phases, namely deployment phase, set up phase, potential sink location determination using LS and final sink location identification. In the deployment phase, nodes and sinks are deployed in the region randomly. In the setup phase, initial sink locations are chosen and grouping of nodes is done. In the third phase, local sink locations are explored so that the objective function is either maximized or minimized. In the last phase, final sink locations are identified. LOA and EOA work iteratively. At each iteration, we perform second and third phase, looking for the best solution.

3. Proposed system

In this paper, we propose a particle swarm optimization (PSO) based algorithm for placement of multiple sink in WSNs represented in figure 1. The algorithm is developed with an efficient scheme of particle encoding and novel fitness function. For the energy efficiency scheme of particle encoding and novel fitness function. For the energy efficiency of the proposed system, we consider various parameters such as Euclidian distance and hop count from the gateways to the sinks. The algorithm by varying the number of gateways and sensor nodes and the results are analyzed to show the efficiency of the proposed algorithm. PSO consists of a predefined number of particles say NP, called swarm. Each particle provides a potential solution. A particle P_i, $1<=i<=N_p$ has position $X_{i,d}$ and velocity $V_{i,d}$, $1<=d<=D$ in the d^{th} dimension of the search space. The dimension D is same for all paricles. A fitness function is used to evaluate each particle for verifying the quality of the solution. In the initialization process of PSO, each particle is assigned with a random position and velocity to move in the search space. During each iteration, each particle finds its own best, personal best called $Pbest_i$ and the global best called Gbest. To reach the global best solution, it uses its personal and global best to update the velocity $V_{i,d}$ and position $X_{i,d}$ using the following equations

$$V_{i,d}(t+1) = \omega \times V_{i,d}(t) + c_1 \times \boldsymbol{\chi_1} \times \left(X_{Pbest_{i,d}} - X_{i,d}\right)$$

$$+c_2 \times \boldsymbol{\chi_2} \times \left(X_{Gbest_d} - X_{i,d}\right) \quad (1)$$

$$X_{i,d}(t+1) = X_{i,d}(t) + V_{i,d}(t+1) \quad (2)$$

Where $0 < \omega < 1$ is the inertia weight, $c_1, c_2, 0 \le c_1, c_2 \le 2$ are the acceleration coefficients and $\chi_1, \chi_2, 0 < \chi_1, \chi_2 < 1$ are the randomly generated values. The updating

process is repeated until it is reached to an acceptable value of $Gbest$. After getting new updated position, the particle evaluates the fitness function and updates $Pbest_i$ as well as $Gbest$ as follows

$Pbest_i = P_i$, if $(Fitness(P_i) < Fitness(Pbest_i))$

$Pbest_i$, otherwise

$Gbest = Pbest_i$, if $(Fitness(Pbest_i) < Fitness(Gbest))$

Gbest, otherwise

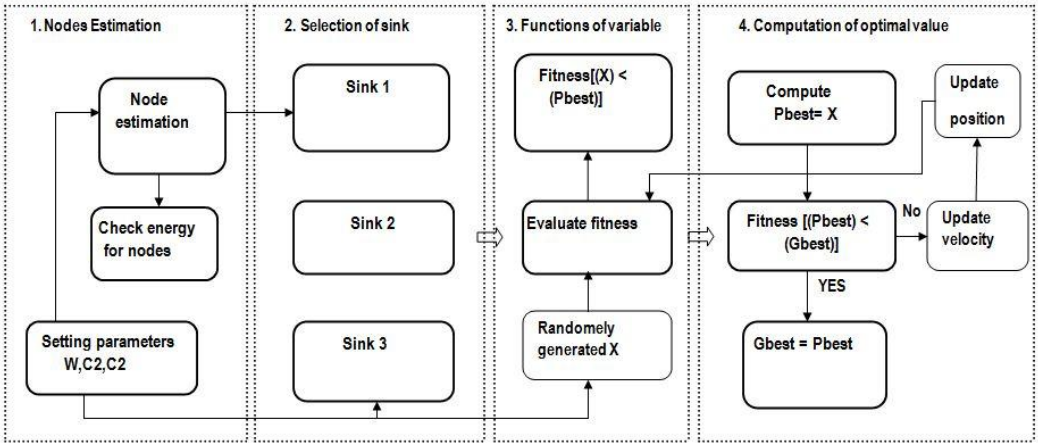

Figure 1. Update of multiple sink selection framework.

3.1. Particle representation and initialization:

In PSO, a particle represents a complete solution. For multiple-sink placement of the proposed algorithm, it represents optimal positions of the sinks with respect to the gateway nodes. Let $P_i = [X_{i,1}(t), X_{i,2}(t), X_{i,3}(t), \ldots..X_{i,D}(t)]$ be the i^{th} particle of the population where each component $X_{i,d}(t) = (x_{id(t),} y_{id}(t))$, $1<=i<=N_p$, $1<=d<=D$, denotes the coordinates of the sink nodes. Then the i^{th} particle can be represented as follows:

$$P_i = [(x_{i1}(t), y_{i1}(t)), (x_{i2}(t), y_{i2}(t)), (x_{i3}(t), y_{i3}(t)), \ldots\ldots, (x_{id}(t), y_{id}(t))]$$

Where N_p denotes the swarm of particles and D represents the number of sinks are supposed to be placed.

Algorithm

Input: set of gateway nodes: $G= \{g_1, g_2, g_3, \ldots, g_m\}$; predefined swarm size : N_p

Number of dimensions of a particle: D=l

Output: optimal positions of sink nodes $SN = \{SN_1\ SN_2\ SN_3 \ldots, SN_l\}$

Step 1: initialize particles P_i, i.j , $1<=i<=N_p$, $1<=j<=D=l$, number of SNs

$X_{i,j}(0) = (x_{i,j}(0), y_{i,j}(0))$ /* deployed positions of sink */

Step 2: for i=1 to N_p do

2.1 calculate fitness(P_i)

2.2 $Pbest_i = P_i$

End for

Step 3: Gbest = {$Pbest_k$/Fitness($Pbest_k$) = min(Fitness($Pbest_i$), 1<=i<=N_p)}

Step 4: for t=1 to Terminate /*Terminate = Max.number of iterations */

For i=1 to N_p do

4.1 Update velocity and position of P_i using eqs (1),(2)

4.2 Calculate Fitness (P_i)

4.3 if Fitness(P_i) < Fitness($Pbest_i$) then

$Pbest_i = P_i$

End if

4.4 if Fitness ($Pbest_i$) < Fitness(Gbest)

Gbest = $Pbest_i$

End if

End for

End for

End for

Step 5: stop

4. Result and discussion

Our experiments are conducted using the NS- 2.34 simulator. We conduct the experiments in two steps. The initial step is to check the viability of our plan, and then deeper study is investigation is done to assess the delay and throughput in more detail. In the first step, there are 43 mobile nodes in the network, and communication starts from source to destination. Here hop-to-hop communication occurs, and we can calculate the distance based on position of an individual node. The individual communication between user to user, numbers of data flows measured. None of the individual traffic rate goes beyond a certain threshold, but the sum of them does. Here we can know the transmission rate of every node based on residual energy. In our work, we can take multiple sinks for receiving the data and using our algorithm based on that best optimal path selection for sink placement. The best placement of sink can be helpful to more data can receive the data. The connections among mobile nodes are UDP connections, and we send CBR (Constant Bit Rate) traffic in each communication channel. The CBR rate of the connections is 512Kb/s. The size of the scenario field is 1000m x 1000m. The routing protocol we use is a revised AODV routing protocol that integrates our PSO-NL, EOA, LOA methods.

Table I: Simulation parameters

PARAMETER	VALUE
Application traffic	CBR

Copyright © 2020 Authors

Transmission rate	8 packets/msec
Radio range	250m
Packet size	1000 bytes
Channel data rate	2Mbps
Maximum speed	25m/s
Simulation time	10secs
Number of nodes	43
Area	1000x1000
Routing protocol	AODV
Routing methods	EOA, LOA, PdSO-NL

Figure 2 demonstrate that end-to-end delay performance of proposed and existing approaches, and it depends on time to vary the output. The performance of the PSO-NL improves delay time which means decreasing the delay between the communication nodes as compared to ELOA and RSP approaches. Similarly, figure 3 and figure 4 discloses the performance graph of throughput and energy respectively where proposed PSO-NL approach obtained superior performance over RSP and ELOA approaches.

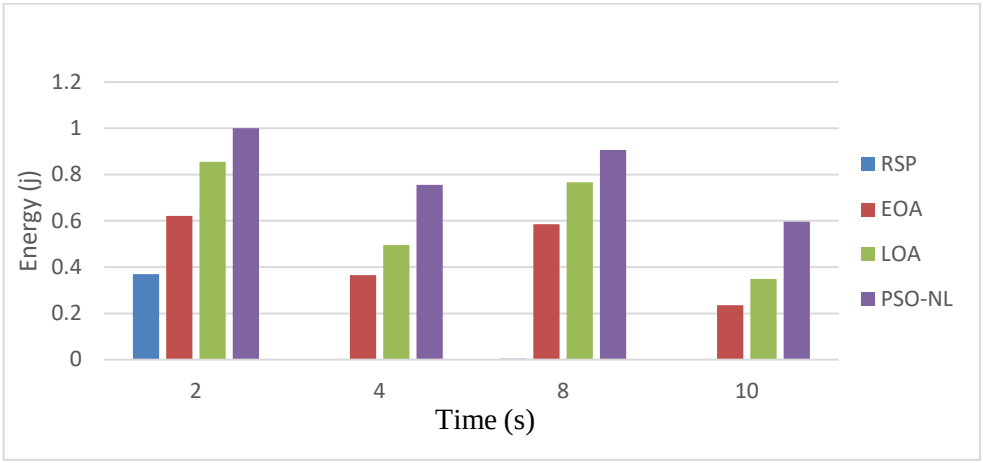

Figure 4: Energy consumption

5. Conclusion

This article proposed multiple-sink placement algorithm based on PSO using efficient particle representation and fitness function. For the energy efficiency of the proposed algorithm, we have considered the Euclidian distance and hop count. The objective of our PSO based sink placement approach is to improve the network lifetime with efficient energy levels to maintain in network. The proposed algorithms are simulated and compared with the EOA, LOA approaches and random sink placement algorithm with respect to various performance metrics. To show the improvement of PSO-NL with an existed exhaustive grid search algorithm, we have calculated network lifetime. It can be observed that the PSO-NL outperforms the existed algorithms.

Abstract

In modern days the cloud data storage is present generations that promote the secure remote data auditing. The existing system considers the problem secure and efficient public integrity auditing for shared dynamic data storage. Cloud data assign stores data in the cloud as well as distribute data number of users. We found the collusion attack in the exiting model. An efficient public integrity auditing method with secure group user revocation based on vector commitment plus verifier total revocation group signature. We find the proposed a new public integrity auditing function to help of Message Authentication Code (MAC) generation and symmetric cryptographic algorithm. The main aim of this paper is to improve privacy and an efficient cloud data storage model to reduce the bandwidth and to improve the data security. This work modifies to number groups to access the data. We deplore scheme for group signature. The cipher text support public checking and efficient user revocation in properties like confidently, efficiency, count ability and traceability. Finally we compare our algorithm with old which shows good result in security. The experimental results are analyzed and evaluated in terms of computation time, block size, key size, number of rounds and cycles per block.

Index Terms: *Data integrity, Public auditing, User revocation component, Cloud Computing, Message Authentication Code (MAC), Message Digest (MD), Symmetric Key Cryptography, Public Integrity Auditing, Security and Data Storage.*

1. Introduction

The improvements and enhancements in cloud computing motivates enterprises and also organizations to outsource data to third party cloud service providers (CSP's) which will result in improvements in the data storage limitation of resource constrain local devices. In market already some cloud storage services are available like simple storage service (S3) online data backup services of Amazon and software like Google Drive, Drop box, Mozy, Bitcasa and Memopal built for cloud application. Cloud computing is computing in which large groups of remote servers are networked to allow centralized data storage and online access to computer services or resources. Clouds can be classified as public, private or hybrid [1]. The criticisms about it are mainly focused on its social implications. This happens when the owner of the remote servers is a person or organization other than the user, as their interests may point in different directions, for example, the user may wish that his or her information is kept private, but the owner of the remote servers may want to take advantage of it for their own business [4]. We introduce publicly verifiable scheme, it helps in various aspects. That is data integrity can be performed not only by data owners, but also by one or more third party auditor. Conversely, the dynamic schemes we mentioned only focus on the gears where there is a data owner and only the data owner could change the data. In recent times, the growth of cloud computing,

Copyright © 2020 Authors

improves that some applications uses cloud service, can use as a collaboration platform [2]. Few of the software development surroundings, one or more users in a group may need to share some of the source code, need to access, modify. At some times they may need to compile and run the shared source code at any time and place. Cloud computing is a new paradigm that is mainly used to provide an economic resource utilization over the internet [5]. It is a method of computing in which the users can increase or decrease their computing resources. Generally, the cloud contains three models as shown Fig 1.

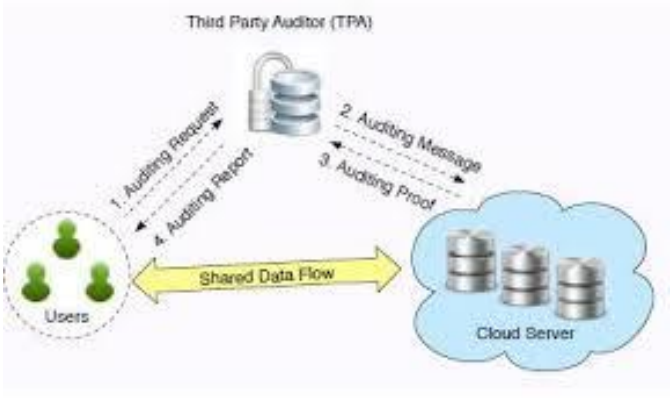

Fig1. Types of cloud security data

The major contributions are as follows:

- The secure and efficient shared data integrate auditing process is explored for cipher text database with the help of multi-user operation [3].

- Here, an efficient data auditing scheme is proposed for providing data integrity by incorporating the primitives of victor commitment, asymmetric group key agreement and group signature [7].

2. Related Work

A large number of researchers have committed significant concentration to the troubles on how to securely outsource local pile up to remote cloud server. The problem of remote data integrity and availability auditing attacks the attestation of many researchers. Sagarika Dev Roy, et.al (2014) proposed a methodology for secure outsourcing of linear Computations into the cloud environment. Outsourcing is a common procedure engaged in the business world when the customer chooses to farm out a certain task to an agent for the benefit of the firm in terms of time and cost [6]. They proposed methodology to detecting a malicious server, in an efficient result verification method. YongjunRen, (2012) proposed designated verifier provable data possession. This plays a major role in public clouds. Designated verifier provable data possession is a matter of crucial importance when the client cannot perform the remote data possession checking. By using the system security model and homomorphism authenticator they designed a new scheme [8]. The scheme removed luxurious bilinear computing process. Furthermore, in this proposal, the cloud storage server is stateless and independent of the verifier. This is an important secure property of any other schemes. In the course of security analysis and performance analysis, their scheme is secure and high efficiency [10]. The asymptotic complexity in computations were more in key generation methodologies. Gentry and Halevi [12] discussed the implementation of Fully Homomorphism Encryption (FHE).

 Copyright © 2020 Authors

The complete working of any encryption methodologies required the functionality called bootstrapping. They provided the optimization in key generation that reduced the complexity with n-dimensional lattices. In a data storage outsourcing services, the permission assigned to the data owner to check whether they stored data correctly or not [9]. In previous work focused on TPA should be able to efficiently audit the cloud data storage without demanding the local copy of data and introduce no additional on-line burden to the cloud user. This paper entirely different compare with previous in the case of privacy. Privacy preserving public auditing for data storage security in cloud computing [11], by C. Wang, Q. Wang, K. Ren, and W. Lou utilize and uniquely combine the public key-based homomorphism authenticator with random masking to achieve the privacy-preserving public cloud data auditing system. In this design, propose to uniquely integrate the homomorphic authenticator with random masking technique. In this protocol, the linear combination of sampled blocks in the server's response is masked with randomness generated by a pseudo random function (PRF). By using random masking, [13] The TPA no longer has all the necessary information to build up a correct group of linear equations and therefore cannot derive the user's data content, and no matter how many linear combinations of the same set of file blocks can be collected. A public verifier, such as a third-party auditor providing expert data auditing services or a data user outside the group intending to utilize shared data, is able to publicly verify the integrity of shared data stored in the cloud server. When a public verifier wishes to check the integrity of shared data, it first sends an auditing challenge to the cloud server. After receiving the auditing challenge, the cloud server responds to the public verifier with an auditing proof of the possession of shared data. Then, this public verifier checks the correctness of the entire data by verifying the correctness of the auditing proof. Essentially, the process of public auditing is a challenge and- response protocol between a public verifier and the cloud server [15].

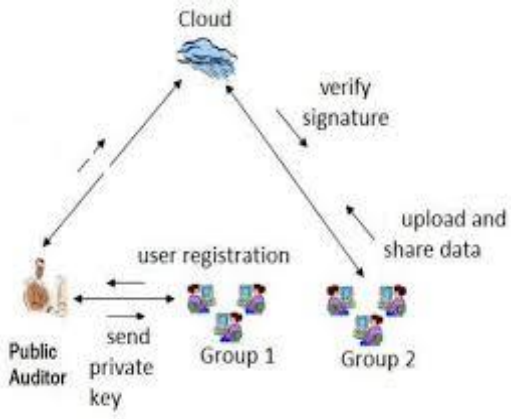

Fig2. System Flow

3. Proposed Work

Data outsourcing hoist security and privacy worry. We need to trust third-party providers for proper implementation of confidentiality, integrity checking, and access control mechanisms. The conventional encryptions have need of particular users to encrypt their data, with the own keys of the user. Therefore, the same data copies of different users will lead to dissimilar cipher texts. It creates integrity checking process is an impossible task. [5] The present system use standard encryption scheme for identifying duplicate blocks,

 Copyright © 2020 Authors

the blocks are stored in cloud. In Cloud Storage, standard encryption of identical files generates same key and same cipher text. As a result, Data de duplication is impossible in encrypted data. When user lost the key, there was impossible to restore the original content of the file. Message digest algorithm provides a viable option to enforce data confidentiality while realizing duplication. It encrypts or decrypts a data copy with the help of a convergent key. By computing cryptographic hash value of the content of the data copy we can obtain the key. After key generation process and data encryption process, users can hang on to the keys. Then the user sends the cipher text to the cloud environment. Ever since encryption is deterministic, the same data copies will generate similar convergent key and the identical cipher text. This permits the cloud to perform de duplication over the cipher texts. Cipher texts are able to decrypt by the corresponding users' with their convergent keys. Convergent encryption practical is to efficiently and reliably manage a huge number of convergent keys. [9] The unique Data block will be selected and those blocks are placed in the cloud service provider's space. We are using crypto graphic algorithm for integrity checking. Message authentication code is the scheme of producing Message digest for input file. The integrity checking should be done by Third party auditor by checking this message digest code. Before Uploading file; data owner must send the hash key to the third party auditor. Third Party Auditor receives the key and verify with cloud service provider to check whether this file is already uploaded or not. In this module, user revokes the content by getting secret key of data owner. Data owner must share the secret key for group users. User downloads the file from the cloud service provider using hash key [14].

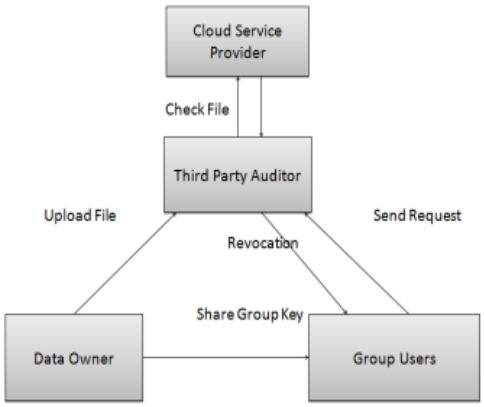

Fig3. Architecture of a proposed system

The proposed cloud storage model the problem of designing public integrity auditing based shared dynamic data with group user revocation is analyzed. The main contributions of this paper are listed as follows: [6]

- An efficient and secure public integrity auditing scheme is proposed for cipher-text base with the help of multi-user operation.
- The primitives of victor commitment, group signature and asymmetric group key agreement are integrated.
- The new features like, traceability and countability are provided at the time of auditing.

It is identified that the upload file is duplicated. Otherwise, it will divided into various blocks, after that the availability of the blocks is also verified. If the block is not exists, it

 Copyright © 2020 Authors

will be given to the Cloud Service Provider (CSP). Hence, the file is downloaded from the server and to access that file, the hash key and data blocks are need to be decrypted. [15] In this work, the two different algorithms such as, Message Digest Code. Message Authentication Code (MAC) algorithm is used for code generation. Then, the symmetric key cryptography algorithm is used for encryption and decryption processes.

Algorithm – MAC Algorithm

Input: Block of file B = (B1, B2, B3 … BN}

Step 1: Generate the hash key;

Step 2: Encrypt the data block with the help of hash key;

Step 3: Generate the tag and hash key from the content of the file;

Output: Obtain the decrypted file with the help of hash key;

1. H(M) = K (Key Generation)
   Where,
   M= Input file
   H(M)=Hash value of file
   K= Hash Key
2. E(K, M)=C (Encryption)
   Where.
   M-File,
   K-Hash Key,
   E-Encryption
   C-Cipher Text
3. Tag(M)=T (Tag Generation)
   Where,
   M-File
   T-Tag from File M

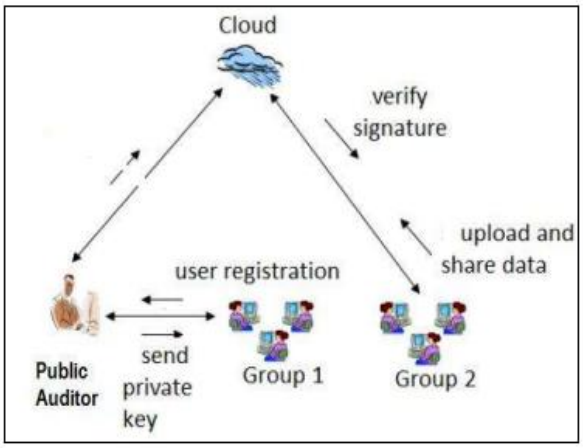
4. Cipher Text Database

In cloud storage outsourcing environment, the outsourced data is usually encrypted database, which is usually implicitly assumed in the exiting academic research. Actually, our scheme could support the auditing of database of both plaintext and cipher text database [5]. It is not straightforward to extend a scheme to support encrypted database. In order to achieve the confidentiality of the data record mx, the client can use his/her secret key to encrypt each mx using a encryption scheme. When there is only one user in the group, the user only needs to choose a random secret key and encrypt the data using a secure symmetric encryption scheme. When the scheme needs to support multi- user data modification, while at the same time keeping the shared data encrypted, a shared secret key among group users will result in single point failure problem [3]. It means that any group user leak the shared secret key will break the confidentiality guarantee of the data. To overcome the above problem, we need to adopt a scheme, which could support group users data modification. Exponentiation (BDHE) assumption in the standard model according to the ASGKA protocol, we consider the case of encrypted database (x, cx), where x is an index and cx is the corresponding cipher value. We provide the detailed changes upon our scheme to support encrypted database [16].

 Copyright © 2020 Authors

1) In the Setup phase, the scheme has to run the key agreement of ASGKA for the group users. Then the database DB = (i,mi) is encrypted by the group key gpk of data owner. Finally, the stored database is a cipher text database DB = (i, ci).

2) In the second step of the Update phase, a group user firstly decrypts the record ci using the ASGKA secret key gsk[∗] to get plaintext database DB = (i,mi). Then, update the data to m′i, and later encrypt the data with the public key gpk of ASGKA scheme to get the new encrypted database DB = (i, c′ i)



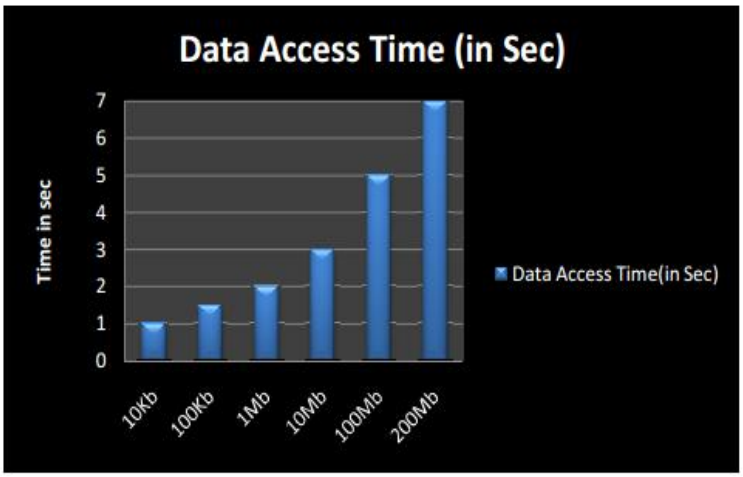


Fig 4. Cipher Text Model

The system is based on proxy re-signature concepts. Blaze et al first proposed the concept of proxy re-signature in [12]. Proxy signature is a digital signature scheme where original user delegates his signing capability to a proxy signer, and then the proxy signer performs message signing on behalf of the original signer [9]. In simple word it allows semi-trusted proxy to work as a converter of signatures between two users belonging to same group

5. Result

We have provided a scheme of auditing the integrity of the shared and dynamic cloud data along with group user revocation. The auditing of the data integrity is secure and reliable. In this paper, the concept of authorized data duplication was proposed to achieve the data security by including differential privileges of users in the duplicate check. The data and associated key primitives consume the space in cloud architecture refers block size. An algorithm effectiveness decided by the low space consumption. Fig 5 shows the variation of block size for both the proposed and existing AES method. The block size for AES is 128 bits and for proposed symmetric cipher block is 65 bits. The optimal steps reduction in proposed work offers 49. 21% reduction in block size. This section demonstrates the implementation results and experimental performance analysis is carried out on the basis of revocation time and overall auditing time by implementing our proposed mechanism. Graphically presented analysis is most feasible analysis of our mechanism with the existing public auditor.

Copyright © 2020 Authors

6. Conclusion

A new public integrity auditing scheme for cloud data storage for this purpose algorithms such as, Message Authentication Code (MAC) generation and symmetric key cryptographic techniques are used in this work. This paper proposed system to realize efficient and secure data integrity auditing for dynamic data. The proposed model consists of the public data auditing. This technique will provide better data confidentiality compare to other methodologies. The main objective of this paper is to reduce the bandwidth and to improve the content integrity in cloud data storage. Our novel design allows efficient user revocation operations to the cloud. Because of keys generated for the data not a user. In addition, scheme allows aggregation of integrity auditing operations for multiple tasks (files) through our batch integrity auditing technique. When compared to other algorithm key size is very small, it is not able to hack easily. It is used for efficient revocation without updating private keys of remaining users. Cloud public verifier plays an important role when dealing with security aspects of cloud. In this paper, we have proposed a new public auditing mechanism for cloud for efficient user revocation while maintaining shared data integrity which allows cloud to re-sign blocks signed by revoked user. In future, concentrate on key management, how to revoke the private keys from the group members

7. Future Work

Designing an efficient public auditing mechanism with the capabilities of preserving identity privacy and supporting traceability is still open. Future work includes improving performance of the overall system using distributed cloud. Even though there is greater performance and efficiency in this mechanism, there is a problem of traceability in this system which is been considered to be continued in future work. Since this mechanism is based on aggregate signatures which are group signatures with compressed storage, the identity of the signer is protected. Proxy re-signature can be carried out on two or more cloud servers which reduces risk of increased in data or users. It also helps in improving security factors

1. Introduction

One of the most popular application to comes with own advantages and disadvantages is Facebook. Today we can see that there are 500k apps is available on Facebook within that 40M apps [2] is stating everyday by the Facebook users. Such changes are consisting of interesting even enjoyable way associated with communicating number of online good friends in addition to different things to do like since getting referrals even enjoying tunes. One example is Myspace supplies developers the API [3] in which facilitates software integration into the Myspace user-experience. In [4] the data detection system for mobile apps has been studied and it is provided a holistic view. The leading sessions and the leading events of the app were studied using the mining leading session's algorithm. In [5], it proposed Facebook's Rigorous Application Evaluator (FRAppE). It failed to recommend to the website the hackers. Online social networks (OSN) are third party apps to enhance the user experience on the platforms. In our previous study [6] we presented preliminary statistics on this dataset We are finding that within the first week after the

They found that about 9% of the studied posts were spam or small. In 2012, Rahman, [11] Improved his previously modify work and developed the FRAppE: A tool is identify small applications by using the application data as features. New examples include the number of permissions required the domain reputation of redirect URI, and others. FRAppE can detect malicious applications with 99.5% accuracy and a low false negative rate 4.1%. Popular websites area unit under fire all the time from phishes, fraudsters and spammers the aim to steal user data and expose users to unwanted spam. They are well funded, with full-time practiced labor, control over compromised and stating accounts, and access to global bonnets. Security our users may be a difficult adversarial learning drawback with extreme scale and cargo needs. Over the past many years, we engineered and deployed a coherent security and protrusive real-time system to shield our users and the social graph.

3. Proposed Solution

The proposed system using the FRApp tool and detect the block the small applications in the Face book. The user is trying to post the offensive words to the user's Face book wall those words or posts are detected using the dictionary and it gets filtered. We found any installation of the malicious app user wall gives total notification that the app found is small whether to install it or not. Offensive words or posts which are related and detected and blocked using the FRAppE tool. These words are posts will not display in the public wall. Instead of that such post will be migrated to the blocked post list a tool stands for Face book's Rigorous Application Evaluator which is helpful in modify the entire system. In Authentication and Authorization module the user in register the data and login into the pages to view their profile to see all the contacts the user

3.1. Detecting Spam on OSNs

We analyzed posts on the walls of small Social networking app users 10% of links posted on Social networking app walls in spam. We develop efficient models for online spam

filtering on OSNs such as Social networking app is used only by the OSN provider; develop a third-party application for spam detection on Social networking app. Others present model find the spam URLs on Social networking app and contrast to all of these efforts rather than classifying individual URLs or posts as spam we aim on identifying small applications is main source of spam on Social networking app.

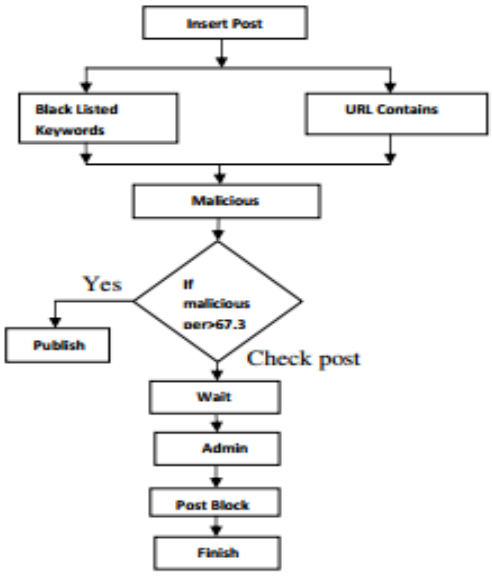

Fig. 3 Proposed Methodology

3.2. Implementing MyPageKeeper

We provide some details on MyPageKeeper's implementation.

Facebook application: First, we implement the MyPageKeeper Facebook application using FBML [12]. We implement our application server using Apache (web server), Django (web framework), and Postgres (database). Once a user installs the MyPageKeeper app in her profile, Facebook generates a secret access token and forwards the token to our application server, which we then save in a database. This token is used by the crawler to crawl the walls and news feeds of subscribed users using the Facebook open-graph API.

Crawler instances and frequency: We run a set of crawlers in Amazon EC2 instances to periodically crawl the walls and news feeds of MyPageKeeper's users. The set of users are partitioned across the crawlers. In our current instantiation, we run one crawler process for every 1,000 users. Thus, as more users subscribe to MyPageKeeper, we can easily scale the task of crawling their walls and news feeds by instantiating more EC2 instances for the task. Our Python-based crawlers use the open graph API, incorporating users' secret access tokens, to crawl posts from Facebook. Once the data is received in JSON format, the crawlers parse the data and save it in a local Postgres database.

Checker instances: Checker modules are used to classify every post as socware or benign. Every two hours, the central scheduler forks an appropriate number of checker modules determined by the number of new URLs crawled since the last round of checking. Thus, the identification of socware is also scalable since each checker module runs on a subset of the pool of URLs. Each checker evaluates the URLs it receives as

input—using a combination of whitelists, blacklists, and a classifier— and saves the results in a database

4. Expected Results

The study presented in this paper is a work in progress with many available future directions. By gathering additional information about what kind of applications users tend to restrict, we can develop an algorithm for application removal recommendations. Moreover, when the same applications are restricted by many users, we can conclude with high likelihood that these applications are fake applications and recommend to Facebook and our users to remove these applications from the social network and their accounts. Another possible future direction is discovering the point in time when the Add-on Users' application numbers start increasing again, and at that point, to give the user a special warning regarding his or her number of applications.

5. Conclusions

In this study, we presented our initial methods and results in studying online social network applications with an aim of improving user's safety and awareness. According to our results, it is possible to predict the number of applications a casual user has with high accuracy. we presented the design and implementation of MyPageKeeper a Facebook application that can accurately and efficiently identify socware at scale. Using data from over 12K Facebook users, we found that the reach of socware is widespread and that a significant fraction of socware is hosted on Facebook itself. Applications present a convenient means for hackers to spread malicious content on Social networks. However, little is understood about the characteristics of malicious apps and how they operate. And finally, we explore the ecosystem of malicious Facebook apps and identify mechanism that these apps use to propagate. We will continue to investigate on hacker's platform dig deep into their ecosystem to reduce the malicious app on Facebook.

Two-Cloud Secure Database for Numeric-Related SQL Range Queries with Privacy Preserving

Ailuri Venkatrami Reddy[1], Racharla Ramya[2]

[1,2]*Assistant Professor, Department of IT*
[1,2]*Malla Reddy Engineering College (A), Hyderabad, Telangana, India.*

Abstract

In the present scenario businesses and people are outsourcing database to accomplish helpful administrations and minimal effort applications. These are buried in the cloud server, which is outside the ability to control of the data proprietor. The SQL Queries require a few secure database schemes for its undeniable working, yet this at long last prompts privacy spillage to the cloud server. For numerical range inquiry (>,< , and so forth.) these neglect to give adequate security insurance. A portion of the difficulties faced are privacy leakage of statistical attributes, access patterns and so on. Likewise, increased number of queries will release more information to the cloud server. Thus, regarding these issues numerous works have been done by various researchers. We have studied some of these research works and analyzed the best possible ways to come to the desired level of privacy preservation in the case of cloud computing. Some of the works studied are the fuzzy logic, range queries, CryptDB order preserving encryption and multi-cloud architecture.

Keywords *— cloud computing, database, privacy preserving, range query*

1. Introduction

In the present circumstances as it can be seen cloud has taken the control over the IT business with its innumerable advantages. It holds the possibility to change an extensive segment of the IT business, making software considerably more appealing as an service. Cloud computing [1] is alluded to as SaaS (Software as a Service) since it renders the applications as administrations over the Web and the hardware and systems software in the data centres that offer those administrations. The hardware of data centre and software is called a cloud Today the clouds can be open/public and in addition private. Private clouds are associated to the inner datacenters of a business or other association, not made accessible to the overall public. Cloud computing in this manner can be compressed as a blend of saas and utility computing, booting out the data centre (little + medium estimated). Security is the chief concern of the cloud computing. Cloud clients confront security dangers both from outside and inside the cloud. Shielding the information from the server itself is the pro of the main issues related with it. The server will by definition control the "bottom layer" of the product stack, which adequately goes around most known security methods. As said the cloud server is accepted as semi-trusted (honest-but-curious). CryptDB [5], a framework that gives confidentiality to applications that utilize database administration frameworks (DBMSes). CryptDB permits to perform queries over

Copyright © 2020 Authors

encrypted data, likewise the SQL's very much characterized set of operators, and queries over encrypted data. CryptDB tends to the hazard of an inquisitive database administrator (DBA) who endeavors to learn private information (e.g., health books, financial articulations, individual data) by keeping an eye on the DBMS server by keeping the DBA from learning private information. It uses a few instruments to accomplish this security functionality. One of the devices being the Order preserving encryption (OPE) [11, 12] is generally utilized as a part of databases to process SQL Questions over encrypted information. It permits to perform order operations on ciphertext like the plaintext for e.g. data server can fabricate index perform range queries [10] and sort the encrypted information like the plaintext. Regardless of going to the security reason well, despite everything it uncovers the order of the ciphertext. Therefore, the objective of security protection of the outsourced information to a cloud server is refined by partitioning the sensitive knowledge into two parts and store them in two non-colluding clouds.

Moreover, a secure database service architecture is acknowledged by utilizing two non-colluding clouds in which the information learning and query rationale is divided into two clouds. Henceforth, perceiving just a single cloud can't help uncovering private data. Other than a progression of intersection protocols to give numeric-related SQL range queries [1] with privacy preservation is additionally executed and it won't uncover order related data to any of the two non-colluding clouds.

2. System Architecture

Our proposed secure database system includes a database administrator, and two non-colluding clouds. In this model, the database administrator can be implemented on a client's side from the perspective of cloud service. The two clouds (refer to Cloud A and Cloud B), as the server's side, provide the storage and the computation service. It briefly depicts the architecture of our outsourced secure database system in our scheme. The two clouds work together to respond each query request from the client/authorized users (availability). For privacy concerns, these two clouds are assumed to be non-colluding with each other, and they will follow the intersection protocols to preserve privacy of data and queries (privacy). In our scheme, the knowledge of stored database and queries is partitioned into two parts, respectively stored in one cloud. The mechanism guarantees that knowing either of these two parts cannot obtain any useful privacy information.

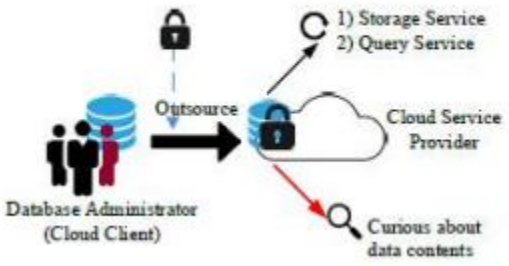

Figure 1. Outsource Database and Services

Copyright © 2020 Authors

As shown in to conduct a secure database, data are encrypted and outsourced to be stored in one cloud (Cloud A), and the private keys are stored in the other one (Cloud B). For each query, the corresponding knowledge includes the data contents and the relative processing logic. We utilize a prototype of knowledge partition, dividing application logic into two parts, which is bristly proposed by Bohli et al. In [16]. The application logic, as a secret knowledge, is partitioned into two parts, each of which is only known to one cloud. This prototype. Intuitively, this two-cloud architecture increases some complexity to some extent, and we will analyze and point out that this overhead is acceptable.

3. Related Work

This Paper analyzes recent research related to single or multiple cloud security and addresses possible solutions. Research on using multi-cloud providers to maintain security has been found to receive less attention from the research community than using individual clouds. This work aims to promote the use of multiple clouds thanks to its ability to reduce security risks affecting the user of cloud computing. We present new preprocessing techniques that allow obtaining interactive query times in large text collections (100 GB of text, served by a single machine). Consider two similarity measures, one in which the query terms coincide with similar terms in the collection (for example Algorithm of algorithm matches or vice versa) and one in which the query terms coincide with terms with a similar prefix in the collection (for example, Alori corresponds to the algorithm). The latter is important when we want to show the results instantly after each keystroke (search while writing). All the algorithms have been completely integrated into the complete search engine.

In this Paper, we define and solve the search for keywords classified as effective but protected on data encrypted in the cloud. We use order preserving symmetric encryption to protect data in the cloud. Although many research techniques are available, they do not offer efficient search results. For example, the search results generated 40 records and in those 30 records are relevant and the remaining 10 records generate irrelevant data. This paper focuses mainly on research methods that will improve the effectiveness of research. We use search methods based on keywords and concepts to retrieve relevant search criteria. This method will restore documents based on broader conceptual entities, which will improve the efficiency of the search.

4. Modules

1. Potential Threats and Privacy Requirements This section describes the potential threats and the privacy requirements when the database is outsourced to public cloud. The stored data contents and the query processes. Although there are many data encryption schemes, some fail to provide sufficient privacy preservation after statistical analysis: Repeated and large-amount query processes not only leak the access patterns, but also disclose the stored encrypted data progressively.

2. Data contents Module: Besides the static properties can disclose the private information of data contents, such properties themselves are already sensitive and private for the client. Order Preserving Encryption(OPE), which is widely used in constructing the secure database, with support of range queries, directly exposes the statistical

 Copyright © 2020 Authors

information in the encryption field. Furthermore, the leakage of statistic properties is part of the nature of outsourced cloud database service: the cloud can learn the statistical properties (like order) by repeated query requests. As an example, It describes such an attack: After two simple queries over one same column, the order relationship of some data in certain column can be determined. There are also some other direct and indirect scenarios to leak statistical properties. In this way, even though the order property is not exposed to the semi-trusted cloud at the beginning, the cloud can gradually find out the order information after many query requests.

3. Query pattern Module. The query pattern also contains privacy information, as they can reveal the client's purpose of the query. Even worse, such pattern can leak some statistical properties, as discussed above. Based on the above discussion, we assert that an outsourced secure database providing numeric-related queries should prevent the following private information from being obtained by the honest-but-curious clouds

4. Privacy of Item Values Modules: An ideal scheme is required to make nothing of the statistical properties be leaked to the curious clouds. However, the privacy leakage of statistical properties in a practical Outsourced database system is inevitable, as returning subset of data rather than universe requires knowledge for filtering. For instance, if the client wants to retrieve a from the outsourced database, a cloud server without any knowledge of the order can only return all items of the database to the client, which is not usable.

5. Conclusion

In this paper, we presented a two-cloud architecture with an intersection for outsourced database service, which ensures the privacy preservation of data contents and SQL range query pattern. At the same time, with the support of range queries, it not only protects the confidentiality of static data, but also addresses potential privacy leakage in statistical properties or after large number of query processes. Security analysis shows that our scheme can meet the privacy preservation requirements. Furthermore, performance evaluation result shows that our proposed architecture are efficient. To achieve the assurances of cloud data integrity and availability and enforce the quality of dependable cloud storage service for users, we propose an effective and flexible distributed scheme with explicit dynamic data support, including block update, delete, and append. We rely on erasure-correcting code in the file distribution preparation to provide redundancy parity vectors and guarantee the data dependability.

18.1 Wireless Body Area Network

18.1.1 Overview

In concern with medical environment, a wireless body area network (WBAN) is a group of energy-constrained, persistent or nonpersistent, and lightweight wireless sensor nodes that are used to monitor the patient's health condition and the medical environment. As per the description given in IEEE 802.15.6 standard, medical environment is one of the crucial applications of WBAN (Jovanov et al. 2000). The applications of WBAN in medical and healthcare environment can be classified into three categories: wearable, implant and remote-controlled WBANs. The wearable WBAN is used in scenarios like monitoring the sleeping disorder, monitoring sport training, etc. Medical field functions like diabetic monitoring, cardio function monitoring, etc. can be fulfilled by wearable WBANs and these types of sensor devices are either implanted in a patient's body or transmitted in the bloodstream (Malan et al. 2004; Otto et al. 2005; Hanson et al. 2009). The remote-controlled WBANs are used for exchange of the patient medical information from one place to another for assisting back-end medical network. This will enable the speedy exchange of medical data on a particular patient from one to another to give speedy treatment.

The sensor nodes in the WBAN can be classified into three types based on their nature of work in the network, namely, coordinator, end nodes, and relay nodes. The communication between the two or more sensor nodes and the communication with other outside networks are coordinated and monitored by the coordinator nodes. Upon monitoring and controlling the sensor nodes,

the coordinator receives or collects medical information from them. Later the collected information is transferred to medical care center or central server for further processing. In general the coordinator could be a personal digital assistant and they may transmit necessary information and notifications to users directly. Due to various limitations like small size, short transmission range, and less battery power, the end nodes are limited to collecting and transferring the sensing data to the nearby coordinator or the relay nodes. The end nodes and relay nodes are normally small-sized sensor devices that consist of sensing unit, power unit, communication, storage, and processing units. Sometimes the relay nodes can act as coordinator node when the actual coordinator is far away from the end nodes. In few cases, the WBAN may have special node called actuator. These nodes are meant for performing some small specific task when they are receiving the signals from the on-patient end nodes (Gyselinckx et al. 2007; Golmie et al. 2005).

18.1.2 Architectures of Wireless Body Area Network

In general, the healthcare monitoring system based on WBANs has been broadly composed of the following three-tier communication:

- Tier 1: Intra-WBAN communication
- Tier 2: Inter-WBAN communication
- Tier 3: Beyond-WBAN communication

Figure 18.1 gives an illustration on the working process of these three components.

18.1.2.1 Tier 1: Intra-WBAN Communication

In the intra-WBAN communication level, the communication between the sensor nodes and the coordinator nodes is considered. This level also includes the communication among the sensor end nodes. Here, the data transmission is limited to 2 m around the human body. Basically the star topology is utilized in the WBAN environment due to the limited size of the network. This also leads to crucial design of WBAN design. However, due to limited transmission range and irregular human body movement, the WBAN has great challenges to attain reliable communication. In WBAN, though the multi-hop communication causes higher transmission delays, at the same time it consumes lower power for transmissions (Cavalcanti et al. 2007).

18.1.2.2 Tier 2: Inter-WBAN Communication

This layer aims to connect the WBAN to broader network to improve or enhance the availability of the WBAN by connecting with the Internet and mobile networks. The entry point to the any mobile network is an access point (AP). Hence, WBAN's coordinator nodes establish a direct connection to these

Principal
Malla Reddy Engineering College
Maisammaguda, Dhulapally,
(Post Via Kompally), Sec'bad-500100

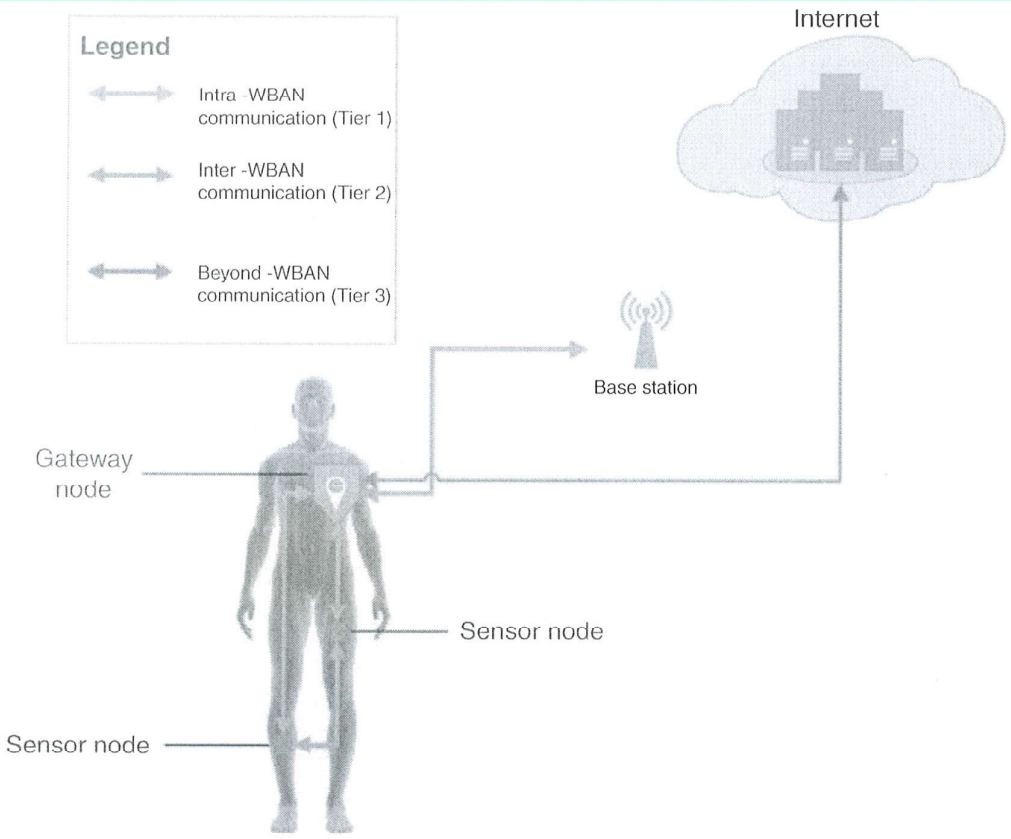

Figure 18.1 WBAN-based healthcare monitoring architecture.

APs, which will enable inter-WBAN communication in a limited space, for example, some conference room in a hospital (Figure 18.2).

18.1.2.3 Tier 3: Beyond-WBAN Communication

The major advantage of the WBAN system is to enable the doctors to perform remote diagnosis and give the formal instructions for treating the patient by the doctors in site. This could be achieved by establishing the communication medium between the AP and the outside work with the help of Internet resources. This kind of environment for the doctors as well as the patient for accessing the treatment database remotely allows the patients to get the automatic notifications about the series of treatments and follow-up of the given treatment (Figure 18.3).

18.1.3 Challenges Faced in System Design

In WBAN, reliability is most concern among anything since the treatments are given based on the values received by the communication. The following

Principal

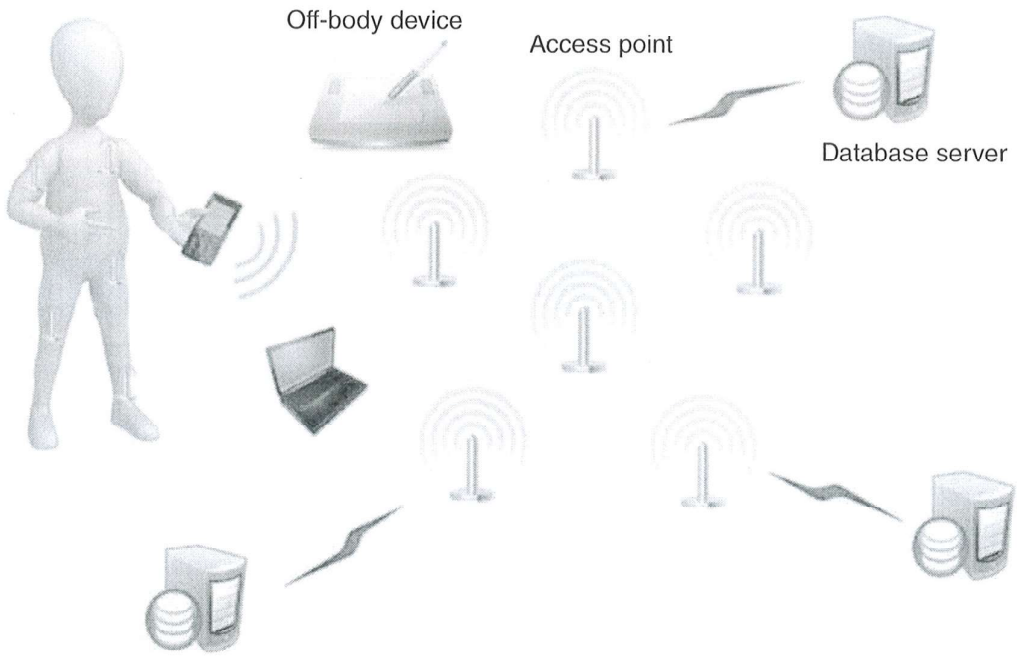

Figure 18.3 Inter-WBAN communication: ad hoc-based architecture.

Principal
Malla Reddy Engineering College
Maisammaguda, Dhulapally,
Secunderabad-500100

are some of the most concerned challenges that need to be addressed in the WBANs (Ullah et al. 2008; Lo and Yang 2005; Ye et al. 2004).

18.1.3.1 Energy Constraint

Unlike wireless sensor networks, the WBANs are needed to be more energy-efficient. This is because the WBAN sensor nodes are likely to be implanted on or inside the human body. Large-sized sensors on or inside the human body will strongly persuade patient's day to day life activities and, hence, should not be larger in size than the WSN nodes.

On the other hand, by aiming the reduction in the size, it should not reduce the lifetime of the sensor devices. Because the nodes heavily depend on the energy of the batteries, these tiny sensors are expected to work for long durations, since replacement or charging is not an easy one. Hence, the transmission will be an effective one and might result in less consumption of energy.

18.1.3.2 Interference in Communication

All on-body and in-body sensor nodes in the human body could be controlled by the centralized coordinator node. This strategy will be the effective one unless there is a movement of the sensor node. For example, consider a case where there are number of patient coming together by wearing number of sensor nodes on them. In this case, the strategy designed for maintaining the coordination among the sensor nodes to their respective coordinator node may fail. This will lead to collision on data transmission to the coordinators. Hence, it is mandatory to have a good network design such that to have effective interference mitigation system to handle the topology changes in a very fast manner.

18.1.3.3 Security

The WBAN handles the personal and private data of the individual patient, that should not be known to anyone. Hence, the primary objective of WBAN system is to maintain such a private data with the highest security. The valuable patient's data stored and handled in the data center cannot be accessed by the public and it should be made available to the doctors irrespective of denial of service (DoS) attacks. Any attack to the data center of WBAN will lead to severe damage and worst results. However, it is very difficult to implement an encryption key mechanism in body area network since it has more limitations on battery, processing capability, storage, and transmission power.

18.1.4 Research Problems

Considering the various challenges in WBANs, this chapter aims to achieve reliable and energy-constrained communication among the sensor nodes and

Principal
Malla Reddy Engineering College
Maisammaguda, Dhulapally,
(Post Via Kompally), Sec'bad-500100

among the coordinator nodes. This chapter also considers some important aspects of network design such as scheduling scheme, fixing the transmission power to the nodes, usage of relay nodes, and number of sensor nodes for any coordinator.

The static scheduling schemes do the scheduling without considering the variation in the wireless channel on the MAC layer. Generally this kind of scheduling produces poor performances due to not avoiding bad channels completely and not demoralizing all good channels. In this chapter, we focus the effectiveness of opportunistic scheduling in less overhead WBAN environment, in which the current status of the wireless channel is considered to adjust the scheduling of the transmission and super-frame length. Also an outage rate is significantly reduced by effective scheduling in the data transmission, and it is illustrated in the following simulation study.

18.2 Proposed Opportunistic Scheduling

18.2.1 Introduction

This simulation study addresses the problem currently faced by the WBAN with fixed scheduling, which failed to react to the channel fluctuations: an opportunistic scheduling approach is proposed and executed. This scheduling utilizes a two-state Markov model and beacon-based time division multiple access (TDMA). Here, the two-state Markov models are used to count the state transition samples, which will be useful when estimating the probability distribution and channel dynamics in which the fixed scheduling failed. We use ρ as a factor to discounting by considering the highly dynamic characteristics of network for coordinating the coordinator nodes. From the studies in the literature, it is shown that the Markov model delivers much better estimations on state values since this method produces more perfect transition probability values for modeling the wireless channel (Patel et al. 2012).

We also propose and prove that the heuristic scheduling method is performing comparatively good and optimal under some insignificant assumptions. Based on the literature study and observation, we further extend the proposed method to dynamic adjustment in length of the super frame according to the status of the channel.

The designed system follows the principle based on super-frame length. Within the super-frame range, the dynamic scheduling does not have much control on it when the length of the frame is small. On the other hand, the current condition of the channel is unreliable or the frame length could not be large.

The simulation results show that the proposed dynamic heuristic scheduling with super-frame adjustment methods results in better performance than

the fixed scheduling and any other opportunistic scheduling approaches considered in the study. In particular, the dynamic scheduling avoids at least 8% of outage when compared with static or fixed scheduling. Also the dynamic heuristic frame length adjustment scheme gains 25% more of the overall system's throughput when compared with the flipping method and 30% than the random method.

18.2.2 System Model and Problem Formulation

18.2.2.1 System Model

This proposed system model adopts star topology with one-hop routing. It is due to the scenario that is considered here in health monitoring environment, where the communication of signals between the sensor nodes and the coordinator node is more frequent. Hence, one-hop communication between the sensor nodes and the coordinator node may result in better throughput. It is recommended to use beacon-enabled TDMA mode of process by IEEE 201.15.4 for WBANs, since the coordinator nodes are mobile devices. At the beginning of every super frame, the beacon frame is broadcasted to all the coordinator nodes in the network for resource allocation and synchronization among the coordinator nodes. Because of this super frame, synchronized process in every node will be activated in the allocated time slots and can go for transmission (Darkins et al. 2008; Akkaya et al. 2005).

Each time slot is defined by two channel states and they are named as good and bad state; also they are represented by 1 and 0, respectively. Based on the literature studies, the Gilbert model is chosen since it is very effective on dynamic behavior of on-body sensor network environment and also the probing of the wireless channel is not feasible. The current status of the coordinator node is monitored only during the node's transmission of signals to the coordinator. On the other hand, during the idle time slots, the system uses the state belief information instead of current channel status to calculate the current status or condition of the channel. For the node i, the state transition matrix at super-frame time slot $P^i(K)$ is represented as follows:

$$P^i(K) == \begin{pmatrix} P^i_{00}(k) & p^i_{01}(k) \\ P^i_{10}(k) & p^i_{11}(k) \end{pmatrix} \tag{18.1}$$

At this state of transition for the ith node, the initial state belief is represented as

$$\begin{bmatrix} P^i_0(k) \\ P^i_1(k) \end{bmatrix} \tag{18.2}$$

Hence, the state belief of the ith node at super-frame time slot n can be premeditated as

$$\begin{bmatrix} P^i_0(n) \\ P^i_1(n) \end{bmatrix}^T = \begin{bmatrix} P^i_0(0) \\ P^i_1(0) \end{bmatrix}^T \prod_{k=1}^{n} \begin{pmatrix} P^i_{00}(k) & P^i_{01}(k) \\ P^i_{10}(k) & P^i_{11}(k) \end{pmatrix} \tag{18.3}$$

Principal
Malla Reddy Engineering College
Maisammaguda, Dhulapally,
(Post Via Kompally), Sec'bad-500100

where

$P_0^i(0)$ – Probability value of channel to be a bad channel.

$P_1^i(0)$ – Probability value to have good channel during the transition.

18.2.2.2 Problem Formulation

By considering the objective as maximizing the successful attempts in a number of packet transmissions from the sensor nodes to the coordinator for attaining higher throughput in the systems, assume that the quality belief of the channel is represented by $h_i^r(\tau)$, which represents the probability values for the ith sensor node to have a good channel at time slot τ in round r. Thus the problem is expressed as follows:

$$\text{Maximize} \sum_{1\le i\le M, 1\le \tau\le T, 1\le r<\alpha} h_i^r(\tau) L_i^r(\tau) \tag{18.4}$$

$$\text{Subject to } \sum_{1\le i\le M} L_i^r(\tau) \le 1$$
$$\sum_{1\le \tau\le T} L_i^r(\tau) \le x_i$$

where

$L_i^r(\tau)$: Scheduling of the node i at slot τ in round r.

x_i: Number of packets to be transmitted by the node i in one round.

M : Number of nodes.

T : Number of slots in a round.

As mentioned previously, the calculation of $h_i^r(\tau)$ is done in each round in an independent manner. These independent local solutions in the attempt of increasing the network throughput by maximizing the successful transmissions at individual rounds will make up the optimal global solution.

18.2.3 Heuristic Scheduling

Based on the study, a greedy method that has low complexity than the other methods is considered to guarantee the tolerable complexity during the scheduling. To accomplish this during the scheduling, the sensor nodes are formed as two different groups. On the one hand, one group will contain the set of sensor nodes whose transmission was successful during the last round. However, on the other hand, the other group combine the set of sensor nodes whose transmission failed or was unsuccessful during the last round (Otto et al. 2006). When a sensor node goes for forwarding more than one packet, then the node's last transmission of packet in that specific round is considered to find which group the node belongs. However, the successful node's transmission must be scheduled before the failed node's transmission. Due to this advantage, a node with the good channel will have the advantage to access the channel before it becomes worse; at the same time the nodes with the bad channel may have sufficient time to recover from the failed state to success state to have good channel.

Principal
Malla Reddy Engineering College
Maisammaguda, Dhulapally,
(Post Via Kompally), Sec'bad-500100

In addition, by using the success rates of the transmission and transition matrix estimation values during the last round, we can calculate state belief in any random time slot of the considered current round. By the same way, the future time slot for the future round also can be estimated. Based on the literature study, almost all the WBAN has the coherence time of 400 ms and it is longer than the length of the super-frame, which is considered in this system design. Hence, the estimated channel belief will be reliable.

The calculation of P_1^i to approximate h_i^r is in the objective function, where the last communication in the previous round is the early state belief of P_1^i. It is proved that P_1^i progress as an exponential function. Here, we skip the round number r and use ϵi to symbolize the probability value of transiting to good channel from bad channel $P_{01}^i(r)$ and δi is considered to represent the probability value of transiting to bad channel from good channel $P_{10}^i(r)$. This is taken by the basis of dynamic channel properties during the scheduling.

The calculation of channel state belief to have good channel at given time t can be represented in the following formula;

$$P_1^i(t) = \begin{cases} \left[1 + \dfrac{\delta_i}{\varepsilon_i}(1-\varepsilon_i-\delta_i)^t\right]\dfrac{\varepsilon_i}{\varepsilon_i+\delta_i}, & \text{Successful node} \\ [1+(1-\varepsilon_i-\delta_i)^t]\dfrac{\varepsilon_i}{\varepsilon_i+\delta_i}, & \text{Failed node} \end{cases} \tag{18.5}$$

where t is the number of time slots away from the initial state, which is the result of the previous transmission.

Here we considered that fluctuation range of the current channel belief could be the heuristic function. In specific, to all successive sensor nodes, we are determining the difference of channel belief of each node between the start and end of the round for all successful node's transmission. Let us assume N_i is a cumulative number of time slots that happened between previous transmission of ith node and commencement of the next round. Also assume every successful transmission is assigned with N_{Good} number of time slots.

Hence, the utility function for successive nodes is calculated as per the given formula (18.6):

$$U_i = P_1^i(N_i) - P_1^i(N_i + N_{\text{good}}) \tag{18.6}$$

Figure 18.4 shows the design of scheduling the node at front that has the larger utility function. Let us assume five sensor nodes, in that one among five nodes failed while transmitting the packet.

Similarly, the failed node's utility function is calculated as per the given formula (18.7):

$$U_i = P_1^i(N_i + T - N_{\text{bad}}) - P_1^i(N_i + T) \tag{18.7}$$

where N_{bad} represents the failed node's time slot and T is the total number of time slots in a single round.

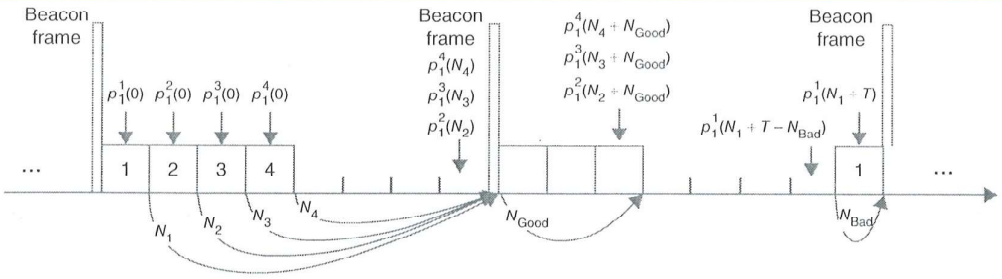

Figure 18.4 Illustration of utility function calculation.

Algorithm 1: Heuristic scheduling

Initialize: $r = 1$, $W^i_{s1,s2}(r) = \theta$, random schedule for 1st round.
While r $\geq$ 1 *do*
Transmission as per the schedule;
for $i = 1,2;$ .....,M do
if S_1 is observed at one slot and S_2 at the next then

$$W^i_{s1,s2}(\mathrm{r}) = W^i_{s1,s2}(\mathrm{r}) + 1;$$

end if
End for
for $i = 1,2,....,\mathrm{M}$ do

$$P^i_{s1,s2}(r) = \frac{W^i_{s1,s2}(r)}{\sum_s W^i_{s1,s2}(r)}$$

End for
To schedule successive nodes at front and failed nodes at last;
Calculate Utility function U_i and sort each group in decreasing order;
$r = r+1;$
End while

This utility function works in such a way that the scheduling process must be fast enough to schedule the node, which has the successive transmission in the previous round, which depreciates fast. Also the scheduling must be completed as early as possible so that the successive node can complete the transmission before the transmission channel becomes bad. Similarly, when a channel state improves from bad state to good state for a node, previous transmission failed. Then this node should be scheduled as soon as possible in its own group. The below pseudo code shows this approach in Algorithm 1.

(Post Via Kompally), Sec'bad-500100

The complexity of the proposed dynamic scheduling approach is represented as $O(M \times N_p + M \log M)$ by assuming that at every round of packet transmission, each sensor node transmits an average of N_p packets. However, this complexity is insignificant for the coordinator nodes whose load is low and has limited number of sensor nodes. In practical, the mere requirement of sharing the same $\varepsilon + \delta$ value by all sensor nodes is true and the proposed dynamic heuristic approach achieved this.

18.2.4 Dynamic Super-Frame Length Adjustment

Based on the literature study, the effectiveness of time slot scheduling within some assured round is relatively limited due to an improper length of the super frame. The reason behind this is that the channel property does not change too much in certain rounds where the length of the super frame is short. In this scenario the process of time slot scheduling will become unimportant. On the other hand, the state belief of a channel converges to steady state and hardly has any details for scheduling when the system has lengthy super frame. Moreover, the length of the super frame changes dynamically when the objective gesture changes (Venkatasubramanian et al. 2005).

Hence, we propose a dynamic Super-Frame length adjustment approach based on temporal difference (TD) error. By this approach, the performance of the proposed dynamic system improves further.

18.2.4.1 Problem Formulation

In the processes of determining the length of the super frame, the coordinator node will act as an agent and it is responsible to make decisions based on "states" and "rewards." The terms states, rewards, and action are defined as follows:

1) *State:* Packet delivery rate (PDR) at the last round.
2) *Action:* Determining length of the super frame T and choosing a packet by its number to deliver in x_ith round.
3) Reward: Reward (rw) = (1 − PDR) + PDR at state.

During the dynamic computation and adjustment of the super frame while data is being transmitted, to maintain the constant rate of data, the length will be calculated by multiple of minutes length T_0. And the total number of packets to be transmitted x_i will be dynamically calculated and adjusted proportionally to T. We use the function $Q(s, a)$, which represents value of performing action a in state s. In every state the approach chooses the action with the highest Q value. The following equation shows the dynamic calculation of action value function:

$$Q(s,a) = \sum_{s'} P(s'|s,a)[rw(s,a,s') + \gamma^{\max}_{a'} Q(s',a')] \tag{18.8}$$

Malla Reddy Engg. College * Hyderabad * 500 100

Principal
Malla Reddy Engineering College
Maisammaguda, Dhulapally,
(Post Via Kompally), Sec'bad-500100

Algorithm 2: Dynamic super frame length adjustment

Initialize Q(s,a) at random, default length of super frame: T_0, default packet no.: x_{i0} in single super frame, r = 1;
while r $\geq$ 1, do
Step 1 : decide action as per Q(s,a) values being ε-greedy. T=a X T_0, x_i=a X x_{i0};
Step 2 : do heuristic forecast and send out with length T and packet no x_i;
Step 3 : scrutinize transmission result and calculate *rw* and the new state s';
Step 4 : revise $Q(s, a)$ belief using
$Q(s,a) \leftarrow Q(s,a) + \alpha[rw + \gamma^{\max}_{a'} Q(s',a') - Q(s,a)]$
Step 5 : s $\leftarrow$ s', $r - r + 1$.
end while

Here we use Q learning method to calculate the Q value in action value function. This is because of considering the difficulties on obtaining the value of transition probability.

$$Q(s,a) \leftarrow Q(s,a) + \alpha[rw + \gamma^{\max}_{a'} Q(s',a') - Q(s,a)] \tag{18.9}$$

Algorithm 2 gives the pseudo code for this above approach.

18.3 Performance Analysis Environment and Metrics

The experiment is conducted by using five sensor nodes and one coordinator node on human body. The time slot is fixed as 5 ms. The number of packets transmitted by every sensor node is assumed as identical (Vijendra 2011). The channel samples are used as datasets. For any subject, five channels are allocated as gain channels. This experiment collects the data from the five sensor nodes that are placed in different locations on the body of an adult object. When the gain at the channel is less than the fixed outage threshold value, outage is starting to occur and results in failed transmission. The final value of the result is arrived by averaging the considered all eight datasets. In the comparison study two other scheduling schemes are also considered to assess the performance of the proposed dynamic scheduling. The first one is random scheduling method, in which the sensor nodes are grouped into successive group and failed group. The second method is flipping method. Here, the performance of the fixed scheduling method is considered as baseline to evaluate the performance of the proposed dynamic scheme. The experiment and the simulations are performed on MATLAB environment.

18.3.1 Heuristic Scheduling with Fixed Super-Frame Length

This section presents the performance of heuristic scheduling over fixed and flipping approaches. Figure 18.5 shows the impact of the number of delivered packets for each sensor nodes in each round of transmission. In this evaluation all the nodes are allowed to have 80 rounds of transmission of packets in order to have a wide range of results with respect to packet delivery ratio. So this simulation will take 400 ms long, which is close to on-body channel's coherence value. The results show that the design of placing the successive nodes at the front and the failed nodes at the last in every individual round gains better packet delivery ratio when compared with fixed scheduling at the outage value of 80 dB. This also shows that the heuristic scheduling approach results with better value than the flipping method.

Figure 18.6 shows the performance of different length of super frames with respect to outage rate reduction. When the length is 20 slots, each sensor node is allowed to transmit two packets. Further, the number of packets to be transmitted increases proportionally, and the length is maintained as constant rate. The figure reveals that the proposed scheduling scheme performs better than the other two considered approaches. The curve presented in the figure has the consistency throughout the simulation. It depicts that a medium length of the super frame has a good balance between the accuracy level of estimated channel state and scheduling outcomes.

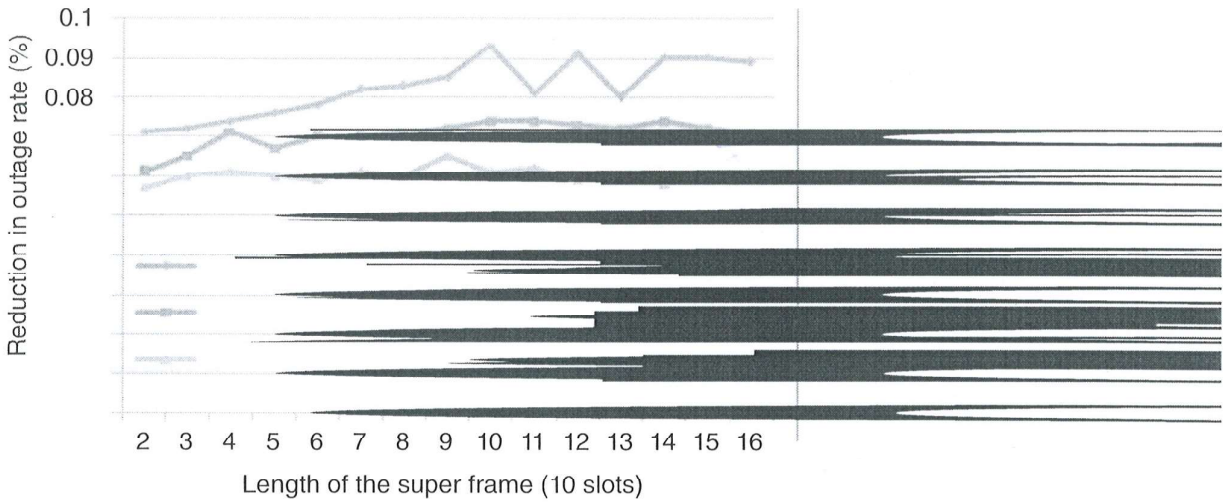

Figure 18.6 Effects of the length of the super frame.

18.3.2 Heuristic Scheduling with Dynamic Super-Frame Length

In this section, we discuss the performance and its comparison of dynamic adjustment of length of the super-frame approach with the proposed heuristic scheduling method. As per the literature study it is observed that the length of the super frame should not be growing large in unreasonable manner. This will effect in worst performance of channel belief estimation of unreliable channel. So it is necessary to restrict the growing of super frame unnecessarily. To achieve this, here we set T_0 as default initial value, which is more over equal value adopted in other models. Figure 18.7 shows the performance of proposed dynamic method. The number of packets to be transmitted per round is fixed in a range of 2–7 for the other fixed length methods. The dynamic method is fixed with the initial value of $X_{i0.}$ The figure depicts that the proposed heuristic scheduling and the variable length schemes are showing better performance than any other static methods.

18.4 Summary

The communication between the coordinator and sensor nodes in WBAN are crucial part to improve the performance of the network. The dynamic and heuristic super-frame length adjustment methods are introduced for measuring and controlling the super-frame length to improve the performance in packet transmissions between the sensor nodes and the coordinator nodes. The heuristic scheme is used to estimate the length of the super frame to regulate the packet transmission, which is based on the utility function. The dynamic adjustment method is also used to estimate the length of the super

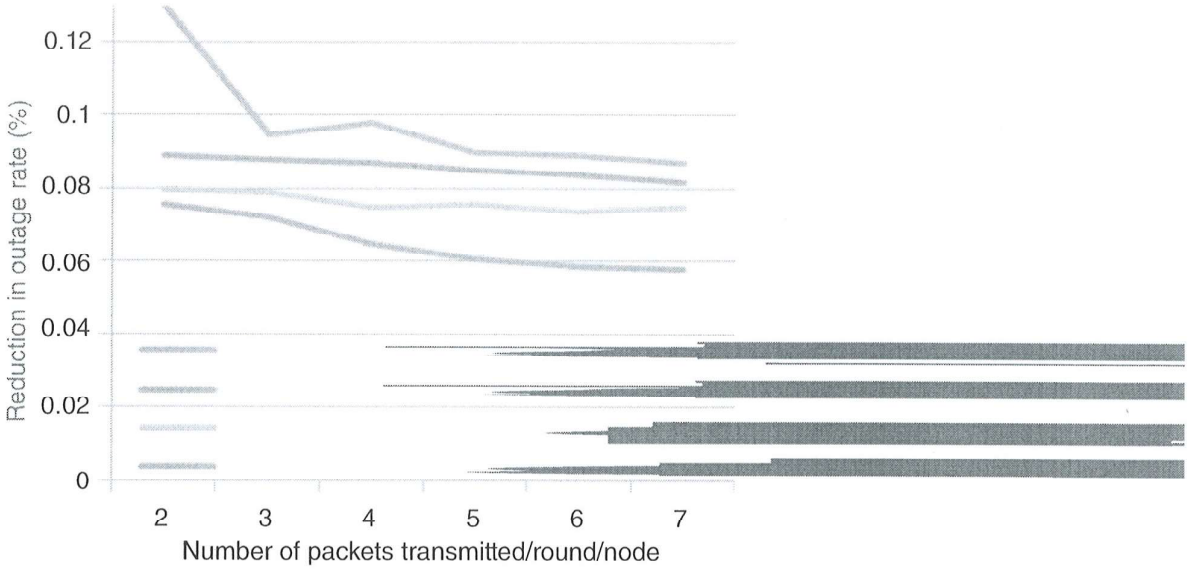

Figure 18.7 Effects of the number of packets in dynamic length.

frame and to improve the efficiency in the packet transmission rate. The performances of the above approaches are compared against two other static methods, namely, flipping and random methods. The simulation results are showing that the heuristic and dynamic frame length adjustment methods are performing better against the static methods in all the considered conditions.

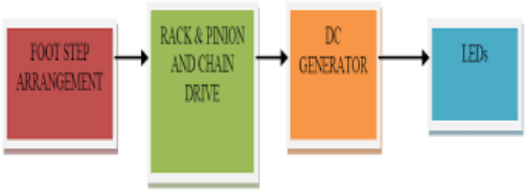
ABSTRACT:

In this project we are generating electrical power as non-conventional method by simply walking or running on the foot step by using rack pinion methods. Non-conventional energy system is very essential at this time to our nation. Non-conventional energy using foot step is converting mechanical energy into the electrical energy. This project using simple drive mechanism such as rack and pinion assemble and chain drive mechanism.For this project the conversion of the force energy in to electrical energy. The control mechanism carries the rack & pinion, D.C generator, battery and inverter control. We have discussed the various applications and further extension also. The D.C generator used in this project is Permanente Magnet D.C generator. The Generator is coupled to the fly wheel Shaft with the help of Spur Gear Mechanism.

Keywords: Footstep, Conventional Energy,Non-conventional Energy system.

1.INTRODUCTION

In this project the weight which acts on the foot step is used to generate electrical energy. When a person walks over the foot step, a force acts on the step. One can simply be amazed by knowing how much energy a person can have just by walking on the floor with normal speed. Whenever a person walks, manages to lose energy towards the floor by means excess weight to the floor. That energy may be used and converted into electrical energy. The Mechanical energy(weight)is converted into electrical energy using drive mechanism, in this case rack and pinion. Generated energy can be stored in batteries. Then the output of the battery is used to lighten the lamps in the room.



2. PROBLEM STATEMENT

Design and fabrication the model of foot step power generation. Also to fabricate the model of the same which would able to show the characteristics of the systems and working according to need.

3. OBJECTIVES

To design and develop the model of Stair case power generation. o fabricate the model which will work on the systems for required application

4. METHODOLOGY

5. LITERATURE REVIEW

[1] "PowerGeneration in Automobile Suspension System" by C.NithiyeshKumar,K.Gowtham, M.Manikandan, P.Bharathkanna, T.Manoj Kumar In this research paper author studied three methods of foot step power generation namely piezoelectric method, rack and pinion method and fuel piston method comparatively and found that the rack and pinion mechanism is more efficient with moderate cost of operation and maintenance

2] "Generation of Electrical Energy from Foot Step Using Rack and Pinion Mechanism" by Md.Azhar, ZitenderRajpurohit, Abdul Saif, NallaAbhinay, P.Sai Chandu In this research paper authors used regulated 5V power, 500mA power supply. Bridge type full wave rectifier is used to rectify the ac output of secondary of 230/12V step down transformer. A rack and pinion is a type of linear actuator including a pair of gears which convert rotational motion into linear motion. The "pinion" engages teeth on the rack. In this paper, since the power generation using foot step get its energy requirements from Non-renewable source of energy. There is no need of power from external sources (mains) and there is less pollution in this source of energy. It is very useful to the places like all roads and as well as all kind of foot step which is used to generate the non-conventional energy like electricity.

[3] "Electrical Power Generation Using Foot Step for Urban Area Energy Applications" by Joydev Ghosh, Amit Saha, Samir Basak, Supratim Sen. In this research paper authors used 80 volts and 40 mA from one coil have been generated from a prototype model as first invention. The second invention provides 95 volts and 50 mA from one coil and this generated power can be used to light LED array and to run DC fan after rectifying the AC or can charge batteries. For high efficiency in the axel of the second gear, they fitted a strong magnet vertically, so that when the gear will rotate due to human body weight the magnet also rotate. The magnet is placed in a loop type copper coil. When the magnet start rotating according to the Faraday's law of electromagnetic induction, there will be induced emf in the coil.

[4] "Power generation through step" by Vipin Kumar Yadav1, Vivek Kumar Yadav1, Rajat Kumar1, Ajay Yadav In these research paper authors used equipments with following specification: Motor Voltage:10 volt Type: D.C. Generator, RPM:1000 rpm, Gear 1-Mild Steel,No. of teeth:59(big gear),No. of teeth:36(small gear),Type: Spur Gear, No. of gear used:2 Spring 1-Load bearing capacity:60-90 kg, Mild Steel,Total displacement:5 inch, Bearing 1- Type: Ball bearing, Bearing no.N35,Shaft 1-Diameter: 15 mm- Material: Mild steel author concluded

that with these method energy conversion is simple efficient and pollution free.

[5] “Power Generation Footstep” by Shiraz Afzal, Farrukh hafeez This paper is all about generating electricity when people walk on the Floor if we are able to design a power generating floor that can produce 100W on just 12 steps, then for 120 steps we can produce 1000 Watt and if weinstall such type of 100 floors with this system then it can produce 1MegaWattAs a fact only 11% of renewable energy contributes to our primary energy. If this project is deployed, then not only we can overcome the energy crises problem but this also contributes to create a healthy global environmental change. In this project a gear system is attached with flywheel which causes to rotate the dynamo as the tile on the deck is pressed The power that is created is saved in the batteries in addition we will be able to monitor and control the amount of electricity generated When an individual passes it push the tile on the ground surface which turn the shaft beneath the tile, turn is limited by clutch bearing which is underpinned by holders. Primary shaft is rotate approx. twice by a single tile push. The movement of the prevailing shaft turn the gearbox shaft which builds it 15 times (1:15) then its movement is smoothen by the help of fly wheel which temporary store the movement, which is convey to the DC generator (it generates 12V 40 amp at 1000 rpm).

[6] “POWER GENERATION FROM STEPS” by Ramesh Raja R, Sherin Mathew This research paper attempts to show how energy can be tapped and used at a commonly used floor steps. The usage of steps in every building is increasing day by day, since even every small building has some floors. A large amount of energy is wasted when we are stepping on the floors by the dissipation of heat and friction, every time a man steps up using stairs. There is great possibility of tapping this energy and generating power by making every staircase as a power generation unit. The generated power can be stored by batteries, and it will be used for slighting the building.

[7] "Electricity Generation from Footsteps; A Regenerative Energy Resource” by Tom Jose V*, BinoyBoban*, Sijo M T* In these research paper author manufactured a model made from stainless steel, recycled car tires and recycled aluminium, also includes a lamp embedded in the pavement that lights up every time a step is converted into energy (using only 5 percent of the generated energy). The average square of pavement produces about 2.1 watts of electricity. And according to author, any one square of pavement in a high-foot traffic area can see 50,000 steps a day. Based on this data, only five units of Pavegen pavement can be enough to keep the lights on at a bus stop all night.

6. WORKING

The complete diagram of the power generation using foot step is given below. The pushing power is converted into electrical energy by proper driving arrangement. The rack & pinion, spring arrangement is fixed at the upper plate and lower plate. The spring is used to return the plate in same position by releasing the load. The gear wheel is coupled

to the smaller motor shaft. The generator is used here, is permanent magnet D.C generator. This arrangement is fitted in FOOT STEPs; the complete arrangement is kept inside the floor level except the pushing arrangement. Basic Components: It consists of the following main parts:

1. MS plate
2. MS Pipes
3. Rack and pinion
4. DC motor
5. FRAME
6. LED lights Etc

7. ADVANTAGES

1. Power is generated simply by walking on the step.
2. Power also generated by running or exercising on the step and implementing this mechanism on treadmills.
3. No need input fuel for power generation.
4. This is a Non-conventional system.
5. Battery is used to store the generated power else we can use directly this generated power for conventional purposes.

8. DISADVANTAGES

1. High Initial Cost

9. APPLICATIONS

1. This can be implemented on railway stations, bus stops, air ports to generate electric power by human physical activity.
2. Also can be implemented in parking lots, electric escalators.
3. This mechanism can be implemented on gymming instruments like cardio machine for power generation and the power generation rate is high.
4. We can use this mechanism in automobile suspension system.
5. In rural areas etc.High Initial Cost

10. CONCLUSION

In concluding the words of our project, since the power generation using foot step gets its energy requirements from the non-renewable sources of energy. There is no need of power from the mains and there is less pollution in this source of energy. It is very useful to the places like all roads and as well as all kind of stair case which is used to generate the nonconventional energy like electricity. It is able to extend this project by using same arrangement and construct in the footsteps/speed breakers so as to increase the rate of power production rate.

ABSTRACT

In this paper, a gear shifting mechanism was designed and applied to make the shifting process more expeditious and less destructible for the driver. The incipient contrivance must be reliable, has a diminutive dimensions, low construction and maintenance cost. This paper aims to gear shifting process utilizing contrivances as: a manual four speed gear box, two pneumatic double acting cylinders, , an electrical motor , limit switches, buttons, , a table (holder) and power supply. According to suggested gear shifting mechanism the control unit select optimum gear shifting ratio for an automobile without operating it manually (utilizing relays). Utilizing this method leaves to the driver the exhilaration of selecting the shifting moment.

Key Words: pneumatic cylinders, Solenoid valves, gear box, gear shifting mechanism, electric motor.

INTRODUCTION

In this project, a gear shifting mechanism is designed and applied to make the shifting process more expeditious and less destructible for the driver. The incipient contrivance must be reliable, with minute dimensions, low construction and maintenance cost. This project aims to ameliorate gear shifting process utilizing contrivances as: a manual four speed gear box, two pneumatic double acting cylinders, two pneumatic two position five ways directional control valves, , an electrical motor, a belt, two pulleys, limit switches, push buttons, bulbs, a table (holder) and power supply. According to suggested gear shifting mechanism the driver can cull the transmission gear ratio without moving his hands from the steering wheel by putting the gear shifting push buttons on the steering wheel. Utilizing this method leaves to the driver the exhilaration of culling the shifting moment. This study describes in detail in an simple way to how to convert the traditional manually gear shifting mechanism to a semi-automated gear shifting mechanism. The development has concluded withal the gearbox, which became much smoother and engenders less noise. Gear shifting mechanism must be facile to utilize and workable, these authoritative ordinances are very paramount especially for minute cars utilized by special needs people. For some drivers, the gear shifting can cause some perplexing at driving specially at critical situations. A crowded road

on a hill or a sudden detour makes an abundance of tension on the driver. One of the difficulties in this situation is to operate the right reduction ratio and engaging it at the right time. This design avails the driver to increment his fixating on the road. Withal reduces the time needed to engage the required. Reduction ratio, which increases the conveyances replication, this design may be considered as an inculcative model for gear shifting mechanism. So, we pointed to the following: 1. The opportune dimensions for the main components holder keeping in mind the integration of other part for enhancement and development. 2. A manual, 4-frontal speed gear box is utilized automobile drive is culled for this design because it is more facile to modify. 3. An electrical motor is utilized to engender mechanical power in lieu of an internal combustion engine, which is arduous to be placed there. It is additionally used to make the engagement process more facile .Motor is variable speed (0 to 9000 rpm) 4. A couple of pulleys and a belt are acclimated to transmit power from the electrical motor to the gear box. 5. To eschew binding in the input shaft caused by the radial force, we utilized a bearing fine-tuned on the holder. 6. We used two pneumatic, double acting cylinders, per pair of gear shifting. 7. Two (five ways, two positions) directional control valves are habituated to transmute the compressed air direction. Every directional valve has 230V ac solenoid that converts electrical power to magnetic puissance, which magnetizes the spool inside the valve; this action transmutes the compressed air direction.

2. OBJECTIVE

The main objective of this system is to minimize the human errors in operating the gears with the avail of automatic technology. Other objectives include optimum gear ratios, reducing wear and tear of the gears, shifting the gear efficaciously, optimum performance of the gear box, optimum force exerted by the cylinders to move the shifting levers (pedals).

3. MODEL COMPONENTS

3.1 Base Frame

The base frame is a structural element that fortifies the entire gear box system. The frame carries the drive system at its lower end which comprises of the LH and RH rear bearing housings. The drive motor is mounted on the base frame.

3.2 Drive system

Drive system comprises of the single phase AC commutator motor with following designations

• Single phase AC moto

r • Commutator motor

• Power = 1/15hp=50 watt

• Speed= 0-6000 rpm (variable)

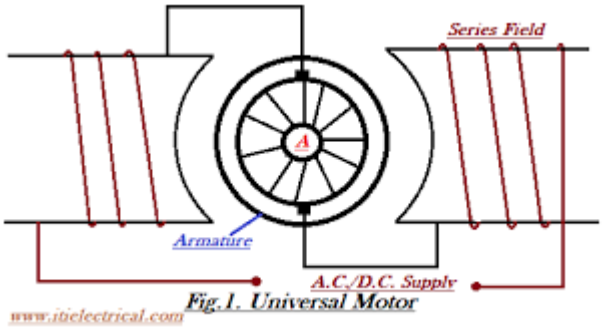

Fig -1: AC commutator Motor

3.3 Pneumatic linear actuator

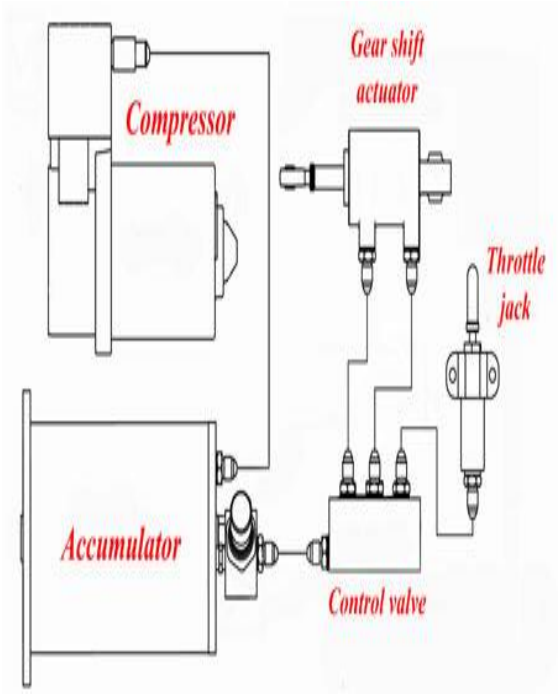
The pneumatic linear actuator is an Standard cylinder SDA 20 x 15.This cylinder is an double acting cylinder that is operated by an pneumatic valve5/2 way. The valve is supplied compressed air from the compressor by denotes of an a AGB operates filter-regulator-lubricator (FRL) unit. This linear actuator is utilized in the following positions, a. 1st gear b. 2nd gear c. 3rd gear d. 4th gear

3.4 Shifter mechanism

The shifter mechanism is an assemblage of levers actuated by the linear actuator as mentioned above. This shifter is mundanely in neutral condition; it shifts the gears at commencement of cycle and releases it at cessation of cycle

. 3.5 Position control system

The position system comprises of the following components; a. 5/2 ways, Solenoid operated, center off, and detent type b. Pneumatic cylinder DPNC connectors The details of this relay system are given in the circuit diagram of the pneumatic system



4. CONSTRUCTION DETAILS

The two solenoid valves are connected to a compressor with the avail of hoses of Ø6mm from which pressurized air is extracted. The solenoid valves are followed by two pneumatic cylinders with the avail of air hoses. The cylinders are followed by a clutch pedal. Contiguous to the clutch pedal gear box and a motor arrangement is present. The construction withal includes a proximity sensor which senses the haste of the wheel. The precise signals are sent tothe solenoid valves by the control unit through the relays. Ergo the input is speed of the wheel sensed by a sensor and the output is shifting of gearaccordingly. The puissance to the control unit is supplied from the 12V battery as well the shifting of gear monitored on an LCD. It withal consists of DC motor, ATMEGA Development board, speed regulator (expeditor), transformer etc.

5. WORKING PROCEDURE

The pneumatic circuit is as shown in fig.2,the motor is started to drive the main shaft by means of belt and pulley arrangement, initially the gear box is in neutral i.e., the output shaft is stationary condition. When the 5/2 way direction control valve -1 is operated the cylinder -1 operates the piston to move in the right hand direction thereby bringing the 3rd gear into engagement, and thus the output shaft starts to rotate thereby transmitting power from the input (motor/engine) to the output (differential). Fig -2: Electro-Pneumatic gear shifting mechanism The flow control valve in the circuit governs the pressure which is of the order of 1.5 to 2 bars, hence the governed pressure causes the gradual push provided to the piston rod which brings about gradual engagement of the gears hence, (effect of gradual clutch release for smooth engagement is not required). When the 5/2 way direction control valve -2 is operated the cylinder -2 operates towards left as the piston rod is locked for movement left , hence first the fork shifter moves towards left bringing on the neutral position and then slides further left to bring the 1st gear into engagement. Similarly the circuit works for

the 2nd and 4th gear. Note: If both the valves i.e., 5/2 way direction control valve - 1&2 are operated simultaneously, the system is arranged such that neutral position will be achieved, hence the system becomes fool proof.

6. CONCLUSION

The pneumatic gear changer was designed and checked for successful working. It was found to be running successfully under all the conditions. By the results, the suggested mechanism is realizable and workable. Using the simplest and required hardware enables to convert the old traditional gear shifting mechanism to semiautomatic one. Using of this mechanism in vehicles leads to make the driving process easier, reduces the risk of destabilizing the car, the lap/stage time, and the chance of miss shifting.

Abstract

A regulation system of one or more supports of the domes of the headlights in a vehicle having a chassis a rear wheel at least one front steering wheel and a roll and steering mechanism operatively connected with the chassis is described. The regulation system comprises articulated connection means between the roll and steering mechanism and the supports for controlling the domes of such headlights so that they rotate such to compensate the roll rotation of the vehicle while driving.

Keyword: -Rack & pinion, Head light, front wheel steering with Ackerman's principle.

INTRODUCTION

Car safety is the avoidance of automobile accidents or the minimization of harmful effects of accidents, in particular as pertaining to human life and health. Special safety features have been built into cars for years, some for the safety of car's occupants only, and some of the safety of others. One of the choices available is Design and fabrication of steering controlled head light system. This device relates to a headlight arrangement for vehicles, and, more particularly, to a head light arrangement operably connected to the steering mechanism of the vehicle for illuminating the proposed path of travel including support brackets operable to support head light members thereon connectable to a frame portion of the vehicle, linkage means interconnecting the brackets for conjoint movement thereof, and means interconnecting one of the brackets to the connector rod of the vehicle whereupon the brackets and headlight members are moved in relation to the direction of vehicle travel. Still, more specifically, this device relates to a headlight arrangement operably connected to the steering and front wheel assembly of an automobile operable to maintain headlight members and front wheels pointed in the same direction at all times.

Objectives

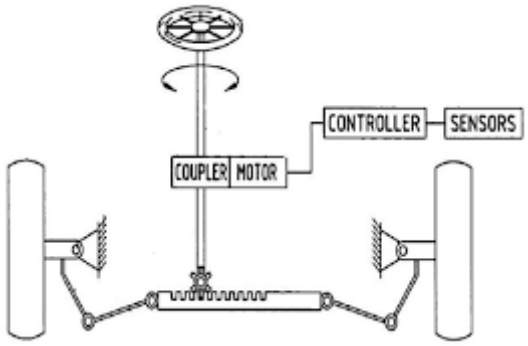
The main objective of this system is to apply automotive vehicle.

- To move the headlight along with steering on sharp turning.
- To keep the headlight beam parallel to road turning as possible as can.
- To change the place of area illuminated by headlight and direct illumination area of headlight in useful direction.
- To improve the visibility area of driver at night so that driver can judge road turning well.
- To prevent road accidents on sharp turning at night specially in hilly areas.

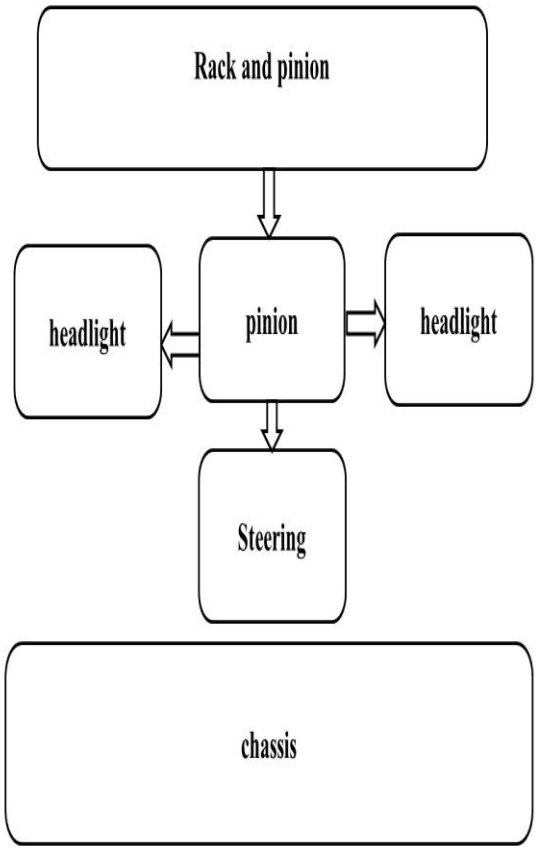
- To increase safety at night.

. **LITERATURE REVIEW**

The present invention relates to a vehicle front lamp light distribution control system and more particularly to a vehicle front lamp light distribution control system capable of raising visibility at the time of cornering by controlling light distribution means of the front lamp. According to1. Japanese Patent Publication No. H5-23216, 2. Japanese Patent Application Laid-Open No. H8-183385, 3. Japanese Patent Application Laid-Open No. H11-78675, and 4. Japanese Patent Application Laid-Open No. H8-192674 Laxmi et al. [1] Design &Fabrication of steering controlled headlights in automobile states, A vehicle head lamp including a fog lamp is provided with a movable reflector and by turning the movable reflector in the steering direction by an amount corresponding to a steering angle of the steering wheel, the light distribution pattern of the front lamp is changed in the direction of vehicle's turn so as to raise visibility at the time of cornering However, according to the aforementioned earlier art, the light distribution pattern of the front lamp is changed in the steering direction of the steering wheel by an amount corresponding to the steering angle when the vehicle turns on an intersection or the like, cornering destination cannot be beamed brightly enough before operating the steering wheel. Therefore, an t capable of beaming the cornering destination prior to operation of the steering wheel has been demanded. Czech Tetra and 1920s Ca dills were early implementer of such a technique, producing in the 1930s a vehicle with a central directional headlamp. The American 1948 Tucker Sera was likewise equipped with a third central headlamp connected mechanically to the steering system. The 1967 French Citroën DS and 1970 Citroën SM were equipped with an elaborate dynamic headlamp positioning system that adjusted positioning in response inputs from vehicle steering and suspension systems, though US regulations required this system to be deleted from those models when sold in the USA. Presently, studied changes are unfolding in automotive lighting technology. Automobile manufacturers - together with suppliers and representatives - currently aspire to develop the headlights of tomorrow. Freeform headlamp is one of the popular design which offers great flexibility and compactness. They suggested that the apparatus for automatically adjusting a direction of a light axis of a vehicle headlight includes a steering angle sensor detecting a steering angle of a steering wheel of a vehicle and a swivel control unit performing swivel control by which the direction of the light axis of the vehicle headlight is adjusted to the target direction in accordance with the steering angle detected by the steering angle sensor. Proposed automatic optical-axis adjusting device for automatically adjusting direction of optical axes of front lights with respect to steering angle of steering wheel An electronic control for automobile headlight utilizing a spherical sensor comprised of a metal ball surrounding by a fluid encapsulated in a spherical sensor which is connected to the spherical sensor system. The automatic optical



axis adjusting device for automatically adjusting direction of optical axis of from lights headlight control apparatus and method controls an irradiation direction of a headlight. This apparatus uses a navigation based swivel angle calculated based upon the shape of a road in a navigation based control period and a steering based swivel angle calculated based upon a steering angle in a steering based control period [2] The optical design, fabrication and the measurement of the freeform reflector headlamps are investigated by Shinde G. et al. [3] proposed the new standard for cornering light system allows not only the conventionally approved ONOFF control mode interlocked with the operation of the turn signal switch but also an automatic ON-OFF control according to the steering wheel angle. The active cornering light system (ACL system) on the new DELICA D: 5 have a dedicated ECU to control the operation of the lamps. On-dong line investigated by car light piloting system objective of the present invention is to provide a steering wheel controlled car light pointing system which automatically turns the lights of the motor car to coincide the projection of the lights with the steering direction of the motor car



WORKING

Steering system is to achieve angular motion of the front wheels to negotiate a turn. This is done through linkage and steering gear which convert the rotary motion of the steering wheel into angular motion of the front road wheels. The parts of steering system are consisting of Steering linkage and Steering gear. Steering Linkage-it depend upon the type of vehicle, wither it is a car which has independent front suspension. Steering linkage for vehicle is defining two types like as Steering Linkage for Vehicle with Rigid Axle Front Suspension and Steering Linkage for Vehicle with Independent Front System.

1 Rack and Pinion Steering Gear:

The rotary motion of the steering wheel is transmitted to the pinion of the steering gear through universal joints. The pinion is in mesh with a rack. The circular motion of the pinion is transferred into the linear rack movement which is further relayed through the ball joints and tie rods to the stub axles for the wheel to be steered. In the figure shows the schematic and actual modal of steering gear mechanism.

CONCLUSION

In the view of forgoing disadvantages inherent in the known types of road tracking headlamps now present in the prior art, the present invention provides a new movable vehicle head light construction wherein the same can be utilized for automatically aiming the head lamps in the same direction of the travel regardless of the terrain of the road. The further object of the system is, this is susceptible of a low cost of manufacturing with regard to both cost and labor and which accordingly is then susceptible of low prices of sale to the public.So there by making such movable vehicle head lamps which are economically low to available to the public

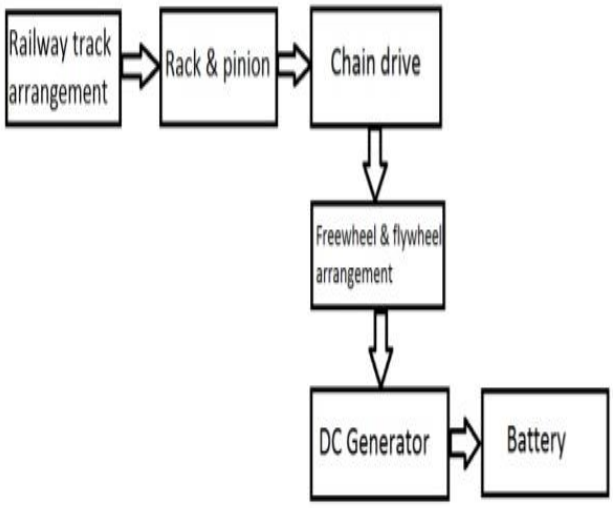
Abstract:

This project using simple drive mechanism such as tension spring assemble and link mechanism. For this project the conversion of the force energy in to electrical energy. The control mechanism carries the rack and pinion, Dynamo generator, battery and inverter control. So this project is implemented to all railway track, the power generation is very high. The initial cost of this arrangement is low. Used energy at an increasing rate for his requirement.**The principle** of this project is conversion of mechanical energy in the form of force into electrical energy.

KEYWORDS: Energy, Energy Harvesting, Non-conventional Method, Rail Road

INTRODUCTION



Man has needed and used energy at an increasing rate for his requirement. Man required energy primarily in the form of food. He derived this by eating plants or animals, which they hunted. With further demand for energy, man began to use the wind for sailing ships and for driving windmills, and the force of falling water to turn water for sailing ships and for driving windmills, and the force of falling water to turn water wheels. Till this time, it would not be wrong to say that the sun was supplying all the energy needs of man either directly or indirectly and that man was using only renewable sources of energy. World is growing at the faster rate with regards to consumption of fuel and so the scarcity of energy as the sources producing them are depletable in nature. Around the world, there were 8,06,000 cars and light trucks on the road consuming 260 billion US gallons 980000 liters of gasoline yearly. The extensive usage of energy has resulted in an energy crisis and there is a need to develop methods of optimal utilization. Which will not only ease the crisis but also preserve the environment. Commuter rail and subway are including railway transportation which play an important role in the economy and quality everyday life. Researches show that the world has already had its enough shares of its energy resources. Fossil fuels pollute the environment , Nuclear energy requires careful handling of both raw as well as waste material. The focus now is shafting more and more towards the renewable sources of energy. which are essentially nonpolluting. In the present day scenario power has become the major need for human life. Energy is an important input in all the sectors of any countries economy. The

increasing population and decreasing conventional sources for power generation. provides a need to think on non-conventional energy resources. To facilitate policymakers and transportation into making informed decisions on operating transportation systems, it is essential that railway track-side equipment (signal lights, wireless communication monitoring devices, positive train control, etc.) are well maintained and operated. When train moves over the track, the track deflects vertically due to load exerted by the train's bogies. The vertical displacement of the track under the weight of a passing train can connected regenerative devices i.e. a vibration energy harvester. The generated power can be stored into the battery and used to power track side equipments. Railroad energy harvesting is no trivial disturbance.In our project we are using these powers for irrigation system to the near by lands and fields and for lamp lights near the track.

PROPOSED SYSTEM

When a train ease up the track, the track deflects in downward direction attributable to the load exerted by the train's bogies. additionally due the deflection of track there's a deflection of timber that is place below the track and thus the flap is occupation downward direction because the flap is occupation a downward direction the spring that is connected to flap get compress in downward direction and thus rack is additionally move in downward direction and attributable to these pinion get rotates and thus larger freewheel turned as a result of each square measure mounted on same shaft. As there's a rotation of larger freewheel then the smaller freewheel is additionally turned through chain drive. The freewheel and regulator square measure mounted on same shaft thus the regulator additionally turned. The regulator is connected to the shaft of the generator therefore if the regulator can turned then there's a rotation shaft generator and power get generated which power is keep into the battery ADVANTAGES • Power generation is solely running the vehicle on this arrangement • Power additionally generated by running or exercise on the brake. • No want fuel input • This could be a Non-conventional system • Battery is employed to store the generated power

Block diagram

ADVANTAGES

• Power generation is solely running the vehicle on this arrangement

• Power additionally generated by running or exercise on the brake.

• No want fuel input

• This could be a Non-conventional system

• Battery is employed to store the generated power

DISADVANTAGES

• Slight inclination is needed within the railway track

• Mechanical moving elements is high

• Initial value of this arrangement is high.

• Care ought to be taken for batteries

APPLICATIONS

Power generation exploitation railway track system will be employed in most of the places like

All highways road speed breaker

All Railway track

• **For Irrigation system:**

The battery will be connected to the relay which will work as a switch.This switch will be activated with the current coming from an op-amp.A comparator op-amp will be used which will be work as a sensing device to sense the moisture in soil.A potentiometer will used to set the minimal voltage. Two cross wires will be placed in the soil with a nominal distance.When the soil is dry,resistance in soil will be around 10k.This will trigger the op-amp to give a output with low resistive path,i.e.fromground.This will connect the coil in relay and pump will be on. And on the contrary,when moisture will be enough,conduction will take place and relay will be switched off.

• **For Lamp lights near track:**

Another application which we are showcasing is lamp lights near track. The energy stored in battery can be used for lights near railway track. As we are searching for of a automatic solution for every problem, hence we are using LDR sensors here to avoid manual switching. The LDR wil allow electricity to flow through it when the photovoltaic cells are inactive and the resistance are low. This happens in the absence of sunlight.So during the day time, the lights connected through the sensors are switched off due to high resistance and evetually will glow in night time. One potentiometer is used for setting a reference value of resistor and a comparator IC to compare the light with the reference and allow the leds to glow.

RESULT

• As our project is Electric power generation using railway track and according to our fabricated model we are glowing LED which indicates the power is generated this is approximately equal to 5 volts. And even we are storing energy in battery by using toggle switch. Which can be utilized to any application.

• In our project we are glowing LED instantly when the train is passing over the roller and some of energy is stored in battery at the same time. And by using toggle switch we are using the pumps for irrigation system. And over all energy generated in our model is 8volts.

• These new design leads to more generation of electricity. And also it is more optimumand reliable in usage. The compact design of the structure leads to its easy and compatible mounting wherever required. Also less number of contact pairs leads to less frictional forces developed. These will lead to non-conventional energy generation which would further be used in the nearby railway infra-structure.

• A train weighing 1,000 kg going up a height of 10 cm on a rumble strip produces approximately 0.98KW power by placing one such speed-track on a busy highway, where about 100 trains pass every minute, about one kilo watt of electricity can be produced every minute.

CONCLUSION

It is ascertained that the electric power is in nice demand, we tend to as applied scientist ought to be in discovered for brand spanking new plan of power generation. As energy will ne'er be created or destroyed, we should always rework it into the shape that we will wont to provide for railroad station instrumentation light-weight, fan, beacon etc. we will implement this method at each entry and going away purpose within the railroad station This arrangement will be employed in completely different application like in foot step or speed breaker in school, faculties and main road for generation ways in which of voltage. so the facility production rate is raised and demand at explicit space will be consummated.

FUTURE SCOPE

This arrangement is slightly changed to construct in foot step and this arrangement is mounted in • colleges, cinema theatres, • searching advanced and • several different buildings

Abstract

In this project we studied a solar grass cutter. A solar Grass cutter is a machine that uses revolving blades to cut a grass at an even length. Even more sophisticated devices are there in every field. Power consumption becomes essential for future. Grass cutter is a very useful device which is very simple in construction. It is used to maintain and upkeep land s in gardens, schools, college's part etc. We have made some changes in the existing machine to make its application easier at reduced cost. Our main aim in pollution control is attained through this. Unskilled operation can operate easily and maintain the land very fine and uniform surface look. In our project, "solar economical grass cutter" is used to cut the different grasses or different grass for the different application.

Key Words: Solar panel, battery, Motor, Pulley system, Grass cutter, pollution.

INTRODUCTION

In large size of grass field is cut manually. The farmer used hand scissors used to cut and maintain grass uniformly. It is not easy and also very difficult to maintain uniform size. Hence, we design to make a grass cutter without any power source due to reduce the power consumption. The unskilled gardener is enough to operate the grass cutter. The grass cutter easy to operate and it consists of Rotary Blade, Roller etc. The blade removes the extra growth of the land and roller gives light pressure to the top surface of Land. It gives fine cutting done fast work done on the land and uniform speed throughout the Land. The project work was very great successful one. It is used to maintain land of our college auditorium land maintenance. The operations involved in the grass production cycle include land clearing, land forming/ land levelling, tillage, and grass establishment, harvesting and post-harvest operations. Grass establishment, harvesting and post-harvest operations. Grass establishment is necessary to eliminate the effect of weeds, pests and disease infestation and to provide suitable conditions for optimum yield. More than 3000 species of weeds had been identified all over the world. The cost of weed management is enormous; however, the opportunity cost of weed management is higher. Weed control measures must be put in place to check the growth and propagation of weeds. Chemical and manual weed control methods are viable alternatives; however, whereas environmental impact of herbicides made chemical method unsustainable, drudgery limits

the size of farm of an individual in sub-Saharan Africa. Introduction of an effective mechanical weeder is expected to encourage subsistent farmers leading to increased production and hence reducing poverty. To achieve this objective, a row grass cutter was developed in the Federal University of Technology, Akure in Nigeria. The weeder was designed, fabricated and tested and found to be very efficient. The machine consists of an abrasive nail- brush mounted on a shaft, transmission system, engine, frame and wheels. The height of cut of the machine is set above the ground level, but works effectively as a weeder. The machine is simple, cost effective and useful for small to medium scale farm holders. A Crop cutter is a machine that uses revolving blades to cut a crop at an even length. Even more sophisticated devices are there in every field. Power consumption becomes essential for future. Crop cutter is a very useful device which is very simple in construction. It is used to maintain and upkeep land s in gardens, schools, college's part etc. We have made some changes in the existing machine to make its application easier at reduced cost. Our main aim in pollution control is attained through this. Unskilled operation can operate easily and maintain the land very fine and uniform surface look. In our project, "crop cutter" is used to cut the different grasses or different crops for the different application.

2. LITERATURE REVIEW

Automated Solar Grass Cutter (February 2017) Ms. Rutuja A. Yadav, Ms. Nayana V. Chavan, Ms. Monika B. Patil, Prof. V .A. Mane According to the author a daily purpose robot which is able to cut the grass in the lawn. The system will have some automation work for guidance and other obstacle detection and the power source that is battery and a solar panel will be attached on the top of the robot because of this reduces the power problem. Automated solar grass cutter are increasingly sophisticated, are self –docking and some contain rain sensors if necessary, nearly eliminating human interaction. The system is switched to automatic mode in which the robot's infrared sensors make a compason between, cut and uncut the grass. The mower continues this process until it completes the job. The system uses 12v batteries to power the vehicle movement motors as well as the grass cutter motor. They also use a solar panel to charge the battery so that there is no need of charging it externally. The grass cutter and vehicle motors are interfaced to an 8051 family microcontroller that controls the working of all the motors. It is also interfaced to an ultrasonic sensor for object detection. The microcontroller moves the vehicle motors in the forward direction in case no obstacle is detected. If in case obstacle is detected by the sensor then the microcontroller stops the grass cutter motor so as to avoid any damage to the object/human/animal coming. [2] Solar Based Grass Cutting (January-June 2017) Ms. Bhagyashri R. Patil, Mr. Sagar S. Patil According to the author, human enlargement in many countries there are studies and trials going on the solar energy and the wind energy, so they made their new concept solar power grass cutting machine. In this concept they cut the grass on the agricultural land or small plants in lawns and gardens. The design of solar powered agricultural equipment will include direct current (DC) motor, a rechargeable battery, solar panel, a stainless-steel

blade and control switch. The automatic grass cutting machine is going to perform the grass cutting operation by its own which means no manpower is essential. The purpose of the project here is to design and build a remote-controlled grass cutter. The device consists of linear blades and it does not affected by climatic conditions. They have used many components for preparing grass cutter like DC Motor (3) for rotating the wheels and blade, wheels (4), battery, Solar panel, IR sensor, Collapsible blade. There are two main components such as transmitter and receiver. Transmitter continuously transmits the rays if any obstacle come in front of grass cutter then the rays are reflected back towards the receiver. The receiver receives the signal in the serial form from encoder but microcontroller requires parallel data for communication so receiver sends data to decoder to convert data in the parallel form and then it is passed to microcontroller.[4] Solar bases wireless grass cutter (IJSTE - International Journal of Science Technology & Engineering, May 2016) According to the author, The idea of autonomous machine used to reduce man power with efficient work has given. Mainly this project explains application of green energy. This knowledge can be used in agricultural field as a future scope. According to the author, it gives description multipurpose grass cutter which is sensor based for special purposes like in grass trimming, hedge trimming etc. utilization of sensor and design calculation are used in proposed system. According to the author, A robot was designed that operates on an on-board, solar charged battery has been designed by the French manufacturer SN Eno. The RoboMower4 the capability of steering itself across a person's lawn. This robot called the Atawa A34, uses built-in infrared sensors to avoid obstacles. This system uses wires buried beneath the surface of the ground [4]

3. BLOCK DIAGRAM DESCRIPTION

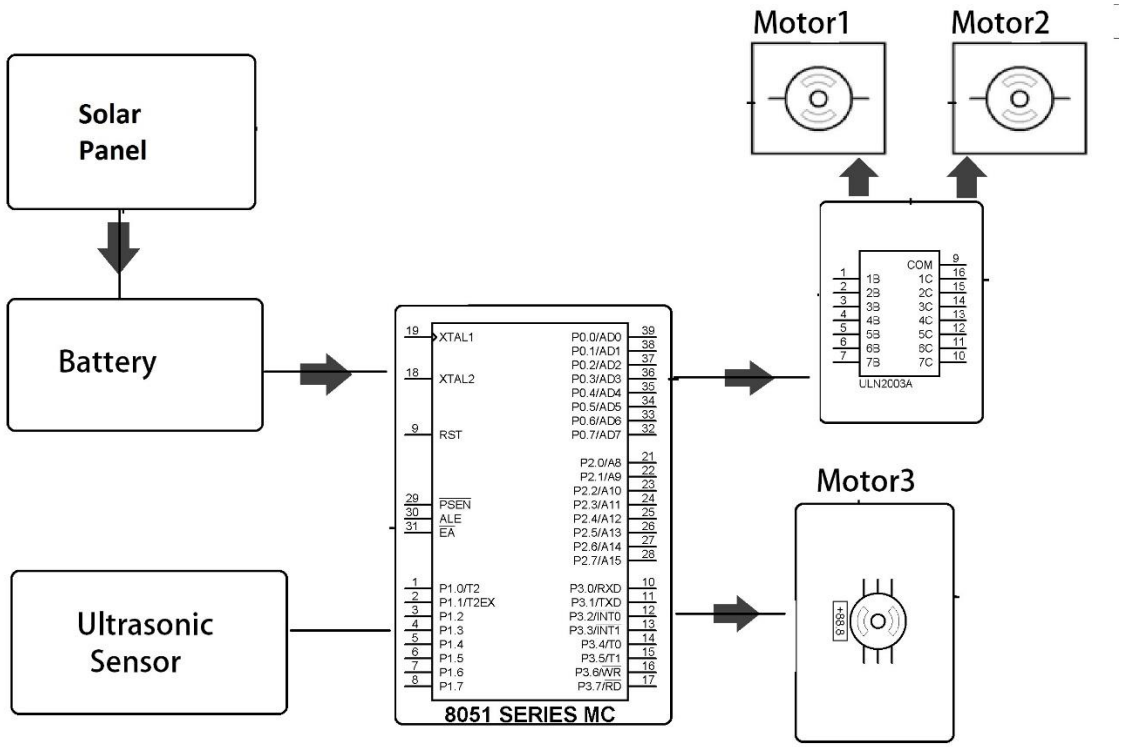

Fig-2: block diagram

3. Mechanism and working layout

The work layout shows the arrangement of3various parts of project. to the end of 3rd shaft and which is power transmit to the cutter mechanism

Fig -3: front view of grass cutter

3.1. WORKING PRINCIPLE

Coming to the working of solar powered grass cutter, it has panels mounted in a particular arrangement at an angle of 45 degree in such way that it can receive solar radiation with high intensity easily from the sun. These solar panels convert solar energy into electrical energy is stored in batteries

by using a solar panel. The main function of the solar charger is to increase the current from the panels while batteries are charging, it also disconnects the solar panel from the batteries when they are fully charged and also connects to the panels when the charging in batteries is low. The motor is connected to the batteries through connecting wires. Between these two mechanical circuit breaker switches is provided. It starts and stops the working of the motor. From this motor, the power transmits ton the mechanism and this makes the blade to slide on the fixed blade and this makes to cut the grass.

3.2. SOLAR ENERGY

Solar radiation is format among the promising new source of energy. India receives annually over 60 x 1000 MWH of solar insulation with a span of 3000 – 3200 hrs in Rajasthan, Gujarat, West of Madhya Pradesh and North of Maharashtra; and 2600 – 2800 hours in the rest of the country excepting Kerala, Assam and Kashmir. Energy from the sun can be utilized in multi various ways. It can be tapped directly from solar radiation in the form of thermal, thermodynamic and photovoltaic energy and indirectly through the production of Phyto man and other related energy sources such as wind, hydropower and ocean energy all of which are the result of solar radiation on the planet Earth. The contribution of these sources in the total consumption of energy in the world is about 15%. The scope for the application of solar energy now stands greatly enhanced through intensive research and development carried out all over world. The major areas that manifest great potential out all over world. The major areas that manifest great potential for immediate.

3.3ADVANTAGES

¬ Compact size and portable

¬ Easy to move from one place to another place

¬ Operating principle is simple.

¬ Non-skilled person also operates this machine

3.4 LIMATATIONS

¬ Large time required to remove the grass

¬ Manually operated

¬ Difficult to operate in rainy season

3.5APPLICATION

¬ For cricket ground

¬ College campus

¬ All playground

4. COST BENEFITS & ANALYSIS:

In our market, the approximate cost of an electric grass cutter is 25000/- coming to our project, we are modelling a solar powered grass cutter.

5. CONCLUSIONS

This project work has provided us an excellent opportunity and experience, to use our limited knowledge. We gained a lot of practical knowledge regarding, planning, purchasing, assembling and machining while doing this project work. We feel that the project work is a good solution to bridge the gates between institution and industries. We are proud that we have completed the work with the limited time successfully. The Crop Cutter is working with satisfactory conditions. We are able to understand the difficulties in maintaining the tolerances and also quality. We have done to our ability and skill making maximum use of available facilities. In conclusion remarks of our project work, let us add a few more lines about our impression project work. Thus, we have developed an "solar economical grass cutter" which helps to know how to achieve low cost automation. By using more techniques, they can be modified and developed according to the applications.

Abstract

In this paper, a review has been conducted on various types of methods which are available for utilizing solar energy for refrigeration purposes. Solar refrigeration methods such as Solar Electric Method, Solar Mechanical Method and Solar Thermal Methods have been discussed. In solar thermal methods, various methods like Desiccant Refrigeration, Absorption Refrigeration and Adsorption Refrigeration has been discussed. All the methods have been assesed economically and environmentally and their operating characteristics have been compared to establish the best possible method for solar refrigeration. Also, the various available technologies for Cooling Thermal Energy Storage (CTES) have been discussed in this paper. Methods like Chilled Water Storage (CWS) and Ice Thermal Storage (ITS) have been compared and their advantages and disadvantages have been discussed. The results of the review reveal Solar Electric Method as the most promising method for solar refrigeration over the other methods. As far as CTES systems are concerned, ITS has advantage over other methods based on storage volume capability, but it has a comparatively lower COP than other available techniques. Keywords: Solar powered refrigeration, Solar Electric Method, Solar Mechanical Method, Solar Thermal Method, CTES system, Chilled Water Storage (CWS) system, ice TES systems, etc.

Introduction

A solar-powered refrigerator is a refrigerator which runs on electricity provided by solar energy. Solar-powered refrigerator are able to keep perishable goods such as meat and dairy cool in hot climates, and are used to keep much needed vaccines at their appropriate temperature to avoid spoilage. Solar-powered refrigerators may be most commonly used in the developing world to help mitigate poverty and climate change. In developed countries, plug-in refrigerators with backup generators store vaccines safely, but in developing countries, where electricity supplies can be unreliable, alternative refrigeration technologies are required. Solar fridges were introduced in the developing world to cut down on the use of kerosene or gas-poweredabsorption refrigerated coolers which are the most common alternatives. They are used for both vaccine storage and household applications in areas without reliable electrical supply because they have poor or no grid electricity at

all. They burn a liter of kerosene per day therefore requiring a constant supply of fuel which is costly and smelly, and are responsible for the production of large amounts of carbon dioxide. They can also be difficult to adjust which can result in the freezing of medicine. The use of Kerosene as a fuel is now widely discouraged for three reasons: Recurrent cost of fuel, difficulty of maintaining accurate temperature and risk of causing fires. There are three methods by which solar energy can be utilized for refrigeration purposes. They are as follows- Solar Electric Method, Solar Mechanical Method and Solar Thermal Method.

Solar Electric Method

In Solar Electric Method, the solar energy is directly converted to DC current by an array of solar cells known as Photovoltaic (PV) panel. Photovoltaic Cells are nothing but semiconductors which allow direct conversion of solar energy to direct current. A part of this current is stored by lead acid battery while the rest is utilized in driving the compressor of the refrigerator. This DC current can be either used to run a DC motor coupled to compressor or an inverter can be used to convert this DC current to AC current for running the compressor. A solar charge controller consisting of capacitor, sensors etc. may be required to stabilize and smoothen the current.

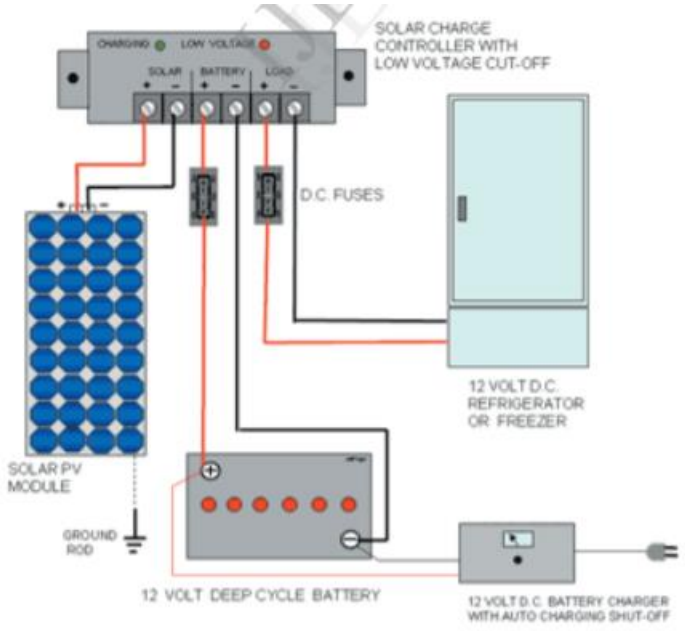

Fig. 1- A typical Solar PV system

A normal Solar PV system includes different components that should be selected according to the system type, site location and applications. The major components for solar PV system are solar charge controller, inverter, battery bank, auxiliary energy sources and loads (appliances).

• PV module – converts sunlight into DC electricity.

• Solar charge controller – regulates the voltage and current coming from the PV panels going to battery and prevents battery overcharging and prolongs the battery life.

• Inverter – converts DC output of PV panels or wind turbine into a clean AC current for AC appliances or fed back into grid line.

• Battery – stores energy for supplying to electrical appliances when there is a demand.

• Load – is electrical appliances that connected to solar PV system such as lights, radio, TV, computer, refrigerator, etc.

• Auxiliary energy sources - is diesel generator or other renewable energy sources.

Solar Mechanical Method

In Solar Mechanical Method, the mechanical power required to drive the compressor is generated by solar driven heat power cycle. Rankine cycle is the heat power cycle considered for this process. In Rankine cycle, fluid is vaporized at an elevated pressure by heat exchange with a fluid heated by solar collectors. A storage tank can be included in this process to provide some high temperature thermal storage. The vapor flows through a turbine or piston expander to produce mechanical power. The fluid exiting the expander is condensed and pumped back to the boiler pressure where it is again vaporized. The efficiency of the Rankine cycle increases with increasing temperature of the vaporized fluid entering the expander. Whereas, the efficiency of a solar collector decreases with increasing temperature of the delivered energy. High temperatures can be obtained by employing concentrating solar collectors that track the sun's position in one or two dimensions.

The disadvantages of using solar trackers are cost, weight and complexity of the system. If tracking is to be avoided, evacuated tubular, compound parabolic or advanced multi-cover flat plate collectors can be used to produce fluid temperatures ranging between 100°C – 200°C. Both intensity of solar radiation as well as difference of temperature between entering fluid and ambient govern the efficiency of solar collector. The efficiency of such a system is lower than solar electric method using non-concentrating PV modules. Solar Mechanical is advantageous only when solar trackers are used but, the use of such systems is limited to large refrigeration systems only i.e.atleast 1000 tons. (refer fig. 2)

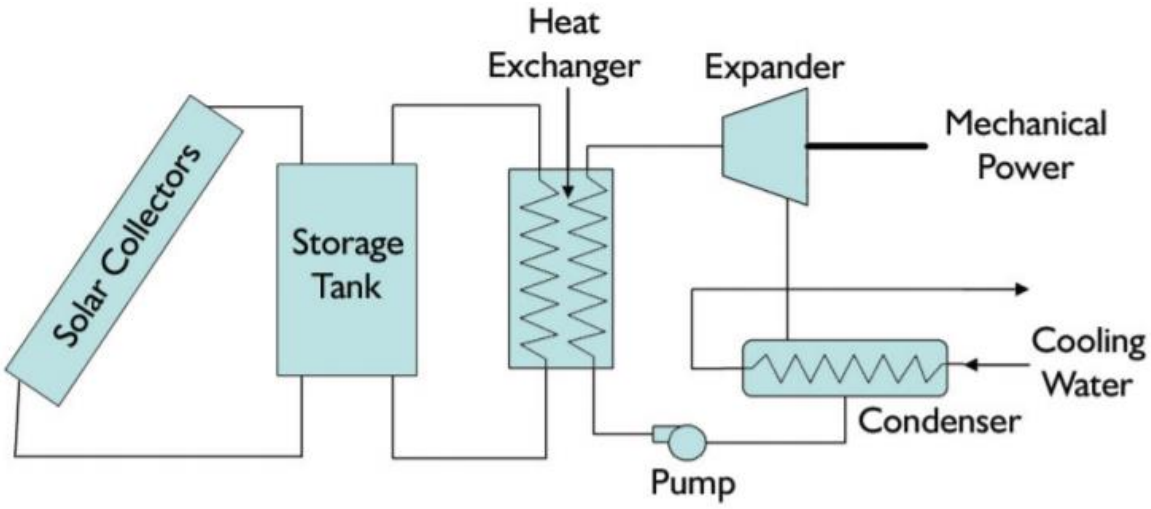

Fig.2- Solar Mechanical Method

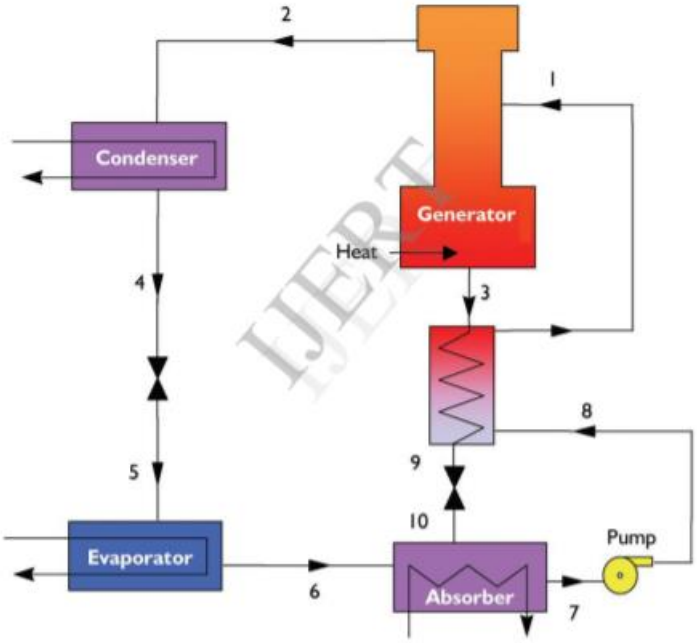
Solar Thermal Method

The main advantage of using Solar Thermal Method is that they can utilize more of the incoming sunlight than photovoltaic systems. In a conventional PV collector, 65% of the incident solar radiation is lost as heat whereas in solar collectors over 95% of the incoming solar radiation is absorbed. But all of this is absorbed energy is not converted to useful energy due to inefficiencies and losses. Collection efficiencies for commercial solar thermal collectors are generally more than double that of crystalline photovoltaic solar collectors. A typical solar thermal refrigeration system consists of four basic components - a solar collector array, a thermal storage tank, a thermal refrigeration unit and a heat exchange system to transfer energy between components and the refrigerated space. Selection of the solar array depends upon the temperature needed for refrigeration system. Generally for temperature range 60-100C, flat plate collectors, evacuated tube collectors and concentrating collectors of low concentration can be used. Concentrating collectors are avoided for residential purposes due to high cost of solar trackers. Selection of the thermal storage tank depends upon the type of storage medium and the temperatures desired. Water is mainly selected for its low environmental impact and high specific heat.



Desiccant

A desiccant system is usually an open cycle where two wheels turn in tandem – a desiccant wheel containing a material which can effectively absorb water, and a thermal wheel which heats and cools inward and outward flows. Warm, humid, outside air enters the desiccant wheel where it is dried by the desiccant material. Next, it goes to the thermal wheel which pre-cools this dry, warm air. Next, the air is cooled further by being re-humidified. When leaving, cool, conditioned air is humidified to saturation and is used to cool off the thermal wheel. After the thermal wheel, the now warm humid air

is heated further by solar heat in the regenerator. Lastly, this hot air passes through the desiccant wheel so that it can dry the desiccant material on its way out of the cycle. Pre-packaged desiccant is most commonly used to remove excessive humidity that would normally degrade or even destroy products sensitive to moisture. Some commonly used desiccants are silica gel, activated charcoal, calcium sulfate, calcium chloride, montmorillonite clay, and molecular sieves.

Absorption

An absorption refrigerator is a refrigerator that uses a heat source (e.g., solar, kerosene-fueled flame, waste heat from factories or district heating systems) to provide the energy needed to drive the cooling system. Absorption refrigerators are a popular alternative to regular compressor refrigerators where electricity is unreliable, costly, or unavailable, where noise from thecompressor is problematic, or where surplus heat is available (e.g., from turbine exhausts or industrial processes, or from solar plants). In absorption, two mainly used cycles are- LiBr (Lithium Bromide) and NH3 (Ammonia Hydrogen). The main difference between them is which substances are used as the refrigerant and absorbent. In a LiBr system, LiBr is the absorbent and water is the refrigerant. In an NH3 absorption system, water is now the absorbent and NH3 is the refrigerant. In both cases, the job of the compressor (in a conventional vapour compression system) is replaced by an absorber and a generator. Concentrated absorbent enters the absorber, which is connected to the evaporator. When refrigerant is boiled off in the evaporator (removing heat from the refrigerated space), vapour (of relatively high pressure) then moves to the LiBr/water absorber where it is absorbed. Next, the mixture moves to the generator where solar heat is supplied to boil off the refrigerant. High-pressure refrigerant vapour then travels to the condenser where heat is rejected to the surroundings to condense the refrigerant back to liquid. Liquid refrigerant goes back into the evaporator, where it can be used again to take in heat from the refrigerated space, which completes the loop.

Adsorption

In this cycle, solar heat is directed to a sealed container containing solid adsorbent saturated with refrigerant. Once this reaches the proper temperature/pressure the refrigerant desorbs and leaves this container as pressurized vapour. That is, the vapour has been compressed with thermal energy. This vapour then travels to a condenser where it turns to liquid by rejecting heat to the surroundings. Expanded, low-pressure liquid refrigerant then flows over the evaporator which pulls heat from the conditioned space to boil off the refrigerant. The refrigerant vapour can then be adsorbed again by the cool adsorbent material easily at night. Although there are similarities between absorption and adsorption refrigeration, the latter is based on the interaction between

gases and solids. The adsorption chamber of the chiller is filled with a solid material (for example zeolite, silica gel, alumina, active carbon and certain types of metal salts), which in its neutral state has adsorbed the refrigerant.

Cooling Thermal Energy Storage (CTES) System

The most important use of CTES systems is to shift the power consumption from peak to offpeak periods. For this reason these systems are also known as “off-peak cooling” systems. The performance of a TES system is described by its co-efficient of performance (COP). The COP of a system during peak and off-peak hours is defined by the chiller and compressor design. CTES systems are generally classified into three types- chilled water, ice storage and eutectic salt TES systems. Among these techniques, the Chilled Water Storage (CWS) and the Ice Thermal Storage (ITS) systems are the most promising ones in case of the normal applications. The ITS system has the

advantages of larger storage volume in comparison with two other systems. However, the COP of the ITS system is much lower than other techniques. In sensible CTES, the storage medium is usually water-based whereas in latent CTES systems, eutectic salts with phase change materials is generally preferred as storage medium. Sensible CTES systems account for most cold TES applications presently. Thermochemical TES may prove useful for cooling TES systems provided ongoing efforts to develop systems are successful. So, in short, the various advantages of using CTES system are: -

- Reduction in electricity bills by shifting the power consumption from peak to off-peak periods.

- Usually, the systems with CTES would consume less operating energy than conventional air conditioning (AC) systems due to constant and comparatively lower temperature during the nights.

- Producing off-peak electricity is cheaper as it would consume less fuel.

- Chiller efficiency is improved by shifting the electricity consumption from daytimes to nights when the ambient temperature (Ta) is considerably low.

- The significant air temperature difference across the Air Handling Unit (AHU) reduces the required air volume required for circulation. Hence, smaller AHUs, less duct working and less electrical equipment's are required.

Chilled Water Storage (CWS)

It is a famous strategy adopted in many countries to save energy by shifting power consumption from peak hours in the daytime to off-peak hours during the nighttimes by employing chilled water to store cool thermal energy. In the past, prior to the successful evolution of thermally stratified systems, many different types of CWS designs have been developed and employed. Designs of CWS were such in order to primarily avoid temperature mixing of chilled water with return water. However, they often require complex tank configurations or piping systems that are expensive and difficult to operate. The CWS systems currently in use can be classified as (a) labyrinth, (b) baffle, (c) tank series, (d) membrane tank. (refer fig.4)

Ice Thermal Storage (ITS) The most popular technique for storing cool thermal energy was the use of ice due to its high latent heat of fusion i.e.hsf = 334 kJ/kg. This method was used especially when the available space was limited. The supplied chiller in this technique must be able to produce charging temperature in the range of -60C to -30C in order to produce ice. Investigations revealed that employing the ITS system would downsize the cooling generation devices such as pipes, ducts and AHUs. This downsizing will help in lowering the primary cost of the HVAC system. The ITS storage technologies are generally categorized by their different combinations of storage media, charging or discharging mechanism. ITS systems can be commonly categorized into the following types –

- Ice Harvesters
- Ice slurry
- Encapsulated Ice
- External melt ice-on-coil storage systems
- Internal melt ice-on-coil storage systems

Ice Harvesters

This technique is a dynamic type of ITS system consisting of an open insulated storage tank and vertical plate surface positioned above the tank. A circulating pump brings the water at a temperature of 00C on the outer surface of the evaporator, which is fed internally with liquid refrigerant. Normally, thickness of the produced ice varies between 8 mm and 10 mm depending on the length of the freezing cycle. (refer fig.5)

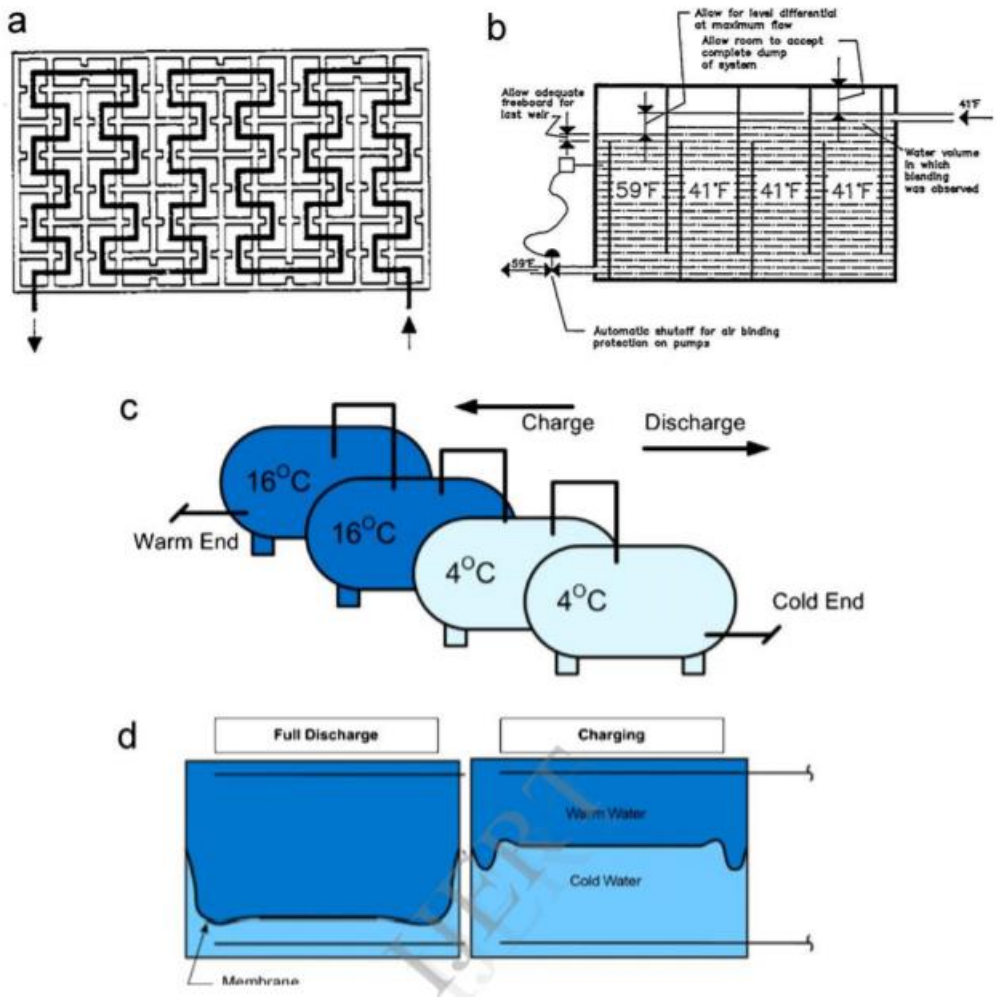


Fig.5- Schematic diagram of a typical ice harvesting ITS system

The ice would then be harvested by feeding a hot gas to the evaporator. The outer surface temperature rises to about 50C causing the ice in contact with the plates to melt and fall into the storage tank. During the discharging period, the chilled water that circulates through the storage tank further reducing the water temperature to cope with the load. Due to the system complexity, only a few manufacturers are involved with these systems, which are normally employed only in special applications.

Literature survey of work carried out by various authors

M. M. Hussain, et al. [1]: The simulation of thermal energy storage (TES) system for HVAC system has been dealt with in this paper. To store cooling capacity, TES system is integrated with conventional HVAC system. Ethylene Glycol is used as a storage medium in this system. Exergy and Energy analyses have been used to determine the thermodynamic performance of the system. Effect of various parameters such as ambient temperature, cooling load and mass of storage on the performance of the TES system has been also studied in this paper. The results of various studies and analyses conducted on TES systems revealed that the storage temperature International Journal of Engineering Research &Technology Vol. 2 Issue 2, February- 2013 ISSN: 2278-0181 www.ijert.org 10 IJERT decreases linearly with time when there is no load and follows the load profile during daytime and decreases linearly with time at the end. Also, it was found out that the storage temperature decreases slightly with increase in ambient temperature when there is no load. COP of the system was found out to decrease sharply with small increase in storage temperature. It was also discovered that for all mass flow rates of discharging fluid, the energy efficiency of the system was found out to be nearly 80%. But, the exergy efficiency of the system decreased with increase in mass flow rate of the discharging fluid and increased with increase in reference temperature.

FakehaSehar, et al. [2]: In this paper, the impact of ice storage systems on the chiller energy consumption for large and medium-sized office buildings in diverse climate zones has been investigated. The various studies indicated that the systems with ice thermal storage (ITS) have higher chiller energy consumptions than the conventional non-storage systems because of the day and night operation of the chiller. By discharging ice storage during the peak hours, the ITS were able to achieve peak energy savings by reducing or even by completely eliminating the chiller operation during the daytime. It was also noticed that climatic zones with summers having high temperatures and relative humidity (RH) increase not only the building cooling load but also the chiller energy consumption by decreasing the cooling intensity of the condenser water, for example- Miami and Las Vegas. But, climate zones with less extreme summers have lower chiller energy consumption due to lower building cooling loads and more cooling of condenser water, for example- Seattle.

Mehmet Azmi Aktacir, [3]: In this study, a PV-powered multi-purpose refrigerator system has been erected to investigate experimentally its daily and seasonal operating performances based on semi-

arid climatic conditions of Sanliurfa province in Turkey. It is one of the sunniest rural regions in the world and hence the need for refrigeration is critical. The overall results revealed that PV-refrigerator system can be reliably used in places where the local grid was unreliable and the refrigeration need is critical. On observation, the following results were observed- Low temperature of 10.6°C was reached in the refrigerator, the highest energy amount produced by PV panels was recorded between 11:00 am and 14:00 pm, amount energy consumed by the refrigerator was determined to be 347.7 Wh/day, the amount of energy stored in the battery bank was 78.2 Wh/day while the amount of electric energy produced by photovoltaic panel was 425.9 Wh/day.

Sanford A. Klein and Douglas T. Reindl, [4]: In this paper, it was stated that the energy use associated with refrigeration system operation and the environmental impacts associated with its generation and distribution often outweigh the choice of environmental friendly refrigerants. In this article, three approaches to use solar energy for refrigeration at temperatures below 0C were reviewed and their operating characteristics were compared. The COP of all the three refrigeration cycles- Solar Electric, Solar Mechanical and Absorption cycles were compared and found to be low due to various barriers like firstly, the solar refrigeration systems are complicated, costly and bulky because of the necessity to locally produce the power required for operation and secondly, the energy source for these systems i.e. solar energy is variable which requires energy storage system that further adds to the system size and cost. The PV system was International Journal of Engineering Research & Technology (IJERT) Vol. 2 Issue 2, February- 2013 ISSN: 2278-0181 www.ijert.org 11 IJERT most viable of all other systems especially for small capacity portable systems whereas the absorption systems were more feasible for large stationary refrigeration systems.

S.M. Hasnain, et al. [5]: In this paper, the incorporation of ice thermal storage with conventional air conditioning systems in Saudi office was studied. This incorporation reduced the peak electric demand, cooling plant capacity and new electric connection charges of an office building. For this study, two different scenarios were studied. The partial ice storage technique adopted for this study reduced the peak electrical load for Scenario-I and Scenario-II, by 15 and 23%, respectively. It was estimated that an ice storage system would reduce the peak cooling load between 35 and 40% in this type of Saudi buildings. The savings that resulted by downsizing the cooling plant overcame the cost of storage and the additional interface equipment. Similarly, it wass also estimated that in Saudi Arabia, the use of ice storage systems with gas turbines for inlet air cooling will increase the turbine's output by 30% and reduce its heat rate by 10% at a mere fraction of the cost of installing the additional capacity for power generation in order to meet the summer peak demand.

Todd Otanicar, et al. [6]: In this paper, a variety of solar cooling schemes have been economically and environmentally analyzed to reveal some key details regarding system choice. For solar electric cooling the system, the cost is highly dependent on the system COP when PV prices remain at the

current levels but when prices are lowered the impact of COP on cost diminishes. For solar thermal cooling, the cost of solar collection is much lower as a percentage of the overall cost, but the cost of the refrigeration system represents a larger percentage of the total cost. Additionally, the paper reveals that the costs for solar thermal cooling are not projected to decrease as much as PV cooling over the next 20 years due to the relatively stable cost of collection and storage. Solar electric cooling, even with the associated impact of refrigerants with global warming impact, have a lower projected emission value of carbon dioxide per kWhr of cooling than any of the thermal technologies due to the much larger COP values associated with solar electric cooling. One additional favorable aspect to solar electric cooling systems is the collector area foot print i.e. for solar PV systems, expected sizes in 2010 were between 24 and 48 m2 as compared to 78 and 106 m2 for solar thermal systems depending on system COP.

David MacPhee, et al. [7]: In this paper, the solidification process for an encapsulated ice TES is investigated. Using Fluent 6.3 software, a domain consisting of one capsule containing water as the PCM and with an outer shell made of PVC is simulated from an initial temperature of 275 K until completely frozen, using ethylene glycol as the heat transfer fluid (HTF). The purpose of this study is to assess how changing capsule geometry, inlet HTF temperature and flow rate affect the performance of the charging process. Using both energy and exergy analyses, efficiencies were calculated for each simulation, while varying the inlet temperature from 267 to 271 K, and choosing three flow rates, Q = 0.87 l/s, 1.74 l/s and 2.61 l/s. The results indicate that considerable cost and energy savings could be realized by utilizing a higher HTF temperature, perhaps a few degrees below the solidification temperature of the PCM. It is possible for the designers to increase flow rate to make up for the increase in charging time associated with this increase in HTF inlet temperature since, the losses associated with viscous dissipation and hence, International Journal of Engineering Research & Technology (IJERT) Vol. 2 Issue 2, February- 2013 ISSN: 2278-0181 www.ijert.org 12 IJERT pressure drop have been shown to be inconsequential compared to other modes of losses. Doing so should allow for an increase in efficiency while still maintaining a working and effective encapsulated ice TES system.

B. Rismanchia, et al. [8]: The work in this paper investigated the feasibility and potential of employing ITS systems for the cooling application of office buildings in Malaysia along with the economical and environmental benefits of utilizing these systems. This study is mainly conducted due to the vast potential that the country has, the statistical data shows that in Malaysia, AC systems are the major energy consumers in office buildings with around 57% share. However, they are not well promoted in Malaysia and their potentials are not yet well investigated. The overall results show that the full storage strategy can reduce the annual costs of the air conditioning system by up to 35% while this reduction is limited to around 8% for a load levelling strategy. By comparing the installation, maintenance and electricity costs of the conventional system with the ITS system, it was found that

for the full storage strategy it will take between 3 and 6 years for the benefits of the investment to be equal with the investment. For the load levelling strategy this period varies between 1 and 3 years. The comparison results between the conventional AC system and the ITS system indicate that a proper design could lead to lower energy consumption due to better utilization of the equipment. It shows that the load levelling strategy consumes around 4% less energy than the conventional AC systems. The annual energy saving stated that the annual CO2 emission reduction for load levelling strategy varies from 3000 to 60,000 ton for the total system capacities of 352 and 7034 kW.

David MacPhee, Ibrahim Dincer, [9]: In this paper, a performance assessment of four main types of ice storage techniques for space cooling purposes, namely ice slurry systems, ice-on-coil systems (both internal and external melt), and encapsulated ice systems is conducted. The ice making techniques are compared on the basis of energy and exergy performance criteria including charging, discharging and storage efficiencies, which make up the ice storage and retrieval process. Losses due to heat leakage and irreversibilities from entropy generation are included. A vapor-compression refrigeration cycle with R134a as the working fluid provides the cooling load, while the analysis is performed in both a full storage and partial storage process, with comparisons between these two. In the case of full storage, the energy efficiencies associated with the charging and discharging processes are well over 98% in all cases, while the exergy efficiencies ranged from 46% to 76% for the charging cycle and 18% to 24% for the discharging cycle. For the partial storage systems, all energy and exergy efficiencies were slightly less than that for full storage, due to the increasing effect wall heat leakage has on the decreased storage volume and load. The results show that energy analyses alone do not provide much useful insight into system behavior, since the vast majority of losses in all processes area result of entropy generation which results from system irreversibilities.

Abstract –

Abrasive Jet Machining (AJM) or Micro Blast Machining is a non-traditional machining process, wherein material removal is affected by the erosive action of a high velocity jet of a gas, carrying fine-grained abrasive particles, impacting the work surface. The process is particularly suitable to cut intricate shapes in hard and brittle materials which are sensitive to heat and have a tendency to chip easily. As Abrasive jet machining (AJM) is similar to sand blasting and effectively removes hard and brittle materials. AJM has been applied to rough working such as debarring and rough finishing. With the increase of needs for machining of ceramics, semiconductors, electronic devices and L.C.D., AJM has become a useful technique for micromachining. The experimental results of the present work are used to discuss the validity of proposed model as well as the other models. With the increase in nozzle tip distance (NTD), the top surface diameter and bottom surface diameter of hole increases as it is in general observation of abrasive jet machining process. As the pressure increases, the material removal rate (MRR) is also increased. The present study has been introduced a mathematical model and the obtained results have been compared with that obtained from the theoretical. Key Words: Abrasive Jet Machine (AJM), LCD, Nozzle Tip Distance (NTD), Material Removal Rate (MRR)

1.INTRODUCTION

Abrasive jet machining (AJM) is a non-traditional machining process that can machine material without generating heat and shock and also without formation of chips. Abrasive processes are usually expensive, but capable of tighter tolerances and better surface finish than other machining processes chances, delectability, costs and safety aspect etc. Abrasive jet machining (AJM) is a process of material removal by mechanical erosion caused by the impingement of high velocity abrasive particles carried by a suitable fluid (usually a gas or air) through a shaped nozzle on to the work piece. Common examples include Cutting, Drilling, Surface finishing, Etching, grinding, honing, and polishing. The erosion phenomenon in an AJM study may be considered in two phases. The first phase consists of transportation problem, that is, the quantity of abrasive particles flown, and the

direction and velocity of impinging particles as determined by the fluid flow condition of solid-gas suspension. The second phase of the problem is the determination of the material removal rate or the erosion rate.

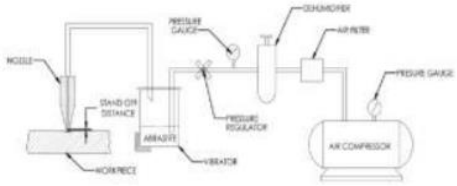

Fig -1: Schematic Layout of Abrasive Jet Machine

The erosion of a surface by impacting solid particles is a discrete and accumulative process. Hence, the models are first made on the basis of a single particle impact. The mechanism of erosion in such cases is complex, involving mechanical, chemical and material properties. The erosion is a function of several variables such as:

a) Speed and angle of impact;

b) Ductility and! or brittleness the impinging particles;

c) Elasticity of the material; of the material and

d) Shape and geometry of impinging particles;

e) Impinging particle diameter to work-material, thickness ratio;

f) Average flow stress; g) Material and density; and

h) Distance between the nozzle mouth and work piece

An AJM set-up may be of two types: one employing a vortex type mixing chamber and the other employing a vibratory mixer. In the former, abrasive particles are carried by the vortex motion of the carrier fluid, whereas in the latter type abrasive particles are forced into the path of the carrier gas by the vibrating motion of the abrasive particle container.

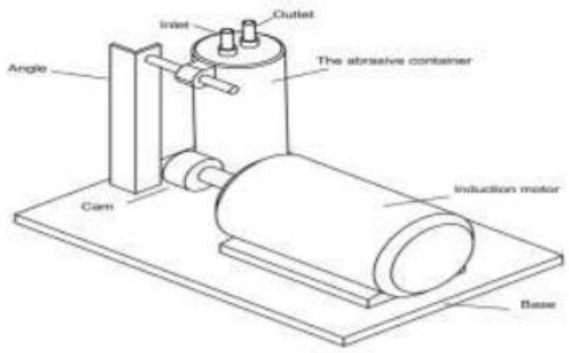

Fig -2: The vibrator assembly

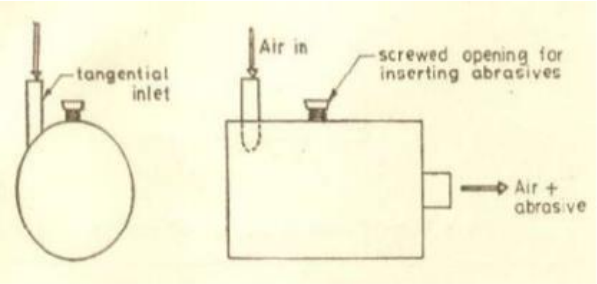

Fig -3: Vortex type mixing chamber

1.1 PROCESS PARAMETERS OF AJM

1.1.1 CARRIER GAS (MEDIUM):

(a) Carbon dioxide,

(b) Nitrogen,

(c) Air: Air is most widely used.

But oxygen never used as a carrier gas due to fire hazards.

1.1.2 ABRASIVE:

Abrasives are available in many sizes ranging from 10 micron to about 1.3 mm. the smaller sizes produce a finish cut and are suitable for polishing, cleaning and grooving. The larger sizes are more suitable for cutting and peening because of their faster cutting action.

a. Aluminium oxide suitable for cutting, grooving and debarring operations.

b. Silicon carbide used for similar operation but for harder material

c. Sodium bicarbonate is useful for light duty work like cleaning, cutting and debarring for soft materials.

d. Dolomite also is suitable for fine etching or polishing work only.

e. Glass beads can be used for polishing surface to a matte finish and debarring work.

1.1.3 VELOCITY OF ABRASIVE:

The jet velocity is a function of nozzle pressure & design. The range of jet velocity is 150-300 m/min.

1.1.4 WORK MATERIAL:

It is recommended for processing of hard, brittle, and glass sheets material.

1.1.5 NOZZLE:

AJM nozzles generally made of WC or Sapphire to resist abrasive wear due to the high velocity abrasive stream. The nozzle has either a right angled or straight edge shape.

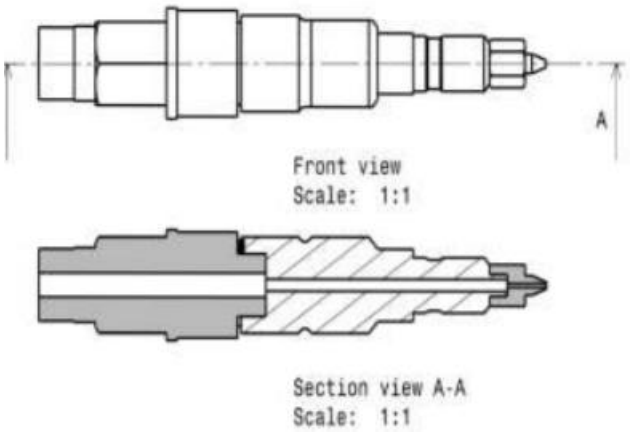

Fig -4: Nozzle

1.1.6 NOZZLE TIP DISTANCE (NTD):

It is the distance between the nozzle tip & work material. It is also called as Standoff Distance (SOD).

1.3 COMPONENTS OF AJM

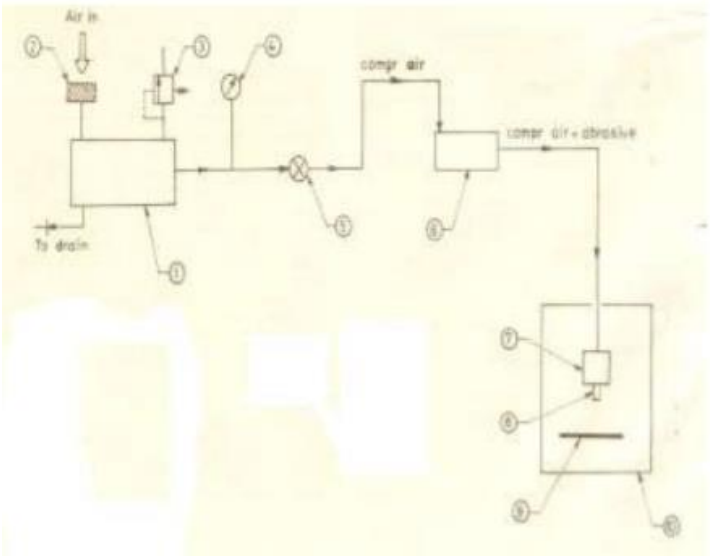

Fig -6: Components of AJM

a) Compressor

b) Air filter cum drier

c) Relief Valve

d) Pressure Gauge

e) Opening Valve

f) Mixing Chamber

g) Nozzle Holder

h) Nozzle

i) Work piece

j) Working Chamber

1.4 PROCESS

Glass was used as a test specimen, was cut into square and rectangular shape for machining on AJM. Specimens were cleaned using air jet and weighed on a sensitive scale, accurate to 0.001 gm. The compressed air from the compressor enters the mixing chamber partly prefilled with fine grain abrasive particles. The vibratory motion of the air created in the mixing chamber carries the abrasive particles to the nozzle through which it is directed on to the workpiece. The nozzle and the work-piece are enclosed in a working chamber with a Perspex sheet on one side for viewing the operation. The abrasive particles used were SiC, Al2O3, Sodium Bicarbonate (grain size 60 microns and 120

microns).The nozzle material was stainless steel and the nozzles used were of different diameters. This type of set-up has the advantage of simplicity in design, fabrication and operation. The equipment cost is much less except the compressor. The machine work-piece was then removed, cleaned and weighed again to determine the amount of material removed from the work piece. The size of hole at the top surface and bottom surface was measured and the results were tabulated.

1.5 ADVANTAGES

a) Ability to cut intricate holes shape in materials of any hardness and brittleness.

b) Ability to cut fragile and heat sensitive material without damage.

c) No change in microstructure as no heat is generated in the process.

d) The process is characterized by lower consumption and capital investment.

e) There is no contact between the tool and work-piece.

f) Good surface finish of 10 to 50 microns is possible with the process using finer abrasive.

g) Cutting action is cool because the carrier gas serves as a coolant.

1.6 DISADVANTAGES

a) Material removal rate is low about 15 mm3 / min.

b) The parts manufactured by this process have to be cleaned.

c) Embedding of the abrasive in the work-piece surface may occur while machining softer material.

d) The abrasive material may accumulate at nozzle and fail the process if moisture is present in the air.

e) It cannot be used to drill blind holes.

f) Nozzle wear rate is high and abrasive particles may get embedded in the work surface.

1.7 APPLICATIONS OF AJM

a) Machining of hard and brittle materials like ceramics, quartz, glass, sapphire, mica etc.

b) Fine drilling and micro-welding.

c) Machining of semi-conductors.

d) Production of intricate profiles on hard and brittle materials.

e) Cleaning and finishing of plastic compounds. Ex. Nylon, Teflon.

2. WORKING PRINCIPLE OF AJM

Fine particles are accelerated in gas stream. The particles are directed towards the focus of machining. As the particle impacts the surface, it causes a small fracture, and the gas stream carries both the abrasive particles and the fractured (wear) particles away.

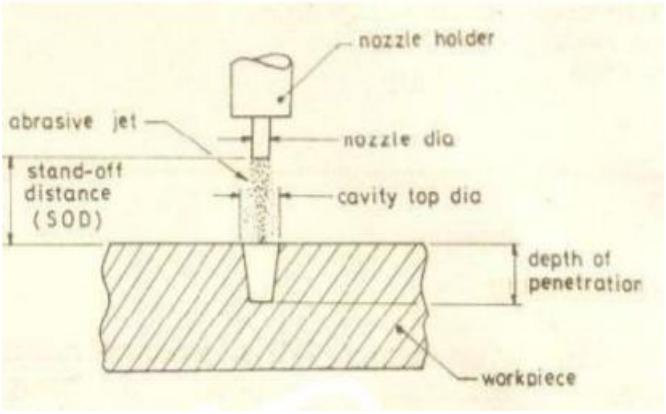

Fig -6: Working principle of AJM

Abrasive jet machining (AJM), also known as abrasive micro blasting, pencil blasting and micro-abrasive blasting. “Abrasive blasting machining process that uses abrasives propelled by a high velocity gas to erode material from the work piece.” The working principle of Abrasive jet machining (AJM) is similar to sand blasting in which AJM effectively removes hard and brittle materials. AJM has been applied to rough working such as debarring and rough finishing. Common uses include cutting heat-sensitive, brittle, thin, or hard materials. Specifically it is used to cut intricate shapes or form specific edge shapes. A machining operation is basically a material removal process, where material is removed in the form of chips. In a machining operation, the output parameter is achieved by controlling various input parameters. Drilling of glass sheets with different thicknesses have been carried out by Abrasive Jet Machining process (AJM) in order to determine its machinability under different controlling parameters of the AJM process.

2.1 EXPERIMENTAL SET-UP

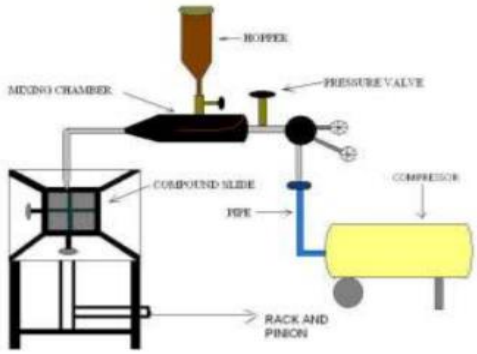

Fig -7: Schematic Diagram of Experimental Set-Up

The compressed air from the compressor enters the mixing chamber partly prefilled with fine grain abrasive particles. The vortex motion of the air created in the mixing chamber carries the abrasive particles to the nozzle through which it is directed on to the work-piece. The nozzle and the workpiece are enclosed in a working chamber with a Perspex sheet on one side for viewing the operation. The nozzle and mixing chamber are shown below.

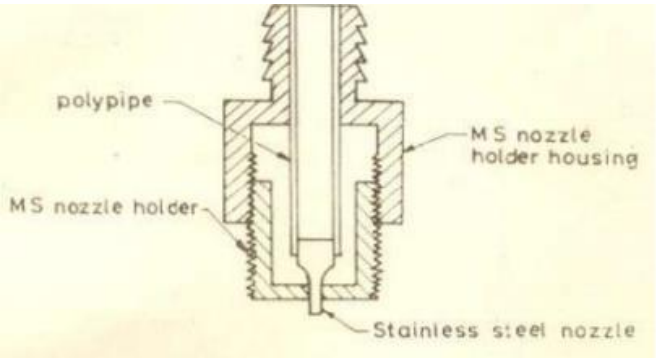

Fig -8: Nozzle Assembly

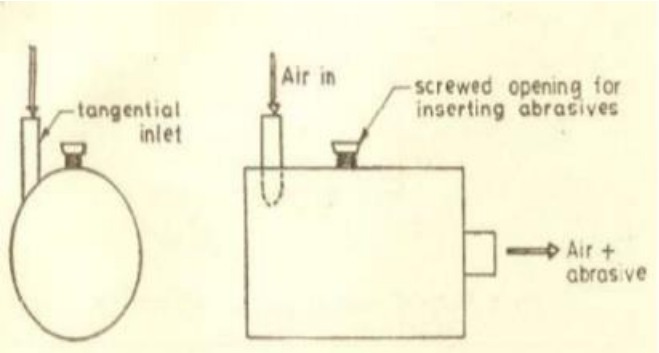

Fig -9: Vortex

Type Mixing Chamber The abrasive particles used were SiC (grain size 60 microns and 120 microns). The nozzle material was stainless steel and the nozzles used were of diameters 1.83 mm and 1.63 mm. This type of set-up has the advantage of simplicity in design, fabrication and operation. The equipment cost is much less except the compressor. The mixture ratio is controlled by the inclination of the mixing chamber. The mixture ratio is defined as: Where mp is the mass flow rate of the abrasive particles and ma the mass flow rate of air.

3. CONCLUSION

It is very clear that AJM is greater Non-conventional machining process which is used as a multipurpose system. It is also a most effective among various affordable systems. This system is eco-friendly. Even some of the companies in India like ABB, L & T and ESSAR are already using this system with CNC programming. This system is also use as Water Jet Machining (WJM) in which abrasives such as garnet, diamond or powders can be mixed into the water to make slurry with better cutting properties than straight water. Further development in WJM is called Hydrodynamic Jet Machining (HJM) which combines the principle of Water Jet Machining and Abrasive Jet Machining process. AJM is also used as Abrasive Flow Machining (AFM), Ultrasonic Machining (USM).

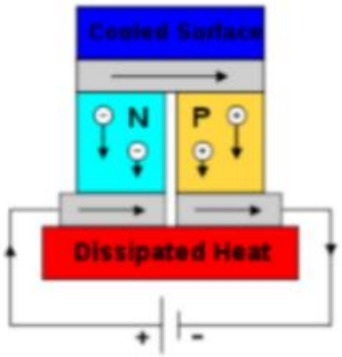
Abstract

The global increasing demand for refrigeration in field of refrigeration air-conditioning, food preservation, vaccine storages, medical services, and cooling of electronic devices, led to production of more electricity and consequently more release of CO2 all over the world which it is contributing factor of global warming on climate change. Thermoelectric refrigeration is new alternative because it can convert waste electricity into useful cooling, is expected to play an important role in meeting today's energy challenges. Therefore, thermoelectric refrigeration is greatly needed, particularly for developing countries where long life and low maintenance are needed. The objectives of this study is design and develop a working thermoelectric refrigerator interior cooling volume of 18L that utilizes the Peltier effect to refrigerate and maintain a temperature from 33 °C to 22 °C. The design requirements are to cool this volume to temperature within a time period of 1 hr and to obtain COP in the range of 0.2 to 0.6. The design requirement, options available and the final design of thermoelectric refrigerator for application are presented.

Key Words: Carbon dioxide, thermoelectric refrigerator, interior cooling volume, time period, COP etc.



1.INTRODUCTION

Refrigeration means removal of heat from a substance or space in order to bring it to a temperature lower than those of the natural surroundings. Thermoelectric cooling is a way to remove thermal energy from a medium, device or component by applying a voltage of constant polarity to a junction between dissimilar electrical conductors or semiconductors. Thermoelectric Refrigeration provides cooling effect by using thermoelectric effect i.e. Peltier effect rather than the more prevalent conventional methods like those using the 'vapor compression cycle' or the 'gas compression cycle'. Thermoelectric Refrigeration finds applications in electronic systems and computers to cool sensitive components such as power amplifiers and microprocessors. TER can also be used in a satellite or space application to control the extreme temperatures that occur in components on the sunlit side and to warm the components on the dark side. In scientific applications like digital cameras and charge-coupled devices (CCDs) TER are used to minimize thermal noise, thereby optimizing the sensitivity

and image contrast. The coefficient of performance (COP) of compression refrigerators decreases with the decrease in its capacity. Therefore, when it is necessary to design a low-capacity refrigerator, TER is always preferable. Also, better control over the space temperature is the major advantage of the TER. Hence, TER is good option for food preservation applications & cooling of pharmaceutical products.

1.1 PRINCIPLE

Peltier Effect: It states that when electric current is maintained in a circuit of material consisting of two dissimilar conductors, one junction becomes cold and the another junction becomes hot.

1.2 MATERIAL REVIEW

Thermoelectric module is made of two different semiconducting materials, which generate thermoelectric cooling effect (Peltier effect) when a voltage of similar polarity & in appropriate direction applied through the connected junction. Two heat sinks & fans are attached to hot and cold sides of thermoelectric module in order to enhance heat transfer and system performance. There exists an optimum current & optimum voltage for maximum coefficient of performance (COP) for a specific module and fixed hot/cold side temperatures.

a good thermoelectric material should have high Seebeck coefficient, high electrical conductivity, and low thermal conductivity. Commonly used thermoelectric materials are Bismuth Telluride (Bi2Te3), Lead Telluride (PbTe), Silicon Germanium (SiGe) and Cobalt Antimony (CoSb3), among which Bi2Te3 is the most commonly used one. These materials usually process a ZT value (figure of merit at temperature) less than one. From 1960s to 1990s,developments in materials in the view of increasing ZT value was modest, but after the mid-1990s, by using nano structural engineering thermoelectric material efficiency is greatly improved. Thermoelectric materials such as primary bulk thermoelectric materials like skutterudites, clathrates and half-Heusler alloys, which are principally produced through doping method are developed but not exploited for commercial use. [10]

The best commercial thermoelectric materials currently have ZT values around 1.0. The highest ZT value in research is about 3. Other best reported thermoelectric materials have figure-of-merit values

of 1.2-2.2 at temperature range of 320-5200C. It is estimated that thermoelectric coolers with ZT value of 1.0 operate at only 10% of Carnot efficiency. Some 30% of Carnot efficiency could be reached by a device with a ZT value of 4. However, increasing ZT to 4 has remained a formidable challenge. Bell also mentioned that if the average ZT reaches 2, domestic and commercial solidstate heating, ventilating and air-cooling systems using thermoelectric material would become practical. [10]

2. LITERATURE REVIEW

Jincan Chena et al.,[1]:- According to non-equilibrium thermodynamics ,cycle models of single-stage and two-stage semiconductor thermoelectric refrigeration were experimentally investigated. By using the three important parameters which governs performance of thermoelectric refrigerator i.e.coefficient of performance (COP), the rate of refrigeration, and the power input, development of general expressions performances of the two-stage thermoelectric refrigeration system took placed. It was concluded that performance of thermoelectric refrigerator depends on temperature ratio of heat sink to cooled space. When this ratio is small, the maximum value of COP of a two-stage thermoelectric refrigeration system is larger than COP of a single-stage thermoelectric refrigeration system; however maximum rate of refrigeration is smaller than that of a singlestage thermoelectric refrigeration system. Hence it is convenient to use single stage thermoelectric refrigerator when ratio is small. When temperature ratio is large two stage thermoelectric refrigerator is observed to be superior than single stage by both parameters i.e. maximum value of COP and maximum rate of refrigeration.

X.C. Xuan et al., [2]:- In this paper Two stage thermoelectric refrigerator was investigated with two design configurations. Two configurations were pyramid style and cuboid style as shown in respective figures. In pyramid style configuration top side is being coldest as current is unidirectional. In cuboid style configuration current can be alternated causing top and bottom side to be switched between heating and cooling mode. To obtain optimization methods other multi stage designs can be used. The point of maximum cooling capacity and maximum COP both were taken into consideration while investigation for optimization for the two-stage TE coolers. It was concluded that value lies between 2.5-3 for both parameters that is optimum limit of ratio of number of thermo electric modules of two stages in pyramid style TE cooler and optimum limit of ratio of electric current between stages of cuboid style TE cooler. Maximum temperature difference of pyramid-style cooler is greater than single stage cooler.

Jun Luo et al., [3]:- Using finite time Thermodynamics theory performance of a thermoelectric refrigeration system, with multielements was analysed. To improve and maximise the cooling load and coefficient of performance (COP) optimisation of the ratio of the heat transfer surface area of the high temperature side to the total heat transfer surface area of the heat exchangers was done. The

analysis of number of parameters which affects optimum performance of Thermoelectric system was done , parameters were number of thermoelectric refrigerating elements, the Seeback coefficients, internal heat conductance, the heat source temperature and internal electrical resistance. As well as the analysis of other parameters like influences of total heat transfer surface area and working electrical current on the optimum performance was done. They concluded that the cooling load and coefficient of performance (COP) of TE system is greatly influenced by total heat transfer surface area and working electrical current. These results can be used for designing and manufacturing of practical Thermoelectric refrigerators.

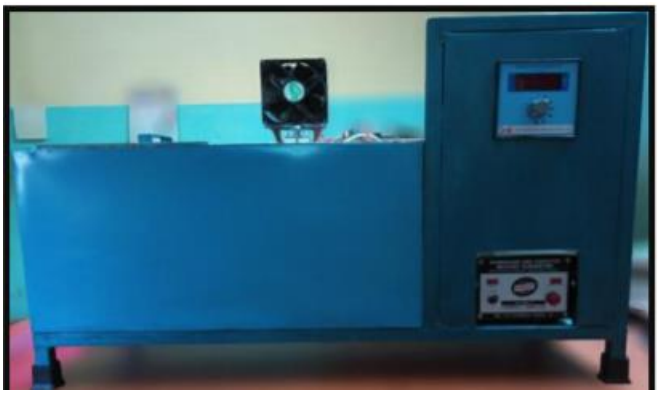
D. Astrain et al.,[4]:- In this paper a device using phase change material based on Thermosyphon principle was developed. This device was used and tested as a heat dissipater for hot side of TE cooler. Performance of TE cooler with this device was compared with TE cooler with conventional heat dissipater made up of fins. It was concluded that with the help of developed phase changing device it is possible to reduce thermal resistance between hot side of TE cooler and atmosphere up to 23.8% at 293 K ambient temperature and 51.4% at 308 K ambient temperature, compared to commercial finned heat sink . Decrease in thermal resistance ultimately causes heat to dissipate more effectively from heat sink of TE cooler, therefore improving the COP of TE cooler. At the same values of temperatures it was observed that COP increases by 26% and 35% respectively.

Yuzhuo Pan, et al, [5]:- Author of this paper designed and analyzed an Irreversible multi-couple thermoelectric refrigerator, which operates between two reservoirs maintained at constant temperature. Effect of other factors like external and internal irreversibility of thermoelectric refrigerator on performance was also studied. They have specified many important parameters which affects coefficient of performance (COP) of system. Results of obtained from experiments leads to knowledge of information about performance characteristics of real multicouple thermoelectric refrigerator. This information may be used to manufacture and design thermoelectric refrigerator which will perform at its optimum level.

Hongxia Xi.et al, [6]:- In this paper Author done survey on solar based driven Thermo electric technology. A brief history of development of solar based driven Thermo electric technology was presented. It's today's status and drawbacks present in current Technologies were reviewed. Applications, future scope, advantages over conventional technology where also discussed. In this paper they have discussed about two main modes, that are solar based thermoelectric power generation and refrigeration. Current status of both Technologies was described. Problems related to this technology and there possible solutions were presented. Ultimately these Technologies with some more development may lead to solve demand of Environment protection and energy conservation.

SuwitJugsujinda et al, [7]:- In this paper they have fabricated thermoelectric refrigerator using thermoelectric cooler. Thermoelectric refrigerator (25 × 25 × 35 cm3) and thermoelectric cooler (4 × 4 cm2). This system was applied to 40 W electric power without any cooling fan as heat dissipater at heat sink. They have measured temperature of this system at ten different points. It was concluded that these experiments results into temperature of cold side of thermoelectric cooler to be decreased from 30°C to -4.2°C for 1 hour and decreased to -7.4°C for 24 hours with heat plate temperature being 50 °C. Temperature of cold side of thermoelectric refrigerator decreased from 30°C to 20°C for 1 hour and decreased further in 24 hours. 3 and 2.5 are the maximum value of coefficient of performance (COP) of thermoelectric cooler and thermoelectric refrigerator respectively. S.A.Omer et al, [8]:- This paper presents some results of thermoelectric refrigeration system using phase change materials (PCM) integrated with thermosyphones. They investigated two models of thermoelectric refrigeration system, one with conventional finned devices as heat dissipater and other with phase change material (PCM) as heat dissipater. After results they have concluded that coefficient of performance (COP) and effectiveness of thermoelectric refrigeration system with Phase Change Material (PCM) is higher than conventional one. They have also compared thermoelectric refrigeration system of two kinds, one is using phase change materials (PCM) without thermal diode and other integrated with thermal diode (Thermosyphones). Results shows that thermosyphones used prevent leakage of heat during power off. Overall they have concluded system can be work with the help of renewable energies like solar energy producing electricity. It is suited for medicine and food storage.

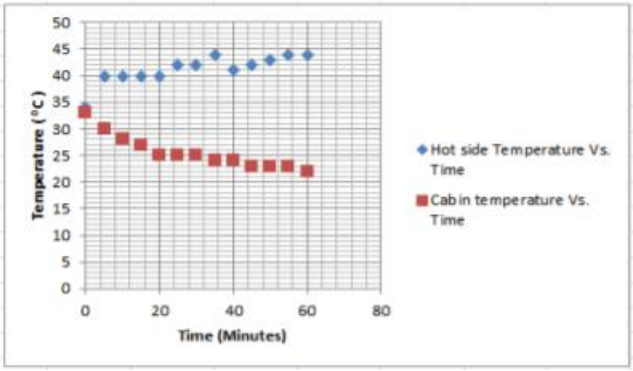
3. CONSTRUCTION



The cabin of volume 21 lit. is fabricated using galvanized sheets and polyurethane foam(puff). The inner surface of the cabin is insulated completely using puff (3.8mm) so as to isolate the cooling cabin from the atmosphere. The thermoelectric module is sandwiched between two CPU heat sinks of different sizes using thermal paste to set a single unit. Thermal paste plays a vital role in conduction of heat from Peltier module to the aluminum heat sinks. One such unit is made. These units are placed in the cut slots with the smaller CPU heat sink facing the interior of the cooling cabin and the larger CPU heat sink on the outside of the cabin to establish greater heat rejection. Additionally, fans are fitted on the inner and outer side of the heat sinks. Electrical connections are made and power is supplied from a 12V battery eliminator. K type thermocouples are placed inside the cabin and outside the heat sink to record the temperatures. Separate control panel containing dc eliminator switches and temperature indicator is made for taking readings.

4. WORKING

Experiments are conducted to analyses the COP. The power supply from the battery eliminator is given to system and readings of temperatures at different places are taken by placing the



thermocouples near modules, at center and outside the heat sink for every 10 minutes of time. The readings are tabulated and check for least temperatures occur in cabin and maximum temperatures occur at the outside heat sink. After that the power is switch OFF and checks for the storage times of the cabin and readings are taken. The tabulated values are plotted as temperature vs time for power ON and OFF conditions.

5. EXPERIMENTAL SETUP

6. RESULT AND DISCUSSION

Sr. No.	Parameter	Values
1	Maximum temperature difference in ºC	22
2	Time taken in minutes	60
3	$(COP)_{theoretical}$	0.4855
4	$(COP)_{actual}$	0.3143

From result table and graphs, it can be concluded that as time goes on increasing, the temperture inside the cabin falls down gradually. At the same time, hot side temperature remains constant (near about 40°C).

7. CONCLUSIONS

1. The Coefficient of performance of the system for TEC1- 12706 is calculated from the average of readings. It is observed that COP of Thermoelectric refrigeration using TEC1-12706 is lesser than COP of VCRS.

2. Solar power can be used as power source to the system as it is a renewable source of energy. This immensely decreases the working cost of the refrigerator and burden on the earth.

3. Liquid cooling at hot side can be used to increase the refrigeration effect.

4. Waste heat can be recovered using ducts for heating purpose.

5. Number of Peltier modules or multistage Peltier modules can be used to increase the cooling effect.

Abstract –

This paper presents different beverage machines each includes unique operation like vend beverage when user will insert coin or design of vending machine depends on FSM etc. Vending Machine is a system which can vend or offer different products normally installed in supermarkets like household goods, railroad lines, offices, institutes and various other public region. Dispense different products is an automated process, without man power easy to save precious time of human normally seen in fast moving cities because of fast paced life. This paper compares different aspects or response like space, time, speed, power dissipation of a vending machine that is automated product to create our day to day life more suitable and to cover market viability. Key Words: Vending Machine, FSM, Human Machine Interaction, Xilinx ISE and Cadence, etc.

1.INTRODUCTION

Vending Machine (VM) is a machine which can automatically vend different products according to user demand. Vending machine is a machine which uses digital and mechanical energy or mechanisms uses actuators etc. in order to dispense items like medicines, food products, passes or licenses to users automatically means without man power on payment into slot. In most cases vending machines receive two sets of instalment, Credit/Debit Cards and Cash. Credit/Debit Card attributes require to be seized for sales along credit cards. Coffee vending machines can be installed anywhere such as bus station, office, residential region, construction, etc. Accordingly, humankind who likes to drink coffee or tea can buy a cup of coffee or tea anywhere and anytime from them.

2. SURVEY ON DIFFERENT VENDING MACHINES

A great flavoring drink permits workers, guest and customers a bit of gratification in a overdone day. All foods, beverages and constituents offered for disposal through vending machines will be constructed, handled and developed in creations.

2.1 Influential Factors of Vending Machine to Enhance the Interaction Performance

General VM buy activity. The entire operation carried 5 steps, namely starting buy, selecting, filtering, instalment and closure. The selected particular performance solutions in each step were clarified and costumers' tasks in each selection were examined.

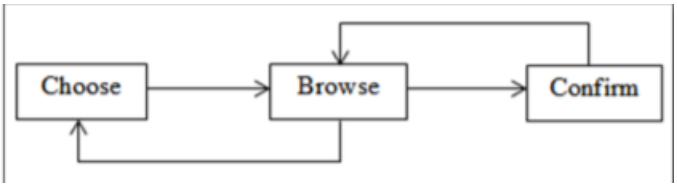

Fig. 1 : Concept of model

Vending machine interface action is mostly divided into four important steps of click, browse, confirm and return. Click, browse and confirm are the three important steps as the main important action. Phase return is considered as an coincidental performance, that is, return demands are constructed when the costumer handles incorrectly. Return is splited into two kinds: return to the previous step and return to the start sheet. Choose - browse - (return) – establish the correctness that can be deliberated into the less time for T=a+b+c as stated by to buying operation. Buy time is being enlarged when the return performance appears. Then the total time for the buy action can be decided as T0=a+b+c+d. They hypothesize that increase the time of buy are 2 return actions: 1. The first time to considering for the return button. 2. Returning to the start sheet, click on the return button and halting on each sheet before this one. The concept of model is shown in above figure. It market viability with improving intellectual benefits or regulation, shortens buy time and stay away from performance defeats.

2.2 Comparison of different attributes in FSM based Vending Machine

They speak about two different set of rules for a vending machine as delineated below and then detecting out the changing speed, timing restraint, power, space demand andusability of logic present in stratixfpga family in order to observe out more well organized and synthesizable that is covert HDL into actual component machine as for this vending machine specification. Vending machine characteristics to be executed is related as below:

1The machine withdraws multiples of Rs10 only.

2. The machine can disburse:

Water:Rs 20 (Wi)

Snacks: Rs 20 (Si)

Soft Drink: Rs30 (Ci)

3. It has a Cancel key or tab (Cc)

4. Only one input may be operate at a time

5. A system can be disbursed in one complete clock cycle

6. If more than Rs 30 is put, the money is automatically that is without physical interaction the extra money come back means returned

7. If no inputs are active lively, the state system remains in same state that is in the current state

. 8. Outputs: All construct a pulse that operates the deliver contraption:

Ro: Return out (all money in the system)

Wo: Water out, Co: Soft drink out

So: Snacks out,

out10: Rs 10 out

Originally the system was in its set initial position or condition which called state A for the design reason. Given an input of Rs 10 the system design moved in its 2nd condition which was state B involved with this point the vending system is griping Rs 10 in its balance and the user has 2 selections either to reject the vending operation with the input of Cc that is cancel which is available on the system or set in another Rs 10 note in the system and go on to the next condition which is state D. Now at this period vending system assembled Rs 20 accordingly user is qualified to select options between water or snacks both of which are of Rs 20 and then go back to its inceptive condition besides beat Cc (cancel) key to finish the operation or besides set in another Rs 10 note in the machine to vend the soft drink which prices Rs 30 so by now the user has extended state G, another Rs 10 note will be directly discarded and signal out10 goes high radiating off the additional Rs 10 out of the system from this condition user can prefer any one of the three outcomes to vend from the vending system that is soft drink (Co), water bottle (Wo) or snacks (So) or one can comparable Cc (cancel) and all money will be get back by forcing Ro signal. Total number of conditions utilized is from A to H that is 8 conditions constructing it a little redundant. Next the same vending system with same characteristics with a little more expert or skillful way so as to reserve some space and condition demand and then observe out the wanted system is well organized or not than the foregoing space proceeding system in phrases of different essential features of a design cycle. Differentiating two dissimilar algorithms, the key difference is under timing restriction permitting positive setup time and negative hold time. One design finding one more additional condition it is better organized in terms of timing restriction and space.

2.3 Smart Coffee Vending Machine

A smart vending system accommodates a sensor and actuator network which made up of a gateway, arising from a person's surroundings sensors, and controllers. A gateway suits an overpass between the network and an implementation managing on a smartphone that is mobile along Bluetooth. The gateway presented with some missives associated to the arising from person's surroundings conditions (for example, cleaning status) of the system from the sensors. Those missives are sent to the supplication. In inclusion, the gateway sends command missives involving the customer's predilection on the taste of coffee to the controllers. On an approach of the verification of abstraction, they establish two magnetic sensors and three controllers. The vending system and the apparatuses established in the vending system. The magnetic sensors are established interior the system: one is connected to the substances mixer and the other is connected to the body of the system. The sensor on the body is joined to a sensor interface which conveys resolute data to the gateway. The sensors react like a switch. If the mixer is isolated from the body, an unsecured happening occurs. Otherwise, a secured happening occurs. The remoteness of the mixer is examined to be the cleaning status of the system. The substances mixer is a tool in which water, coffee, sugar and powered coffee creamer are motley to create a cup of coffee. As a much of remnant of thosesubstances are connected to the internal exterior of the blender, the blender should be cleaned from time to time. The blender has to be disconnected from the system while it has been washed. Accordingly, it is supposed that the blender is wash if it is isolated from the system. By the supposition, the role of the sensors examines whether the system is washed or not for a definite time interval. With the details of data collected from the sensors, the gateway computes the constituting wave of cleaning for a particular time and regulates whether the system is clean or not. The gateway conveys these detailed data to a smart phone application when the supplication links to the gateway. The controllers adjust and manage the quantity of coffee, sugar and powered coffee creamer depending on whether to customer's predilection on the taste of coffee. The customer's predilection is collected from a smartphone supplication through the gateway. Each controller handles the gyration of a motor which regulates the quantity of each substance. The quantity of the gyration is handled in three steps: less, normal, and much. Smart vending system which can automatically that means without man power and without physical contact with that object evaluate its own under cover situated arising from person's surrounding conditions and handle the quantity of coffee, sugar, and powered coffee creamer to create a cup of coffee depending on whether to customer's predilection on the taste of coffee. A sensor and actuator network which made up of a gateway, magnetic sensors, and controllers and a smartphone supplication depended on Android. The network and the supplication interchange some data through Bluetooth.

2.4 Automatic Beverages Vending Machine and it's performance on Cadence and Xilinx 13.1

The popular behavior of any vending favors the as a result of steps with available make different depended on the end user demands. The systems generally work, when some money is set in a time period. Then, a key or tab requires to be forced or a bar dragged. If the exact amount value is loaded into the time period of the system, the selected object will be dribbled to a flat container, where it can be drawn out by the person creating the buy. Selection: User creates a selection of product. Waiting for money placing: When user puts money or cash, money token allows the quantity of cash or money placed into the vending system. Product Delivery: If accurate quantity of cash value is placed the product will be dropped and if there is any assess will quantity that will be get back to user. Service: The vending system will request for service if the product is not able to be used in the system.

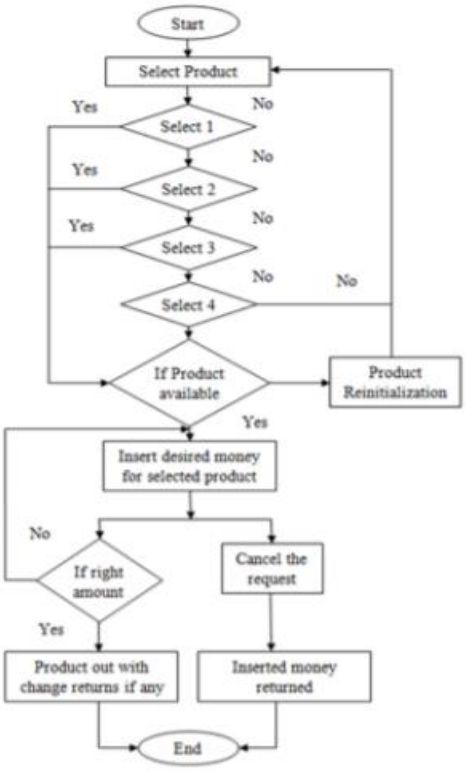

Fig. 2 : Flowchart for Vending machine

This same design they executed or contrivance on xlinix 13.1 and cadence so ultimately they judge regarding these execution, operating cadence permits optimized or improving efficiency related to space, power and delay.

2.5 Vending Mahine based on the short message payment

The vending system is predominantly collected of 3 parts: vending system correlated interact with system (containing vending system interface plate, monolithic integrated circuit and GPRS module), GPRS communication networks which are containing mobile diverting middle of GPRS base station

controller, GPRS service support node as well as GPRS backbone networks etc. and the control center. The vending system communication interface module is predominantly collected with of monolithic integrated circuit and GPRS module and so on.

The monolithic integrated circuit obtains vending system's condition or position information via the Multi drop bus (MDB) protocol, reserves it to the burn and then sealants the user datagram protocol (UDP) data packet depending on whether to the user datagram protocol (UDP) agreement's message data, seals the IP data newspaper in addition to the IP highest part, and then seals the point to point protocol (PPP) frame depending on whether to the point to point protocol (PPP) frame's form, broadcast it to the managing main center through the GPRS module by the IP protocol, assembles communication between monolithic integrated circuit and GPRS module via PPP. The user first sends the information data to the guest facility managing center and then the buying or selling from user center sends back the information frame to the user and the vending system GSM module. The user inputs the information data frame on the vending system and then the automatic managing vending system handles the information data frame to send the managing instructions automatically. The information data frame which the GSM module accepts is transferred to the buying and selling action of user center to assemble the last information data processing. The short message payment by acquiring M68HC11 and MC35 and construct it have the task of the short message shopping and assemble it simple to use and handle.

3. EXAMPLE OF IMPLEMENTATION OF VENDING MACHINE USING XILINX 14.2

Vending system that sells soda canes that costs are a 20 each. Additionally system has only 3 types of coins: 10, 20 and 50. System purpose is to design a state machine with different conditions that regulates when to disburses a cane, how to get back the change. In this design cane pay no attention to the volume of the storage, which means, it will suppose that there will ever be cane in the vending system. Also, suppose that only one operation could be created in every “clock cycle” or position. Understanding the possibilities : There are quite few options:

1) invading no money

2) placing 10 reproduced by another 10 => acquiring the can

3) placing 10 reproduced by 20 => accepting modification => acquiring a cane

4) placing 10 reproduced by 50 => accepting modification => getting a cane

5) placing 20 and acquiring the cane

6) placing 50 => accepting change => acquiring a cane.

State Diagram:

Fig. 3 : State Diagram

Explaining the states:

1) put_money: this is the first condition after idle condition; here the user sets in the coins.

2) in_5: If the user place 50, the system proceed to this condition. Pay attention that the machine gives back a 20 change without disbursing the cane yet.

3) change_1: after providing a 20 change for the user who paid 50 they require to get back another 10 change. Here, in this condition they do absolutely that. Again, note that the cane still has not been disbursed yet.

4) in_1, in_3, in_6: acquire to those conditions be controlled on the sum of money that been entered by the user.

5) soda_out: disbursing out the soda cane.

Simulation Result:

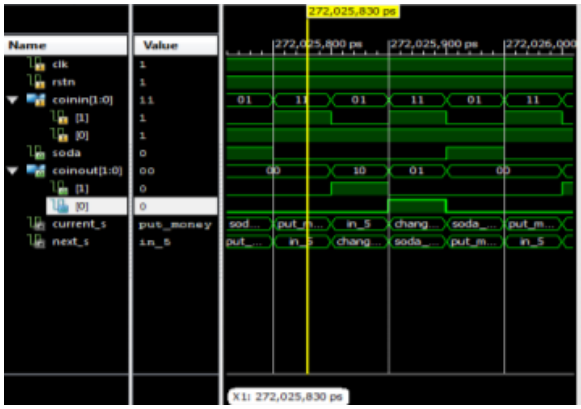

Fig. 4: Waveforms gives detailed information about system

4. CONCLUSIONS

Compared different vending machines and all are designed with different aspects like area, power and delay because of time, switching speed, etc. In smart coffee vending machine is more optimized system with customer preferences. Because according to customer choice they can also select amount to prepare coffee or tea. This is optimized system with some aspects which are power, area and time. Also explain with one example of dispensing soda according to inserted coin to cover market feasibility.

WIND ENERGY VEHICLE

Mr. M. Vishnu Teja [1], Mr. N. Sri Chandrahas [2]

Asst.Prof Mr. M. Vishnu Teja [1], Dept of Mining Engineering, Malla Reddy Engineering College (Autonomous) Maisammaguda, Dhullapally post, via Kompally, Secunderabad-500100 India

Asst.Prof Mr. N. Sri Chandrahas [2], Dept of Mining Engineering, Malla Reddy Engineering College (Autonomous) Maisammaguda, Dhullapally post, via Kompally, Secunderabad-500100 India

Abstract-

Due to scarcity of fossil fuel in future and its detrimental effect on the environment, an alternative energy has to be discovered. Wind power is clean and sustainable natural resources that has yet to be fully utilized in the automotive industry. Also, the sun is probably the most important source of renewable energy available today. The hybrid system has been designed and installed to generate power which combines wind turbine and solar panel. The hybrid model system is renewable energy system, which helps conserve energy by reducing the use of fuel in vehicle. Hence developing a new method for the economical evaluation of Hybrid Systems for electricity production. Keywords- Scarcity, fossil fuel, environment, alternative energy, natural resources, renewable energy.

1. INTRODUCTION

Here the hybrid car is specially designed so that the energy limitation can be easily overcome y using the hybrid technology. As the battery running are beneficial for the society and more often this type of technology is fruitful for the environment. so to overcome the energy limitation we have installed wind with solar energy and that is called the regeneration of A. Reducing Carbon Dioxide Emissions The most effective way to reduce carbon dioxide (CO2) emissions is to reduce fossil fuel consumption. Many strategies for reducing CO2 emissions from energy are crosscutting and apply to homes, businesses, industry, and transportation.

B. SOLAR ENERGY

Solar energy is radiant light and heat from the Sun harnessed using a range of ever-evolving technologies such as solar heating, photovoltaic's, solar thermal energy, solar architecture and artificial photosynthesis. The large magnitude of solar energy available makes it a highly appealing source of electricity.

C.WIND ENERGY

Wind power is the use of air flow through wind turbines to mechanically power generators for electricity. Wind power, as an alternative to burning fossil fuels, is plentiful, renewable, widely distributed, clean, produces no greenhouse gas emissions during operation, and uses little land.

2. FIELD OF INVENTION

The fixed wind powered electricity generation systems in use, till now are dependent on wind direction and the force of the wind. But the wind is not available at all places and all time throughout the year. Therefore, there exists an immense need of a system for generating electricity from wind induced by moving vehicles which is available throughout the year at various places and with sufficient force of wind. Also solar powered electric vehicle is there but need to install it as an auxiliary fuel for fuel vehicle. Therefore, need of inventing a hybrid renewable energy source as an auxiliary source for fuel vehicle. Therefore, this invention provides a solution to the problem for generating electricity in this manner.

3. OBJECTIVES

1. The main object of the present invention is to provide a method and a system for generating electricity using easily available wind induced by moving vehicles and solar energy in transit or in operation.

2. The other objective is to provide a solution for reducing pollution created by fuel vehicle by use of freely available renewable energy source i.e. solar and wind energy.

4. METHODOLOGY

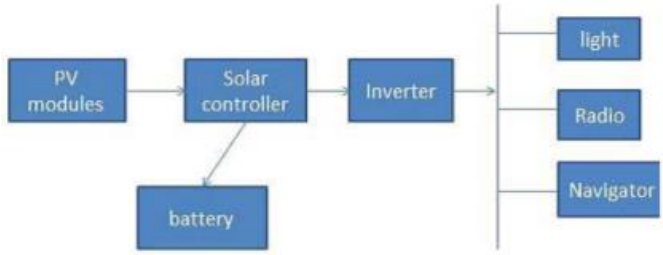
This paper deals with how energy can be stored by moving or standstill vehicle which has a fuel kit using wind and solar energy.

5. WORKING

Here first of all the vehicle that is presently running on battery say for ola electric vehicle can be modified by installing various new circuits. The solar panel will charge the battery on the day time. The circuit attached to the battery will protect the battery from damages the sunlight intensity is more in the summer the solar panel passes more amount of voltage than required by the battery and this leads to the battery damage so forstabilizing the voltage the circuit will be installed between the solar and the battery. As there is no one in the electric car we can install the carborator fan and the fan will be attached to the generator and the vehicle is in moving position even in the night time when the solar panel will not work the battery will be charged through the wind energy that is from

the fan with dynamo attached and the battery will be charged. Clips are attached so that the user can change power source for charging the battery from solar to wind when required. And in another part the sensor based circuit is also installed this circuit will connected to the motors of the vehicle in the night time or at that when the driver forgets to apply brake in the traffic portion or when driver fall asleep while driving in the night time this sensor circuit will continuously bypass the invisible rays and the rays will detect the in front object of the vehicle if suddenly in front objects say for any vehicle has applied brake and the driver forgets to apply brake this sensor will automatically will calculate the distance and the both objects comes closer then the sensor will pass command to the circuit and the brakes will be applied automatically. This system can save lot of life even it can avoid accidents. For increasing the loading capacity of the motor the gear section that is the gear box is also installed that will increase the loading capacity of the motor without consuming more voltage and power from the battery.

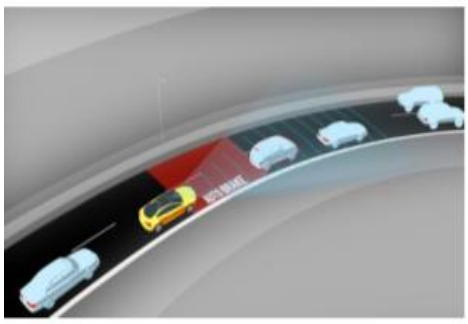
Chart -1: CIRCUIT DIAGRAM



A. CONVERSION OF WIND ENERGY INTO ELECTIC ENERGY:

In this prototype the wind capturing device is a fan. Fan is mounted on the front side of the chesis with the truncated cone in front of it. Fan will get rotated by the wind blown by the blower which will get directed toward the fan due to cone where in actual it will be the wind around the vehicle when vehicle is in running condition. Rotating fan will convert the captured kinetic energy of wind into mechanical energy .The centre shat motor which is connected to battery will convert this mechanical energy into electric energy which is going to stored in the battery. Fig shows below the energy stored by prototype from wind energy.

B. **CONVERSION OF SOLAR ENERGY INTO ELECTRIC ENERGY:**



Solar panel is situated on the top of battery in the prototype. Where in actual vehicle it will be mounted on the upper body of chess is of four wheeler. While the vehicle in running position or stand still and have a sufficient solar energy the solar panel will trap that energy and due to the photovoltaic effect of solar panel, it will convert this solar energy into electric energy which will get stored into the battery.

6. AUTOMOTIVE TRACKING SENSORS

The sensors used to track objects and monitors, the movement of the host vehicle as well as the movement of the surrounding objects to predict collisions are known as 'tracking sensors'. In automotive applications, cost of the sensor is a major factor.

7. ADVANTAGES

1. Zero Carbon emission

2. Accidents are avoided due to automatic braking

3. Use of brushed motor

4. Vehicle speed has been increased

5. Can run in the city as well as on highways.

8. DIS-ADVANTAGES:

1. Limited vehicle speed

2. Limited distance covered

3. Takes more time to charge the battery.

4. Only can be used in city.

9. CONCLUSIONS

After making the final completion of project it is found that project is in working condition. It is found that prototype captured the solar energy through solar panel and wind energy through fan induced on it. There are huge potential for producing electricity from renewable sources. This paper gives a clear idea that vehicle powered with the help of solar energy and wind energy is more effective than fuel vehicle.

WIND MILL BASED WATER PUMPER

Mr. P. Shashikanth[1], Mr. G. Harish Kumar[2]

Asst.Prof Mr. P. Shashikanth[1], Dept of Mining Engineering, Malla Reddy Engineering College (Autonomous) Maisammaguda, Dhullapally post, via Kompally, Secunderabad-500100 India

Asst.Prof Mr. G. Harish Kumar[2], Dept of Mining Engineering, Malla Reddy Engineering College (Autonomous) Maisammaguda, Dhullapally post, via Kompally, Secunderabad-500100 India

Abstract –

The main source of energy has been coal, oil, natural gas, nuclear energy, wood and coal. However, all these sources are limited and are the main cause of pollution and this has led to development and more focus on sustainable energy supply with minimum pollution effects. Hence research and analysis has shown that wind energy, solar energy and biomass are the most prominent solutions to the above problems because they are eco-friendly and readily available in nature. Wind energy can be generated using windmills that provide mechanical energy that is used directly on machinery e.g. water pump and grinder; or wind turbines that provide electrical energy. The main objective of our project was to design a windmill and therefore our scope will be limited to a windmill for water pumping water. Windmills are classified into two main types based on the axis about which they rotate. Horizontal axis has the main rotor shaft running horizontally and if the rotor must be oriented in the direction of the wind, a wind vane is coupled with a servomotor. Vertical axis has the main rotor shaft running vertically. The rotor assembly can have two or more blades depending on the desired solidity. In our design, we used a horizontal axis windmill with 3 blades, tensile strength 31 N/mm², density 0.855 g/cm3, length of blade 30 inch (2.5 feet) and strength of blade is 4500- 6000 psi. Key Words: natural resources, renewable energy, wind pumps, insufficient fuels, aerodynamic blade.

1.INTRODUCTION

Energy today has become ultimate need of world. Today every application which has been develop in the world require energy supply for its functioning but population of the world is increasing causes tremendous pressure on the energy and mineral resources leading to their exploitation. More ever the greenhouse gases are increasing due to exploitation of these resources. So we need to focus an alternative solution for this problem. Light, wind, Biomass, water etc. are some of the alternative for this problem. Wind is one of the most clean and highly abundant resources in nature.

1.1 Definition

Wind This is air in motion and it is a natural resource that is freely available in space and moves at varying speeds depending on the geographical location Wind energy Wind energy originates from solar energy where the sun heats the atmosphere unevenly causing some parts to be warmer than others. The warmer patches of air rise and other air patches blow in to replace them. Thus alternating air flow which results in wind. Windmill Windmills are machines that are used to harness the kinetic energy of the wind which blows over the blades rotor assembly causing it to rotate on a shaft. The resulting shaft power is then used to provide mechanical work for pumping water.

1.2 Objective

- Lifting the water without using electricity and fossil fuel.
- Setup must be non-polluting and less noise operation.
- Setup cost should be less and maintenance free, one time investment is preferable.
- It must produce some amount of power.
- Installation must be easy and cheap.
- Fuel must be cheap, clean and renewable.
- Solution for the above problem must be eco friendly

2. MATERIAL SELECTION

There are various materials available for design of blade such as wood, fiber, steel, aluminum, carbon fiber, polypropylene plastic. Out of which we have used polypropylene plastic (pp) type material for our design because of following reasons: Polypropylene blade performance and also to decrease process temperatures by adding special particles like nano, fillers.etc in order to replace the current thermo sets by utilizing the benefits associated with the thermoplastics like emission free, process-ability, recyclability, and weld-ability. Polypropylene materials offer higher strength to weight properties than thermo sets, therefore leading to lighter aero foils which can lead to cheaper transport costs and reduced turret weights.

3. MANUFACTURING

3.1 DESIGN OF BLADE

Aerodynamic performance is fundamental for efficient rotor design. Aerodynamic lift is the force responsible for the power yield generated by the turbine and it is therefore essential to maximize this force using appropriate design. A resistant drag force which opposes the motion of the blade is also

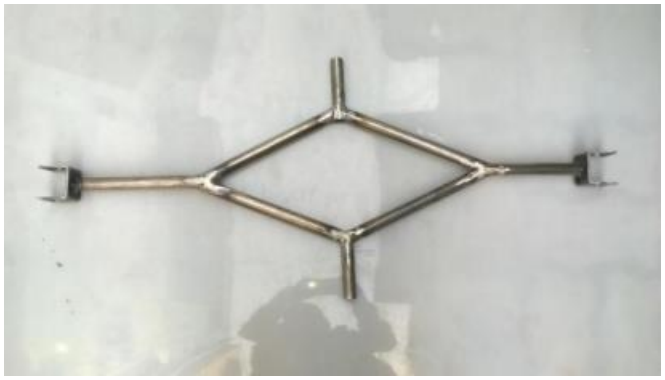
generated by friction which must be minimized. Turbines operate for long periods at ground level where insect and dust particulate build up is problematic. This build up known as fouling can have detrimental effects on the lift generated. Provision is therefore made for the reduced sensitivity to fouling of wind turbine specific aero foil designs. The structural requirements of turbine blades signify that aero foils with a high thickness to chord ratio be used in the root region. Such aero foils are rarely used in the aerospace industry. Thick aero foil sections generally have a lower lift to drag ratio. Special consideration is thereforemade for increasing the lift of thick aero foil sections for use in wind turbine blade designs.

3.2 CRANK SHAFT

Another most important component for the smooth functioning of prototype is crankshaft. Crankshaft should poses high strength, rigidity and toughness due to these requirement they are manufactured by casting and forging production techniques. Crankshaft is component connected between the turbine blade and connecting rod. With the rotation of turbine blade, certain mechanical motion is obtained which is transmitted to the crankshaft leading to rotary motion of connecting rod with piston in the pumping assembly.

3.2.1 DESIGN OF CRANKSHAFT

The size of crankshaft was too large so we have fabricated it to the required size for our project. Above table shows the original size & required size.



3.3 CONNECTING ROD

Connecting rod is long slender component between crankshaft and piston assembly via sew-saw mechanism. Mechanical motion obtained from the crankshaft for the reciprocation of piston rod in pumping assembly is transmitted via connecting rod. Connecting rod should have high ultimate tensile stress, resistance for the bending, fatigue stresses so it should be manufactured by casting and forging production techniques

3.4 SEW-SAW MECHANISM

Sew-saw mechanism is the basic principle for reciprocation of piston in pumping assembly is achieved by sew-saw mechanism. Blade rotate further leading to the rotary motion of crankshaft. This rotary motion is further transmitted in the form of transverse motion for the reciprocation of piston rod in pumping assembly.

3.5 PUMP

There are two types of pumps;

1. Volumetric (Positive displacement pump)

2. Centrifugal (Roto-dynamic pump)

Out of which we have used positive displacement pump. Positive Displacement Pump are further categorized as

- Rotary lobe pump
- Progressive cavity pump
- Rotary gear pump
- Piston pump

- Diaphragm pump
- Screw Pump
- Gear pump
- Hydraulic pump

Hence for better displacement and sufficient water discharge we have used “Piston Pump (single acting reciprocating pump)” Piston pumps are generally connected to a surface-mounted motor and used to pump water from shallow wells, surface water sources, and pressurized storage tanks, or through long pipes. The suction head is limited to 6 meters. They are not tolerant to silt, sand, or abrasive particles because the piston seals are easily damaged. Filters may be used to remove the dirt

4. WORKING

To conduct trail, we have done set up of wind operated water pump. Windmill blades made up of polypropylene (pp) plastic. Turbine is fixed on crank shaft. Crank shaft is mounted on supporting stand. To permit relative angular motion crank shaft is mounted between bearings. One end of connecting rod is connected to crank shaft and other end connected to sew-saw mechanism by using connecting pin. A piston rod of pump is connected to one end of sew-saw mechanism. All these assembly mounted on structure insucha manner so that we should get the desired motion of piston rod. When wind is imparted on blade kinetic energy of wind is converted into mechanical energy as an angular motion of crank shaft. This angular motion of crank shaft is converted into transverse motion by sew-saw mechanism. Transverse motion is given to piston of pump so that piston will move in transverse direction. When crankshaft rotates the piston will moves in upward and downward direction inside the cylinder. When piston moves from bottom dead centre to top dead centre of cylinder, vacuum is created due to which water is sucked inside cylinder. When piston moves from top dead centre to bottom dead centre pressure of water increased above atmospheric pressure at the end water is discharged through pipe. Due to pump is single acting reciprocating pump thus there is alternate flow of water in the delivery pipe. The shaft power can be used to generate electricity by using alternator, which is mounted on crankshaft.

6. CONCLUSION

The goal of project is accomplished from the requires analysis and fabrication of prototype that is utilization of wind power to pumping water and generate electricity. Most preferable and suitable material from the design consideration point of view satisfying all the optimum condition and requirement is found to be Polypropylene Plastic. From result we have seen the efficiency of aerodynamic shape blade.

ACKNOWLEDGEMENT

Abstract:

In our project wind energy is used to rotate the wind blades. This blade coupled to the shaft. At the end of shaft, the flywheel is placed. The eccentric arrangement is provided in the flywheel. When the blade rotates automatically fly wheel also rotates. Due to the eccentric arrangement the rotation motion of the flywheel is converted into linear motion. This reciprocating motion is given to the handle of the pumping system. The up down motion of the handle is given to the piston, where the water is sucked using pressure variation from lower ground. Finally the water is supplied to the outlet. Wind blade provides the continuous motion which helps to supply the water continuously .Since time immemorial, the main source of energy has been coal, oil, natural ga s, nuclear energy, wood and coal. However, all these sources are limited and are the main cause of pollution and this has led to development and more focus on sustainable energy supply with minimum pollution effects. Hence research and analysis has shown that wind energy, solar energy and biomass are the most prominent solutions to the above problems because they are eco -friendly and readily available in nature. Keyword: Fly wheel, Reciprocating pump, Blade, and etc….

INTRODUCTION

Energy from the air can be utilized in multi various ways. It can be tapped directly from air in the form of electrical energy. The contribution of these sources in the total consumption of energy in the world is about 15%. The scope for application of air energy now stands inherently enhanced through intensive research and development carried out all over the world. Air can be directly utilized for the purpose of cooking and drying. By the same time, it can be also used for boiling of water, air heating and refrigeration. Furthermore, wind energy can be utilized for driving motors for pollution free riding at this time, where air pollution plays a major problem for environmentalist

II. EXPERIMENTAL PROCEDURE

The experimental analysis of this project started with a detailed study of various mechanisms that could be used in this project and their practical applications. Since this project involves the effective

utilization of energy derived when a nature air the design aspects may not actually coincide with the requirements for the fabrication and practical applications. Hence, the method of Reverse Engineering was adopted in this project. As per this method the tower was first fabricated based on the requirements with standard parts keeping in mind various safety precautions. Testing and then the basic designing of the parts followed this. If any of the parts was found to possess strength lesser than the required, it was replaced by a standard part of greater strength. The wind energy is converted into mechanical energy. Initially this project had a nature air area and tower with a fly wheel leaf reciprocating pump arrangement .Also the rotation of the flywheel was not found to be satisfactory, reducing the efficiency of the leaf. This flywheel and leaf has a velocity ratio of 1:1. Leaf is attached to the flywheel. Windmills generally consist of two basic types with the classification being based on the orientation of the axis of the rotor. The main classifications are discussed below:

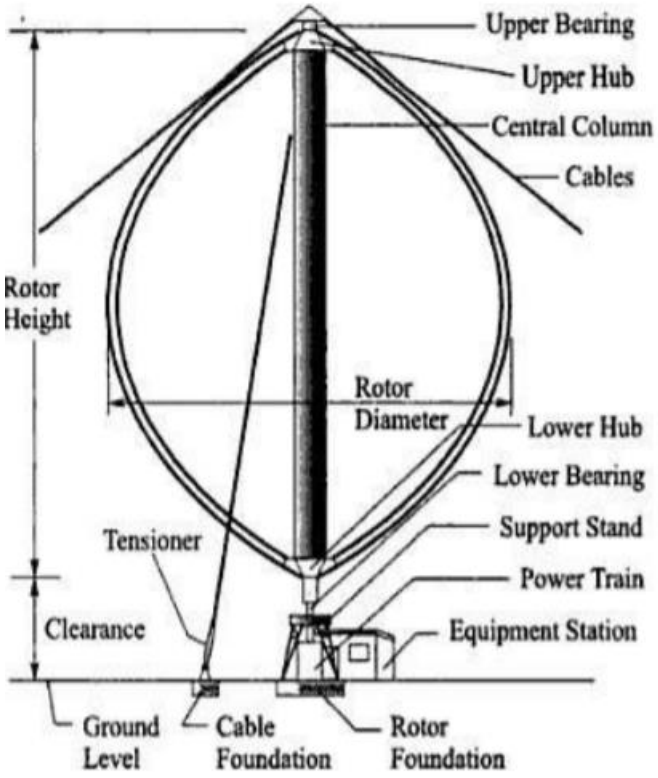

Figure.1. Wind Mill with Pump

2.1 Vertical Axis Wind Turbine (VAWT)

This has blades which are arranged on the vertical axis and are rotated by wind and therefore it doesn't require a yaw mechanis m since it can harness wind from any direction. It does not rely on the direction of the wind to generate power as in the case of the horizontal axis. They usually operate closer to the ground which has an advantage of allowing for placement or replacement of heavy equipment. However this is a disadvantage as winds are lower near ground level hence less power output. 2.2 There are two main types of the VAWT namely: Savonius It operates like a water wheel

which uses drag forces. It has a simple design and is therefore relatively simple and cheaper to build. It is mostly used in situations that do not require large amounts of power. However, it is less powerful than most HAWT because it uses drag to rotate itself and has a higher power to weight ratio. The total amount of turning torque of the mechanism relies on the drag force on each blade. Darrius It uses blades similar to those used in the horizontal axis wind turbine (HAWT). It has two or more curved blades that depend on wind in order to revolve around a central column. It functions by generating a lift using the rotating motion of the blades. The wind acting on the blade creates a rearward momentum change which propels the blade in the direction of rotation. This cannot occur unless the blades are already rotating and therefore they require a separate means of starting i.e. they are not self-starting. Figure.2. Vertical Axis Wind Turbine

2.3 Horizontal Axis Wind Turbine (HAWT)

It has blades that are similar in design to aircraft propellers where air flow over the air foil shaped blades produces a lifting force that turns the rotor. They should be placed on towers to ensure maximum use of the winds at higher levels. For large scale types, they have an active yaw mechanism with wind direction sensors and motors that will rotate the nacelle. In both upwind and downwind the rotors should be perpendicular to the direction of wind and if the rotor is held in a fixed position, only 21% of the wind energy will be captured (Wortman, 1983).For upwind type, the rotor rotation is accomplished by using a vane to measure the direction of the wind and then the information is communicated to the yaw drive. The yaw drive then drives the rotor so that the turbine is facing the direction of wind for maximum harness. They don’t suffer from wind shade phenomenon as the wind is tapped early enough before obstruction by the tower. For downwind types, they don’t use a yaw drive because the wind itself orients the turbine. The blades are situated on the downwind side and therefore capture the wind and rotate following its direction. These designs are prone to “wind shade” a process in which the wind flow is obstructed by an object e.g. the tower thus reducing amount of wind and therefore a reduction in the power output.

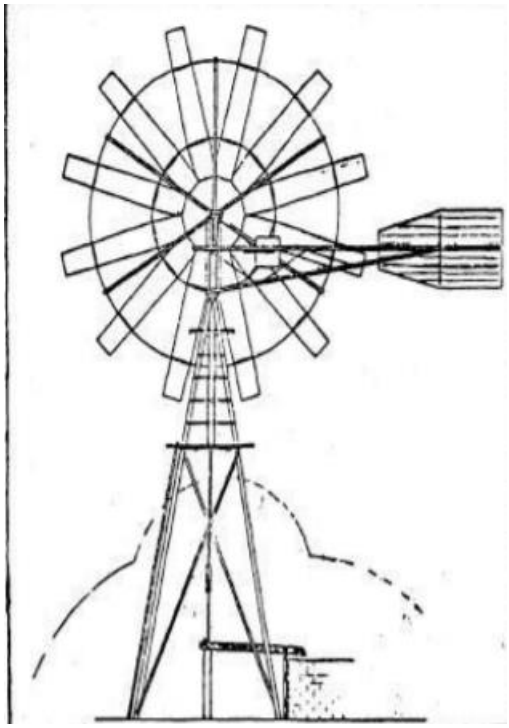

Figure.3. Wind Mill

III. DES CRIPTION

3.1 Field of the Invention

The present invention relates generally to the recovery of water from an underground source through the use of a reciprocating pump system. The present invention relates more specifically to an improved water pumping system adapted to be driven by a windmill that utilizes an air lift fluid pump for generating a flow of water to the surface.

3.2 Description of the Related

Art Water pumping windmills may be found on farms and ranches worldwide and provide critical water supply for domestic and livestock use, especially in areas where electrical and fuel driven pumps are not practical. The type of technology associated with these windmill water pumps has enjoyed continuous use since the late 19th Century and may be generally illustrated by U.S. Pat. No. 1,632,188 assigned to the Dempster Mill Manufacturing Company (1927). This type of windmill pumps water by means of a positive displacement, reciprocating pump, submerged below the static water level of a drilled well. The pump is conventionally connected and supported by a water discharge pipe which leads to the surface and a reservoir for the water. The pump is driven by a reciprocating rod, typically made of wood or fiberglass, which reaches down from the windmill's transmission to the pump through the discharge pipe. It is typical in reciprocating water pumps of this type to utilize a barrel or cylinder within which a piston is moved in a reciprocating motion by the pump rod. Both the piston and the bottom of the pump barrel incorporate check valves that allow

water to flow only in the upper direction. The check valve at the bottom of the cylinder is commonly called the foot valve, while the valve in the piston is commonly called the lift valve. When the piston is lifted by the pump rod attached to the surface windmill, the lift valve closes and the piston lifts the entire column of water above it until water overflows out of the discharge pipe at the surface. At the same time a slight suction is formed under the piston causing the foot valve to open and water to flow in under thepiston. During the next half of the cycle the piston moves down causing the foot valve to close and the lift valve to open such that water flows through the piston into a position to be lifted during the next half cycle. Water flow valves, such as those described above, must be periodically replaced. The lift valve, which is typically made of leather or rubber, eventually wears due to particles of sand or earth in the water. Other check valves involved with the system also have finite useful lives and must be replaced on a regular basis. Replacement typically involves the removal of the pump rod, discharge pipe and pump by lifting the entire assembly up from the drilled well in order to access the valves. Such replacement efforts involve considerable labour and expense and greatly affect the down time of the windmill pumping system. Obviously, many efforts have been made in the past to replace the windmill pumping system powered by electrical motors and internal combustion engines. The present concern relates only to such efforts that have sought to improve upon wind driven pumping systems. One effort in the past is described in U.S. Pat. No. 3,367,281 issued to Gray on Feb. 6, 1968 entitled apparatus for pumping water from wells using wind power. The Gray patent discloses a water pumping device in which compressed air is generated by a windmill, stored in a tank, controlled through a pressure regulator, and delivered to a displacement type water pump. This invention, although not overly complex, is not directly adaptable to the typical windmill structure. The Gray disclosure describes a down stroke of a windmill pump rod as the compression stroke which does not lend itself well to application in conjunction with typical windmills that are designed to apply force and power on the upstroke of the pump rod. The pump rod conventionally made of wood would likely snap if used to compress air on the down stroke. The Gray invention also utilizes solenoid valves that are electrically controlled to effectuate the air compression cycle. Such electrically controlled valves are typically not practical in remote windmill locations. Finally, the Gray invention further requires the use of an air hold-up means and a pressure regulator. U.S. Pat. Nos. 4,385,871 and 4,358,250 provide further examples of inventions generally related to the conversion of wind energy into compressed air for the purpose of water pumping. These earlier efforts, however, also do not address an appropriate adaptation of the air compressing mechanis m to the typical windmill structure or to the utilization of the same in conjunction with an air injection type water pump. **IV. S ELECTION OF SITE TO WORKING**

The viability of a windmill is greatly affected by its location. The site must have sufficient wind power to move the windmill and also be away from obstructions that might cause turbulence. The speed of wind for a given location is not constant and thus the climatic condition of the site should be

examined for over on a year and recorded on a wind map which is then used to analyze the suitability of the sit. To avoid distractions, most windmills are located on hilly areas or the rigs are tall enough to ensure the rotor is far above the obstacles. The site of our windmill had been identified and there was no need for selection of another site. However, we did an analysis on the site to determine its suitability and the findings were as follows. The location of the windmill is strategically away from tall buildings and tree.

V. CONCLUS ION

The total torque output of the windmill is 106.4572 Nm and this is sufficient to sustain the desired flow rate of (0.1736 X 10-3) m3 per second with a maximum head of 30m, and also to overcome other barriers to 5motion e.g., friction. The number of blades used is 24 with a total surface area of 0.5585 m2 and this gives a solidity of 0.8, the minimum (optimum) value of solidity for a windmill and therefore ensures conformity with the standard specifications. Gears and bearings are subject to very high heat losses due to friction and this will be greatly minimized by application of oil and grease and therefore greatly improving the efficiency. All materials used are locally available and at a low cost making the model economically viable.
